This task describes how to ensure that the message sets observe daylight saving time (DST) in line with the 2007 U.S. changes.

If your message sets use a named time zone that is *not* changing DST in line with the 2007 U.S. changes, you do not need to do anything.

If you are using a GMT-04:00, GMT-05:00, GMT-06:00, GMT-07:00, or GMT-08:00 named time zone with DST, that must observe DST in line with the 2007 U.S. changes, do the following steps on every computer on which the integration node is running:

1. Set the environment variable MQSI_USE_NEW_US_DST to an initial value: Y, for example.
2. Restart the integration node to use the changed DST.

Message Sets: Configuring documentation properties: Message sets

Document a message set in the IBM App Connect Enterprise Toolkit.

Before you begin

Complete the following tasks:

- “Message Sets: Creating a message set” on page 2250
- “Message Sets: Opening an existing message set” on page 2250

About this task

To configure the documentation for a message set:

Procedure

1. In the Message Set editor **Properties Hierarchy**, click **Message set**. The documentation text field appears in the Details view, with all the other logical properties of the message set.
2. Configure the documentation properties shown in the Details view to your requirements.

   You can use the `Documentation` property to set user-defined keywords and their value. These keywords are propagated to the integration node when you deploy the message set in a BAR file. These keywords are used to give additional information about the message set when you display deployed message set properties in the IBM App Connect Enterprise Toolkit. See “Message Sets: Message set version and keywords” on page 2173 for more information.
3. Save your changes by clicking **File** > **Save**, or by pressing Ctrl+S. Alternatively, click **File** > **Save All**, or press Ctrl+Shift+S.

Results

Message Sets: Deleting a message set

If you want to delete a message set from your message model, you must delete the message set project that contains the message set.

Procedure

1. Switch to the Integration Development perspective.
2. In the Application Development view, right-click the message set project folder that contains the message set that you want to delete and click **Delete** on the pop-up menu.

   This opens the **Confirm Project Delete** window, which asks whether you want to delete the message set project that you have specified.

3. Click **Also delete contents .....** to delete the contents of the message set project, or click **Do not delete contents** to cancel the deletion of the message set project. Pressing the Esc key on your keyboard also cancels the deletion of the message set project.

Results

Important: When you delete a message set project, the action cannot be undone after you have confirmed the deletion. All folders and associated files for the message set project are deleted.

Message Sets: Working with a message definition file

Create, open, and delete a message definition file.

Before you begin

Tip: In IBM App Connect Enterprise, *message model schema* files contained in applications, integration services, and libraries are the preferred way to model messages for most data formats. Message sets are required if you use the MRM or IDOC domains. For more information about message modeling, see "Message modeling concepts" on page 2134.

You must have completed the following task:

- "Message Sets: Creating a message set" on page 2250

About this task

This topic area describes the tasks that are involved in working with a message definition file:

- "Message Sets: Opening an existing message definition file" on page 2261
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Deleting a message definition file" on page 2264

Message Sets: Opening an existing message definition file

This task topic describes how to open an existing message definition file in the Message Definition editor; you can then view and edit the contents of the file.

About this task

To open an existing message definition file:

Procedure

1. Switch to the Integration Development perspective.
2. In the Application Development view, right-click the message definition file (file extension `*.mxsd`) that you want to open, and select **Open**.

   This opens the Message Definition editor for the message definition file that you have specified.

   Tip: The Eclipse framework lets you open resource files with other editors. However, you are advised to use only the IBM App Connect Enterprise Toolkit Message Definition editor to work with message definition files, because this editor correctly validates any changes that are made to the message definition files. Other editors might not do this.
3. View or edit the data in the file as required.

Results

Message Sets: Creating a message definition file

Creating an empty message definition file to contain your message model objects.

Before you begin

You must have completed the following task:

- "Message Sets: Creating a message set" on page 2250

About this task

You must create a message definition file before you can create the message model objects. The message definition file contains the logical and physical model definitions of the objects in XML Schema form.

You can create the message definition file in one of the following ways:

- Create the message definition file from scratch, see "Message Sets: Creating a message definition file from scratch" on page 2262.
- Base your message definition file on an existing resource (for example, an XML Schema file, an IBM supplied message, an XML DTD file, a C header file, a COBOL file, or a WSDL file), see "Message Sets: Creating a message definition file from an existing resource" on page 2263.
- Copy a message definition file from one message set to another.

  If you do copy a message definition file from one message set to another, you must check that the source and target message sets have identical physical formats, and that namespaces are enabled.

  If the source and target namespaces do not have identical formats, the physical format of the message definition file might be replaced by the default information applied to the target message set.

Message Sets: Creating a message definition file from scratch

Create an empty message definition file to contain message model objects.

Before you begin

You must have completed the following task:

- "Message Sets: Creating a message set" on page 2250

About this task

You must create a message definition file before you can create the message model objects. The message definition file contains the logical and physical model definitions of the objects in XML Schema form.

To create an empty message definition file from scratch:

Procedure

1. Switch to the Integration Development perspective.
2. Open the New Message Definition File wizard.

   To do this, right-click the message set project in the Application Development view that you are adding the message definition file to, and click **New> Message Definition File** on the pop-up menu.

   The **Message Definition File** panel of the wizard is displayed. The target message set list is filtered to only show artifacts in the active working set.
3. Click the message set, type a name into the File name field, and click **Next**.
4. Step through the remainder of the wizard, completing the details as required.

Results

The new empty message definition file, with the name that you have specified and a file extension of `*.mxsd`, opens in the Message Definition editor; you can use the editor to create your own message

definitions. If you have chosen to use a target namespace, a directory structure that is based on the URI that you have supplied is created. The new message definition file is placed within this directory structure, which appears in the Application Development view.

Message Sets: Creating a message definition file from an existing resource
You must create a message definition file before you can create the message model objects. The message definition file contains the logical and physical model definitions of the objects in XML schema form.

Before you begin

You must have completed the following task:

- "Message Sets: Creating a message set" on page 2250

About this task

To create a new message definition file that is based on an existing resource:

Procedure

1. Switch to the Integration Development perspective.
2. Open the appropriate New Message Definition File From wizard.

   Right-click the message set project in the Application Development view that you are adding the message definition file to, and click **New> Message Definition File From**.

   A submenu shows the list of resources from which you can choose.
3. Choose the resource on which to base your new message definition.

   Click one of the following resources:

   - **C Header File**
   - **COBOL File**
   - **CORBA IDL File**
   - **Database Definition File**
   - **IBM Supplied Message**
   - **SCA Import or Export**
   - **WSDL File**
   - **XML DTD File**
   - **XML Schema File**

   The first panel of the corresponding wizard is displayed.
4. Step through the remainder of the wizard supplying the details as required.

   For more information about using the New Message Definition File wizards, see Message Sets: New message definition file wizards.

Results

The new message definition file, with the name that you have specified and a file extension of `.mxsd`, opens in the Message Definition editor. You can use the editor to create your own message definitions. If you have chosen to use a target namespace, a directory structure that is based on the URI that you have supplied is created. The new message definition file is placed within this directory structure, which is shown in the Application Development view.

Message Sets: Deleting a message definition file

You can delete a message definition file from your message model.

About this task

To delete a message definition file from your message model:

Procedure

1. Switch to the Integration Development perspective.
2. In the Application Development view, right-click the message definition file (file extension `*.mxsd`) that you want to delete, then click **Delete**.

   Alternatively, select the message definition file that you want to delete in the Application Development view, then, from the menu bar, click **Edit** > **Delete**, or press the Delete key.
3. In the **Confirm Resource Delete** window, click **Yes** to delete the message definition file.

   Click **No**, or press the Esc key, to cancel the deletion of the message definition file.

Results

Important: All files and objects that are associated with the message definition file are deleted. This action cannot be undone.

Message Sets: Working with MRM message model objects

Add, configure, and delete objects.

Before you begin

You must have completed the following tasks:

- “Message Sets: Creating a message set” on page 2250
- “Message Sets: Creating a message definition file” on page 2262

About this task

This topic area describes the tasks that are involved in working with message model objects:

- “Message Sets: Adding MRM message model objects” on page 2264
- “Message Sets: Configuring MRM message model objects” on page 2277
- “Message Sets: Deleting objects” on page 2292

Message Sets: Adding MRM message model objects

Various tasks are involved in adding message model objects to a message definition file.

Before you begin

You must have completed the following tasks:

- “Message Sets: Creating a message set” on page 2250
- “Message Sets: Creating a message definition file” on page 2262

Before starting any of the tasks in this topic area, you must first open the message definition file to which you want to add message model objects in the Message Definition editor. See “Message Sets: Opening an existing message definition file” on page 2261 for further details.

About this task

This topic area describes the tasks that are involved in adding message model objects to a message definition file:

- "Message Sets: Adding a message" on page 2265
- "Message Sets: Adding a message from a global element" on page 2266
- "Message Sets: Adding a global element" on page 2267
- "Message Sets: Adding a local element" on page 2268
- "Message Sets: Adding an element reference" on page 2268
- "Message Sets: Adding a wildcard element" on page 2269
- "Message Sets: Adding a global attribute" on page 2270
- "Message Sets: Adding a local attribute" on page 2270
- "Message Sets: Adding an attribute reference" on page 2271
- "Message Sets: Adding a wildcard attribute" on page 2271
- "Message Sets: Adding a simple type" on page 2272
- "Message Sets: Adding a complex type" on page 2274
- "Message Sets: Adding a simple type to an element or attribute" on page 2281
- "Message Sets: Adding a complex type to an element" on page 2282
- "Message Sets: Adding a global group" on page 2274
- "Message Sets: Adding an attribute group" on page 2275
- "Message Sets: Adding a group reference" on page 2276

Message Sets: Adding a message
Add a message to a message model.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261

About this task

To add a message to your message definition file:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Messages** then click **Add Message** on the pop-up menu.

   A simple message is immediately added to your message model and is assigned a default name.
4. Either type a new name for the message or press **Enter** to accept the default.

   Tip: When you add a message to your message model, an associated complex type and global element with the same name as the message are also created. The global element and the message cannot have different names and changing the name of one changes the names of both. The complex type can be renamed.

Results

You can now configure the properties of the message to your exact requirements. For further information about configuring message model objects see "Message Sets: Configuring MRM message model objects" on page 2277.

Message Sets: Adding a message from a global element
Add a message from a global element to a message model.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261
- "Message Sets: Adding a global element" on page 2267 (This must be a global element of complex type)

About this task

To add a message from a global element to your message model:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Messages** then click **Add Message From Global Element** on the pop-up menu to open the **Add Message From Global Element** window.

   This window lists all the global elements of a complex type that are not already associated with a message.
4. In the **Select a global element of complex type that is not already used for a message** list, click the global element that you want to use to create your message.
5. Click **OK**.

   This immediately adds a message with the same name as the selected global element to your message model.

Results

You can now configure the properties of the message to your exact requirements. For further information on configuring message model objects see "Message Sets: Configuring MRM message model objects" on page 2277.

Message Sets: Adding a message from a global type
Add a message from a global type to your message model.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261

- "Message Sets: Adding a global element" on page 2267 (This must be a global element of complex type)

About this task

To add a message from a global type to your message model:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Messages** then click **Add Message From Global Type** on the pop-up menu to open the **Add Message From Global Type** window.

   This window lists all the global complex types that are not already associated with a message.
4. In the **Select a global complex type** list, click the global complex type that you want to use to create your message.
5. Click **OK**.

   This immediately adds a message with the same name as the selected global complex type to your message model.

Results

You can now configure the properties of the message to your exact requirements. For further information on configuring message model objects see "Message Sets: Configuring MRM message model objects" on page 2277.

Message Sets: Adding a global element
Add a global element to a message model.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261

About this task

To add a global element to your message model:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Elements and Attributes** then click **Add Global Element** on the pop-up menu.

   This adds a global element of type string to your message model, and assigns a default name.
4. Either type a new name for the global element or press Enter to accept the default.

Results

You can now configure the global element to your requirements. For further information on configuring message model objects see “Message Sets: Configuring MRM message model objects” on page 2277.

Message Sets: Adding a local element
Add a local element to a message, type, group, or complex element.

Before you begin

You must have completed the following tasks:

- “Message Sets: Creating a message set” on page 2250
- “Message Sets: Creating a message definition file” on page 2262
- “Message Sets: Opening an existing message definition file” on page 2261

This task assumes that you have previously added the relevant message, type, group, or complex element to your message model.

About this task

To add a local element to a message, type, group, or complex element:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the object (message, complex type, group, or complex element) to which you are adding a local element then click **Add Local Element** on the pop-up menu.

   A local element of type string is added to the message model and is assigned a default name.
4. Either type a new name for the local element or press **Enter** to accept the default.

Results

You can now configure the local element to your exact requirements. For further information about configuring message model objects see “Message Sets: Configuring MRM message model objects” on page 2277.

Message Sets: Adding an element reference
Add an element reference to a message, type, group, or complex element.

Before you begin

You must have completed the following tasks:

- “Message Sets: Creating a message set” on page 2250
- “Message Sets: Creating a message definition file” on page 2262
- “Message Sets: Opening an existing message definition file” on page 2261

This task assumes that you have previously added the relevant message, type, global group, or complex element to your message model.

About this task

To add an element reference to a message, type, global group, or complex element:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the object (message, complex type, group, or complex element) to which you are adding the element reference, then click **Add Element Reference** on the pop-up menu.

   This adds a default element reference to the message model object that points to an existing global element. This existing global element might be in the current message definition file or in a message definition file defined under **Includes** or **Imports** for the current message definition file. For further information about Imports and Includes, see "Message Sets: Linking from one message definition file to another" on page 2293.

Results

You can now configure the element reference to your exact requirements. For further information about configuring message model objects see "Message Sets: Configuring MRM message model objects" on page 2277.

Message Sets: Adding a wildcard element
Add a wildcard element to a message, type, group, or complex element in a message model.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261

You can add a wildcard element to a message, type, group or complex element. This task assumes that you have previously added the relevant message, type, group or complex element to your message model.

About this task

To add a wildcard element to a message, type, group or complex element:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the message model object (message, complex type, group or complex element) to which you are adding the wildcard element then click **Add Wildcard Element** on the pop-up menu.

   A wildcard element is added and appears in the Outline view.

Results

You can now configure the wildcard element to your exact requirements. For further information on configuring message model objects see "Message Sets: Configuring MRM message model objects" on page 2277.

Message Sets: Adding a global attribute
Add a global attribute to your message model.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261

About this task

To add a global attribute to your message model:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Elements and attributes** then click **Add Global Attribute** on the pop-up menu.

   A global attribute of type string is immediately added and is assigned a default name.
4. Either type a new name for the global attribute or press Enter to accept the default.

Results

You can now configure the global attribute to your requirements. For more information on configuring message model objects see "Message Sets: Configuring MRM message model objects" on page 2277.

Message Sets: Adding a local attribute
Add a local attribute to a message, complex type, or complex element.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261

You can add a local attribute to a message, complex type, or complex element. This task assumes that you have previously added the relevant message, complex type, or complex element to your message model.

About this task

To add a local attribute to a message, complex type or complex element:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.

3. In the Outline view, right-click the object (message, complex type, complex element, or attribute group) to which you are adding the local attribute then click **Add Local Attribute** on the pop-up menu.

   A local attribute of type string is immediately added to the message model object and is assigned a default name.
4. Either type a new name for the local attribute or press **Enter** to accept the default.

Results

You can now configure the local attribute to your requirements. For further information about configuring message model objects see "Message Sets: Configuring MRM message model objects" on page 2277.

Message Sets: Adding an attribute reference
Add an attribute reference to a message, complex type, or complex element.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261

You can add an attribute reference to a message, complex type, or complex element. This task assumes that you have previously added the relevant message, complex type, or complex element to your message model.

About this task

To add an attribute reference to a message, complex type or complex element:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the message model object (message, complex type, complex element, or attribute group) to which you are adding the attribute reference then click **Add Attribute Reference** on the pop-up menu.

   This action adds a default attribute reference to the message model object that points to an existing global attribute.

Results

You can now configure the attribute reference to your exact requirements. For further information about configuring message model objects see "Message Sets: Configuring MRM message model objects" on page 2277.

Message Sets: Adding a wildcard attribute
Add a wildcard attribute to a message, complex type, or complex element.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262

- “Message Sets: Opening an existing message definition file” on page 2261

You can add a wildcard attribute to a message, complex type, or complex element. This task assumes that you have previously added the relevant message, complex type, or complex element to your message model.

About this task

To add a wildcard attribute to a message, complex type or complex element:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the object (message, complex type, complex element, or attribute group) to which you are adding the wildcard attribute then click **Add Wildcard Attribute** on the pop-up menu.

   A wildcard attribute of type string is immediately added to the message model object and is assigned a default name.
4. Either type a new name for the wildcard attribute or press **Enter** to accept the default.

Results

You can now configure the wildcard attribute to your requirements. For further information about configuring message model objects see “Message Sets: Configuring MRM message model objects” on page 2277.

Message Sets: Adding a simple type
Add a simple type to your message model.

Before you begin

You must have completed the following tasks:

- “Message Sets: Creating a message set” on page 2250
- “Message Sets: Creating a message definition file” on page 2262
- “Message Sets: Opening an existing message definition file” on page 2261

About this task

To add a simple type to your message model:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Types** then click either **Add Simple Type Restriction**, **Add Simple Type List**, or **Add Simple Type Union** on the pop-up menu.
   - For a restriction, a simple type of base type string is added, and assigned a default name.
   - For a list, a simple type of item type string is added, and assigned a default name.
   - For a union, a simple type with a single member type of string is added, and assigned a default name.

4. Either type a new name for the simple type or press **Enter** to accept the default.

Results

You can now configure the simple type to your exact requirements.

If the simple type is a restriction:

- You can change the base type using the editor Properties view.
- You can set the value constraints associated with the simple type. See "Message Sets: Setting value constraints" on page 2283.
- You can replace the base type with a new local simple type. In the Outline view right-click simple type and click one of:
  - **Add Simple Type Restriction**. This option replaces the base type with a new simple type restriction, with a base type of string. You can configure the restriction as described in 'If the simple type is a restriction'. The result is that the original simple type becomes a restriction of a restriction.
  - **Add Simple Type List**. This option replaces the base type with a new simple type list, with an item type of string. You can configure the list as described in 'If the simple type is a list'. The result is that the original simple type becomes a restriction of a list. It appears as a list in the editor, because a restriction of a list is itself a list, but you can also set certain value constraints.

If the simple type is a list:

- You can change the item type using the editor Properties view.
- You can replace the item type with a new local simple type. In the Outline view right-click the simple type and click one of:
  - **Add Simple Type Restriction**. This option replaces the item type with a new simple type restriction, with a base type of string. You can configure the restriction as described in 'If the simple type is a restriction'. The result is that the original simple type becomes a list of a restriction.
  - **Add Simple Type Union**. This option replaces the item type with a new simple type union, with a single member type of string. You can configure the union as described in 'If the simple type is a union'. The result is that the original simple type becomes a list of a union.

If the simple type is a union:

- If the member type of string is not required, in the Outline view right-click the string and click Delete.
- You can add further members to the union. In the Outline view right-click the simple type and click one of:
  - **Add Union Member Type**. This option adds a union member that is an existing simple type. Use the type selection dialog to select the simple type required.
  - **Add Local Member Type Restriction**. This option adds a union member that is a new simple type restriction, with a base type of string. You can configure the restriction as described in 'If the simple type is a restriction' referred to earlier.
  - **Add Local Member Type List**. This option adds a union member that is a new simple type list, with an item type of string. You can configure the list as described in 'If the simple type is a list' referred to earlier.
  - **Add Local Member Type Union**. This option adds a union member that is a new simple type union, with a single member type of string. You can configure the new union as described in 'If the simple type is a union'.
- New members are added to the end of the union. To change the order of a member, in the Outline view select the member and drag it to the required position in the union. All union members that are existing simple types must occur ahead of all members that are local restrictions, lists, and unions, so reordering is subject to this rule.

For further information about configuring message model objects see "Message Sets: Configuring MRM message model objects" on page 2277.

Message Sets: Adding a complex type
Add a complex type to your message model.

Before you begin

You must already have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261

About this task

To add a complex type to your message model:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Types** then click **Add Complex Type** on the pop-up menu.
   A complex type is added and is assigned a default name.
4. Either type a new name for the complex type or press Enter to accept the default.

Results

You can now configure the complex type to your requirements. For further information on configuring message model objects see "Message Sets: Configuring MRM message model objects" on page 2277.

Message Sets: Adding a global group
Add a global group to your message model.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261

About this task

To add a global group to your message model:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Groups** then click **Add Group** on the pop-up menu.
   A global group is added to your message model and is assigned a default name.
4. Either type a new name for the global group or press **Enter** to accept the default.

Results

You can now configure the global group to your requirements. For further information about configuring the properties of message model objects see "Message Sets: Configuring MRM message model objects" on page 2277.

Message Sets: Adding a local group
Add a local group to a message, type, global group, or complex element.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261

You can add a local group to a message, complex type, group, or complex element. This task assumes that you have previously added the relevant message, complex type, group, or complex element to your message model.

About this task

To add a local group to a message, complex type, group, or complex element:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the object (message, complex type, group, or complex element) to which you are adding the local group then click **Add Local Group** on the pop-up menu.

   A local group is immediately added to the message model with type composition set to *sequence* by default.

Results

You can now configure the local group to your requirements. For further information about configuring message model objects, see "Message Sets: Configuring MRM message model objects" on page 2277.

Message Sets: Adding an attribute group
Add an attribute group to your message model.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261

About this task

To add an attribute group to your message model:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Groups** then click **Add Attribute Group** on the pop-up menu.

   A global attribute group is added to your message model and is assigned a default name.
4. Either type a new name for the attribute group or press **Enter** to accept the default.

Results

You can now configure the attribute group to your requirements. For further information about configuring the properties of message model objects see "Message Sets: Configuring MRM message model objects" on page 2277.

Message Sets: Adding a group reference
You can add a group reference to a message, type, global group, or complex element.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261

You can add a group reference to a message, complex type, group, or complex element. This task assumes that you have previously added the relevant message, complex type, group, or complex element to your message model.

About this task

To add a group reference to a message, complex type, group or complex element:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the object (message, complex type, group, or complex element) to which you want to add a group reference then click **Add Group Reference** on the pop-up menu.

   A group reference is immediately added to your message model.

Results

You can now configure the group reference to your requirements. For further information on configuring the properties of message model objects see "Message Sets: Configuring MRM message model objects" on page 2277.

Message Sets: Adding an attribute group
Add an attribute group reference to a message model.

Before you begin

You must have completed the following tasks:

- “Message Sets: Creating a message set” on page 2250
- “Message Sets: Creating a message definition file” on page 2262
- “Message Sets: Opening an existing message definition file” on page 2261

About this task

To add an attribute group to your message model:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Groups** then click **Add Attribute Group** on the pop-up menu.
   An attribute group is added to your message model and is assigned a default name.
4. Either type a new name for the attribute group reference or press Enter to accept the default.

Results

You can now configure the attribute group to your requirements using the Message Definition editor. For further information on configuring the properties of message model objects see “Message Sets: Configuring MRM message model objects” on page 2277.

Message Sets: Configuring MRM message model objects

Various tasks are involved in configuring MRM message model objects

Before you begin

You must have completed the following tasks:

- “Message Sets: Creating a message set” on page 2250
- “Message Sets: Creating a message definition file” on page 2262
- “Message Sets: Adding MRM message model objects” on page 2264 (You must have added one or more objects to your message model)

Before starting any of the tasks in this topic area, you must first open the message definition file for which you want to configure message model objects in the Message Definition editor. See “Message Sets: Opening an existing message definition file” on page 2261 for further details.

About this task

This topic area describes the tasks that are involved in configuring message model objects:

- “Message Sets: Renaming objects” on page 2278
- “Message Sets: Reordering objects” on page 2278
- “Message Sets: Copying objects” on page 2279
- “Message Sets: Pasting objects” on page 2280
- “Message Sets: Changing the type of an element or attribute” on page 2280
- “Message Sets: Setting value constraints” on page 2283
- “Message Sets: Configuring logical properties: Message model objects” on page 2284
- “Message Sets: Configuring documentation properties: Message model objects” on page 2286

- "Message Sets: Configuring physical properties" on page 2287
  - "Message Sets: Configuring Custom Wire Format (CWF) properties: Message model objects" on page 2287
  - "Message Sets: Configuring XML Wire Format properties: Message model objects" on page 2290
  - "Message Sets: Configuring TDS properties: Message model objects" on page 2288
  - "Message Sets: Applying default physical format settings: Message model objects" on page 2291
- "Message Sets: Deleting objects" on page 2292

Message Sets: Renaming objects
You can rename message model objects in the IBM App Connect Enterprise Toolkit.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261
- "Message Sets: Adding MRM message model objects" on page 2264 (You must have added one or more objects to your message model)

About this task

Objects in the IBM App Connect Enterprise Toolkit such as files, messages and elements can have different physical representations. Eclipse handles renaming differently depending on the object.

Tip: Not all objects can be renamed. For example, you cannot rename wildcards, local groups, or local types, because they do not have a name.

If an object can be renamed the usual way to do it is as follows:

Procedure

1. Switch to the Integration Development perspective.
2. In the Outline view, right-click the object that you want to rename then click **Rename** on the pop-up menu.

   Alternatively, right-click the object in the Message Definition editor **Overview** tab then click **Rename** on the pop-up menu.

   In both cases, depending on the object, either a renaming dialog opens or you will now be able to edit the name of the object directly.
3. Type the new name for the object.
4. If the renaming dialog is open, either press Enter or click **OK**.

Results

Message Sets: Reordering objects
Reorder message model objects within a message definition file.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261

- “Message Sets: Adding MRM message model objects” on page 2264 (You must have added one or more objects to your message model)

About this task

To reorder objects within a message definition file:

Procedure

1. Switch to the Integration Development perspective.
2. Click the object that you want to move.
   For example, you could select a local element within a message in either the Outline view or Properties Hierarchy.
3. Use the mouse to drag the object to its new location.

   Tip: As you drag the object and the mouse cursor passes between objects, a black line appears, showing where the current focus is. If you try to drag the object to a location that it cannot be moved to (including objects that are highlighted as the cursor passes over them), the object remains in its original position when you release it.

Results

Message Sets: Copying objects
You can copy an object in a message definition file, such as a message for a local element object, or types for a complex type object.

Before you begin

You must have completed the following tasks:

- “Message Sets: Creating a message set” on page 2250
- “Message Sets: Creating a message definition file” on page 2262
- “Message Sets: Opening an existing message definition file” on page 2261
- “Message Sets: Adding MRM message model objects” on page 2264 (You must have added one or more objects to your message model)

About this task

To copy an object:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window** > **Show View** > **Outline**.
3. In the Outline view, right-click the message model object that you want to copy, then click **Copy**.
   Alternatively, right-click the object in the Message Definition editor **Overview** tab, then click **Copy**.

Results

The object is now copied.

Message Sets: Pasting objects
Paste objects that you have previously copied within the same message definition file

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261
- "Message Sets: Adding MRM message model objects" on page 2264 (You must have added one or more objects to your message model)
- "Message Sets: Copying objects" on page 2279

About this task

You can paste objects that you have previously copied within the same message definition file.

You can only copy and paste an object within the same message definition. You cannot copy an object and paste it into another message definition, either within the same message set or in a different message set.

To paste an object in the message definition from which you copied it:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the location where you are going to paste the object then click **Paste** on the pop-up menu.

   Alternatively, right-click the object in the Message Definition editor **Overview** tab then click **Paste** on the pop-up menu.

   The object appears in the new location with a default name which you can change if you want to.
4. Either type a new name for the object or press **Enter** to accept the default.

What to do next

Note: When you copy and paste objects within the message set, where physical properties exist for that object, these settings are not pasted, but are set to default values.

Tip: If you cannot select **Paste** from either menu, you might be trying to paste to a location that is not valid. For example, you cannot paste a complex type into a local element.

Message Sets: Changing the type of an element or attribute
You can change the type to a local element, global element, local attribute, or global attribute.

Before you begin

You must already completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261
- "Message Sets: Adding MRM message model objects" on page 2264 (You must have added one or more objects to your message model)

About this task

You can change the type of an element or attribute in your message model to another existing type, or you can create a new simple type or a new complex type.

To change the type of an element or attribute to an existing type:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window** > **Show View** > **Outline**.
3. In the Outline view, click the element for which you want to change the type.
4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area.
5. In the Properties Hierarchy click **Logical Properties** > **Global Element** (or **Logical Properties** > **Local Element**, **Logical Properties** > **Global Attribute**, or **Logical Properties** > **Local Attribute**).

   If necessary, expand **Logical Properties** by clicking **+**.
6. In the Details view, in the **Type** property, click the new type that you require.

   Tip: If the type you require is not displayed, you can find it by clicking **(More...)** in the list. This displays the **Type Selection** window with additional options. If you know which type you require, specify the first letter in the text box at the top of the **Type Selection** window. Matching types are then displayed, making the selection process easier.
7. When you have selected the type that you require, click **OK**.

Results

The change to the type is applied wherever the element or attribute occurs.

The task above explains how to switch to an existing type. If you want to create a new simple type or a new complex type, select **(New Simple Type Restriction)**, **(New Simple Type List)**, **(New Simple Type Union)**, or **(New Complex Type)** in the **Type** list (see step 6 above). For information on how to create a new simple type or a new complex type see “Message Sets: Adding a simple type to an element or attribute” on page 2281 or “Message Sets: Adding a complex type to an element” on page 2282.

Message Sets: Adding a simple type to an element or attribute
You can add a simple type to a local element, global element, local attribute, or global attribute.

Before you begin

You must have completed the following tasks:

- “Message Sets: Creating a message set” on page 2250
- “Message Sets: Creating a message definition file” on page 2262
- “Message Sets: Opening an existing message definition file” on page 2261

This task assumes that you have previously added the relevant element or attribute to your message model.

About this task

To add a new simple type:

Procedure

1. Switch to the Integration Development perspective.

2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, click the element to which you want to add a new simple type.
4. In the Message Definition editor, click the **Properties** tab.
5. In the Properties Hierarchy, click **Logical Properties > Global Element** (or **Logical Properties > Local ElementLogical Properties > Global Attribute**, or **Logical Properties > Local Attribute**).
6. In the Details view, in the **Type** property, select **(New Simple Type Restriction)**, **(New Simple Type List)**, or **(New Simple Type Union)** to open the relevant **New Simple Type** window to create a simple type of the type that you specify.
7. In the **New Simple Type** window, in the **Base Type** list, click the type that you want to use.
8. Optional: If you want to add the new simple type as a global simple type, select the **Create as Global Simple Type** check box and specify the name for your new simple type in the **Name** field.
9. Click **OK**.

   A simple type is immediately added to your message model.

Results

Any changes that you make are reflected throughout where the element to which you have added a new simple type occurs.

Message Sets: Adding a complex type to an element
You can add a complex type to a local element, global element, local attribute, or global attribute.

Before you begin

You must have completed the following tasks:

- “Message Sets: Creating a message set” on page 2250
- “Message Sets: Creating a message definition file” on page 2262
- “Message Sets: Opening an existing message definition file” on page 2261

This task assumes that you have previously added the relevant element or attribute to your message model.

About this task

When you add a complex type to an element or attribute, you can either create a new complex type or derive a new complex type from an existing base type.

To add a new complex type:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit.

   If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, click the element to which you want to add a new complex type.
4. In the Message Definition editor, click the **Properties** tab.
5. In the Properties Hierarchy, click **Logical Properties > Global Element** (or **Logical Properties > Local ElementLogical Properties > Global Attribute**, or **Logical Properties > Local Attribute**).
6. In the Details view, in the **Type** list, click **(New Complex Type)** to display the **New Complex Type** window.

7. If you want to create a new local complex type, click **Create a Local Complex Type**, in the **Composition** list, click the option that you require.
8. If you want to derive a new local complex type from an existing base type:
   a) Click **Derive a new Local Complex Type from existing base type**.
   b) In the **Base Type** list, click the base type that you want to use.
      Depending on the base type you select, the **Composition** and **Derived By** lists might become active.
   c) If the **Composition** and **Derived By** lists are active, click the options that you require in both lists.
9. If you want to add the new complex type as a global complex type, select the **Create as Global Complex Type** check box, and specify a name for your new complex type in the **Name** field.
10. Click **OK** to close the **New Complex Type** window and add the new complex type to your message model.

Results

Any changes that you make are reflected throughout where the element to which you are adding the complex type occurs.

Message Sets: Setting value constraints
You can set the value constraints associated with a simple type.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261
- "Message Sets: Adding a simple type" on page 2272 or "Message Sets: Adding a simple type to an element or attribute" on page 2281 (You must have added one or more global or local simple types to your message model)

About this task

Value constraints are usually associated with a simple type; they refine a simple type by defining limits on the values which the simple type can represent. To set the value constraints associated with a simple type:

Procedure

1. Switch to the Integration Development perspective.
2. In the Outline view, click the simple type you are updating.
   If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window** > **Show View** > **Outline**.
3. Display the **Properties** tab of the Message Definition Editor by clicking **Properties** in the lower-left corner of the editor area.
   The Properties Hierarchy displays the following nodes:
   - Logical Properties
   - Physical Properties
   - Documentation

4. In the Properties Hierarchy under **Logical Properties** click **Value Constraints**.
   This displays the current value constraints settings for the selected simple type in the Details pane.
   Tip: If **Value Constraints** is not in view, expand **Logical Properties** by clicking **+**.
5. Set the value constraints for the selected simple type by making the appropriate changes to the information shown in the Details pane.

Results

Setting an enumeration

About this task

An enumeration restricts which values can be set for the value constraint. For example, "ABC" and "123". Use this section to create a list of fixed values that the associated type must match.

To set an enumeration:

Procedure

1. Click **Add** to the right of the **Enumerations** field.
   This adds an enumeration that has a default enumeration (for example *enumeration1*).
2. Type the data that you want to set for this value constraint.
3. Press Enter on your keyboard.
4. Repeat the above steps for each enumeration that you are adding.

Setting a pattern

About this task

Set a pattern to indicate that the value constraint defines a string used as a regular expression that must be matched by the data in the associated type. The regular expression syntax supported is XML Schema regular expressions.

See Message Sets: Regular expression syntax for a list of supported regular expression syntax elements.

To set a pattern:

Procedure

1. Select **Add** to the right of the **Patterns** field.
   This adds a pattern that has a default pattern (for example *pattern1*) and is in update mode.
2. Type the data that you want to set for this value constraint.
3. Press Enter on your keyboard.
4. Repeat the above steps for each pattern that you are adding.

Message Sets: Configuring logical properties: Message model objects
You can configure the logical properties of an object that has previously been added to the message model.

Before you begin

You must have completed the following tasks:

- “Message Sets: Creating a message set” on page 2250
- “Message Sets: Creating a message definition file” on page 2262
- “Message Sets: Opening an existing message definition file” on page 2261

- "Message Sets: Adding MRM message model objects" on page 2264 (You must have added one or more objects to your message model)

About this task

To configure the logical properties of an object that is part of the message model:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit and is displaying the following information:
   - The name of the message definition file
   - Messages
   - Types
   - Groups
   - Elements and Attributes

   If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window** > **Show View** > **Outline**. If the information listed above is not displayed, ensure that the message definition file is open in the Message Definition editor. Message definition files have an `.mxsd` file extension.
3. In the Outline view, select the message model object for which you want to configure the logical properties:
   a) Depending on the type of the object that you are selecting, expand **Messages**, **Types**, **Groups** or **Elements and Attributes** as appropriate by clicking **+**.
   b) Click the object that you want to select within the expanded node.
4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area.

   The Properties Hierarchy displays the following nodes:
   - Logical Properties
   - Physical Properties
   - Documentation

   The type (for example, Local Element or Global Element) of the message model object that you selected in the Outline view is displayed under each of these nodes.

   If the items under **Logical Properties** are not in view, expand **Logical Properties** by clicking **+**.
5. Display the logical properties of the selected object in the Details view of the Message Definition editor, by clicking the appropriate item under **Logical Properties**.
6. Configure the logical properties of the selected item to your requirements by making the appropriate changes to the information shown in the Details view.
7. Save your changes by clicking **File** > **Save message_definition_file.mxsd** or by pressing Ctrl+S. Alternatively click **FileSave All** or press Ctrl+Shift+S.

Results

Message Sets: Configuring documentation properties: Message model objects
You can configure the documentation properties of an object that has previously been added to the message model.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261
- "Message Sets: Adding MRM message model objects" on page 2264 (You must have added one or more objects to your message model)

About this task

To configure the documentation properties of an object contained within a message definition file:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit and is displaying the following information:
   - The name of the message definition file
   - Messages
   - Types
   - Groups
   - Elements and Attributes

   If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window** > **Show View** > **Outline**. If the information listed above is not displayed, ensure that the message definition file is open in the Message Definition editor. Message definition files have an `.mxsd` file extension.
3. In the Outline view, select the message model object for which you want to configure the documentation properties by taking the following steps:
   a) Depending on the type of the object that you are selecting, expand **Messages**, **Types**, **Groups** or **Elements and Attributes** as appropriate by clicking **+**.
   b) Click the object you want to select within the expanded node.
4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area.

   The Properties Hierarchy displays the following nodes:
   - Logical Properties
   - Physical Properties
   - Documentation

   The type (for example, Local Element or Global Element) of the message model object that you selected in the Outline view is displayed under each of these nodes.

   Tip: If the items under **Documentation** are not in view, expand **Documentation** by clicking **+**.
5. Display the logical properties of the selected object in the Details view by clicking the appropriate item under **Documentation**.

6. Configure the documentation properties of the selected item to your requirements by typing text into the **Documentation** field.

   Right-clicking in the field allows you to select options for undoing changes you have made, cutting or copying text from the field, pasting text into the field, deleting highlighted text or selecting all text in the field.
7. Save your changes by clicking **File** > **Save message_definition_file.mxsd** from the menu or pressing Ctrl+S. Alternatively, from the menu, click **File** > **Save All** or press Ctrl+Shift+S.

Results

Message Sets: Configuring physical properties
Working with the physical properties of message model objects.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261
- "Message Sets: Adding MRM message model objects" on page 2264 (You must have added one or more objects to your message model)

The tasks in this topic area assume that you have added one or more physical formats to a message set. For further information see "Message Sets: Adding a Custom Wire Format (CWF)" on page 2254 or "Message Sets: Adding an XML wire format" on page 2256 or "Message Sets: Adding a TDS physical format" on page 2255.

About this task

When you have added objects to your message model it is likely that you will want to configure the physical properties of these objects. The following tasks relate to configuring the physical properties of message model objects:

- "Message Sets: Configuring Custom Wire Format (CWF) properties: Message model objects" on page 2287
- "Message Sets: Configuring XML Wire Format properties: Message model objects" on page 2290
- "Message Sets: Configuring TDS properties: Message model objects" on page 2288
- "Message Sets: Applying default physical format settings: Message model objects" on page 2291

Message Sets: Configuring Custom Wire Format (CWF) properties: Message model objects
You can configure the Custom Wire Format (CWF) properties of a message model object by using the Message Definition editor

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261
- "Message Sets: Adding a Custom Wire Format (CWF)" on page 2254
- "Message Sets: Adding MRM message model objects" on page 2264 (You must have added one or more objects to your message model)

About this task

To configure the *CWF* properties of a message model object:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit and is displaying the following information:
   - The name of the message definition file
   - Messages
   - Types
   - Groups
   - Elements and Attributes

   If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window** > **Show View** > **Outline**. If the above hierarchy is not displayed, ensure that the message definition file is open in the Message Definition editor. Message definition files have an `.mxsd` file extension.
3. In the Outline view, select the object for which you want to configure the CWF properties by doing the following.
   a) Depending on the type of the object that you are selecting, expand **Messages**, **Types**, **Groups** or **Elements and Attributes** by clicking **+**.
   b) Click the object you that want to select within the expanded node.
4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area.

   In the Message Definition editor, in the Properties Hierarchy, the name of each of the physical formats that have been added to the message set appears under **Physical Properties**. The object type (for example, Local Element or Global Element) of the message model object that you selected in the Outline view is displayed under each physical format shown.

   Tip: If the physical formats are not in view in the Properties Hierarchy, expand **Physical Properties** by clicking **+**. By default the CWF physical format is called Binary1 but could have a user defined name instead.
5. Under **Physical Properties**, click the object type for the message model object that you have chosen to configure under the CWF physical format.

   The CWF properties of your selected message model object appear in the Details view.
6. Configure the CWF properties of the selected object to your requirements by making the appropriate changes to the information shown in the Details view.

   Note: It is not possible to configure disabled fields.
7. Save your changes by clicking **File** > **Save message_definition_file.mxsd** or pressing Ctrl+S. Alternatively click **FileSave All** or press Ctrl+Shift+S.

Results

Message Sets: Configuring TDS properties: Message model objects
You can configure the Tagged/Delimited String (TDS) properties of a message model object.

Before you begin

You must have completed the following tasks:

- “Message Sets: Creating a message set” on page 2250
- “Message Sets: Creating a message definition file” on page 2262

- "Message Sets: Opening an existing message definition file" on page 2261
- "Message Sets: Adding a TDS physical format" on page 2255
- "Message Sets: Adding MRM message model objects" on page 2264 (Adding one or more objects to your message model)

About this task

To configure the *TDS* properties of a message model object:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit and is displaying the following information:
   - The name of the message definition file
   - Messages
   - Types
   - Groups
   - Elements and Attributes

   If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window** > **Show View** > **Outline**. If the above hierarchy is not displayed, ensure that the message definition file is open in the Message Definition editor. Message definition files have an `.mxsd` file extension.
3. In the Outline view, select the object for which you want to configure the TDS properties by taking the following steps:
   a) Depending on the type of the object that you are selecting, expand **Messages**, **Types**, **Groups** or **Elements and Attributes** by clicking **+**.
   b) Click the object that you want to select within the expanded node.
4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area.

   In the Message Definition editor, in the Properties Hierarchy, the name of each of the physical formats that have been added to the message set appears under **Physical Properties**. The object type (for example, Local Element or Global Element) of the message model object that you selected in the Outline view is displayed under each physical format shown.

   Tip: If the physical formats are not in view in the Properties Hierarchy, expand **Physical Properties** by clicking **+**. By default the TDS physical format is called Text1 but could have a user defined name instead.
5. Select the **Properties** tab located in the lower-left corner of the Message Definition editor.
6. Under **Physical Properties**, under the TDS physical format, click the object type for the message model object that you have chosen to configure.

   The TDS physical format properties of your selected message model object appear in the Details view.
7. Configure the TDS physical format properties of the selected object to your requirements by making the appropriate changes to the information shown in the Details view.

   Note: It is not possible to configure disabled fields.
8. Save your changes by selecting **File** > **Save message_definition_file.mxsd** from the menu or press Ctrl+S. Alternatively, from the menu, select **File** > **Save All**, or press Ctrl+Shift+S.

Results

Message Sets: Configuring XML Wire Format properties: Message model objects
You can configure the XML Wire Format properties of a message model object.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261
- "Message Sets: Adding an XML wire format" on page 2256
- "Message Sets: Adding MRM message model objects" on page 2264 (You must have added one or more objects to your message model)

About this task

To configure the *XML Wire Format* properties of a message model object:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit and is displaying the following information:
   - The name of the message definition file
   - Messages
   - Types
   - Groups
   - Elements and Attributes

   If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window** > **Show View** > **Outline**. If the above hierarchy is not displayed, ensure that the message definition file is open in the Message Definition Editor. Message definition files have an `.mxsd` file extension.
3. In the Outline view, select the object for which you want to configure the XML Wire Format properties by taking the following steps:
   a) Depending on the type of the object that you are selecting, expand **Messages**, **Types**, **Groups** or **Elements and Attributes** by clicking **+**.
   b) Click the object that you want to select within the expanded node.
4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area.

   In the Message Definition editor, in the Properties Hierarchy, the name of each of the physical formats that have been added to the message set appears under **Physical Properties**. The object type (for example, Local Element or Global Element) of the message model object that you selected in the Outline view is displayed under each physical format shown.

   Tip: If the physical formats are not in view in the Properties Hierarchy, expand **Physical Properties** by clicking **+**. By default the XML Wire Format is called XML1 but could have a user defined name instead.
5. Under **Physical Properties**, under the XML Wire Format, click the object type for the message model object that you have chosen to configure.

   The XML Wire Format properties of your selected message model object appear in the Details view of the Message Definition editor.
6. Configure the XML Wire Format properties of the selected object to your requirements by making the appropriate changes to the information shown in the Details view.

   Note: It is not possible to configure disabled fields.

7. Save your changes by clicking **File** > **Save message_definition_file.mxsd** or pressing Ctrl+S. Alternatively select **File** > **Save All** from the menu or press Ctrl+Shift+S.

Results

Message Sets: Applying default physical format settings: Message model objects
You can apply the default physical format settings to a message model object that is contained in a message definition file.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261
- "Message Sets: Adding MRM message model objects" on page 2264 (You must have added one or more objects to your message model)

This task assumes that you have added one or more physical formats to the relevant message set. For further information see "Message Sets: Adding a Custom Wire Format (CWF)" on page 2254 or "Message Sets: Adding an XML wire format" on page 2256 or "Message Sets: Adding a TDS physical format" on page 2255.

About this task

To apply the default physical format setting to a message model object previously added to a message definition file:

Procedure

1. Switch to the Integration Development perspective.
2. In the Outline view, click the object to which you want to apply default physical format settings.
3. Click the **Properties** tab located in the lower-left corner of the Message Definition editor.
4. Check that the Message Definition editor Properties Hierarchy displays the following information:
   - Logical Properties
   - Physical Properties (For each of the physical formats that have been added to the message set, the name of the physical format appears under **Physical Properties**. Under each physical format the type of message model object that you selected is displayed as a child.)
   - Documentation

   Ensure that **Physical Properties** in the Properties Hierarchy is fully expanded by clicking **+**.
5. Right-click on the message model object type underneath the physical format to which you want to apply the default settings then click **Apply default physical format settings**.

   The default physical format settings for the message model object that you selected are applied without warning.
6. Save your changes by clicking **File** > **Save message_definition_file.mxsd** from the menu or pressing Ctrl+S. Alternatively, from the menu, click **File** > **Save All**, or press Ctrl+Shift+S.

Results

Message Sets: Deleting objects

Delete an object from your message model.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261
- "Message Sets: Adding MRM message model objects" on page 2264 (You must have added one or more objects to your message model)

About this task

To *remove* objects contained within a message definition file:

Procedure

1. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
2. In the Outline view, right-click the object that you want to remove then click **Delete** on the pop-up menu.

   Alternatively right-click the object in the Message Definition editor **Overview** tab, and then click **Delete**.

   The type of object and the relationship that it has with other objects determines whether the object is now deleted without a confirmation window appearing, or whether a confirmation window opens with a list of all the objects that will be deleted along with the one that you have selected.
3. If a confirmation window opens, click **OK** to delete the objects.

   Tip: You can undo a deletion by selecting **Edit> Undo**, provided that you have not saved the changes that you have made.

Results

Message Sets: Creating a multipart message

A multipart message occurs when you embed a message in another message.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261

About this task

To create a multipart (embedded) message:

Procedure

1. Switch to the Integration Development perspective.

2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window** > **Show View** > **Outline**.
3. In the Outline view, add one of the following objects to your message model:
   - A complex type (for further information on completing this task see "Message Sets: Adding a complex type" on page 2274)
   - A global group (for further information on completing this task see "Message Sets: Adding a global group" on page 2274)
   - A local group (for further information on completing this task see "Message Sets: Adding a local group" on page 2275)

   Tip: You can also use a local ANONYMOUS complex type when creating a multipart message. For further information see "Message Sets: Adding a complex type to an element" on page 2282.
4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area.
5. In the Properties Hierarchy, under **Logical properties**, click one of the following items, depending on which of these you added in step 3:
   - **Complex Type**
   - **Global Group**
   - **Local Group**
6. In the Details view, make the following changes to the displayed logical properties:
   a) In the **Composition** drop-down list, click **message**.
   b) In the **Content validation** drop-down list, click **Open**, **Closed** or **Open Defined**, depending on your requirements. Note that if the embedded message is defined in a different message set, you must click **Open**.

      For further information about using these three options, see MRM content validation.

Results

Note: There are a number of different ways for the parser to identify an embedded message within a message bit stream. For further information on identifying a message within another message refer to the following concept topics.

Message Sets: Linking from one message definition file to another

Add an 'include', or an 'import' to the file that you want to reference.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Creating a message definition file" on page 2262
- "Message Sets: Opening an existing message definition file" on page 2261

About this task

There are two ways to link one message definition file to another: either you can add an 'include', or you can add an 'import', for the file that you want to reference.

To check whether a message definition file currently includes or imports other files:

1. Open the message definition file in the Message Definition editor.
2. In the Outline view, in the displayed hierarchy, select the `.mxsd` file.

3. In the Properties Hierarchy, expand **Imports** or **Includes** as appropriate to display a list of the other files that the currently selected file includes or imports.

Include

About this task

Use the include option if you want to link to a message definition file with the same namespace, or if you want to link to a message definition file with no target namespace from a message definition file with a target namespace (chameleon behavior). You must also add an include rather than an import if you want to link a message definition file with no target namespace to another message definition file that also has no target namespace.

Note: A message definition file can only reference objects in another message definition file if this other file has been included directly, so you might have a problem if you try to use the include option to include message definition files that are themselves included within other message definition files.

This task assumes that you have opened an existing message definition file.

To add an include to a message definition file:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, click the message definition (`.mxsd`) file name.
4. Display the **Properties** tab of the Message Definition Editor by clicking **Properties** in the lower-left corner of the editor area.
5. In the Properties Hierarchy, right-click **Includes** then click **Add Include** on the pop-up menu.

   The "**Select Message Definition file to include**" window opens.
6. In the Message Sets pane, select the message definition file that you want to include. If the message definition files within your project are not visible in this pane, expand the project hierarchy by clicking **+**.
7. Click **Finish**.

   The message definition file that you selected in step 4 is included within the message definition file that you opened before beginning this task.

Import

About this task

You use the import option if you want to link a message definition file to another message definition file in a different namespace. You cannot add an import from the same namespace. This restriction includes linking from a message definition file with no target namespace to another message definition file with no target namespace.

To add an import to a message definition file:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Outline view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. If the Outline view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window** > **Show View** > **Outline**.
3. In the Outline view, click the message definition (`.mxsd`) file name.

4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area.
5. In the Properties Hierarchy, right-click **Imports** then click **Add Import**. The "**Select Message Definition file to import**" window opens.
6. In the Message Sets pane, select the message definition file that you want to import from the workspace. If the message definition files within your project are not visible in this pane, expand the project hierarchy by clicking **+**.
7. Click **Finish**.

   The message definition file that you selected in step 4 is imported into the schema of the message definition file that you opened before beginning this task.

Message Sets: Working with a message category file

This topic area lists the tasks that are involved when working with a message category file.

About this task

- "Message Sets: Creating a message category file" on page 2295
- "Message Sets: Opening an existing message category file" on page 2296
- "Message Sets: Adding a message to a message category" on page 2297
- "Message Sets: Deleting a message from a message category" on page 2297
- "Message Sets: Viewing or configuring message category file properties" on page 2298
- "Message Sets: Deleting a message category file" on page 2298

Message Sets: Creating a message category file

Create a message category file to add categories that you can use to group different message sets.

Before you begin

Complete the following task:

- "Message Sets: Creating a message set" on page 2250

About this task

To create a message category file, complete the following steps.

Procedure

1. Open the **New Message Category File** wizard:
   a) Click **File** > **New** > **Other**.
   b) Expand **Integration Bus - Message Set Development**.
   c) Select **Message Category File**, then click **Next**.
2. In the first pane, select the `Category Kind` for the type of category that you are creating.
   - other. This value indicates that this message category represents a generic grouping of messages. The Category Usage field is disabled.
   - wsdl. This value indicates that this message category represents a WSDL operation. The specified category name is used as the WSDL operation name.

3. Optional: If you set `Category Kind` to wsdl, specify the WSDL operation type by selecting one of the following values for the `Category Usage` field, then click **Next**.
   - wsdl:request-response
   - wsdl:solicit-response
   - wsdl:one-way
   - wsdl:notification
4. Select a folder under the target message set for the new message category file to be saved. The message set folder view is filtered to show only resources in the active working set.
5. In the **File name** field, type a name for the new message category file, then click **Next**.
   The file is automatically given the file extension of `.category`.
6. Select all messages that you want to add to the new category.
   Use **Shift-click** to select a range of messages, and **Ctrl-click** to select or clear individual messages. You cannot complete the creation of the category file without adding one or more messages, and setting the **Role Type** and **Role Usage** values of each message correctly.
7. Click **Finish**.

Results

The message category file is created in the message set folder that you selected. The new message category file opens in the **Message Category** editor, so that you can view and edit it as required.

Message Sets: Opening an existing message category file

This describes how to open an existing message category file in the Message Category editor so that you can view or edit it.

Before you begin

To complete this task, you must have completed the following task:

- “Message Sets: Creating a message category file” on page 2295

About this task

To open an existing message category file:

Procedure

1. Switch to the Integration Development perspective.
2. In the Application Development view, right-click the message category file (with a file extension of `.category`) that you want to open, then click **Open** on the pop-up menu.
   This opens the message category file that you have selected in the Message Category editor.
3. View and edit the message category file as required.

Results

Tip: The Eclipse framework lets you open resource files with other editors. You are advised to only use the IBM App Connect Enterprise Toolkit Message Category editor to work with the message category files because this editor correctly validates changes made to the files. Other editors might not do this.

Message Sets: Adding a message to a message category

You can add a message to a message category file by using the Message Category editor.

Before you begin

You must have completed the following tasks:

- "Message Sets: Adding MRM message model objects" on page 2264 (to create at least one message)
- "Message Sets: Creating a message category file" on page 2295
- "Message Sets: Opening an existing message category file" on page 2296

About this task

To add a message to a message category file:

Procedure

1. Open the Message Category editor.
2. In the Properties Hierarchy, open the **Add Messages** window by right-clicking **Message Category**, then clicking **Add Messages**.

   The **Add Messages** window lists all the messages that are available for adding to the message category file. All messages that are in the message set but have not already been added to the category are displayed.
3. Select the message or messages that you would like to add.

   Use **Shift-click** to select a range of messages and **Ctrl-click** to select or clear individual messages.
4. Click **OK**.

   The selected message or messages are added to the message category and now appear in the Properties Hierarchy.

   Tip: Until you save the message category file, you can undo all additions that you make. To undo a change, right-click **Message Category** in the Properties Hierarchy, then click **Undo**. If you have added multiple messages, this action removes all the messages that you have added. If you want to remove a single message, right-click this message, then click **Undo**. To redo an addition after undoing it, use the **Redo** option.
5. Save and validate the additions that you have made to the message category file by clicking **File** > **Save**, or by pressing Ctrl+S.

Results

When you have saved the message category file after adding a message, you can no longer undo the addition of this message by using the **Undo** option. To remove a message after saving your changes, delete the message from the message category file.

When you have added a message to a message category file, you can configure its properties, according to your requirements, in the Message Category editor Details view.

Message Sets: Deleting a message from a message category

Delete a message from a message category file.

Before you begin

To complete this task, you must have completed the following tasks:

- "Message Sets: Creating a message category file" on page 2295
- "Message Sets: Opening an existing message category file" on page 2296
- "Message Sets: Adding a message to a message category" on page 2297

About this task

To delete a message from a message category file:

Procedure

In the Message Category editor, in the Properties Hierarchy, right-click the message that you want to delete, then click **Delete** on the pop-up menu.

Tip: The message is deleted from the message category file immediately, without a warning appearing first.

Results

Message Sets: Viewing or configuring message category file properties

This topic describes how to view or configure the properties of a message category file and associated messages using the Message Category editor.

Before you begin

To complete this task, you must have completed the following tasks:

- "Message Sets: Creating a message category file" on page 2295
- "Message Sets: Opening an existing message category file" on page 2296
- "Message Sets: Adding a message to a message category" on page 2297 (You must have added one or more messages to your message category file)

About this task

To configure the properties of a message category file:

Procedure

1. Switch to the Message Category editor in the Integration Development perspective.
2. To view or configure the properties of a message category, click **Message Category** in the Properties Hierarchy.

   From the Details section of the Message Category editor you can now view the properties of the message category and make any changes to the properties that are necessary.
3. To view or configure the properties of a message in the message category file, click the name of the message in the Properties Hierarchy.

   From the Details section of the Message Category editor you can now view the properties of the message and make any changes to the properties that are necessary.
4. If you have changed any of the properties in the message category or messages, you can save those changes by selecting **File** > **Save** from the menu.

What to do next

Note: Note that some combinations of `Message Category Usage`, `Role Type` and `Role Usage` are not valid for WSDL and will result in task list errors being generated.

Message Sets: Deleting a message category file

You can delete a message category file from your message model.

Before you begin

To complete this task, you must have completed the following task:

- “Message Sets: Creating a message category file” on page 2295

About this task

To delete a message category file:

Procedure

1. Switch to the Integration Development perspective.
2. In the Application Development view, right-click the message category file (`*.category` file extension) that you want to delete, then click **Delete**. Alternatively select the message category file in the Application Development view, then either click **Edit** > **Delete**, or press the Delete key.
3. On the **Confirm Resource Delete** window, click **Yes** to delete the message category file. Alternatively, to cancel the message category file deletion, either click **No** or press the Esc key.

Results

Tip: After you have deleted a message category file, the action cannot be undone.

Message Sets: Working with data structures

You can create a message definition file in a message set by importing from XML Schema, XML DTD, SCA import or export components, IBM supplied messages, WSDL definitions, IDL files, C header files, and COBOL copybooks. This topic area describes how to import from these data structures using the command line or the IBM App Connect Enterprise Toolkit.

About this task

Tip: In IBM App Connect Enterprise, *message model schema* files contained in applications, integration services, and libraries are the preferred way to model messages for most data formats. Message sets are required if you use the MRM or IDOC domains. For more information about message modeling, see “Message modeling concepts” on page 2134.

Before you attempt to create a message definition from a data structure, by using the IBM App Connect Enterprise Toolkit, you are advised to read “Importing files from the file system into the IBM App Connect Enterprise Toolkit” on page 2319.

The following tasks topics relate to importing by using the IBM App Connect Enterprise Toolkit:

- “Message Sets: Importing from C” on page 2300
- “Message Sets: Importing from COBOL copybooks” on page 2302
- “Message Sets: Importing from IBM supplied messages” on page 2303
- “Message Sets: Importing SCA import or SCA export components” on page 2304
- “Message Sets: Generating an IBM Integration Bus SCA definition from a message set” on page 2316
- “Message Sets: Exporting an SCA Import or Export from an IBM Integration Bus SCA definition” on page 2305
- “Importing from WSDL” on page 2305
- “Message Sets: Importing an IDL file” on page 2309
- “Message Sets: Importing from XML DTD” on page 2310
- “Message Sets: Importing from XML Schema” on page 2311

The following task relates to importing by using the command line:

- “Message Sets: Importing from the command line” on page 2301 for C header files, COBOL Copybooks, XML DTDs and XML Schemas.

Message Sets: Importing from C

Create a message definition file from a C header file for use in the MRM and IDOC domains.

Tip: In IBM App Connect Enterprise, *message model schema* files contained in applications, integration services, and libraries are the preferred way to model messages for most data formats. Message sets are required if you use the MRM or IDOC domains. For more information about message modeling, see "Message modeling concepts" on page 2134. For information about how to import a C header file for use by DFDL domain, see Creating a DFDL schema file by using the New Message Model wizard.

Before you begin

Complete the following tasks:

- "Enabling message set development" on page 2248
- "Message Sets: Creating a message set" on page 2250
- "Importing files from the file system into the IBM App Connect Enterprise Toolkit" on page 2319

Be aware of the following points:

- The wizard can import C header files with `.h`, `.c` and `.css` extensions. If your source file has a different extension you must rename it before attempting to import it.
- If the message set to which you are adding the new message definition file *does not* have an Custom Wire Format (CWF) layer only the logical information appears in the model. You can add the physical layer to the message set before or after importing a C header file, but you should add the physical layer *before* importing it to ensure that it is populated with settings from the C header file.
- You can import a C header file from the command line using **`mqsicreatemsgdefs`**.

About this task

The following steps cover both creating a completely new message definition file and overwriting the contents of an existing file.

To create a message definition file from a C header file:

Procedure

1. Switch to the Integration Development perspective.
2. Open the New Message Definition File wizard by clicking **FileNew Other** from the IBM App Connect Enterprise Toolkit menu.

   A window opens in which you can select a wizard.
3. Expand **Message Broker - Message Set Development**, select **Message Definition**, and click **Next**.

   The New Message Definition File wizard opens.
4. In the displayed list of options, click **C header file** then click **Next**.
5. Step through the remainder of the wizard completing the details as required.

Results

When you have completed importing the C header file using the wizard:

- Carefully check for any errors in the report that is created when the file is imported. You can find this report in the `log` directory within the project containing the message definition that you have attempted to create. The report has a `.c.report.txt` file extension, prefixed with the name that you specified for the new message definition file.
- Review the messages shown in the IBM App Connect Enterprise Toolkit task list to check whether any new warnings or errors have appeared.

Message Sets: Importing from the command line
This describes how to use the command line importer **mqsicreatemsgdefs** to import C, COBOL copybooks, XML DTD or XML Schema in order to populate a message set with message definitions.

Before you begin

Tip: A *message set* is the original container for message models used by IBM App Connect Enterprise. In IBM App Connect Enterprise, *message model schema* files contained in applications and libraries are the preferred way to model messages for most data formats. Message sets continue to be supported, and are required if you use the MRM or IDOC domains. If you need to model data formats for use in the MRM or IDOC domains, you must first enable message set development in the IBM App Connect Enterprise Toolkit. For more information, see "Enabling message set development" on page 2248 .

Before you attempt this task, you should read the following information:

- command

The command line importer allows you to create a new message set, into which the message definition files will be placed. When you create a new message set from the command line, only the logical information is created by default. However, the command line importer allows you to create a new message set based on an existing message set. The physical format information from the base message set is also created in the new message set. If you want physical format information to be created as well, you must take the following steps before you invoke the **mqsicreatemsgdefs** command:

1. Using the IBM App Connect Enterprise Toolkit, create a message set in your workspace that is to be used as a base message set.
2. To this base message set, add the physical formats that you want to be created in your new message set.

About this task

To import C, COBOL copybooks, XML DTD or XML Schema using the command line:

Procedure

1. Close the IBM App Connect Enterprise Toolkit.

   This must not be running when you use the command line importer.
2. Invoke the **mqsicreatemsgdefs** command from a command prompt specifying the message set project name, path name of the source files folder, and any other optional parameters that you require. If you want to add physical formats to the new message set that the **mqsicreatemsgdefs** command creates, specify the base message set that contains these physical formats as the `-base` parameter on the import command line.
3. When the command has completed, open `mqsicreatemsgdefs.report.txt`.

   This report is created when you invoke the **mqsicreatemsgdefs** command and by default is written to the directory from which you invoked the command. The report provides you with the following information:

   - Details of the parameters that were used when **mqsicreatemsgdefs** was invoked.
   - The message set level action.
   - The name of the file or files that have been imported.
   - Details of the import process (for example, any warnings that have been generated and message model objects that have been created).
   - The number of files imported.
4. Start the IBM App Connect Enterprise Toolkit and switch to the Integration Development perspective.

   The message definition file that was created when you invoked **mqsicreatemsgdefs** is visible in the project that you specified.

Results

If an error occurs during the import of a C, COBOL copybook, XML DTD, or XML Schema file, carefully check any errors that the importer reports. By default, all errors are written to the screen and to the log file described above. To gather additional information about the import, specify the `-v` (Verbose) command line parameter. This parameter displays more detailed information as the import proceeds.

Message Sets: Importing from COBOL copybooks

This topic describes how to create a new message definition from a COBOL data structure using the New Message Definition File wizard in the IBM App Connect Enterprise Toolkit.

Tip: In IBM App Connect Enterprise, *message model schema* files contained in applications, integration services, and libraries are the preferred way to model messages for most data formats. Message sets are required if you use the MRM or IDOC domains. For more information about message modeling, see "Message modeling concepts" on page 2134. For information about how to import a COBOL copybook for use by DFDL domain, see "Creating a DFDL schema file by using the New Message Model wizard" on page 2223. For an overview of how to use the COBOL importer, go to the Rational Application Developer for WebSphere Version 8.5.5 product documentation online and search for *COBOL Importer overview*.

Before you begin

Complete the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Importing files from the file system into the IBM App Connect Enterprise Toolkit" on page 2319

Be aware of the following points:

- The wizard can import COBOL files with `.cbl`, `.ccp`, `.cob` and `.cpy` extensions. If your source file has a different extension, you must rename it before attempting to import it.
- If the message set to which you are adding the new message definition file *does not* have a Custom Wire Format (CWF) layer, or a Tagged/Delimited String (TDS) format layer, only the logical information appears in the model.

  You can add the physical layer to the message set before or after importing a COBOL data structure but ensure that you add the physical layer *before* you import the data structure to ensure that it is populated with settings from the COBOL copybook.
- You can import a COBOL data structure from the command line using **`mqsicreatemsgdefs`**.
- The copybook must not contain field names that are COBOL reserved keywords.
- The COBOL importer can only import files that have file names of 60 characters long or less. If you attempt to import a COBOL file with a name longer than 60 characters, the COBOL importer fails with the message `IWAA0652E: File name cannot be longer than 60 characters`.
- Linux The COBOL importer requires 32-bit versions of the Linux operating system libraries. Some of these libraries are not installed by default on the following distributions:

  Red Hat Enterprise Linux V6 64-bit
  Ubuntu 10.4 or later, 32-bit and 64-bit

  For details of which libraries to install, see https://www.ibm.com/support/docview.wss?uid=swg21512074

About this task

The following steps cover creating a new message definition file and overwriting the contents of an existing file.

To create a message definition file from a COBOL data structure:

Procedure

1. Switch to the Integration Development perspective.
2. Open the New Message Definition File wizard by clicking **File>New>Other** from the IBM App Connect Enterprise Toolkit menu.

   A window opens in which you can select a wizard.
3. Expand **Integration Bus - Message Set Development**, select **Message Definition File**, and click **Next**.

   The New Message Definition File wizard opens.
4. Click **COBOL file**, then click **Next**.
5. Step through the remainder of the wizard supplying the details as required.

   For more information, see Message Sets: New message definition file wizard: Create a new message definition file from a COBOL file.

Results

When you have completed importing the COBOL file using the wizard:

- Carefully check for any errors in the report that is created when the file is imported. You can find this report in the `log` directory within the project containing the message definition that you have attempted to create. The report has a `.cobol.report.txt` file extension, prefixed with the name that you specified for the new message definition file.
- Review the messages shown in the IBM App Connect Enterprise Toolkit task list to check whether any new warnings or errors have appeared.

Message Sets: Importing from IBM supplied messages

You can create a new message definition file from an IBM supplied message.

Before you begin

You must have completed the following task:

- "Message Sets: Creating a message set" on page 2250

About this task

The following steps describe how to create a new message definition file, and how to overwrite the contents of an existing file.

To create a message definition from an IBM supplied message:

Procedure

1. Switch to the Integration Development perspective.
2. Open the New Message Definition File wizard by clicking **File** > **New** > **Message Definition File From** on the IBM App Connect Enterprise Toolkit menu.
3. In the displayed list of options, select **IBM supplied message** and click **Next**.
4. Complete the fields of the panel that is displayed by the wizard.

   See Message Sets: New message definition file wizard: IBM supplied message.

Results

When you have finished the import of the IBM supplied message:

- Carefully check for any errors in the report that is created when the file is imported. You can find this report in the `log` directory within the project that contains the message definition that you have created. The report has a `.xsd.report.txt` file extension, prefixed with the name that you specified for the new message definition file.

- Review the messages shown in the IBM App Connect Enterprise Toolkit task list to check whether any new warnings or errors are displayed.

Message Sets: Importing SCA import or SCA export components

You can use the New Message Definition File wizard in the IBM App Connect Enterprise Toolkit to import SCA import or SCA export components from WebSphere Integration Developer. You must import an SCA import or SCA export into the workspace to provide an Integration Bus SCA definition for use in configuring the SCA nodes.

Before you begin

You can import from SCA import or export by creating a message set and using the New Message Definition File wizard. Before you start, you must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Importing files from the file system into the IBM App Connect Enterprise Toolkit" on page 2319

About this task

Note: From Version 7.5 onwards, WebSphere Integration Developer has been renamed IBM Integration Designer. Information in this topic that refers to WebSphere Integration Developer Version 7 is also applicable to IBM Integration Designer Version 7.5.

Ensure that the SCA import or SCA export components that you import from WebSphere Integration Developer use SOAP 1.1 bindings; a validation error occurs if you attempt to import SCA Import or SCA Export components that have been generated with SOAP 1.2 bindings.

The following steps are required to create a new message definition file, or to overwrite the contents of an existing file.

To create a message definition from an SCA import or SCA export:

Procedure

1. Switch to the Integration Development perspective.
2. Open the New Message Definition File From wizard by clicking **File** > **New** > **Message Definition File From ...** on the IBM App Connect Enterprise Toolkit menu.
3. In the displayed list of options, select **SCA Import or Export** and click **Next**.

   Alternatively, open the wizard by right-clicking a file with extension `.zip` that was previously imported into the IBM App Connect Enterprise Toolkit and clicking **New> Message Definition File From ...** on the menu.
4. Step through the remainder of the wizard supplying the details as required.

   You must choose whether the SCA import or SCA export that you want to import is in the current workspace in the IBM App Connect Enterprise Toolkit or is outside the workspace.

   Check boxes provide options to:

   - Copy the source file (or files) into the 'importFiles' directory of the message set project. By default, this check box is cleared.
   - Add appropriate supported domains if they do not exist. Selecting this check box adds the XMLNSC domain for all binding types; the SOAP domain is also added for web service bindings.
   - Create an appropriate physical format if one does not exist. By default, this check box is selected.

   Note:

   - The panels and options that are available in the wizard are dependent on the settings that you select.
   - Some fields in the wizard might not be available perhaps because the field has a mandatory setting, or because the field has only one possible value, or because the field is not being used as a result of other settings that have been made.

Message Sets: Exporting an SCA Import or Export from an IBM Integration Bus SCA definition

You can use the New Message Definition File wizard in the IBM App Connect Enterprise Toolkit to export SCA import or SCA export components. You must export an SCA import or SCA export if the IBM Integration Bus SCA definition is to be used by IBM Integration Designer.

Before you begin

You must have completed the following task:

- "Message Sets: Generating an IBM Integration Bus SCA definition from a message set" on page 2316

About this task

The following steps are required to export an SCA Import or Export from an IBM Integration Bus SCA definition:

Procedure

1. Switch to the Integration Development perspective.
2. In the Application Development view, right-click the folder that contains the SCA definition from which you want to export an SCA import or SCA export and select **Export** to start the Export wizard.
3. In the displayed list of options, select **Message Sets** > **SCA Import or Export from Integration Bus SCA Definition** and click **Next**. This action starts the SCA Import or Export from Integration Bus SCA Definition wizard.
4. Step through the remainder of the wizard and provide the details as required.

   Check boxes provide options to:

   - Overwrite existing files without warning. By default, this check box is cleared.
   - Apply working set filtering to artifact selections on this page. By default, this check box is selected.

   Note:

   - The panels and options that are available in the wizard are dependent on the settings that you select.
   - Some fields in the wizard might not be available. This might be because the field has a mandatory setting, or because the field has only one possible value, or because the field is not being used as a result of other settings that have been made.

Results

The wizard creates a folder on the file system that contains the individual files from the IBM Integration Bus SCA definition (.import or .export, .wsdl and .xsd files).

What to do next

In IBM Integration Designer, import the SCA import or export component and WSDL that have been exported from IBM App Connect Enterprise. Do not select the XSD files. See *Importing WSDL files* in the IBM Integration Designer product documentation.

Importing from WSDL

You can import a WSDL file into an application or library, or import a WSDL file into a message set.

About this task

The following sections describe how to import WSDL files:

- "Importing a WSDL file into an application or library" on page 2306
- "Importing a WSDL file into a message set" on page 2307

Before you begin

Ensure that you have completed the following tasks:

- Read about applications and libraries in "Resource management overview" on page 1942.
- Create an application or library by following the instructions in "Creating an application" on page 1963 or "Creating a library" on page 1964.

When you import a WSDL file into an application or library, all the WSDL files that are referenced are imported into the specified folder. If there are multiple WSDLs with the same name but with different paths, then the files are suffixed with an increasing index number. For example: If there are multiple files that are named `my.wsdl` in the context of import, then these files are renamed to `my1.wsdl`, `my2.wsdl`, `my3.wsdl`, and so on, in the specified folder.

About this task

To import a WSDL file into an application or library, complete the following steps.

Procedure

1. In the Application Development view, right-click an application or library, then click **New** > **Message Model**.

   The **New Message Model** wizard opens.
2. Select **SOAP XML**, then click **Next**.
3. Select **I already have WSDL for my data**, then click **Next**.
4. The name of the application or library that you selected in step 1 is shown. You can choose another application or library to contain your WSDL file, or you can create a new application or shared library by clicking **New**.
5. Optional: Specify a root destination folder. Click **Browse** to select an existing folder or create a new one.

   The imported WSDL and schema files are placed under the root folder with the same organization as the source files. The files are not placed in directories that match the namespace of the WSDL or schema files.
6. Optional: Specify an XML schema file. This field is completed automatically when you select a file from your workspace or your file system. By default, the XML schema file shares the name of the imported file.
7. Select the WSDL file to import from your workspace, or from an external URL, then click **Next**.
8. Select the bindings to import, then click **Finish**.

   For each binding that you import, a message root is created for every global element that is used by a part in the operations of the binding.

Results

Files are created and are shown under the selected application or library in the Application Development view.

What to do next

Configure an existing SOAP node by dragging a deployable WSDL file onto the node.

Before you begin

Ensure that you have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Importing files from the file system into the IBM App Connect Enterprise Toolkit" on page 2319

The wizards for message set development have been provided for compatibility with previous versions of the product. To develop message sets in WebSphere Message Broker Version 8.0 and later, you must activate the message set development wizards by completing the following steps.

1. Click **Window** > **Preferences**.
2. Expand Integration Development and click **Message Sets**.
3. Select **Enable menus for Message Set development**, then click **OK**.

About this task

The following steps describe how to create a new message definition file, or overwrite the contents of an existing file.

Procedure

1. In the Application Development view, right-click the message set project, then click **New** > **Message Definition File From** > **WSDL file**.

   The **New Message Definition File** wizard opens.
2. Step through the wizard, completing the details as required.

   You must choose whether the WSDL file, or files, that you want to import are in the current workspace in the IBM App Connect Enterprise Toolkit or are outside the workspace.

   Select the appropriate check boxes to control the following behavior:

   - Copy the source file (or files) into a directory of the message set project. By default, this check box is cleared.
   - Add the SOAP and XMLNSC domains to your message set so that you can use the SOAP nodes. By default, this check box is selected.

   The panels and options that are available in the wizard depend on the settings that you select. Some fields in the wizard might not be available, because the field has a mandatory setting, the field has only one possible value, or the field is not being used as a result of other settings that have been made.

Results

When you have finished importing the WSDL file or files, complete the following steps.

- Check carefully for any errors in the report that is created when the file is imported. You can find this report in the `log` directory in the project that contains the message definition that you have created. The report has a `<wsdl-file-name>.wsdl.report.txt` file descriptor, where `<wsdl-file-name>` is the name of the WSDL definition that you are importing.
- Review the messages that are shown in the IBM App Connect Enterprise Toolkit task list to check whether any new warnings or errors are shown.

Required SOAP Envelope and SOAP encoding message definitions are automatically added to your message set during the import. If required, you can also import these definitions manually by using the New Message Definition File wizard, by selecting the new option **IBM supplied message**.

Message Sets: Accepting self-signed certificates when importing WSDL
You can import WSDLs that reference schemas on self-signed secure HTTPS servers, by adding security certificates to the Java Virtual Machine JVM.

About this task

The following procedure enables you to add certificates from the SSL server to each instance of your JVM.

If you are using Windows 7, you must enter the commands from a console that has administration privileges.

Procedure

1. Obtain the certificate from the server (it is a `.cer` file) and copy it into your filesystem. somewhere.

   This example uses `D:\mb.cer`
2. Open a command prompt and navigate to your Java runtime environment (JRE) bin directory that is located in your IBM App Connect Enterprise install directory, for example, `C:\Program Files\IBM\ACE\12.0.`*n*`.0\tools\common\jdk\jre\bin`.
3. Type in `keytool -printcert -file D:\mb.cer`
4. You obtain some output, and the important parameter to check is the `CN= value`.

   The value should be the same as the server name from which the WSDL is requesting files.
5. Input the certificate into a new keystore file.
   a) This procedure assumes that you can store your keystore file in `D:\mb.keystore`

      Note, that the alias must be the same name as the server and the name can be anything you require.

      For example, the name can be of the form `<userID>.<servername>.ibm.com` or `subdomain.integrationbus.com`

      The example within this topic uses the form `<userID>.<servername>.ibm.com`
   b) Type in:

   ```
   keytool -import -alias <userID>.<servername>.ibm.com -file
    D:\mb.cer -keystore D:\mb.keystore
   ```

   c) Import the certificate into a keystore file.

      You are either asked for a password, or you need to create a password when the system requests one. This is the password used in Step “7” on page 2308, and the example within this topic uses the word `password`.
   d) Select `Yes` to trust the certificate.
6. Add the keystore as an argument when you start IBM App Connect Enterprise.

   You must do this so that you can use the certificates you have just added to the keystore.
   a) Go back to `C:\Program Files\IBM\ACE\12.0.`*n*`.0\tools`.
7. Type in:

   ```
   mb -vmargs -Djavax.net.ssl.trustStore=d:\\mb.keystore
    -Djavax.net.ssl.trustStorePassword=password
   ```

8. Validate and import the WSDL

Results

You obtain a console output that is of the following format:

```
C:\Program Files\IBM\ACE\12.0.n.0\tools\common\jdk\jre\bin>keytool -printcert -file d:\
mb.cerOwner: EMAILADDRESS=jdoe@xx.ibm.com, CN=<userID>.
```

C:\Program Files\IBM\ACE\12.0.n.0\tools>
```

If an error occurs during the import of a WSDL definition, carefully check any errors that are reported. By default, all errors are written both to the screen and to the file that has the format `*.wsdl.report.txt`.

Message Sets: Importing an IDL file

You can use the New Message Definition File wizard in the IBM App Connect Enterprise Toolkit to create a message definition from an IDL file.

Before you begin

Complete the following tasks:

- “Message Sets: Creating a message set” on page 2250
- “Importing files from the file system into the IBM App Connect Enterprise Toolkit” on page 2319
- Ensure that you have a valid IDL file. If you select an IDL file that is not valid, you see an error message and you cannot complete the wizard. When you import an IDL file, supported and unsupported operations are listed. You can import an IDL file that contains operations with types that are not supported by IBM App Connect Enterprise, but if you try to call an unsupported operation, you see an error message. The CORBA IDL file must contain at least one interface that has one operation. For more information about the IDL operations that are supported, see “CORBA support” on page 1155.
- For more information about how IDL types correspond to XML schema types, see “IDL data types” on page 1156.

About this task

The following steps describe how to use an IDL file to create a message definition file or overwrite the contents of an existing file.

Procedure

1. Right-click the message set, then click **New** > **Message Definition File From** > **CORBA IDL File** to open the New Message Definition File From wizard.

2. Complete the wizard by following the on-screen instructions.
   a) Select an IDL file either from the list of files in your workspace, or by using **Browse** to search outside your workspace.

      If you have imported an IDL file that contains includes, select the top-level IDL file.
   b) Ensure that the check box to add the DataObject domain to the message set is selected. By default, this check box is selected.
   c) Optional: You can provide a target namespace.
   d) By default, the message definition file name is the same as the name of the IDL file. You can change the name of the message definition file.
   e) If the IDL or message definition file exists, click **Next**. To rename or overwrite the existing files, select them.
3. Click **Finish**.
4. After you have imported the IDL file, check for errors.
   - Check for errors in the report that is created when the file is imported. You can find this report in the `log` directory of the project that contains the new message definition. The report is named `<idl-file-name>.idl.report.txt`, where `<idl-file-name>` is the name of the IDL file that you are importing.
   - Check for errors in the IBM App Connect Enterprise Toolkit task list.

Results

When you have finished importing the IDL file, the message definition opens. A read-only copy of the IDL file is stored in the `CORBA IDLs` folder.

For each IDL file, a single message definition is created. (If you have imported an IDL file that contains includes, all the elements and types in the IDL files are generated into a single message definition.) In the message definition, two messages are created for each operation in the IDL file (one message for the request, and one for the response), and a message is created for each user-defined exception. The request has a child element for each in and inout parameter; the response has a child element for each inout and out parameter, and a child element named "_return" for the return type of the operation.

The name of these elements is based on the interface name and operation name; for example, for the operation *sayHello* in the Interface *Hello*, the request element is called *Hello.sayHello*, and the response element is called *Hello.sayHelloResponse*. If the interface is contained in a module, the request and response element names are qualified with the names of the modules. For example, if the operation *sayHello* in the Interface *Hello* is contained in *ModuleB*, which in turn is contained in ModuleA, the response element would be called *ModuleA.ModuleB.Hello.sayHelloResponse*.

Another message definition is created with a message for each CORBA system exception.

What to do next

Develop a message flow, as described in “Developing a message flow with a CORBARequest node” on page 1163.

Message Sets: Importing from XML DTD

You can create a new message definition from an XML DTD by using the New Message Definition File wizard in the IBM App Connect Enterprise Toolkit.

Tip: In IBM App Connect Enterprise, *message model schema* files contained in applications, integration services, and libraries are the preferred way to model messages for most data formats. Message sets are required if you use the MRM or IDOC domains. For more information about message modeling, see “Message modeling concepts” on page 2134. For information about how to import an XML DTD for use by the XMLNSC domain, see “Creating an XML schema file by using the New Message Model wizard” on page 2244.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Importing files from the file system into the IBM App Connect Enterprise Toolkit" on page 2319

Before you begin this task, you should be aware of the following points:

- If the message set to which you are adding the new message definition file *does not* have an XML wire format (XML) layer only the logical information appears in the model. You can add the physical layer to the message set before or after importing from a XML DTD, but you should add the physical layer *before* importing it to ensure that it is populated with settings from the XML DTD.
- It is also possible to import an XML DTD from the command line using **mqsicreatemsgdefs**.
- The file extension must be `.dtd` in lowercase.

About this task

The following steps cover both creating a completely new message definition file and overwriting the contents of an existing file.

To create a message definition from an XML DTD:

Procedure

1. Switch to the Integration Development perspective.
2. Open the New Message Definition File wizard by clicking **File> New> Message Definition File** from the IBM App Connect Enterprise Toolkit menu.
3. In the displayed list of options, click **XML DTD file** to select it then click **Next**.
4. Step through the remainder of the wizard completing the details as required.

Results

When you have completed importing the XML DTD using the wizard:

- Carefully check for any errors in the report that is created when the file is imported. You can find this report in the `log` directory within the project containing the message definition that you have attempted to create. The report has a `.dtd.report.txt` file extension, prefixed with the name that you specified for the new message definition file.
- Review the messages shown in the IBM App Connect Enterprise Toolkit task list to check whether any new warnings or errors have appeared.

The message definition file is created from the XML DTD and is opened in the Message Definition editor so that you can check the imported information and make any required changes. While you are checking the newly created message definition file, review any messages that appear in the IBM App Connect Enterprise Toolkit task list to see whether you need to make any corrections to resolve errors or warnings relating to the new file.

Message Sets: Importing from XML Schema

You can use the New Message Definition File wizard in the IBM App Connect Enterprise Toolkit to create a new message definition from an XML Schema

Before you begin

Tip: In IBM App Connect Enterprise, *message model schema* files contained in applications, integration services, and libraries are the preferred way to model messages for most data formats. Message sets are required if you use the MRM or IDOC domains. For more information about message modeling, see "Message modeling concepts" on page 2134. For information about how to create an XML schema, see "Creating an XML schema file by using the New Message Model wizard" on page 2244.

you must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Importing files from the file system into the IBM App Connect Enterprise Toolkit" on page 2319

Before you begin this task, you should be aware of the following points:

- If the message set to which you are adding the new message definition file *does* have an XML wire format layer, but *no* namespace support, the imported schema is modified to remove namespaces. For this reason, you should enable namespace support before importing a schema.
- If the message set to which you are adding the new message definition file *does not* have an XML wire format layer, but *does* have namespace support, only the logical information appears in the model. For this reason, you should add the physical layer to the message set before importing the schema. This ensures that the message set is populated with the settings and values from the schema. The XML Schema is not modified to remove namespaces.
- If the message set to which you are adding the new message definition file *does not* have an XML wire format layer, and *does not* have namespace support, only the logical information appears in the model and the imported schema is modified to remove namespaces.
- If you are working with a message set that does not have namespace support, you must specify the preferences that apply when you import a schema into the message set. These preferences allow you to specify how the importer treats certain individual schema constructs. You can either reject the schema if any occurrences of the construct are encountered or modify occurrences of the construct. If you choose modify, the importer modifies all occurrences of the construct.
- The extension to the XML Schema file must be `.xsd` in lowercase.

About this task

The following steps create a completely new message definition file or overwrite the contents of an existing file.

To create a message definition from an XML Schema file:

Procedure

1. Switch to the Integration Development perspective.
2. Open the New Message Definition File wizard by clicking **File> New> Message Definition File** on the IBM App Connect Enterprise Toolkit menu.

   Alternatively, you can open the wizard by right-clicking an `*.xsd` file that was previously imported into the IBM App Connect Enterprise Toolkit and clicking **New> Message Definition File** on the menu.
3. In the displayed list of options, click **XML Schema file** to select it, and then click **Next**.
4. Step through the remainder of the wizard, competing the details as required.

   The processing time for importing the XML Schema varies according to the size and complexity of that schema. In a large and complex schema, it can take some time to import the file, generate the log file and display any task list warnings or errors.

Results

When you have finished importing the XML Schema using the wizard:

- Carefully check the log file for any warnings or errors in the report that is created when the file is imported. These warnings and error messages give information about whether the schema failed to import or needed to be modified to enable it to be successfully imported. You can find this report in the `log` directory structure within the project that contains the message definition that you have tried to create. The report has a `.xsd.report.txt` file extension, prefixed with the name that you specified for the new message definition file.
- Review the messages that are shown in the IBM App Connect Enterprise Toolkit task list to check whether any new warnings or error messages have appeared. Although you might have imported a

perfectly valid schema, the task list will display warnings or error messages for any errors that exist in the message definition file. The following situations are examples where messages appear:

- If the XML Schema that you are importing contains xsd:key, xsd:keyref and xsd:unique constructs, warning messages appear in the task list to tell you that these constructs are unsupported and will be ignored by the integration server. If you prefer to delete these constructs, open the message definition file in the Message Definition editor, and delete the constructs as described in "Message Sets: Deleting objects" on page 2292. Deleting the constructs also removes the warning messages from the task list. If you decide not to delete the constructs, they remain in the message model but are not be deployed to the integration server, or used for any other purpose. The warning messages remain in the task list, but you can use the message model normally.
- If the XML Schema that you are importing contains xsd:redefine constructs, error messages appear in the task list to tell you that this construct is unsupported. If you right-click the error messages and select **Quick Fix**, you can choose to convert the xsd:redefine constructs into xsd:include constructs. This also removes the error messages.
- If the XML Schema that you are importing contains xsd:attribute constructs that contain both a fixed value and a default value, error messages appear in the task list to tell you that this construct is unsupported. However, the schema is still imported and the fixed value is used, not the default value. The error messages can be ignored.
- If you are importing a collection of related XML Schema files and the Message Definition Editor cannot resolve the links between two of the imported files, messages appear in the task list to say that referenced types or other objects cannot be found.

Message Sets: Generating documentation from message sets and message flows

You can generate documentation from your message sets, message flows, subflows, message definition files, message maps, Java files, ESQL files, and deployable WSDL files.

About this task

To generate documentation that describes your message sets, message flows, subflows, message definition files, message maps, Java files, ESQL files, and deployable WSDL files, complete the following steps.

Bidirectional text is not fully supported in generated documentation. For example, if you enter text in the IBM App Connect Enterprise Toolkit that has a right-to-left orientation, the text is displayed in the generated documentation with a left-to-right orientation.

Procedure

1. Switch to the Integration Development perspective.
2. In the pop-up menu of the Application Development view, right-click a message set project, a message set, a message flow, a subflow, a message definition file, a Java file, an ESQL file, or a deployable WSDL file, and select the action **Generate Documentation**.

   The Documentation Generation wizard opens.
3. Provide the information that is requested to describe the documentation report that you want, and click **Next** to move to the next panel of the wizard.
4. Step through the wizard, clicking **Next** to move to a new panel, and clicking **Finish** when you have described all the information that you want your report to document.

Message Sets: Generating XML Schemas

You can generate either a single XML Schema from a message definition file, or multiple XML Schemas from a message set.

About this task

To generate a single XML Schema from a message definition file, see "Message Sets: Generating an XML Schema" on page 2315.

To generate multiple XML Schemas (one from each message definition file in a message set) see "Message Sets: Generating multiple XML Schemas" on page 2314.

Message Sets: Generating multiple XML Schemas

You can generate an XML Schema for each message definition file in a message set.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Working with a message definition file" on page 2261
- "Message Sets: Working with MRM message model objects" on page 2264

Note: IBM App Connect Enterprise uses XML Schema 1.0 to describe the logical structure of messages.

Tip: You should replace any deprecated constructs before you generate XML Schema representations of your models.

About this task

Procedure

1. Switch to the Integration Development perspective.
2. In the Application Development view, right-click the message set folder from which you want to generate XML Schemas, and click **Generate> XML Schemas**.
3. The **Generate XML Schemas** window is displayed, and you must put into the **Zip file name** field the name of the compressed file (`*.zip` file extension) that you want to contain the generated XML Schemas.
4. Select a destination folder for this compressed file. You can choose a location either inside or outside the workspace:
   - Click **Create in a workspace directory** and select the required destination folder from the expanded workspace directory. The contents of the folder that you select are overwritten.

     If you want to create a new folder:

     a. Click the desired location.

     b. Click **Create New Folder**.

     c. Click OK
   - Click **Export to an external directory** and click **Browse** to expand the directory. Select a folder from the expanded directory. The contents of the folder that you select are overwritten.

     If you want to create a new folder:

     a. Click the desired location.

     b. Click **Make New Folder** and type the name of the new folder into the directory tree.

     c. Click OK

5. Optional: Choose from the list given in the **XML Wire Format** field an XML wire format that you want to use to generate the XML Schemas.

   Tip: You must have previously added one or more XML Wire Format layers to the message set if you want to use an XML physical format when you generate XML Schemas. For further information see "Message Sets: Adding an XML wire format" on page 2256.
6. If you do not want strict generation of an XML Schema, clear the **Strict generation** check box at the bottom of the **Generate XML Schemas** page.

   By default, this check box is selected.

   Tip: For further information on strict and lax generation of an XML Schema, see "Generation of XML schema" on page 2205.
7. Click **Finish**.

   The compressed file that contains your generated XML Schemas is created.

Message Sets: Generating an XML Schema

You can generate an XML schema from a message definition file.

Before you begin

You must have completed the following tasks:

- "Message Sets: Creating a message set" on page 2250
- "Message Sets: Working with a message definition file" on page 2261
- "Message Sets: Working with MRM message model objects" on page 2264

Note: IBM App Connect Enterprise uses XML Schema 1.0 to describe the logical structure of messages.

Tip: You should replace any deprecated constructs before generating XML Schema representations of your models.

About this task

This task topic describes how to generate an XML Schema from a message definition file:

Procedure

1. Switch to the Integration Development perspective.
2. In the Application Development view, right-click the message definition file (`*.msxd` file extension) from which you want to generate an XML Schema, then click **Generate** > **XML Schema** on the menu.
3. The **Generate XML Schema** window is displayed, and the message definition file that you selected is highlighted. The message definition file list is filtered to only show artifacts in the active working set. If this is not the message definition file from which you want to generate an XML Schema, select the correct message definition file.
4. Optional: From the drop down list at the bottom of the **Generate XML Schema** window, select the XML Wire Format that you want to use to generate the XML Schema.

   Tip: You must have previously added one or more XML Wire Format layers to a message set if you want to use an XML physical format when you generate XML Schema. For further information see "Message Sets: Adding an XML wire format" on page 2256.
5. If you do not want strict generation of an XML Schema, clear the **Strict generation** check box at the bottom of the **Generate XML Schema** page.

   By default, this check box is selected.

   Tip: For further information on strict and lax generation of XML Schema, see "Generation of XML schema" on page 2205.
6. Click **Next** to move to the next page of the wizard.

7. Select a destination folder for the XML Schema. You can choose a location either inside or outside the workspace:
   - Click **Create in a workspace directory** and select the required destination folder from the expanded workspace directory. The contents of the folder that you select are overwritten.

     If you want to create a new folder:

     a. Click the desired location.

     b. Click **Create New Folder**.

     c. Click OK
   - Click **Export to an external directory** and click **Browse** to expand the directory. Select a folder from the expanded directory. The contents of the folder that you select are overwritten.

     If you want to create a new folder:

     a. Click the desired location.

     b. Click **Make New Folder** and type the name of the new folder into the directory tree.

     c. Click OK
8. Click **Finish**.

   Your XML Schema is generated.
9. Use the Application Development view to locate the destination folder that you specified for the generated XML Schema.

   This folder contains a file with exactly the same name as your message definition file with the file extension `*.xsd`. This is the generated XML Schema. To view this file, right-click it, then click **Open** on the menu. This opens the schema editor.

   Tip: The **Design**, **Source** or **Graph** tabs located in lower-left corner of the schema editor provide you with different views of generated XML Schema.

Results

Message Sets: Generating an IBM Integration Bus SCA definition from a message set

IBM App Connect Enterprise creates an IBM Integration Bus SCA definition from existing message definitions.

Before you begin

You must have created a message set that contains message definitions. The wizard gives an error if the set of message definitions is empty.

About this task

To generate an IBM Integration Bus SCA definition:

Procedure

1. Switch to the Integration Development perspective.
2. In the Application Development view, right-click the folder that contains the message set file from which you want to generate an IBM Integration Bus SCA definition, and select **Generate** > **IBM Integration Bus SCA definition**.

   This action starts the **Generate Integration Bus SCA Definition** wizard.

3. Step through the wizard providing the details as required.

   Some of the panels and options are subject to settings that you make within the wizard and might not always be shown. Also, some fields in the wizard might be grayed out. This happens when a field has a mandatory setting, or when the field is not used because of settings that have already been made in other fields.

   By default, the wizard creates the IBM Integration Bus SCA definition in the message set project.

Results

On completion of the **Generate Integration Bus SCA Definition** wizard, you have generated either a `.insca` or a `.outsca` IBM Integration Bus SCA definition that is stored in the SCA category under the message set project.

A `.insca` IBM Integration Bus SCA definition is a compressed file that contains an SCA import and all the XSDs and WSDLs that are referenced directly or indirectly by the SCA import and a `.outsca` IBM Integration Bus SCA definition is a compressed file that contains an SCA export and all the XSDs and WSDLs that are referenced directly or indirectly by the SCA export.

Specifically, the IBM Integration Bus SCA definition contains:

- A WSDL interface that contains one or more operations.
- XSDs that correspond to the messages that are used in the operations defined in the interface.
- If you have selected a web services binding, the WSDL contains service and binding information that defines the endpoint.
- If you have not selected a web services binding, the SCA Import or Export must contain binding information for another binding that is supported by IBM App Connect Enterprise.

Message Sets: Generating a WSDL definition from a message set

To ensure the highest interoperability of your web services, use the document style of WSDL whenever possible. If rpc style WSDL is necessary, use literal encoding.

Before you begin

Before you start you must already have completed the following tasks:

- “Enabling message set development” on page 2248
- “Message Sets: Creating a message set” on page 2250

Replace any deprecated constructs before generating WSDL representations of your message models.

About this task

To generate a WSDL definition:

Procedure

1. Switch to the Integration Development perspective.
2. In the Application Development view, right-click the folder that contains the message set file from which you want to generate a web service definition, and select **Generate** > **WSDL Definition**.

   This starts the **Generate WSDL** wizard.
3. Step through the wizard completing the details as required.

   Some of the panels and options are subject to settings that you make within the wizard and might not always be shown. Also, some fields in the wizard might be greyed out. This happens when a field has

a mandatory setting, or when the field is not used because of settings that have already been made in other fields.

By default, the wizard creates the WSDL in the message set project. If you are going to use the WSDL to configure a SOAP node, create the WSDL in the message set, not the message set project.

Results

On completion of the **Generate WSDL** wizard, you have generated a WSDL definition. The file extension for WSDL files is .wsdl, and the file extension for any imported schema files in multi-file mode (where the WSDL definition is split over a number of files) is .xsd.

This following is an example of the WSDL that is generated for a JMS binding:

```
<wsdl:service name='HTTP'>
  <wsdl:port binding='tns:JMSSoapBinding' name='HTTP'>
    <wsdlsoap:address
       location='jms:/queue?destination=jms/MyQueue&amp;
                 connectionFactory=jms/MyCF&amp;
                 priority=5&amp;
                 targetService=GetQuote'/>
  </wsdl:port>
</wsdl:service>
```

Note: The various parts of the location string are broken over separate lines for clarity, but are generated as a continuous string without additional white space.

Applying a Quick Fix to a task list error

During the creation, migration and manipulation of message models, warnings or errors might occur; these are listed in the Problems view of the Integration Development perspective. Some of these warnings or errors can be cleared by applying a Quick Fix.

About this task

The types of warnings or errors that can be cleared using a Quick Fix are those where the construct has a broken link, where the construct has a facet that is not legal, or where the construct has been imported, and where a warning or error has occurred, but has been kept to ensure the integrity of structure that is being imported. This allows you to fix the problem in the most appropriate way.

To apply a Quick Fix:

Procedure

1. Switch to the Integration Development perspective.
2. Ensure that the Problems view is visible in the Integration Development perspective of the IBM App Connect Enterprise Toolkit.

   If the Problems view is not visible, from the IBM App Connect Enterprise Toolkit menu, click **Window** > **Show View** > **Problems**.
3. In the Problems view, right-click the task list warning or error that you want to apply the Quick Fix to, then click **Quick Fix**.

   Note that **Quick Fix** might not be available for the problem that you are trying to fix.
4. Step through the windows that are displayed, making the selections that are required to ensure that the fix is applied in the appropriate way.

Results

When the Quick Fix has successfully been applied to the task list warning or error, it is removed from the Problems view.

Importing files from the file system into the IBM App Connect Enterprise Toolkit

You can import files from the file system into the IBM App Connect Enterprise Toolkit by using the Import wizard, by dragging, or by copying.

About this task

Use one of the following options to import files for use by your selected project:

- "Using the Import wizard" on page 2319
- "Dragging and dropping" on page 2320
- "Copying and pasting" on page 2320

You can then select the imported file in the New Message Definition File wizard to create a message definition that is based on the contents of this file.

Using the Import wizard

About this task

Use the Import wizard to import all the files, or a selection of files, from the specified source.

To import files using the Import wizard:

Procedure

1. In the Application Development view, click the project folder into which you are going to import the files.
2. Open the Import wizard by clicking **File** > **Import**.
3. On the Select page of the Import wizard, click either **File System** or **Archive file**, depending on the type of resource that you are importing.
4. Click **Next**.
5. On the File System page, in the **Directory** field, specify the import source.

   Either type the source name in the field, or click **Browse** and select the parent directory, or compressed file that contains the file or files that you want to import. Then click **OK** (directory) or **Open** (compressed file).

   Tip: Directories from which you recently imported files are shown in the list in the **Directory** field.
6. Using the left and right panes that are displayed under the **Directory** field, specify the folders or files, or both, that you want to import.

   Consider the following points when you are making your selections:

   - To import the entire contents of a folder, select the check box for this folder in the left pane. To view secondary folders within a folder, expand the folder by clicking the plus sign (**+**).
   - To import a specific file or files within a folder, use the right pane to select the individual files that you want to import. If you select a file or files in the right pane, the check box for the folder that contains these files is disabled in the left pane to indicate that only some of the files in the folder will be imported.
   - To restrict the type of files that you are importing, click **Filter Types**, then, on the **Select Types** window, select the check boxes for the file types that you want to include, and click **OK**. If you want

to include files with extensions that are not shown in the list, type these extensions in the **Other Extensions** field.

- To select all the folders and files that are shown on the File System page, click **Select All**.
- To clear all the folders and files that are currently selected on the File System page, click **Deselect All**.

The **Select the destination for imported resources** field is already set to the name of the project folder that you selected in step 2.

7. Optional: To change the destination project or folder, click **Browse** to open the **Folder Selection** window.

   Select an alternative project folder by clicking the folder, then clicking **OK**.
8. Optional: To overwrite existing resources and not have a warning displayed, select the **Overwrite existing resources without warning** check box.

   This check box applies to both compressed files and file systems.
9. File system import only: Select one of the following options, depending on the folder structure that you want to create:

   - **Create complete folder structure**
   - **Create selected folders only**
10. Click **Finish**.

Results

The files that you selected are imported and are shown in the Application Development view under the project folder that you selected.

Dragging and dropping

About this task

You can use the drag-and-drop method to import files from your file system into the IBM App Connect Enterprise Toolkit. Drag the resources that you are importing to the exact location in the Application Development view where you want the resources to be. Do not drag them onto a blank area in the Application Development view.

To import files by dragging:

Procedure

1. In your file system, locate the file or folder that you want to import into the IBM App Connect Enterprise Toolkit.
2. Drag the file or folder to a specific location in the Application Development view.

   When you are dragging resources into the Application Development view, the project or folder into which you are trying to drop the resource is selected.
3. Ensure that the file or folder is copied into the IBM App Connect Enterprise Toolkit.

Results

Copying and pasting

About this task

You can use the copy and paste function of your operating system as a method of importing a file system into the IBM App Connect Enterprise Toolkit.

To import files by copying and pasting:

Procedure

1. Locate the file or directory that you want to import into the IBM App Connect Enterprise Toolkit.
2. Using the copy and paste function in the operating system, copy the file or directory to your system clipboard.
3. Select the destination for the file or directory in the Application Development view.
4. From the IBM App Connect Enterprise Toolkit menu, click **Edit** > **Paste**.

Results

The files or directories are copied into the IBM App Connect Enterprise Toolkit, and placed into the location that you selected.

Developing user-defined extensions

A user-defined extension is a component that you design and implement to extend the function of IBM App Connect Enterprise.

About this task

You can create and implement the following types of user-defined extension:

- Connectors
- User-defined nodes
- User-defined parsers
- User-defined exits

The user-defined extensions that you create can be used with the nodes and parsers that are supplied with the product, and with nodes and parsers that are supplied by independent software vendors.

For more information about each type of user-defined extension that you can create, see "User-defined extensions overview" on page 2321. These topics help you to understand how your user-defined extension interacts with other components of IBM App Connect Enterprise, such as message flows and their associated integration servers. A good understanding of the integration node architecture helps you to plan and construct user-defined extensions more effectively.

To create a user-defined extension, follow the instructions in the appropriate topic:

- "Developing connectors" on page 2351
- "Developing user-defined nodes from a subflow project" on page 2382
- "Developing user-defined parsers" on page 2434
- "Developing user-defined exits" on page 2443

You can write user-defined nodes in C or Java, or you can use a subflow to create a node. You write connectors in Java, and you write user-defined parsers and exits in C.

User-defined extensions overview

A user-defined extension is an optional component that you design and create to extend the functionality of IBM App Connect Enterprise.

You can create the following types of user-defined extension:

- Input nodes
- Message processing nodes
- Output nodes

- Connectors
- Parsers
- User exits

The user-defined nodes and parsers that you create can be used with the nodes and parsers that are supplied with the product, and with nodes and parsers that are supplied by other vendors. You can configure a user-defined node to use a user-defined parser.

You can write user-defined exits and parsers only in the C programming language. You can write user-defined nodes in the C or the Java programming languages, or you can use a subflow as a user-defined node. You can write connectors in the Java programming language only. You must compile user-defined nodes and parsers that are written in C into a loadable implementation library (LIL), and user exits that are written in C into a loadable exit library (LEL): that is, a shared library on Linux and UNIX systems, or a dynamic link library (DLL) on Windows systems. You must package connectors and user-defined nodes that are written in Java as a JAR file. You must import any user-defined nodes that you create into the IBM App Connect Enterprise Toolkit before you can use them. You must create a connector for the runtime environment, and a user-defined node to represent the connector in a message flow.

To achieve platform independence, use the ANSI standard C or Java programming languages, and avoid platform-specific code in your user-defined extension.

The following topics help you to understand how your user-defined extensions interact with other components of IBM App Connect Enterprise, such as message flows and integration servers. A good understanding of the integration node architecture helps you to plan and construct user-defined extensions more effectively.

- "Why use a user-defined extension?" on page 2322
- "Why use a user exit?" on page 2328
- "Which type of user-defined extension to use" on page 2331
- "Which language to use to implement a user-defined extension" on page 2350

Why use a user-defined extension?

Use a user-defined node or parser when the built-in resources do not provide the required functions.

Before you start to create your user-defined extension, be clear about its purpose. Most tasks can be performed by using the functions already provided with IBM App Connect Enterprise, but you might need a user-defined extension for your particular task.

To write user-defined extensions you need to be a skilled programmer, with some knowledge of IBM App Connect Enterprise and its architecture, therefore make sure that you have the skills and knowledge required. You also need the time to test and debug your user-defined node or parser, and a safe environment in which to do this.

Also note that the maintenance and servicing of your own user-defined extensions is your responsibility. You should ensure that there will be someone available who can perform future updates or fixes.

A user-defined extension might be appropriate in the following situations:

- When you cannot manipulate the supplied nodes or parsers to perform the function you require. For example, you might want to connect to another software component in your message flow outside of IBM MQ. If there is no supplied node for doing this, you must create your own.
- When you can improve performance, ease of use, or reliability by using your own user-defined extensions in place of the supplied nodes or parsers.
- If the available choices are not appropriate for your requirement. You can create user-defined extensions to handle internal, customer-specific, or generic commercial message formats.

Consider the following design factors when you are planning or writing a user-defined node or parser. You should be familiar with the concepts covered in the following topics before designing a user-defined extension.

Errors and exception handling

Correct handling of errors and exceptions is important for correct integration node operation. You must consider how and when your user-defined extension must handle errors and exceptions.

The errors and exception handling here describes factors that you must consider when you develop user-defined extensions for IBM App Connect Enterprise in the C programming language. If you are developing user-defined extensions using the Java programming language, you can use standard Java error and exception handling methods. If, for example, IBM App Connect Enterprise throws an exception internally, a Java exception of class **MbException** is made available.

The integration node generates C++ exceptions to handle error conditions. These exceptions are caught in the relevant software layers in the integration node, and are handled accordingly. However, programs written in C cannot catch C++ exceptions, and all exceptions thrown, by default, bypass all C user-defined extension code and are caught in a higher layer of the integration node.

Utility functions, by convention, typically use the return value to pass back requested data; for example, the address or handle of an integration node object. The return value sometimes indicates that a failure has occurred. For example, if the address or handle of an integration node object could not be retrieved, zero (CCI_NULL_ADDR) is returned. Additionally, the reason for an error condition is stored in the return code output parameter, which is, by convention, part of the function prototype of all utility functions. If the utility function completed successfully and `returnCode` was not null, `returnCode` contains CCI_SUCCESS. Otherwise, it contains one of the return codes described here. You can test the value of `returnCode` to determine whether a utility function was successful.

If the call to a utility function causes the integration node to generate an exception, the error is visible to the user-defined extension only if it specified a value for the `returnCode` parameter to that utility function. If a null value was specified for `returnCode`, and an exception occurs:

- The user-defined extension is not be aware of that exception
- The utility function does not return to the user-defined extension
- Execution control passes to higher layers in the integration node stack to process the exception

Therefore, a user-defined extension cannot perform its own error recovery. If, however, the `returnCode` parameter is specified, and an exception occurs, a return code of CCI_EXCEPTION is returned. In this case, `cciGetLastExceptionData` or `cciGetLastExceptionDataW` (the difference being that `cciGetLastExceptionDataW` returns a CCI_EXCEPTION_WIDE_ST which can contain Unicode trace text) can be used to obtain diagnostic information on the type of exception that occurred. The data is returned in the CCI_EXCEPTION_ST or CCI_EXCEPTION_WIDE_ST structure.

If there are no resources to be released, do not set the returnCode argument in your user-defined extension. Not setting this argument allows exceptions to bypass your user-defined extensions. These exceptions can then be handled higher up the IBM App Connect Enterprise stack, by the integration node.

Message inserts can be returned in the CCI_STRING_ST members of the CCI_EXCEPTION_ST structure. The CCI_STRING_ST allows the user-defined extension to provide a buffer to receive all required inserts. The integration node copies the data into this buffer, and returns the number of bytes output and the actual length of the data. If the buffer is not large enough, no data is copied and the "dataLength" member can be used to increase the size of the buffer, if required.

The user-defined extension can set a non-null value for `returnCode` and provide its own error recovery, if required. The utility function calls return to the user-defined extension and pass their status through

`returnCode`. All exceptions that occur in a utility function must be passed back to the integration node for additional error recovery to be performed; that is, when CCI_EXCEPTION is returned in `returnCode`. You do this by calling `cciRethrowLastException`, after the user-defined extension has completed its own error processing. Calling `cciRethrowLastException` causes the C interface to re-throw the last exception so that it can be handled by other layers in the integration node. In the same way as the C **`exit`** call, **`cciRethrowLastException`** does not return in this case.

If an exception occurs and is caught by a user-defined extension, the extension must not call utility functions except `cciGetLastExceptionData`, `cciGetLastExceptionDataW`, or `cciRethrowLastException`. An attempt to call other utility functions results in unpredictable behavior that can compromise the integrity of the integration node.

If a user-defined extension encounters a serious error, `cciThrowException` or `cciThrowExceptionW` can be used to generate an exception that is processed by the integration node in the correct manner. The generation of such an exception causes the supplied information to be written to the system log (syslog or Eventviewer) if the exception is not handled. The information is also written to trace (if trace is active).

Types of exception and integration node behavior

The integration node generates a set of exceptions that can be passed to a user-defined extension. These exceptions can also be generated by a user-defined extension when an error condition is encountered. The exception classes are:

Fatal
Fatal exceptions are generated when a condition occurs that prevents the integration node process from continuing execution safely, or where it is integration node policy to terminate the process. Examples of fatal exceptions are a failure to acquire a critical system resource, or an internally-caught severe software error. The integration node process terminates following the throwing of a fatal exception. Fatal exceptions are logged.

Recoverable
These exceptions are generated for errors which, although not terminal in nature, mean that the processing of the current message flow has to be ended. Examples of recoverable exceptions are invalid data in the content of a message, or a failure to write a message to an output node. When a recoverable exception is thrown, the processing of the current message is canceled on that thread, but the thread recommences execution at its input node. Recoverable exceptions are not logged.

Configuration
Configuration exceptions are generated when a configuration request fails. This can be because of an error in the format of the configuration request, or an error in the data. When a configuration exception is thrown, the request is rejected and an error response message is returned. Configuration exceptions are not logged.

Parser
These exceptions are generated by message parsers for errors that prevent the parsing of the message content or creating a bit stream. A parser exception is treated as a recoverable exception by the integration node. Parser exceptions are normally logged unless they are considered as recoverable exceptions.

Conversion
These exceptions are generated by the integration node character conversion functions if invalid data is found when trying to convert to another data type. A conversion exception is treated as a recoverable exception by the integration node and is therefore not logged.

User
These exceptions are generated when a Throw node throws a user-defined exception. User exceptions are logged.

Database
These exceptions are generated when a database management system reports an error during integration node operation. A database exception is treated as a recoverable exception by the integration node. Database exceptions are logged if they result in a fatal condition.

Storage management in user-defined nodes

Consider issues that relate to storage management when you develop user-defined extensions in the C programming language.

If you are developing user-defined extensions using the Java programming language, you can use standard Java string handling methods.

All memory that is allocated by a user-defined extension must be released by the user-defined extension. The construction of a node at run time causes the `cniCreateNodeContext` function to be invoked, which allows the user-defined extension to allocate node instance specific data areas to store a context. The address of the context is returned to the integration node, and is passed back from the integration node when an internal method causes a user-defined extension function to be invoked; thus, the C user-defined extension can locate and use the correct context for the function processing.

The integration node passes addresses of C++ objects to the user-defined extension, which are used as handles to be passed back on subsequent function calls. Your C user-defined extension must not manipulate or use these pointers in any way, for example, by trying to release storage using the `free` function. Such actions cause unpredictable behavior in the integration node.

The `cniCreateNodeContext` implementation function is invoked whenever the underlying node object has been constructed internally. It is called when an integration node is defined with a message flow that uses a user-defined node. This activity is not necessarily the same as creating (or reusing) a thread to execute a message flow instance that contains the node. The `cniCreateNodeContext` function is called only once, during the configuration of the message flow, regardless of how many threads are executing the message flow.

Similar considerations apply to user-defined parsers, and the corresponding implementation function `cpiCreateContext`.

String handling in user-defined nodes

Consider issues that relate to string handling when you develop user-defined extensions in the C programming language.

If you are developing user-defined extensions using the Java programming language, you can use standard Java string handling methods.

To enable an integration node to handle messages in all languages at the same time, text processing within the integration node is done in UCS-2 Unicode. UCS-2 Unicode character strings are also used across the Java and C language user-defined extension APIs to pass and return character data. Attributes are received in XML configuration messages as character strings, regardless of data type. If the true data type of an attribute is not a string, the `cniSetAttribute` function must perform the necessary verification and conversion before storing the attribute value. Similarly, when an attribute value is retrieved using `cniGetAttribute2`, conversion must be performed to a UCS-2 Unicode character string before returning the result.

`CciChar` defines a 16-bit character with UCS-2 Unicode representation. A `CciChar*` is a string of such characters terminated with a `CciChar` of 0. By default, a `CciChar` is represented by type `wchar_t`. However, some platforms do not have a convenient way of representing UCS-2 constants in source code, typically because of 4-byte `wchar_t` or EBCDIC representation. For example, a source-code constant such as L"ABC" expands to 12 bytes on Solaris.

For this reason, WebSphere IBM Integration provides the utility functions `cciMbsToUcs` and `cciUcsToMbs`. Use these functions, where appropriate, to ensure portability of your user-defined nodes.

Threading considerations for user-defined extensions

Message processing nodes and parsers must work in a multi-instance, multithreaded environment. Many node objects or parser objects are available, each with several syntax elements, and many threads can be executing methods on these objects.

An instance of a message flow processing node is shared and used by all the threads that service the message flow in which the node is defined. Parsers are invoked on the same thread as the nodes, therefore, if the flow is using multiple threads, the parsers are as well.

A user-defined extension must use this model. If a user-defined node requires global data or resources, you must protect the global data or resources by using semaphores to serialize access across threads. However, such serialization can result in performance bottlenecks. Avoid using global data and resources to create a more scalable solution.

The functions implemented by user-defined extensions must be reentrant, and any functions that they invoke must also be reentrant. All user-defined extension utility functions are fully reentrant.

Although a user-defined extension can create additional threads if required, all C utility functions and Java methods must be invoked on the same thread that called the `cniEvaluate` function in C or the `evaluate` method in Java, as appropriate for the language in which the node is written. If the same thread is not used, your code might compromise the integrity of the integration node and cause unpredictable behavior. Any additional threads must not call the user-defined extension API. The API must only be used from the main thread that is invoked by the Integration node.

For information about the `cniEvaluate` function see cniEvaluate.

ODBC restrictions for user-defined nodes

The ODBC environment cannot be accessed using the Java or C language user-defined extension API.

Database access must be performed using the supplied processing nodes, or by using the following implementation functions supplied for that purpose:

- cniSqlCreateStatement
- cniSqlExecute
- cniSqlSelect
- cniSqlDeleteStatement

Java Database Connectivity

Types 2 and 4 JDBC drivers are supported, but are not provided with the integration node.

User-defined extensions in the runtime environment

Before you design and implement user-defined extensions, familiarize yourself with the core components. Ensure that you also understand the basic IBM App Connect Enterprise runtime architecture.

Ensure that you are familiar with the following runtime components and concepts:

- Integration servers and integration nodes
- “User-defined extensions execution model” on page 2326

Also make sure that you understand the following concepts:

- “Message flows overview” on page 483

When you have gained an understanding of the runtime environment, read the following topics to help you understand how your user-defined extension interacts with the runtime components.

- “C user-defined input node life cycle” on page 2332
- “Java user-defined input node life cycle” on page 2333
- “C user-defined message processing nodes life cycle” on page 2336
- “Java user-defined message processing nodes life cycle” on page 2338
- “User-defined output node life cycle” on page 2343
- “User-defined parser life cycle” on page 2345

User-defined extensions execution model

The execution model is the system used to start message flows through a series of nodes.

When an integration server is initialized, the appropriate loadable implementation library (LIL) files and Plug-in Archive (PAR) files are made available to the runtime environment. The integration server runtime process starts, and creates a dedicated configuration thread. You are responsible for ensuring that a user-

defined node is thread-safe. If a node updates a variable across multiple threads, appropriate locking must be in place. Do not compromise this threading model in your implementation of user-defined nodes. Consider the following points:

- An input message sent to a message flow is processed only by the thread that received it.
- A single instance of a user-defined extension might be invoked on several threads concurrently.
- The message flow execution environment is conceptually like procedural programming. Nodes that you insert into a message flow are like subroutines called using a function call interface. However, rather than a call-return interface, in which parameters are passed in the form of input message data, the execution model is referred to as a propagation-and-return model.

As an example, consider a message flow in which you use both user-defined nodes and parsers. You use a user-defined node to process messages, and a user-defined parser to parse messages; both the node and parser contain implementation functions. The integration node calls the implementation functions, or callback functions, when certain events occur:

- When an input message is received by the message flow and is propagated to the user-defined node:
  - For C nodes, the integration node calls the `cniEvaluate` function for the user-defined node. See cniEvaluate.
  - For Java nodes, the integration node calls the `evaluate` method that is implemented by the user-defined node.
- If the user-defined node wants to query the message to decide what to do with it, the node calls a C utility function or a Java method, as appropriate for the language in which the node is written.

The integration node invokes the user-defined parser on one of its implementation functions, for example `cpiParseFirstChild`. This function instructs the parser to build the parse tree. The parser builds the tree by invoking utility functions that create elements in the parse tree, for example `cpiCreateElement`. The parser can be called many times by the integration node.

Node and parser factory behavior

The node factory and the parser factory assume roles in declaring a message flow node to the integration node or defining a parser.

Each loadable implementation library (LIL) has one node factory, or one parser factory, or has both. A node factory can identify many message flow nodes, and a parser factory can identify many parsers.

When the integration node loads the LIL, it calls the following functions:

- **`bipGetMessageflowNodeFactory`**

  After the operating system has loaded and initialized the LIL, the integration node calls initialization function `bipGetMessageflowNodeFactory`. The `bipGetMessageflowNodeFactory` function calls the utility function `cniCreateNodeFactory`, which passes back a factory name (or group name) for all the message flow nodes that your LIL supports.

- **`bipgetparserfactory`**

  After the operating system has loaded and inoitialized the LIL, the integration node calls initialization function `bipgetparserfactory`. The `bipgetparserfactory` function defines the name of the factory that the user-defined parser supports, and the classes of objects, or shared object, that the factory supports. The initialization function `bipgetparserfactory` calls the utility function `cpiCreateParserFactory`, which passes back a factory name (or group name) for all the parsers that your LIL supports.

Before the node factory is returned, the integration node calls the following functions:

1. **`cniCreateNodeFactory`**

   This function creates a single instance of the node factory in the integration node.

2. **cndDefineNodeClass**

   This function defines the name of a node class that a node factory supports, and identifies the nodes that the node factory can create.

Before the parser factory is returned, the integration node calls the following functions:

1. **cpiCreateParserFactory**

   This function creates a single instance of the named parser factory in the integration node.

2. **cpiDefineParserClass**

   This function defines the name of a parser class that a parser factory supports, and identifies the parsers that the factory can create.

See the following topics for information on these functions:

- cniCreateNodeFactory
- cpiCreateParserFactory
- cniDefineNodeClass
- cpiDefineParserClass

Why use a user exit?

Use a user exit to intercept the progress of messages through message flows without having to redesign the message flow.

User exits provide a mechanism to apply actions (such as monitoring, message tracking, and auditing) operationally to deployed message flows at run time.

You can use user exits to call (by using callbacks) your custom C code, which is provided in a loadable exit library (LEL), at key points in message transactions in deployed message flows. These user exits can use utility functions from the user-defined extensions APIs to extract details of the integration node, integration server, message flow, node, and message assembly. In addition, the user exits can use utility functions from the user-defined extensions APIs to modify parts of the message assembly.

To write user exits, you must be a skilled programmer with an understanding of IBM App Connect Enterprise and its architecture. Testing and debugging user exits can be time-consuming, and must be done in a safe environment. You must also maintain and service your own user exit.

Consider the following design factors when you plan and write a user exit:

- The effect on performance

  User exit callbacks are run inline with the current message transaction; that is, progress of the transaction is blocked until the return from the callback is received. Updating the message in a user exit callback can affect performance, particularly if the input message would not otherwise be changed in the message flow.

- Message parse timing

  On-demand parsing, referred to as partial parsing, is used to parse a message bit stream only as far as is necessary to satisfy the current reference in the message assembly. A user exit can navigate the message at each of its callback points, which can mean that the parse timing of the message flow is changed when you enable the user exit.

- Error handling

  To ensure that the error handling that is provided by the designer of a message flow that is being intercepted by a user exit continues to operate as designed, you must program the user exit in the following way:

  – All internal errors must be handled within the user exit, and the normal return from the callback must enable the message flow transaction to complete as normal.
  – All exception condition that is encountered when the user exit calls utility functions in the user-defined extensions APIs must be returned to the flow for normal error processing. This behavior is achieved by calling `cciRethrowLastException()` to cut short the callback processing.

Exploiting user exits

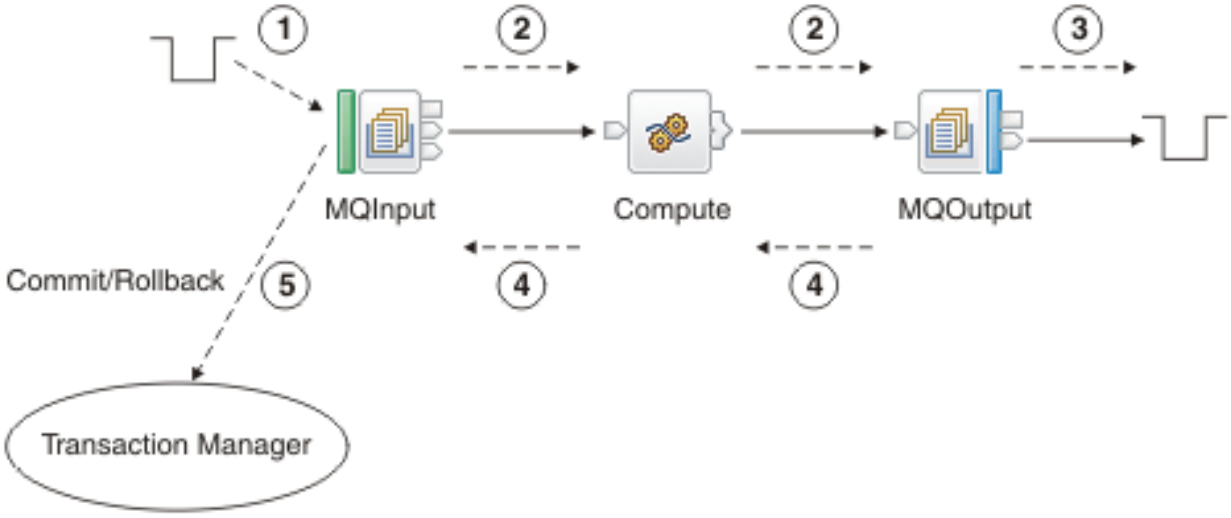
Your message flows can benefit from user exits.

Before you begin

- Read "User exits" on page 2349.
- Read "Why use a user exit?" on page 2328

About this task

The following diagram illustrates how a user exit works. The numbered events are described after the diagram. The MQInput node is used as an example, but the function applies to all input nodes, including user-defined input nodes. Similarly, the Compute and MQOutput nodes can be replaced by any equivalent nodes.



1. (`cciInputMessageCallback`) The message is dequeued from the input source (read into the flow).

   Built-in nodes and user-defined nodes differ slightly in how user exits are called. For built-in input nodes, the user exit is called as soon as possible after the data is read from the external source. For user-defined input nodes, the user exit is called just before the node propagates the message.
2. (`cciPropagatedMessageCallback`) The message is propagated to the message flow node for processing.
3. (`cciOutputMessageCallback`). A request message is sent to the output node's transport. Transport-specific destination information is written to WrittenDestination in the LocalEnvironment (for example, this information includes the queueName and msgId for an IBM MQ message). The call is made when a node successfully puts a message to a transport, from either an output or a request

node. The outputMessageEvent is called by built-in nodes only. The topic for each node that supports WrittenDestination information contains details about the data that it contains.

Note: If you use a destination list with IBM MQ or JMS nodes, a single callback is made after the message is sent to the last destination in the list. The node provides details of the message that is sent to each destination in the WrittenDestination information in the LocalEnvironment tree.

4. (`cciNodeCompletionCallback`) Node processing completes.
5. (`cciTransactionEventCallback`) The user exit is called after the transaction completes so that user exit processing is not part of that transaction. The user exit is invoked even if no transactional processing is completed by the flow.

   Where the message flow property `Commit Count` is greater than one, many-to-one ratios exist between events 1 and 5. This ratio also exists for some scenarios that are specific to the particular input node; for example, when an MQInput node is configured with the `Commit by Message Group` property selected.

You can write a user exit to track any number of these events. For each of these events, the following data is available to the user exit. All access is read-only, unless stated otherwise:

- The message is dequeued:
  - Bit stream
  - Input node
  - Environment tree (read and write)
- The message is propagated to the node:
  - Message tree (body element read and write)
  - LocalEnvironment tree (read and write)
  - Exception list
  - Environment tree (read and write)
  - Source node
  - Target node
- A message is sent to a transport:
  - Message tree (body element read and write)
  - LocalEnvironment tree (read and write)
  - Exception list
  - Environment tree (read and write)
  - Output or request node
- Message flow node processing completes:
  - Message tree (body element read and write)
  - LocalEnvironment tree (read and write)
  - Exception list
  - Environment tree (read and write)
  - Message flow node
  - Upstream node
  - Exception (if any)
- The end of the transaction:
  - Input node
  - Exception (if any)
  - Environment tree (read and write)

You can register multiple user exits, and, if they are registered, they are invoked in a defined order (see command). Any changes that are made to the message assembly (the message and environment) by a user exit are visible to subsequent user exits.

When the user exit is invoked, it can query the following information:

- Message flow information:
  - Message flow name
  - Integration node name
  - Integration node's queue manager name
  - Integration server name
  - Message flow's commit count property
  - Message flow's commit interval property
  - Message flow's coordinated transaction property
- Message flow node information:
  - Message flow node name
  - Message flow node type
  - Terminal name
  - Message flow node properties

The user exit can also do the following tasks:

- Navigate and read the message assembly (Message, LocalEnvironment, ExceptionList, Environment)
- Navigate and write the Message body, LocalEnvironment, and Environment tree.

You can register the user exits on a dynamic basis, without needing to redeploy the configuration.

Which type of user-defined extension to use

The types of user-defined extension that you can write include user-defined nodes, user-defined parsers, user-defined exits, and using a subflow as a user-defined node.

The following topics describe the different types of user-defined extension in more detail:

- "User-defined nodes" on page 2331
- "User-defined parsers" on page 2345
- "Connectors" on page 2348
- "User exits" on page 2349
- "Using a subflow as a user-defined node" on page 2344

User-defined nodes

User-defined nodes are the main mechanism for extending the functions of IBM App Connect Enterprise.

The most common uses for a user-defined node are:

- Calling an external system for which IBM App Connect Enterprise does not provide nodes
- Calling already defined program libraries that perform a transformation or calculation that is required in the design of a message flow
- Packaging a subflow

Before you consider constructing a user-defined node, make sure that no built-in node is available to perform the required actions. For example, you might have considered creating a user-defined node to perform the following tasks, but you can use a JavaCompute node instead:

- Allowing programming languages other than ESQL to be used for coding message flow functions
- Performance advantages in performing some actions in compiled code

- Complex functions that are not available in ESQL, such as the large number of classes provided in JS2E

The following topics describe the different types of user-defined node in more detail:

- "User-defined input nodes" on page 2332
- "User-defined message processing nodes" on page 2336
- "User-defined output nodes" on page 2343
- "Using a subflow as a user-defined node" on page 2344

User-defined input nodes
A user-defined input node is an extension to the integration node that provides a new input node in addition to the nodes supplied with the product.

You create user-defined input nodes by using the C or Java programming language, or from a subflow, to provide message input to a message flow from a message queue when you want your integration node to accept messages from a transport protocol other than IBM MQ.

You can use a user-defined input node to receive data from an external data source and to allow that data to be processed in an integration node. In this way, you can complement the primitive input node types provided by IBM App Connect Enterprise.

You cannot use a user-defined input node to provide the In terminal to a message subflow. If you want to provide the In terminal to a subflow, you must use the supplied Input node.

Before writing a user-defined node, make sure that you are familiar with the concepts that are introduced in "Why use a user-defined extension?" on page 2322 and "User-defined extensions in the runtime environment" on page 2326.

C user-defined input node life cycle
A user-defined input node that is written in the C programming language progresses through several stages during its lifetime.

The stages of the life cycle are:

- Registration
- Instantiation
- Processing
- Destruction

Registration

During the registration phase, the integration node discovers which resources are available and which LILs can provide them. In this instance, the resources available are nodes. The phase starts when an integration server starts. The LILs are loaded on the startup of an integration server, and the integration node queries them to find out what resources they can provide.

A CciFactory structure is created during the registration phase, when the user-defined node calls **`cniCreateNodeFactory`**.

The following APIs are called by the integration node during this stage:

- `biGetMessageflowNodeFactory`
- `bipGetParserFactory`

The following API is called by the user-defined node during this stage:

- `cniCreateNodeFactory`

Instantiation

An instance of a user-defined input node is created when the **`mqsistart`** command starts or restarts the integration server process, or when a message flow that is associated with the node is deployed.

The following APIs are called during this phase:

- **cniCreateNodeContext**. This API allocates memory for the instantiation of the user-defined node to hold the values for configured attributes. This API is called once for each message flow that is using the user-defined Input node.
- **cniCreateInputTerminal**. This API is invoked within the `cniCreateNodeContext` API, and is used to tell the integration node what input terminals, if any, your user-defined input node has.

  Your user-defined input node only has input terminals if it is also acting as a message processing node. If this is the case, it is typically better to use a separate user-defined message processing node to perform the message processing, rather than combine both operations in one, more complex, node.
- **cniCreateOutputTerminal**. This API is invoked within the `cniCreateNodeContext` API, and is used to tell the integration node what output terminals your user-defined input node has.
- **cniSetAttribute**. This API is called by the integration node to establish the values for the configured attributes of the user-defined node.

During this phase, a CciTerminal structure is created when `cniCreateTerminal` is called.

Processing

The processing phase begins when the `cniRun` function is called by the integration node. The integration node uses the `cniRun` function to determine how to process a message, including determining the domain in which a message is defined, and invoking the relevant parser for that domain.

A thread is demanded from the message flow's thread pool, and is started in the run method of the input node. The thread connects to the integration node's queue manager, and retains this connection for its lifetime. When a thread has been allocated, the node enters a message processing loop while it waits to receive a message. It remains in the loop until a message is received. If the message flow is configured to use multiple threads, thread dispatching is activated.

The message data can now be propagated downstream.

The following APIs are called by the integration node during this phase:

- **cniRun**. This function is called by the integration node to determine how to process the input message.
- **cniSetInputBuffer**. This function provides an input buffer, or tells the integration node where the input buffer is, and associates it with a message object.

Destruction

A user-defined input node is destroyed when the message flow is redeployed, or when the **mqsistop** command is used to stop the integration server process. You can destroy the node by implementing the `cniDeleteNodeContext` function.

When a user-defined input node is destroyed in one of these ways, you should free any memory used by the node, and release any held resources, such as sockets.

The following APIs are called by the integration node during this phase:

- `cniDeleteNodeContext`. This function is called by the integration node to destroy the instance of the input node.

Java user-defined input node life cycle
A user-defined input node that is written in the Java programming language progresses through several stages during its lifetime.

The stages of the life cycle are:

- Registration
- Instantiation
- Processing
- Destruction

Registration

During the registration phase a user-defined input node written in Java makes itself known to the integration node. The node is registered with the integration node through the static `getNodeName` method. Whenever an integration node starts, it loads all the relevant Java classes. The static method `getNodeName` is called at this point, and the integration node registers the input node with the node name specified in the `getNodeName` method. If you do not specify a node name, the integration node automatically creates a name for the node based on the package in which it is contained.

Using a static method here means that the method can be called by the integration node before the node itself is instantiated.

Instantiation

A Java user-defined input node is instantiated when an integration node deploys a message flow containing the user-defined input node. When the node is instantiated, the integration node calls the constructor of the input node's class.

When a node is instantiated, any terminals that you have specified are created. A message processing node can have any number of input and output terminals associated with it. You must include the `createInputTerminal` and `createOutputTerminal` methods in your node constructor to declare these terminals.

To handle exceptions that are passed back to your input node, use `createOutputTerminal` to create a catch terminal for your input node. When the input node catches an error, the catch terminal processes it in the same way as an MQInput node would. You can allow most exceptions, such as exceptions that are caused by deployment problems, to pass back to the integration node, and the integration node will warn the user of any possible configuration errors.

As a minimum, your constructor class needs only to create these output terminals on your input node. However, if you need to initialize attribute values, such as defining the parser that will initially parse a message passed from the input node, you should also include that code at this point in your input node.

Processing

Message processing for an input node begins when the integration node calls the `run` method. The `run` method creates the input message, and should contain the processing function for the input node.

The `run` method is defined in `MbInputNodeInterface`, which is the interface used in a user-defined node that defines it as an input node. You must include a `run` method in your node. If you do not include a `run` method in your user-defined input node, the node source code will not compile.

When a message flow containing a user-defined input node is deployed successfully, the integration node calls the node's run implementation method, and continues to call this method while it waits for messages to process.

When a message flow starts, a single thread is dispatched by the integration node, and is called into the input node's `run` method. If the `dispatchThread()` method is called, further threads can also be created in the same `run` method. These new threads immediately call into the input node's `run` method, and can be treated the same as the original thread. The number of new threads that can be created is defined by the `additionalInstances` property. Make sure that threads are dispatched after a message has been created, and before it is propagated, to ensure that only one thread at a time is waiting for a new message.

The user-defined input node can choose a different threading model and is responsible for implementing the chosen model. If the input node supports the `additionalInstances` property, and `dispatchThread()` is called, the code must be fully re-entrant, and any functions that are invoked by the node should also be re-entrant. If the input node forces single threading, that is, it does not call `dispatchThread()`, the node documentation must state that setting the `additionalInstances` property has no effect on the input node.

For more information on the threading model for user-defined input nodes, see "Threading considerations for user-defined extensions" on page 2325.

Destruction

A Java user-defined input node is destroyed when the node is deleted or the integration node is shut down. You do not need to include anything in your code that specifies the node should be physically deleted, because this can be handled by the garbage collector.

However, if you want notification that a node is about to be deleted, you can use the **onDelete** method. You might want to do this if there are resources that you want to delete, other than those that will be garbage collected. For example, if you have opened a socket, this will not be properly closed when the node is automatically deleted. You can include this instruction in your **onDelete** method to ensure that the socket is closed properly.

Planning user-defined input nodes
Before you develop a user-defined input node, plan and design its content and purpose.

Analysis

Before you develop a user-defined input node, ask yourself the following questions:

- Do you need to create a custom input node?

  You must include at least one input node in a message flow. Which one you choose depends on the source of the input messages:

  - If the messages arrive at the integration node on an IBM MQ queue, use the MQInput node.
  - If SOAP messages are received over HTTP, use the SOAPInput node.
  - If other messages are received over HTTP, use the HTTPInput node.
  - If the messages are received from a JMS source, use the JMSInput node.
  - If the messages are received from an EIS, use the PeopleSoftInput, SAPInput, or SiebelInput node.
  - If the messages are retrieved from files, use the FileInput node.
  - If the message source is any other, you must use a user-defined input node.

  For information about using more than one input node in a message flow, see "Using more than one input node" on page 597.
- To successfully input the data concerned, does the input node have to interface with vendor software? If so, does the API that enables access to this software break your threading model?
- Do you need a new user-defined parser to interpret the body (payload) of the message generated by this input node, or can it be parsed by a standard built-in parser?
- Do you need the user-defined input node to operate the message flow instance in which it resides under transactional control as a globally-coordinated transaction?
- Do you need the new user-defined input node to offer configuration options?
- Do you need messages propagated by this input node to be processed by the following primitives?
  - All primitive output nodes
  - ResetContentDescriptor nodes

Design considerations

Before developing and implementing your input node, decide on the following factors:

- Which message parser will initially parse the input message.
- Whether to override the default message parser attribute values for this input node.
- Which threading model is appropriate for the input node.
- What kind of message processing and transaction support will the node support.
- Which configuration attributes required by the input node should be externalized for alteration by the message flow designer.
- What optional node APIs will the user-defined node provide.

- How you will handle general development issues:
  - “Threading considerations for user-defined extensions” on page 2325
  - “Storage management in user-defined nodes” on page 2325
  - “String handling in user-defined nodes” on page 2325
  - “Errors and exception handling” on page 2323
  - Expected message formats for primitive nodes that expect specific header folders.

When you design nodes to be used as extensions to WebSphere Event Broker, the following restrictions apply:

- User-defined input nodes can support only XML, BLOB, and the IBM MQ parsers, because the MRM parser is not shipped with WebSphere Event Broker and user-defined parsers are not supported.
- User-defined nodes must not allow users to evaluate user ESQL code, because the use of ESQL in WebSphere Event Broker is not supported. For example, nodes that expose the input to **MbSQLStatement** as a node attribute are effectively emulating a Compute node.

User-defined message processing nodes
A user-defined message processing node is a node that you can create to complement the supplied built-in node types.

You might consider the use of a user-defined message processing node in the following situations:

- Your messages need transformations that the built-in nodes do not provide. For example, you might need a currency converter node.
- You want to reuse a subflow.
- You want to hide a message flow implementation by packaging it in a user-defined node.

Combine your user-defined nodes with the built-in nodes to create message flows that meet your exact business requirements.

C user-defined message processing nodes life cycle
A user-defined message processing node for the C programming language goes through various stages.

This topic covers the objects that are created and destroyed, and the implementation functions and classes that are called in the following stages:

- Registration
- Instantiation
- Processing
- Destruction

The information in this topic applies to both output nodes and message processing nodes. Both of these node types can be considered together, because although a message processing node is typically used to process a message, and an output node is used to provide an output in the form of a bit stream, you can use either type of node to perform either of these functions.

Registration

A user-defined message processing node is registered with the integration node when the LIL that contains the node has been loaded and initialized by the operating system.

The integration node calls **bipGetMessageflowNodeFactory** to establish the function of the LIL, and how the LIL should be called.

The **bipGetMessageflowNodeFactory** function in turn calls the **cniCreateNodeFactory** function, which returns a factory or group name for all of the nodes that are supported by your LIL.

The LIL should then call the utility function **cniDefineNodeClass** to pass both the name of each node and a virtual function table of the function pointers of the implementation functions.

Instantiation

During the instantiation phase, an instance of a user-defined message processing node is created. The phase starts when the integration node creates a message flow and calls the **cniCreateNodeContext** function for each instantiation of the user-defined node in that message flow. The **cniCreateNodeContext** function is that which is specified in the **iFpCreateNodeContext** field of the CNI_VFT struct passed to **cniDefineNodeClass** for that node type. This function should allocate the resources required for that node, including memory such that the instantiation of the user-defined node can hold the values for the configured attributes.

The integration node will create a node instance and call **cniCreateNodeContext** on the following occasions:

- Message flow is created:
  - Integration node is being started (user has run mqsistart). Any message flows previously deployed are re-created when the integration node starts.
  - Integration server is being reloaded (user has run mqsireload). Any message flows that have been deployed previously are re-created when the integration server reloads.
  - A severe error has occurred within the integration server which results in the integration server being restarted.
- Message flow is redeployed. When a message flow is changed and redeployed, the integration node processes redeploy by deleting all nodes in the flow and then re-creating them with the new configuration.

Note: A message flow is not created when starting an integration server. Stopping an integration server simply stops all flows and does not delete the flow or bring the process down. Restarting an integration server, starts the message flows but does not re-create the message flows.

Within **cniCreateContext**, the user-defined extension calls the two functions **cniCreateInputTerminal** and **cniCreateOutputTerminal** in order to establish what input and output terminals the message processing node has.

Processing

During the processing phase of the life cycle of a user-defined message processing node, the message is transformed in some way, when some processing operation takes place on the input message.

When the integration node retrieves a message from the queue and that message arrives at the input terminal of your user-defined node, the integration node calls the implementation function **cniEvaluate**. This function is used to decide what to do with the message.

You can use a range of node utility functions in your user-defined message processing node to perform a range of message processing functions, such as accessing the message data, accessing ESQL, transforming a message object, and propagating a message. You should include the node utility functions you are going to use to process the message within the **cniEvaluate** function.

This interface does not automatically generate a properties subtree for a message. It is not a requirement for a message to have a properties subtree, although you might find it useful to create one to provide a consistent message tree structure regardless of input node. If you want a properties subtree to be created in a message, and you are also using a user-defined input node, you must do this yourself

Destruction

When a user-defined message processing node has processed a message, you should ensure that it is destroyed, to release any system resources that it used, and to release any data areas specific to the node instance, such as context, that were acquired when the message was constructed or processed.

An instance of a user-defined message processing node is destroyed when the integration node calls the **cniDeleteNodeContext** function.

The integration node calls **cniDeleteNodeContext** when the instance of the node is deleted. The following events can cause a node to be deleted:

- Controlled termination of the integration server process:
  - Integration node is being stopped (user has run mqsistop)
  - Integration server is being reloaded (user has run mqsireload)
  - A severe error has occurred within the integration server, which results in the integration server being restarted.

  Note: This does NOT include stopping an integration server. Stopping an integration server simply stops all flows, and does not delete the flow or bring the process down.
- Message flow is deleted.
- Message flow is redeployed. When a message flow is changed and redeployed, the integration node processes redeploy by deleting all nodes in the flow and then re-creating them with the new configuration.

Java user-defined message processing nodes life cycle
During the lifecycle of the user-defined nodes that you create in Java, objects are created and destroyed, and different methods and classes called.

Every node goes through the following stages:

- Registration
- Instantiation
- Processing
- Destruction

The information here applies to both output nodes and message processing nodes. Both of these node types can be considered together, because although a message processing node is typically used to process a message, and an output node is used to provide an output, in the form of a bit stream, from a message, you can use both types of node to perform either of these functions.

Registration

The registration phase occurs when a user-defined message processing node that is written in Java contacts the integration node, or registers with the integration node.

Whenever an integration node starts, it loads all relevant LIL files and Java classes. To ensure that a message processing node is registered with the integration node, you must provide the integration node with a class that implements the `MbNodeInterface` interface and is contained in the classpath used by the integration node.

Instantiation

A Java user-defined message processing node is instantiated when an integration node deploys a message flow that contains the user-defined message processing node. When the node is instantiated, the constructor of the message processing node class is called.

When a node is instantiated, all terminals that you have specified are created. A message processing node can have an unlimited number of input and output terminals associated with it. You must include the `createInputTerminal` and `createOutputTerminal` methods in your node constructor to declare these terminals.

Output terminals include out, failure, and catch terminals. Use the `createOutputTerminal` class within the node class constructor in order to create as many output terminals as you require.

As a minimum, you must create only these output terminals by using your constructor class. However, if you need to initialize attribute values, you must also include that code at this point in your message processing node.

If you want to handle exceptions that are passed back to your message processing node, it is good practice to do this by creating a failure terminal for your user-defined message processing node, by using the `createOutputTerminal` method. It is sensible to use the failure terminal for this process because that is the terminal to which errors are propagated.

Make sure that all exceptions that are caught by the message processing node are dealt with properly. If you do not include a failure terminal, the message processing node does not attempt to handle the exception. If your message flow does not contain a method of exception handling, all exceptions thrown are passed back to the input node, where the input node deals with the exceptions.

If you do catch exceptions, make sure that you rethrow all exceptions that the message processing node cannot deal with. This action causes the exception to be passed back to the input node for handling; for example, when you want to rollback a transaction.

Processing

During the processing phase of the life cycle of a user-defined message processing node, the message processing node takes the logical hierarchy of the message and processes it in some way.

Destruction

A Java user-defined message processing node is destroyed when the node is deleted, or the integration node is shut down. You do not have to include anything in your code to specify that the node is physically deleted, because this process can be handled by the garbage collector.

However, if you want notification that a node is about to be deleted, you can use the `onDelete` method. You might want to receive notification if the node has resources that you want to delete, other than those that will be garbage collected. For example, if you have opened a socket, it is not properly closed when the node is automatically deleted. You can include this instruction in your `onDelete` method to ensure that the socket is closed properly.

Planning user-defined message processing nodes
Plan how to write your message processing node or output node, and how to navigate the message within the node.

Design factors

Before developing and implementing your message processing node, consider the following points:

- Which parser will parse messages.
- Whether to override the default message parser attribute values for this message processing node.
- What is the appropriate threading model for the message processing node.
- How to implement the end of message processing and transaction support that the node must support.
- What configuration properties required by the message processing node must be externalized for alteration by the message flow designer.
- What optional node APIs will the user-defined node provide.
- General development issues:
  - “Threading considerations for user-defined extensions” on page 2325
  - “Storage management in user-defined nodes” on page 2325
  - “String handling in user-defined nodes” on page 2325
  - “Errors and exception handling” on page 2323
  - Expected message formats for built-in nodes that expect specific header folders, see Element definitions for message parsers

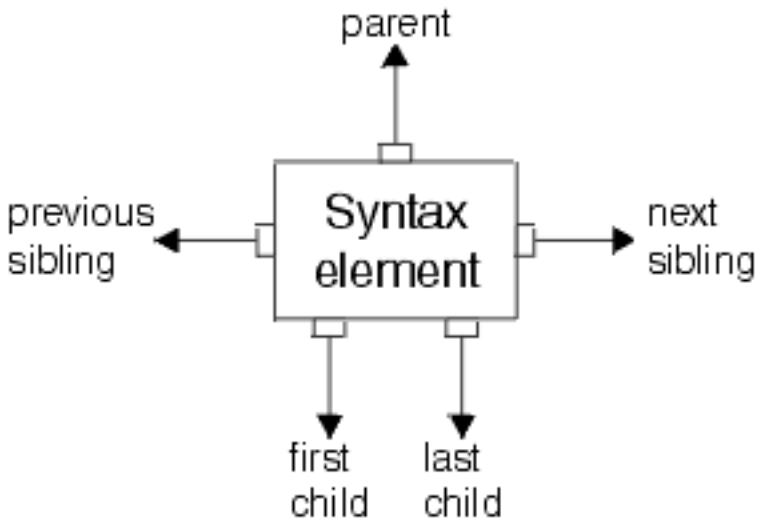
Syntax element navigation

The integration node provides functions that your node can call to traverse the tree representation of the message, as well as functions and methods that support navigation from the current element to other elements:

- Parent
- First child
- Last child

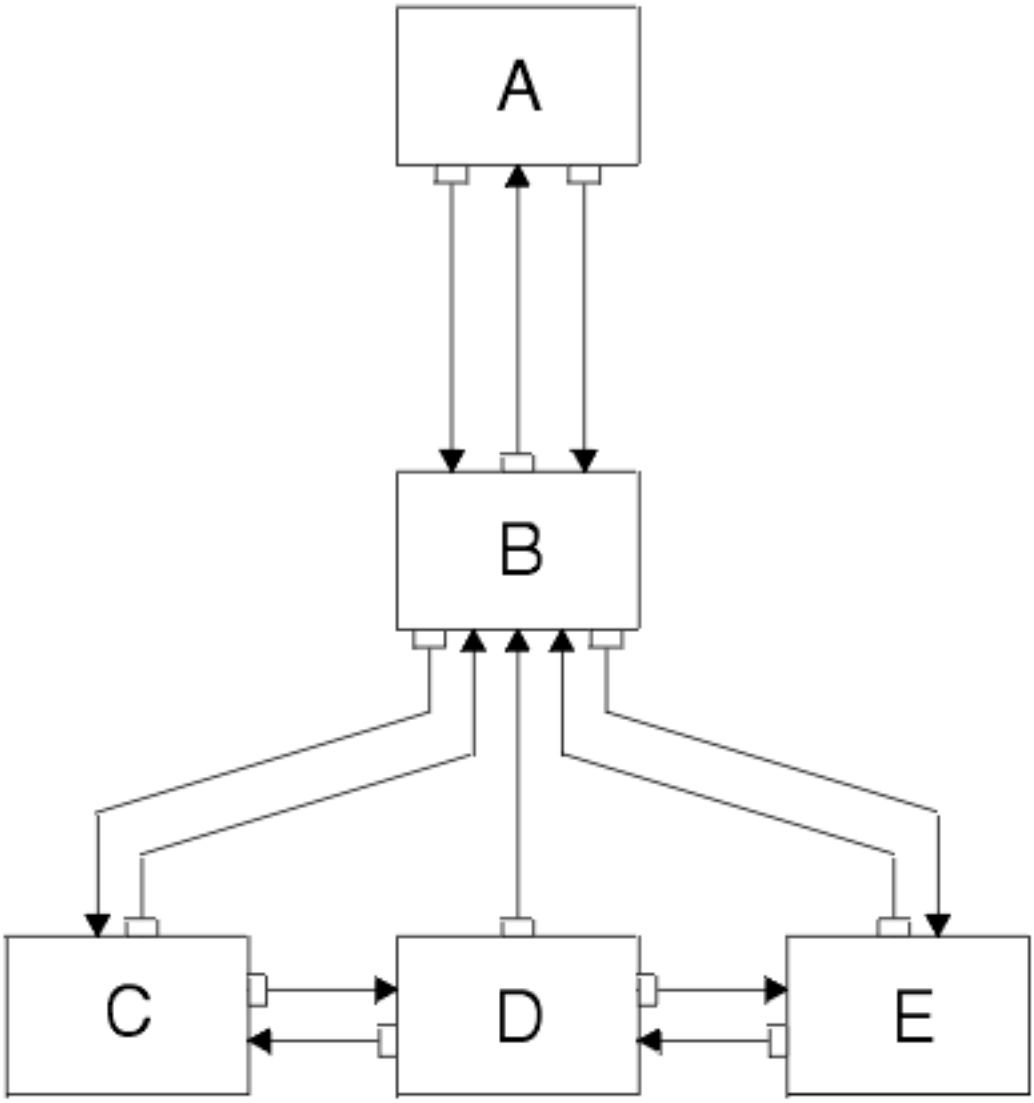
- Previous (or left) sibling
- Next (or right) sibling

These relationships are shown in the following diagram.



Other functions and methods support the manipulation of the elements themselves, with functions and methods to create elements, to set or query their values, to insert new elements into the tree, and to remove elements from the tree. See C node utility functions and C parser utility functions, or the Javadoc information for more details.

The following diagram describes a simple syntax element tree that shows a full range of interconnections between the elements.

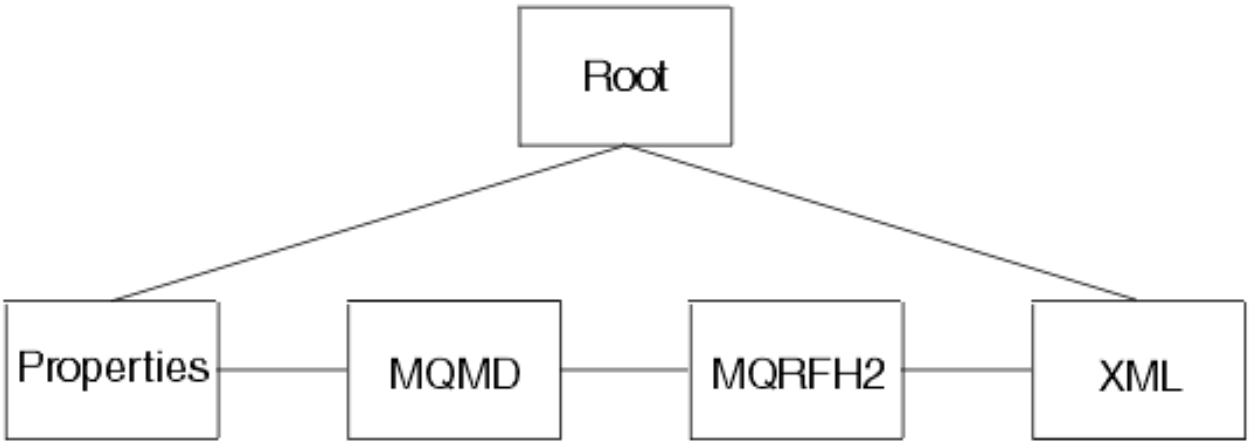


The element **A** is the root element of the tree. It has no parent because it is the root. It has a first child of element **B**. Because **A** has no other children, element **B** is also the last child of **A**.

Element **B** has three children: elements **C**, **D**, and **E**. Element **C** is the first child of **B**; element **E** is the last child of **B**.

Element **C** has two siblings: elements **D** and **E**. The next sibling of element **C** is element **D**. The next sibling of element **D** is element **E**. The previous sibling of element **E** is element **D**. The previous sibling of element **D** is element **C**.

The following diagram shows the first generation of syntax elements of a typical IBM MQ message received by an integration node. (Not all messages have an MQRFH2 header.)



These elements at the first generation are often referred to as folders, in which syntax elements that represent message headers and message content data are stored. In this example, the first child of root is the Properties folder. The next sibling of Properties is the folder for the MQMD header. The next sibling is the folder for the MQRFH2 header. The last folder represents the message content, which (in this example) is an XML message.

The previous figure includes an MQMD and an MQRFH2 header. All messages that are received by a processing node that handles IBM MQ include an MQMD header; a number of other headers can also be included.

Navigating an XML message

Consider the following XML message:

```
<Business>
  <Product type='messaging'></Product>
  <Company>
    <Title>IBM</Title>
    <Location>Hursley</Location>
    <Department>IBM MQ</Department>
  </Company>
</Business>
```

In this example, the elements are of the following types:

Name element
Business, Product, Company, Title, Location, Department

Value element
IBM, Hursley, WebSphere MQ

Name-value element
type='messaging'

Use supplied node utility functions and methods (or the similar parser utility functions) to navigate through a message. Using the XML message shown, you must call `cniRootElement` first, with the message received by the node as input to this function. In Java, you must call `getRootElement` on the incoming MbMessage object. This call returns an MbElement that represents the root of the element. Do not modify this root element in the user-defined node.

The figure of the first generation of the syntax elements of a typical message that is received by the integration node, shows that the last child of the root element is the folder containing the XML parse tree. Navigate to this folder by calling `cniLastChild` (with the output of the previous call as input to this function) in a C node, or by calling the method `getLastChild` on the root element, in a Java node.

Only one element (`<Business>`) is at the top level of the message, therefore call `cniFirstChild` (in C) or `getFirstChild` (in Java) to move to this point in the tree. Use `cniElementType` or `getType` to get its type (which is `name`), followed by `cniElementName` or `getName` to return the name itself (`Business`).

The element <Business> has two children, <Product> and <Company>. Use cniFirstChild or getFirstChild followed by cniNextSibling or getNextSibling to navigate to each child in turn.

The element <Product> has an attribute (type='messaging'), which is a child element. Use cniFirstChild or getFirstChild to navigate to this element, and cniElementType or getType to return its type (which is name-value). Use cniElementName or getName to get the name. To get the value, call cniElementValueType to return the type, followed by the appropriate function in the cniElementValue group, in this example it is cniElementCharacterValue. In Java use the method getValue, which returns a Java object representing the element value.

The element <Company> has three children, each one having a child that is a value element (IBM, Hursley, and IBM MQ). Use the functions already described to navigate to them and access their values.

Other functions are available to copy the element tree (or part of it). The copy can then be modified by adding or removing elements, and changing their names and values, to create an output message. See C node utility functions and C parser utility functions, or the Java user-defined node API, for more information.

User-defined output nodes

A user-defined output node is an extension to the integration node that provides a new message flow output node in addition to the nodes supplied with the product.

If you want your message flow to send messages by using a protocol that is not supported by IBM App Connect Enterprise, you can create your own output node.

IBM App Connect Enterprise provides the following output nodes:

- MQOutput - delivers an output message from a message flow to an IBM MQ queue
- MQReply - sends a response to the originator of the input message.
- Publication - filters output messages from a message flow and transmit them to subscribers who have registered an interest in a particular set of topics.
- JMSOutput - sends a message to a JMS destination
- EmailOutput - sends an email message to one or more recipients
- FileOutput - writes a message to a file

If the target application expects to receive message in any other way, you must use a user-defined output node.

User-defined output nodes can be considered together with user-defined message processing nodes. Conceptually, these two kinds of user-defined nodes are the same. Although a message processing node is typically used to process a message, and an output node is used to provide an output, in the form of a bit stream, from a message, you construct output nodes and message processing nodes in a similar way, and you can use either type of node to perform either function.

You can also create a user-defined output node from a subflow, see “Using a subflow as a user-defined node” on page 2344

For more information about user-defined output nodes, read the topics that cover user-defined message processing nodes, see “User-defined message processing nodes” on page 2336.

User-defined output node life cycle

The life cycle of a user-defined output node follows the same pattern as the life cycle of user-defined message processing nodes.

The following topics describe the life cycle of user-defined message processing nodes; read the topic that corresponds to your type of output node:

- “C user-defined message processing nodes life cycle” on page 2336
- “Java user-defined message processing nodes life cycle” on page 2338

Although a message processing node is typically used to process a message, and an output node is used to provide an output in the form of a bit stream, you can use both types of node to perform either of these functions.

Planning user-defined output nodes
A user-defined output node generates an output bit stream from a message tree.

Optionally, you can connect the node to another node and propagate the message tree for further processing. User-defined output nodes and message processing nodes are, therefore, structured in the same way. All relevant information for output nodes is included in "Planning user-defined message processing nodes" on page 2339.

Using a subflow as a user-defined node
You can develop a user-defined node that packages a subflow from scratch, in the same way that you can create any other user-defined node that has its implementation based on Java, or base it on an existing subflow.

The project that contains user-defined nodes can be exported as a plug-in that is installed in the development environment of the user. The nodes that are packaged in the plug-in are displayed in the palette in the **Message Flow** editor, and can be used in a message flow in the same way as a built-in node.

Packaging a subflow as a user-defined node provides all the benefits of a subflow, such as reusability and maintainability, as well as the following benefits:

- The user-defined node can be distributed to other developers as a plug-in.
- The user-defined node hides the implementation details of the subflow from developers who reuse the subflow.
- The user-defined node prevents developers who reuse the subflow from modifying it.
- The subflow is displayed in the palette in the Message Flow editor.

Video: Creating and using a subflow user-defined node

This video demonstrates the capability to create a subflow user-defined node using the toolkit. After creating the subflow user-defined node, it is used in another installation of App Connect Enterprise in a message flow to deploy and test the flow.

Limitations

- You cannot use user-defined nodes that are created from subflows in subflows that are defined in `.subflow` files.
- Message flows that contain user-defined nodes that are created from subflows must be included in BAR files as compiled message flow (`.cmf`) files. The shared libraries that are referenced by applications that include user-defined nodes cannot be deployed together because shared libraries need to be deployed as source. For more information, see "Adding resources to a BAR file" on page 2470.
- All the flow resources (Maps, ESQL, XSL, or other external resources), except Java code and message sets, that are referenced in the subflow, must be located in the user-defined node project.
- A user-defined node can reference another user-defined node in the same or different user-defined node project, but it must not reference anything from a regular integration project.
- The user-defined node project can have references to other projects, such as message set and Java projects.
- If the user-defined node references a message set, you must deploy the message set to the runtime separately. You can copy the message set to your workspace and deploy it through the BAR file.
- A subflow implementation of a user-defined node can contain other subflows, but all the subflows must be contained in the user-defined node project.
- Promoted properties from the nodes within the subflow are supported. Configurable promoted properties from nodes in the subflow are displayed as configurable node properties in the **BAR** editor.

- User-defined properties (UDP) on the subflow are supported. If you create multiple instances of user-defined nodes in your flow, each type of user-defined property that you define must have the same value in each instance.
- You can use the same subflow more than once to construct a flow of your own.
- You can use node types that have named correlators to create a user-defined node; for example:
  - Asynchronous request and response nodes
  - Route and Label nodes
  - Aggregation nodes
  - TimeoutControl and TimeoutNotification nodes

  These paired nodes use a unique ID string to match the pair of nodes. Therefore, you must not use more than one instance of this type of user-defined node in a flow, an integration server, or an integration node because the correlation ID will no longer be unique.
- Resources in the plug-in space are visible to all projects in the workspace. Keep user-defined nodes and their associated flows, maps, ESQL, and other similar resources, in appropriately named broker schemas. Do not put such resources in a default schema, or schemas with special names, for example, `mqsi`.

"Creating a user-defined node from a subflow" on page 2419
Create user-defined nodes either from scratch, or by using an existing subflow.

User-defined parsers

A user-defined parser is a program that interprets the bit stream of an incoming message and creates an internal representation of the message in a tree structure. A user-defined parser can also regenerate a bit stream for an outgoing message from the internal message tree representation

Create a user-defined parser when the IBM App Connect Enterprise parsers are not sufficient to parse user-defined messages.

Do not use user-defined parsers to provide connectivity or transformation functions. In most cases, the MRM or other IBM supplied parsers are capable of passing most standard type of format. You can also parse a message and construct a message tree in a user-defined node without the need to write a parser. For example, a user-defined node that reads emails from a POP3 server can parse the email and construct a message tree without the need to write a user-defined parser.

If the parser is going to be used only in a user-defined node, you do not need to use a user-defined parser. However, consider a user-defined parser if the parser will be called from other message flow nodes.

User-defined parser life cycle

Various stages exist in the life of a user-defined message flow parser.

These stages are involved:

- Registration
- Instantiation
- Processing
- Destruction

This topic describes the interactions that take place between WebSphere IBM Integration components when you run a user-defined parser. It explains each stage in terms of the events that start each stage, and the events that occur during and after each stage, and the APIs that are called. Understanding the concepts here help you to design and develop your parser more effectively.

Registration

The first phase in the user-defined parser's life cycle is the registration phase. The purpose of the registration phase is to register the user-defined parser with the integration node. This phase starts when the integration server starts.

Instantiation

The parser is created during the instantiation phase of the parser life cycle. When an input message is received, or an output message is built in a Compute node, the relevant parser is identified, and parser requirements are taken from the message header, such as the MQMD. The integration node starts and loads the Loadable Implementation Library (LIL) and the parser factory. Before the `cpiCreateContext` function is called, the integration node creates a name element as the effective root element for the parser. However, this element is not named. The parser should name this element in the `cpiSetElementName` function. The integration server process creates an instance of the parser, and the integration node makes a call to `cpiCreateContext` to allow the parser object to acquire the appropriate section of the message.

The integration node then makes a call to `cpiParseBuffer`. `cpiParseBuffer` performs any necessary initialization, and returns the length of the message content that the parser is taking ownership of. The parser assesses how much of the message data to parse, and claims the appropriate number of bytes.

Whenever an instance of a user-defined parser object is created, the context creation implementation function `cpiCreateContext` is also invoked by the integration node. This call allows the parser to allocate instance data associated with the parser. A `cpiDeleteContext` function to delete the context of the parser object is also required.

Processing

During the processing phase, the parser manipulates, alters, and references elements within the message object. The message flow processing phase begins when any message processing activity occurs, such as navigation, that requires access to an element within a message that does not exist in the integration node's internal model representation of the message concerned.

During the message flow processing phase, the parser is invoked in response to attempts to navigate into the message tree. The parser examines the buffer that was allocated when `cpiParseBuffer` was called, and creates any necessary message elements.

The parser can then navigate through the message elements, using any or all of the following parser implementation functions:

- `cpiParseFirstChild`
- `cpiParseLastChild`
- `cpiParsePreviousSibling`
- `cpiParseNextSibling`

These functions are invoked when any form of navigation is made (such as a filter expression that specifies a message field) into the part of the syntax element tree that logically represents the data for a message format supported by a user-defined parser. This navigation occurs when an operation within the integration node requires a syntax element tree to be built or extended.

Consider the following points when deciding how best to navigate the syntax element tree:

- A Syntax element has five pointers to its parents, siblings, and first and last children, so that a finite set of navigations is available.
- The same internal classes are used to perform all of these navigations.
- The parser does not control the navigation. The ESQL or a user-defined node makes the decision about the direction in which to navigate, and the order in which the navigational parser implementation functions are invoked. The user-defined parser has no control over the direction and order, and needs to respond correctly to the chosen navigation scheme; for example, parsing right to left, as well as left to right.
- When writing a user-defined parser, place the parser code in a parseNextItem function. This function should build the syntax element tree one element at a time, setting names, values and complete flags appropriately. How you implement this function depends on the nature of the bit stream to be parsed. The supplied sample parser demonstrates this behavior.

When the parser has finished parsing the relevant parts of the syntax element tree, it calls cpiWriteBuffer. This function appends its portion of the syntax element tree to the bit stream in the message buffer that is associated with the parser object, and creates the output message.

Destruction

The Destruction phase is the final phase in the user-defined parser life cycle. When the parser has written its portion of the syntax element tree to the bit stream and created the output message, the system resources that were created by the integration node for the parser to use need to be released.

The destruction phase begins when the **mqsistop** command is used to stop the execution process.

Planning user-defined parsers
Read about the concepts that you should consider before you develop a user-defined parser.

When you have considered the information provided here, and are ready to develop your own parser, use the instructions in "Developing user-defined parsers" on page 2434 to construct your parser.

Analysis

Before you start to create your own parser, be clear about its purpose. You can perform most tasks using the functions that are provided with IBM App Connect Enterprise, so you might not need to create a user-defined parser for your particular task.

Before you construct and implement a user-defined parser, consider the following questions:

- Do you need to create a user-defined parser?

  If the available parsers in IBM App Connect Enterprise are not appropriate for your needs, define your own parser to parse internal, customer-specific, or generic commercial message formats.
- Does IBM App Connect Enterprise already provide a parser for the domain or message header?

  See "Parsers" on page 520 for details of message domains for which the supplied parsers can accept input messages, and message headers with which the supplied parsers can work.
- Does the syntax of the in-house or commercial message dictate a format that can be parsed?
- To parse the message successfully, does the parser need to interact with vendor software? If so, does the API that enables access to this software break your threading model?
- Do you need to process multi-part, multi-format messages?

  IBM App Connect Enterprise does not support multi-part, multi-format messages. A multi-part MRM message must consist of messages that are all in the same format.
- What type of parsing strategy will provide best performance?

  IBM App Connect Enterprise supports partial parsing, which allows your parser to parse only relevant fields in a message. Using partial parsing can save system resources.

Partial and full parsing

IBM App Connect Enterprise supports *partial parsing*. If an individual message contains hundreds or even thousands of individual fields, the parsing operation requires considerable memory and processor resources to complete. An individual message flow might reference only a few of these fields, or none at all, so it is inefficient to parse every input message completely. For this reason, IBM App Connect Enterprise allows parsing of messages on an as-needed basis. (This ability does not prevent a parser from processing the entire message in one step, and some parsers are written to process the entire message in this way.)

Each syntax element in a logical message has two bits that indicate whether all the elements on either side of an element are complete, and whether its children are complete. Parsing is typically completed in a bottom-to-top, left-to-right manner. When a parser has parsed the siblings of a particular element that precede the given element and the first child, it sets the first completion bit to one. Similarly, when the pointer to the next sibling of an element is complete, as well as its last child pointer, the other completion bit is set to one.

In partial parsing, the integration node waits until a part of the message is referenced, and invokes the parser to parse that part of the message. Message processing nodes refer to fields within a message using hierarchical names. The name begins at the root of the message and proceeds down the message tree until the particular element is located. If an element is encountered without its completion bits set, and further navigation from this element is required, the appropriate parser entry point is called to parse the necessary part of the message. The relevant part of the message is parsed, appropriate elements are added to the logical message tree, and the element in question is marked as complete.

If you do not need to parse the full bit stream, you can use partial parsing. During partial parsing, a parser is called recursively until the requested element is returned, or until the message tree has been marked as complete, and the requested element is known not to exist.

Whether you choose to perform a full or partial parse depends on how the message will be processed. If most field elements within the message are likely to be accessed during processing, performing a full parse of the message when an attempt is made to access it is typically more efficient, particularly for smaller messages.

However, if most field elements within the message are not likely to be accessed during processing, performing a partial parse of the message when an attempt is made to access a specific field is typically more efficient, particularly when the message size grows.

Specific types used by parsers
Specific types are used when a parser needs additional information that is associated with some or all the elements in a tree in order to generate the bit stream.

For the XML parser, the specific type information is used to mark special elements such as components, processing instructions, and CDATA sections. The methods `getSpecificType` and `setSpecificType` are used by user-defined nodes to query this information and to generate message trees that use these special types.

Developers of user-defined parsers can generate their own specific type values to control special handling characteristics in their parser code using the existing C user-defined parser interface. The `getSpecificType` and `setSpecificType` methods enable Java user-defined nodes to fully use this parser capability.

Connectors
A connector is a type of user-defined extension that facilitates connection between IBM App Connect Enterprise and an external system, or *endpoint*.

Use the connector framework to develop a connector for a specific application or technology. You can use the connector framework to build reusable connectors that are not already available, reducing the need to build these interactions manually every time you need them. A connector can encapsulate complex interactions that you would otherwise achieve by using multiple message flow nodes.

You might need to use a connector in the following circumstances:

- You need to connect to an external system by using a proprietary protocol that is not supported by IBM App Connect Enterprise.
- A remote system publishes events over HTTP by using stateful, connection-oriented protocols such as XMPP or SIP. In this case, the standard IBM App Connect Enterprise HTTP nodes are not sufficient because they are stateless.
- Data from an earlier database that uses a non-standard client API or library must be integrated with later systems by using IBM App Connect Enterprise.

You create a connector for the runtime environment, and a user-defined node that represents the connector in a message flow.

For more information, see “Connectors overview” on page 2351

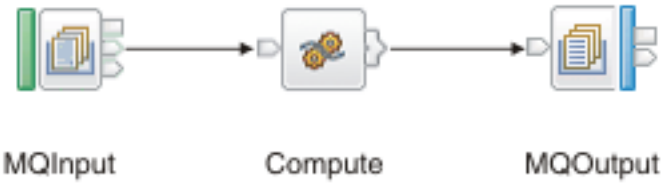
User exits

A user exit is user-provided custom software, written in C, which can be used to track data passing through message flows.

User-provided functions can be invoked at specific points during the life cycle of a message while it passes through the message flow, and can invoke utility functions to query information about the point in the flow, and the contents of the message assembly. The utility function can also modify certain parts of the message assembly. For more information about using user exits, see “Why use a user exit?” on page 2328

The user exits can be invoked when one or more of the following events occur:

- The end of a unit-of-work (UOW) or transaction (COMMIT or ROLLBACK).
- A message passes between two nodes.
- A message is successfully enqueued or sent to a transport in an output, reply, or request node.
- A message is dequeued or received in an input, response, or TimeoutNotification node.



In the basic message flow shown here, you can track messages at three levels:

- Transaction level
- Node level
- Input or output level

At the transaction level, you can track the following events:

- Messages being read into the flow
- Completion of the transaction

At the node level, you can track the following events:

- A message passing from one node to another
- Completion of processing for one node

At the message input or output level, you can track the following events:

- Messages being read into the flow
- Messages being written from the flow

Therefore, you can track five different types of event, which occur in the following sequence:

1. A message is dequeued from the input source (read into the flow).
2. A message is propagated to the node for processing.
3. A request message is sent to the output node's transport, and transport-specific destination information is written to "WrittenDestination" in the LocalEnvironment.
4. Node processing is completed.
5. The transaction ends.

For information about the user exit sample that is provided with IBM App Connect Enterprise, see “Transaction tracking user exit sample” on page 2446.

Which language to use to implement a user-defined extension

You can use Java or C to implement a user-defined extension.

You can use C to implement all types of user-defined extension except for connectors. You can use Java to implement user-defined nodes and connectors only.

If you can, use Java for user-defined nodes and connectors, and use C for everything else.

You must compile user-defined nodes, parsers, and exits that are written in C into a loadable implementation library (LIL): that is, a shared library on Linux and UNIX systems, or a dynamic link library (DLL) on Windows systems. You must package user-defined nodes and connectors that are written in Java as a JAR file.

To achieve platform independence, use the ANSI standard C or Java programming languages, and avoid platform-specific code in your user-defined extension.

Implementing the supplied user-defined extension samples

IBM App Connect Enterprise provides some sample code to help you understand how to write user-defined nodes and parsers.

About this task

The sample code consists of a sample parser, and the following sample nodes:

Node	Description
Switch	A node, implemented in both C and Java versions, that propagates an input message to one of several output terminals depending on the message content.
Transform	A node, implemented in both C and Java versions, that performs a simple message transformation.

Each sample node consists of the source files and some files that you can use to test each node. For the sample parser there are only source files. See Sample node files and Sample parser files for details of the sample files and where to find them.

To implement the supplied samples from the sample code that is installed with IBM App Connect Enterprise, complete the following steps:

Procedure

1. Compile the samples by following the instructions in “Compiling a Java user-defined node” on page 2418 or “Compiling a C user-defined extension” on page 2400.
2. Install the user-defined extension in an integration node domain by following the instructions in “Installing user-defined extension runtime files on an integration node” on page 2455.
3. Copy and extract the `SampleNodesProject.zip` file.

   On a computer that has the IBM App Connect Enterprise Toolkit installed, extract the `install_dir\server\sample\extensions\nodes\com.ibm.samples.nodes\SampleNodesProject.zip` file to the `dropins` directory.

   For example, on Windows, the default location to extract the file to is `C:\Program Files\IBM\ACE\12.0.n.0\tools\dropins`.
4. Restart the IBM App Connect Enterprise Toolkit, specifying the `-clean` option.

   For example, on Windows, open a command line, navigate to the installation directory (by default `C:\Program Files\IBM\ACE\12.0.n.0\tools`) and run the command **`mb.exe -clean`**. For more information about where to copy the files, see Installing a user-defined extension to current and past versions of.

5. Open the IBM App Connect Enterprise Toolkit and switch to the Integration Development perspective.

   The category called "Sample nodes" is now visible in the palette, and the sample nodes are shown below it. Documentation about the sample nodes is also visible in the help system under "Samples".
6. Include the sample nodes in a message flow.

   For more information, see “Adding a message flow node” on page 618.
7. Deploy the message flow.

   For more information, see Chapter 7, “Deploying integration solutions,” on page 2463.
8. For the Switch and Transform nodes, you can put a message to the input queue of the message flow and observe the results by completing the following steps:
   a) Ensure that the message flow that contains the sample node is deployed successfully.

      For more information, see “Checking the results of deployment” on page 2485.
   b) Use the Enqueue message function to put the sample input messages (provided in `.xml` files) to the input queue named on the input node of the message flow.

      For more information, see “Debug: putting a test message on an input queue” on page 666.

   You can also use a Trace node or the Flow debugger to see what is happening in your message flow.

Developing connectors

You can create connectors that can be used in IBM App Connect Enterprise to interact with applications or data sources.

About this task

A connector is a type of user-defined extension that facilitates connection between IBM App Connect Enterprise and an external system, or *endpoint*. A connector developer can use the connector framework to create a connector and required resources, such as a message flow node. You begin by creating a connector provider, which is the library that provides the connectors for a particular technology or type of endpoint. A connector provider has one connector factory that can create connectors of different types: input, output, and request. You then create a user-defined node to expose the capabilities of the connector to a message flow. IBM App Connect Enterprise associates a user-defined node with a runtime connector by using standard property names and values, which you define on the user-defined node.

For more information, see “Connectors overview” on page 2351.

Before you develop a connector, understand the endpoint to which you are connecting, and decide which interaction patterns are appropriate. If a connector does not exist, you can implement a connector factory, then create one or more types of connector.

To develop a connector, complete the following tasks:

- “Developing a connector for the IBM App Connect Enterprise runtime environment” on page 2353
- “Testing a connector in Eclipse (optional)” on page 2363
- “Developing a user-defined node to represent a connector” on page 2364
- “Installing a connector in IBM App Connect Enterprise” on page 2369
- “Installing the user-defined node for a connector in the IBM App Connect Enterprise Toolkit” on page 2370
- “Testing a connector in IBM App Connect Enterprise” on page 2370

Connectors overview

A *connector* helps IBM App Connect Enterprise to interact with external applications or data sources.

Companies often build their own internal applications to which they want to connect. You can connect through web services, or access data directly from a database to connect to applications. However, you can also use the connector framework to develop a connector for a specific application or technology. You can use the connector framework to build reusable connectors that are not already available, reducing

the need to build these interactions manually every time you need them. A connector can encapsulate complex interactions that you would otherwise achieve by using multiple message flow nodes.

You might need to use a connector in the following circumstances:

- You need to connect to an external system by using a proprietary protocol that is not supported by IBM App Connect Enterprise.
- A remote system publishes events over HTTP by using stateful, connection-oriented protocols such as XMPP or SIP. In this case, the standard IBM App Connect Enterprise HTTP nodes are not sufficient because they are stateless.
- Data from an earlier database that uses a non-standard client API or library must be integrated with later systems by using IBM App Connect Enterprise.

Connectors

Connectors take one of three forms, depending on the style of interaction that they use:

Input connector

Input connectors listen for external events or receive data from external sources. These connectors constitute the starting point of a message flow. Polling for input is a special case of an input connector that is supported in the connector framework.

Output connector

Output connectors send data or publish events to external systems without expecting to receive a response.

Request connector

Like output connectors, request connectors send data, but expect to receive a response in return.

Connectors for a particular application or technology are Java classes, which are packaged as a JAR file. This JAR file also contains the following resources:

- A factory class to create the connectors for that application or technology
- Supporting classes or Java libraries that are required to make the connectors function as required
- An XML descriptor file

A JAR file that provides connectors for a particular application or technology is called a *connector provider*.

Hosting connectors

Connectors constitute the runtime part of connecting to external systems or applications. You deploy connectors by installing the connector runtime files on an integration node (see “Installing a connector in IBM App Connect Enterprise” on page 2369).

During initialization, connectors get services, such as logging and security, from IBM App Connect Enterprise. A standard Java logger is provided to all connectors to allow the connector to use the logging and trace framework of IBM App Connect Enterprise.

To use connectors in IBM App Connect Enterprise, you must also create a user-defined node to expose the capabilities of the connector to a message flow.

Developing a connector for the IBM App Connect Enterprise runtime environment

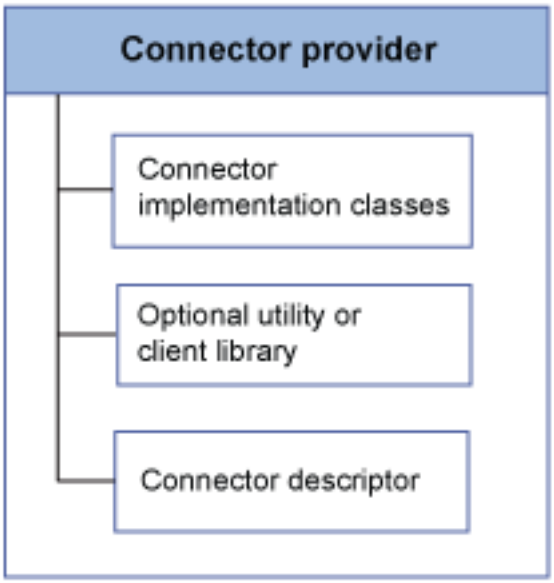
To develop a connector, you must create and compile a connector for the IBM App Connect Enterprise runtime environment, then install the connector files on an integration node.

Before you begin

For more information about connectors, see “Connectors overview” on page 2351.

About this task

To develop a connector, you create the Java classes that describe the connector factory, the connector type, and the interaction type. You also create a connector descriptor file to associate the runtime connector with a user-defined node. You can include a utility or client library. For example, you might want to use an existing library to communicate with a particular protocol, instead of creating your own.



You begin by creating the connector factory class. You then create the appropriate classes for the type of connector. A single connector provider can contain more than one connector type. You do not need to create a connector of every type for a connector provider.

Procedure

To create a connector for the runtime environment, complete the following tasks:

1. “Creating a connector factory” on page 2354.
2. Create one or more types of connector:
   - “Creating an input connector” on page 2355
   - “Creating an output connector” on page 2357
   - “Creating a request connector” on page 2359
3. “Creating a connector descriptor file” on page 2361.
4. “Packaging a connector for the runtime environment” on page 2362

Creating a connector factory

Use the connector factory to create input, output, and request connectors.

About this task

You do not need to create all types of connector for a connector provider. For example, if you want systems to send status messages to users, you might create an input connector and an output connector, which uses an instant messaging application to send messages.

Procedure

1. Create a Java project.

   For example, to create a Java project in the IBM App Connect Enterprise Toolkit, click **File** > **New** > **Project** and select **Java Project**.

   Your Java project is shown in the Package Explorer view of the Java perspective. Right-click the project to add new classes and interfaces.

2. Add the Connector API JAR file to the class path of your Java project.

   You can find the Connector API JAR file at *install_dir*/server/classes/cmnCon.jar (for example, on Windows, C:\Program Files\IBM\IIB*version*\server\classes\cmnCon.jar).

3. Create a connector factory with the Connector Framework API by extending the AbstractConnectorFactory class.

   Javadoc documentation for the Connector Framework API is available at Connector API.

   The AbstractConnectorFactory class implements a ConnectorFactory interface. The cardinality of ConnectorFactory to connector provider is one-to-one. For example, if you want to connect to a particular resource, and you are creating a request connector and an input connector, one ConnectorFactory is required for all types of interaction.

   The following example of a connector factory Java file demonstrates how to create a connector factory that has an input, output, and request connector:

```
package connector.database;

import com.ibm.connectors.AbstractConnectorFactory;
import com.ibm.connectors.ConnectorException;
import com.ibm.connectors.InputConnector;
import com.ibm.connectors.OutputConnector;
import com.ibm.connectors.RequestConnector;

public class myConnectorFactory extends AbstractConnectorFactory {

 public myConnectorFactory() {
  // TODO You can create shared resources that are used by all connectors
  // for this provider. If the resources depend on properties that are provided
  // on initialisation, create those resources in the onInitialise() method,
  // when the properties are available.
 }

 @Override
 protected void onInitialise() throws Exception {
  // TODO This method is called after the factory has been initialised with its properties,
  // the provider name, and connector services, which are all available via getters on
  // this class. A standard Java logger is created under the provider name,
  // and it is available by using getLogger().

 }

 @Override
 public String getInfo() {
  // TODO This method returns a human-readable descriptive string for this provider,
  // such as name, version number, and organisation.
  return null;
 }

 @Override
 public InputConnector createInputConnector(String name)
   throws ConnectorException {
```

```
  // TODO This method creates and returns an input connector for this provider
  return null;
 }

 @Override
 public OutputConnector createOutputConnector(String name)
   throws ConnectorException {
  // TODO This method creates and returns an output connector for this provider
  return null;
 }

 @Override
 public RequestConnector createRequestConnector(String name)
   throws ConnectorException {
  // TODO This method creates and returns a request connector for this provider
  return null;
 }

}
```

What to do next

After you create the connector factory, create one or more connectors by following the instructions in the appropriate topic:

- “Creating an input connector” on page 2355
- “Creating an output connector” on page 2357
- “Creating a request connector” on page 2359

Creating an input connector

Create an input connector by extending the AbstractInputConnector class.

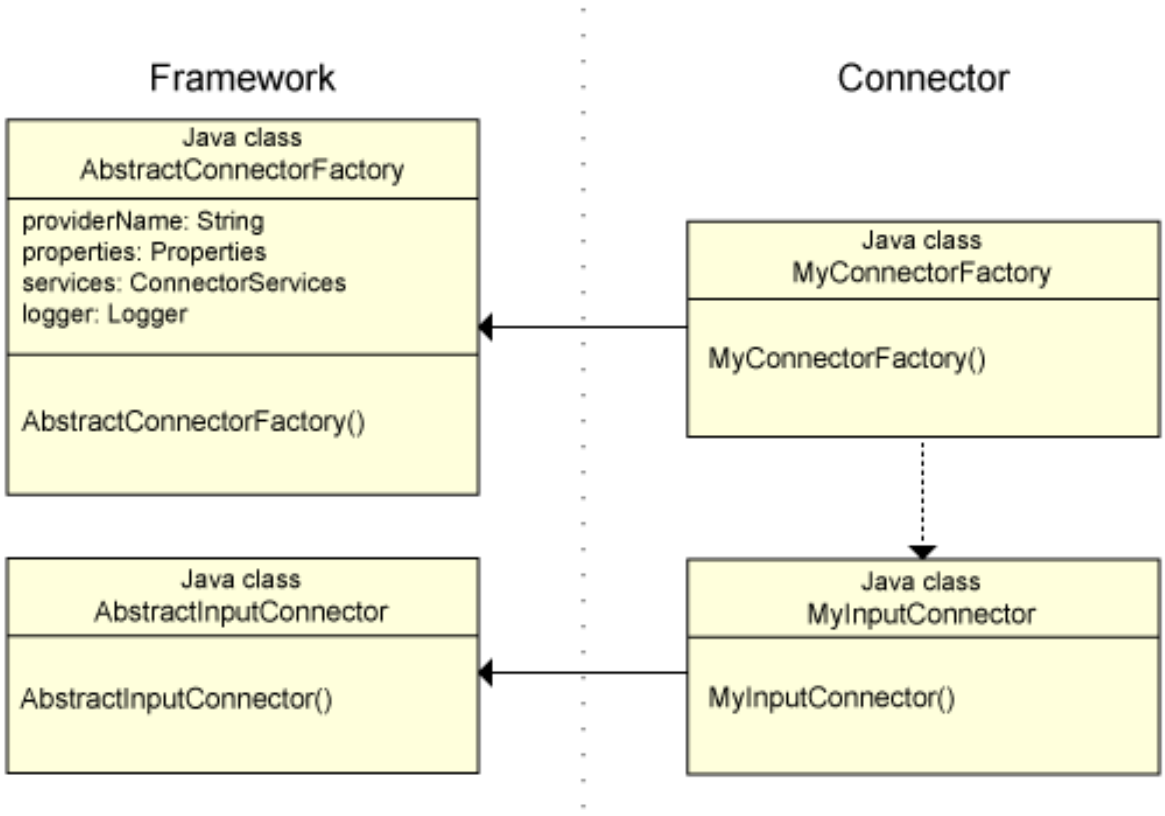
Before you begin

Create a connector provider by following the instructions in “Creating a connector factory” on page 2354.

About this task

Create an input connector when you want to listen for external events or receive data from external sources. Input connectors constitute the starting point of a message flow. Polling for input is a special case of an input connector that is supported in the connector framework.

The following example shows the Java classes that you need to create for an input connector:



Procedure

To create an input connector, extend the AbstractInputConnector class.

Javadoc documentation for the Connector Framework API is available at Connector API.

The following example of an input connector JAVA file demonstrates how to create an input connector:

```
package connector.database;

import java.util.Properties;

import com.ibm.connectors.AbstractInputConnector;
import com.ibm.connectors.ConnectorException;

public class myInputConnector extends AbstractInputConnector {

 @Override
 protected void onInitialise() throws Exception {
  // TODO This method is called after the properties and container services have been
  // saved.
  // You can call getLogger() to get a Java logger named with your connector's assigned name
  // You can call getProperty(<name>) to get a named property provided via the Toolkit
  // You can create any resources you need here (and destroy them on terminate())
  // or you can wait until start() (destroying them on stop())
  getLogger().fine("Initialisation complete");
 }

 @Override
 public void start() throws ConnectorException {
  // TODO Implement the code here to start listening for input depending on the technology
  // being used.

  // You can call getCallback().processInboundData() to pass incoming input to the host
 application
  // Input data should be a byte array. Properties may also be returned. These will form part of
 the
  // ongoing message to be processed by the message flow.
  byte[] data = null;
  Properties props = new Properties();
  getCallback().processInboundData(data, props);
```

```
 }

 @Override
 public boolean isStarted() {
  // TODO You need to track the state of the input connector since it varies depending on
  // the technology being used.
  return false;
 }

 @Override
 public void stop() throws ConnectorException {
  // TODO Close down any input listeners here.

 }

 @Override
 public void terminate() throws ConnectorException {
  // TODO Release any resources here
 }

}
```

What to do next

After you create the connector factory and connector, create the `connector.xml` descriptor file (see “Creating a connector descriptor file” on page 2361).

Creating an output connector

Create an output connector by extending the AbstractOutputConnector and AbstractOutputInteraction classes.

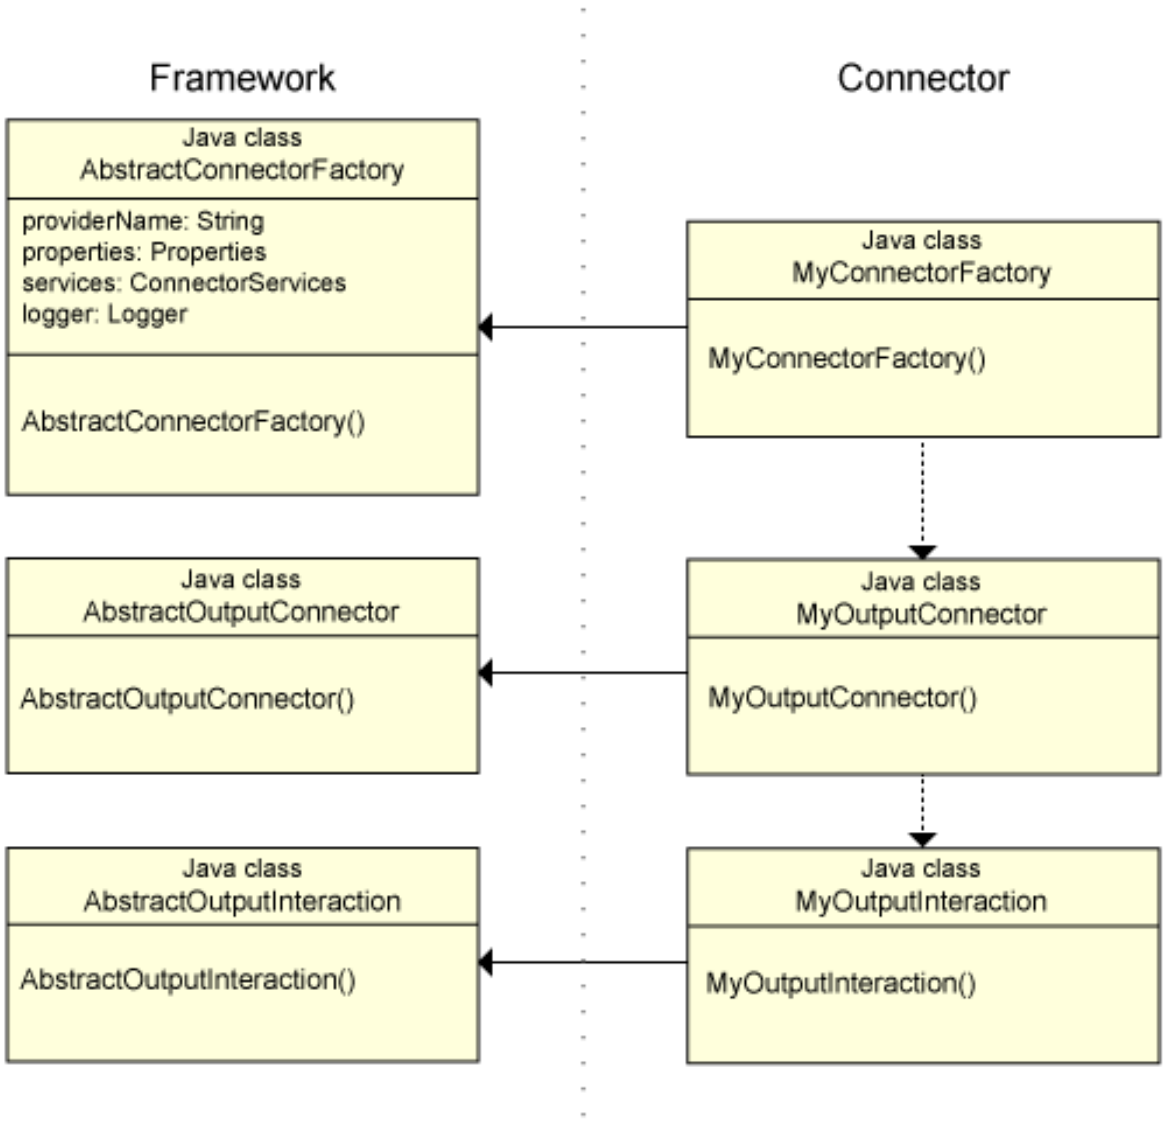
Before you begin

Create a connector provider by following the instructions in “Creating a connector factory” on page 2354.

About this task

Create an output connector when you want to send data or publish events to external systems without receiving a response.

The following example shows the Java classes that you need to create for an output connector:



Procedure

1. To create an output connector, extend the AbstractOutputConnector class.

   Javadoc documentation for the Connector Framework API is available at Connector API.

   The following example of an output connector Java file demonstrates how to create an output connector.

```
package connector.database;

import com.ibm.connectors.AbstractOutputConnector;
import com.ibm.connectors.ConnectorException;
import com.ibm.connectors.OutputInteraction;

public class myOutputConnector extends AbstractOutputConnector {

 @Override
 public OutputInteraction createOutputInteraction() throws ConnectorException {
  // TODO Create the output interaction here. The interaction is the object
  // that represents the actual output (even if it doesn't actually perform it).
  // The interaction will receive any dynamic properties configured by the message
  // flow, as well as the actual data to be sent
  return null;
 }
```

```
}
```

The connector framework calls the createOutputInteraction method when a message is to be processed.

2. Configure the output interaction by extending the AbstractOutputInteraction class.

   The following example of an output interaction Java file demonstrates how to create the output interaction:

```
package connector.database;

import java.util.Properties;

import com.ibm.connectors.AbstractOutputInteraction;
import com.ibm.connectors.ConnectorCallback;
import com.ibm.connectors.ConnectorException;

// The output interaction class publishes data to a remote system.
// Currently, the data to send is received as a byte array, and it
// should return a properties object in return that describes the outcome.
// Dynamic properties may be passed in to configure the output per-message.
public class myOutputInteraction extends AbstractOutputInteraction {

 @Override
 public Properties send(Properties overrideProperties, Object data)
   throws ConnectorException {
  byte[] byteData = (byte[]) data;
  // TODO Implement code here to send the byte data to the external
  // system. Return any details (eg success, no of bytes sent) in
  // a properties object which will be available to downstream nodes
  // within the message flow
  return null;
 }

 @Override
 public long asyncSend(Properties overrideProperties, Object data,
   ConnectorCallback callback) throws ConnectorException {
  // TODO Send asynchronously and return a 'ticket'. Currently
  // unsupported/unused.
  return 0;
 }

}
```

What to do next

After you create the connector factory and connector, create the `connector.xml` descriptor file (see “Creating a connector descriptor file” on page 2361).

Creating a request connector

Create a request connector by extending the AbstractRequestConnector and AbstractRequestInteraction classes.

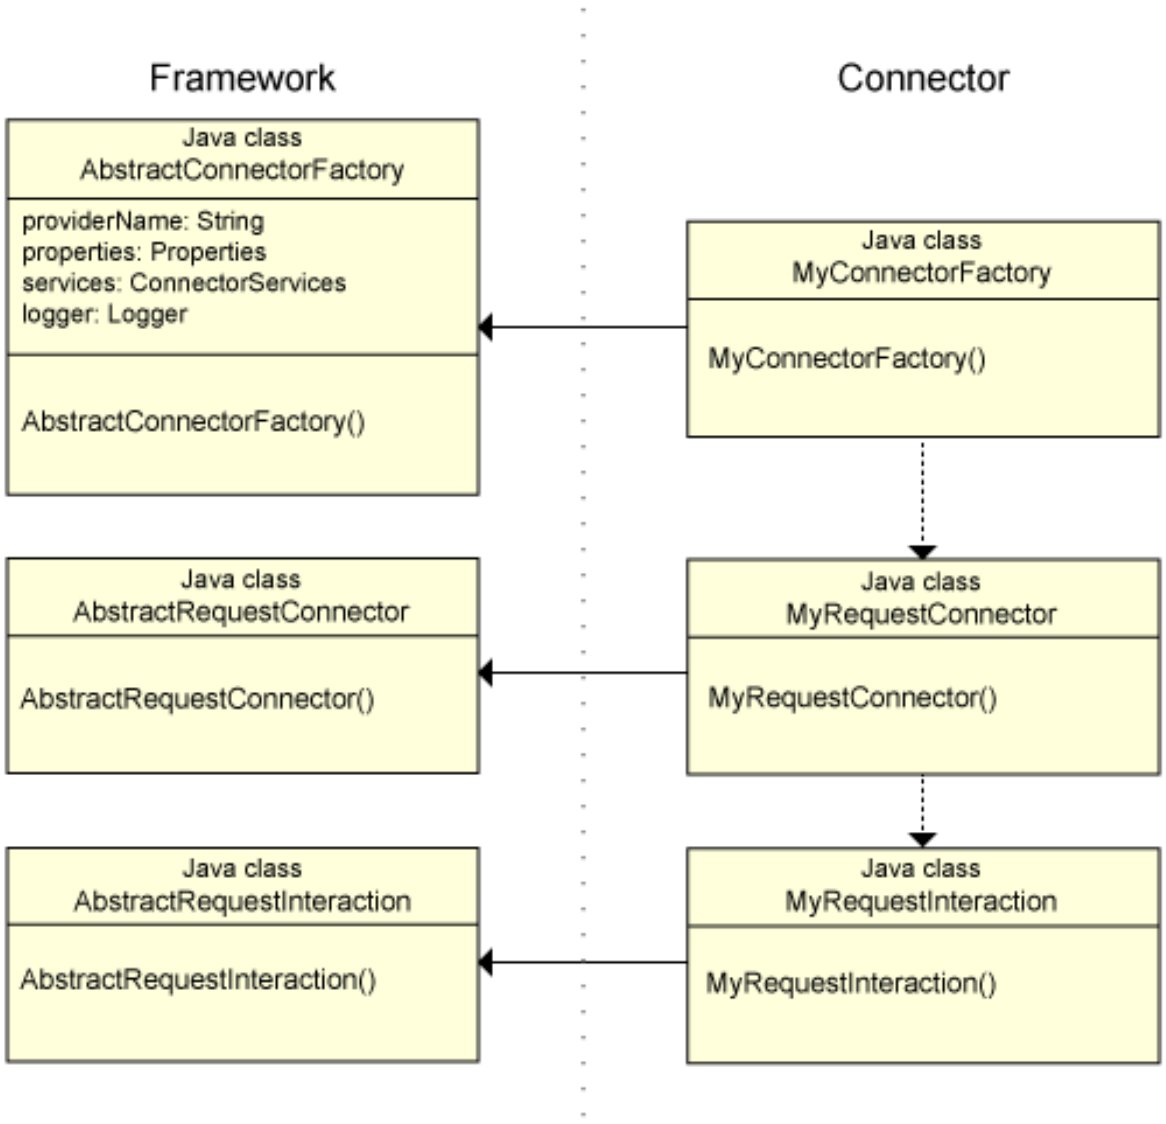
Before you begin

Create a connector factory by following the instructions in “Creating a connector factory” on page 2354.

About this task

Create a request connector when you want to send data, or publish events to external systems, and receive a response.

The following example shows the Java classes that you need to create for a request connector:



Javadoc documentation for the Connector Framework API is available at Connector API.

Procedure

To create a request connector, complete the following steps.

1. Create the connector by extending the AbstractRequestConnector class.

   The following example request connector Java file demonstrates how to create a request connector:

```
package connector.database;

import com.ibm.connectors.AbstractRequestConnector;
import com.ibm.connectors.ConnectorException;
import com.ibm.connectors.RequestInteraction;

public class myRequestConnector extends AbstractRequestConnector {

 @Override
 public RequestInteraction createRequestInteraction() throws ConnectorException {
  // TODO Create the request interaction here. The interaction is the object
  // that represents the actual request (even if it doesn't actually perform it).
  // The interaction will receive any dynamic properties configured by the message
  // flow, as well as the actual data to be sent
  return null;
 }
```

```
}
```

The connector framework calls the createRequestInteraction method when a message is to be processed.

2. Specify the request connector interaction by extending the AbstractRequestInteraction class.

   The following example of a request interaction Java file demonstrates how to create the request interaction:

```
package connector.database;

import java.util.Properties;

import com.ibm.connectors.AbstractRequestInteraction;
import com.ibm.connectors.ConnectorCallback;
import com.ibm.connectors.ConnectorException;

// The request interaction class performs a request/response with a remote system.
// Currently, data is received as a byte array, and should return a byte array in
// response. Dynamic properties may be passed in to configure the request per-message.
public class myRequestInteraction extends AbstractRequestInteraction {

 @Override
 public Object request(Properties overrideProperties, Object data)
   throws ConnectorException {
  byte[] input = (byte[]) data;
  // TODO Implement code here to send the byte data to the external
  // system. Return the response which currently must be a byte array.
  byte[] output = new byte[0];
  return output;
 }

 @Override
 public long asyncRequest(Properties overrideProperties, Object data,
   ConnectorCallback callback) throws ConnectorException {
  // TODO Request asynchronously and return a 'ticket'. Currently
  // unsupported/unused.
  return 0;
 }

}
```

What to do next

After you create the connector factory and connector, create the `connector.xml` descriptor file (see “Creating a connector descriptor file” on page 2361).

Creating a connector descriptor file

A connector descriptor file is used to associate the runtime connector with a user-defined node. This file creates a link between the logic in a message flow and the code that is called at run time.

Before you begin

Create a connector factory and appropriate connectors. For more information, see “Developing a connector for the IBM App Connect Enterprise runtime environment” on page 2353.

About this task

The `connector.xml` descriptor file contains the elements **`connectorProvider`** and **`connectorFactory`**:

- The **`connectorProvider`** element contains the name of the provider, which can include multiple interaction types. Therefore, the provider name is the same if you are creating an input connector, an output connector, and a request connector for that provider.
- The **`connectorFactory`** element identifies the fully qualified name of the provider's factory class (for example, `connector.database.myConnectorFactory`). This property identifies the implementation class that extends the AbstractConnectorFactory class in the Connector framework.
- The **`connectorFactory properties`** are available to the connector factory during initialization.

IBM App Connect Enterprise associates the runtime connector with a user-defined node by using these properties. The **connectorProvider** element in the `connector.xml` file must match the **connectorName** property on the user-defined node.

Procedure

To create the `connector.xml` descriptor file, complete the following steps.

1. Create an XML file that is called `connector.xml` and specify the **connectorProvider** and **connectorFactory** elements.

   Here is an example of a `connector.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
 <connectorProvider name="myDatabaseConnector">
     <connectorFactory className="connector.database.myConnectorFactory">
         <properties>
             <property name="name1" value="value1"/>
         </properties>
     </connectorFactory>
 </connectorProvider>
```

2. Save the `connector.xml` file in your Java project, at the root of the `src` folder.

What to do next

After you create the connector factory, connectors, and connector descriptor file, package the appropriate files (see "Packaging a connector for the runtime environment" on page 2362.

Packaging a connector for the runtime environment

Package your connector so that it can be installed in a runtime environment.

Before you begin

Create the connector factory, connectors, and connector descriptor file. For more information, see "Developing a connector for the IBM App Connect Enterprise runtime environment" on page 2353.

About this task

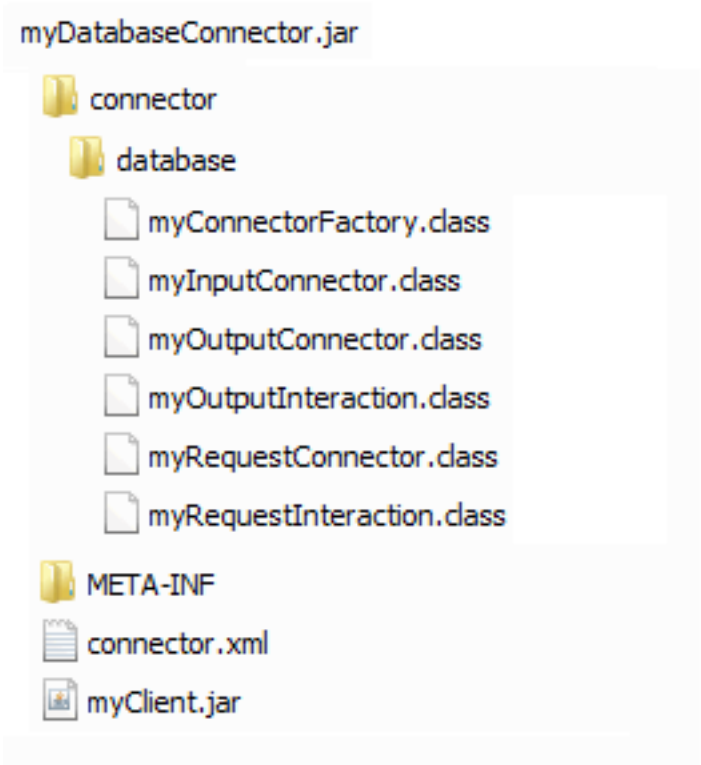
Procedure

To package the connector, complete the following steps:

1. In Eclipse, click **File** > **Export**.
2. In the **Export** wizard, expand **Java**, and select **JAR file**, then click **Next**.
3. Select your Java project from the list of files in your workspace.
4. Select **Export all output folders for checked projects**.
5. Select the location in the file system for your JAR file.

Results

Your connector is packaged into a JAR file and saved at the specified location. The following example shows the structure of files in the JAR file, and includes an input, output, and request connector. In this example, `myClient.jar` is a library that is used by the connectors. You can create your own library, or acquire one from a third party.



What to do next

After you package the connector, install it in a runtime environment. For example, see "Installing a connector in IBM App Connect Enterprise" on page 2369.

Testing a connector in Eclipse (optional)

To test a connector outside a container such as IBM App Connect Enterprise, create a JUnit test case and run that test case in Eclipse.

Before you begin

- Complete the connector development steps for the runtime environment in "Developing a connector for the IBM App Connect Enterprise runtime environment" on page 2353.
- Ensure that you have access to the endpoint with which your connector interacts.

About this task

When you create a connector, you can test it by creating a JUnit test case. You can run the test case in Eclipse, without the need to install a container, such as IBM App Connect Enterprise.

Procedure

To test a connector in Eclipse, complete the following steps:

1. Create some mock classes for your connector.
2. Create a JUnit test case to test the methods of your classes.
3. To run the test, right-click the Java test case in the Package Explorer or Application Development view and click **Run as** > **JUnit Test**.

Results

The output from the test in the console window shows a number of interactions with the endpoint.

Developing a user-defined node to represent a connector

To use a connector in a message flow, you must create, package, and install a user-defined node for the IBM App Connect Enterprise Toolkit

Before you begin

Create the connector for the runtime environment by completing the tasks in "Developing a connector for the IBM App Connect Enterprise runtime environment" on page 2353.

About this task

To use a connector in a message flow, you create a user-defined node in the IBM App Connect Enterprise Toolkit. You package the node, then distribute it so that message flow developers can install it in the appropriate location.

To implement a connector in IBM App Connect Enterprise, complete the following tasks:

Procedure

1. "Creating a user-defined node for a connector" on page 2364
2. "Configuring the user-defined node properties and terminals for your connector" on page 2365
3. "Packaging the user-defined node project for a connector" on page 2368

Creating a user-defined node for a connector

Create a user-defined node that uses a connector in a message flow.

Before you begin

Create the connector factory, connectors, and connector descriptor for the runtime environment by completing the tasks in "Developing a connector for the IBM App Connect Enterprise runtime environment" on page 2353.

About this task

The project that contains a user-defined node is a user-defined node project. When you create a user-defined node, you can add it to an existing user-defined node project, or you can create a new project. A user-defined node project can contain more than one user-defined node. Typically, all user-defined nodes for a particular connector provider are contained in the same project. For example, if you create an input, output, and request connector for a connector provider, all three types of connector have a user-defined node in the same project.

Procedure

To create a user-defined node, complete the following steps:

1. In the IBM App Connect Enterprise Toolkit, click **File** > **New** > **User-defined Node**.

   The **New User-defined Node** wizard opens.
2. Select an existing user-defined node project, or click **New** to create a new project.

   The following steps assume that you create a new project.
3. In the **New User-Defined Node Project** wizard, select **Create a new category** and enter a name for the category.

   This category is displayed on the message flow node palette.
4. Enter a project name.
   For example, use the same name as the connector provider.

   When you enter the project name and move to another field, the other fields in the wizard are filled automatically.
5. Click **Finish**.

6. In the **New User-Defined Node** wizard, specify a schema for this node.

   Do not use the default schema or any other common schema, such as `mqsi`, which might cause file name clashes.

   For example, you might use the same package name that is used for the runtime connector, such as `connector.database`.
7. In **Name**, specify a name for the node.

   The name must be one of the following values:

Connector interaction type	User-defined node name
Input	ComIbmEventInput
Output	ComIbmOutput
Request	ComIbmRequest

8. In **Display name**, enter a name for the node to include on the message flow node palette. For example, set the display name to `My Database Input`. This name is used in trace and error logs to represent the user-defined node.
9. In **Tooltip on palette**, enter some appropriate text; for example, "Input node for a database".
10. Select **Implemented in Java/C**.
11. Optional: Import an icon to represent your node.
12. Click **Finish**.

Results

A `.msgnode` file for the new user-defined node is created and is added to the project in the Application Development view. A `.properties` file of the same name is also created. The `.msgnode` file is opened in the **Message Node** editor.

What to do next

Configure the user-defined node properties for your connector by following the instructions in "Configuring the user-defined node properties and terminals for your connector" on page 2365.

Configuring the user-defined node properties and terminals for your connector

Configure the properties for your user-defined node and add input or output terminals so that you can connect it to other nodes in a message flow.

Before you begin

Create the plug-in files for your user-defined node by following the instructions in "Creating a user-defined node for a connector" on page 2364.

About this task

When you create the plug-in files for your user-defined node, a `.msgnode` file is opened in the **Message Node** editor of the Integration Development perspective. You can now add terminals and properties to the node:

- "Adding terminals to the node" on page 2365
- "Defining properties for the node" on page 2366

Adding terminals to the node

About this task

When you are creating user-defined nodes for connectors, you can add specific types of terminal according to the interaction type. User-defined nodes for connectors cannot have dynamic terminals. For

detailed information about how terminals work for different interaction types, see “User-defined node terminals for connectors” on page 2367.

Procedure

1. Open the `.msgnode` file for your user-defined node.
2. If the **Terminals** page is not already displayed, click the **Terminals** tab at the bottom of the **Message Node** editor.
3. Add an output terminal and name it "failure". The name is case-sensitive and must use lowercase characters.

   This terminal is used if the connector issues an exception at run time.
4. If you are creating an input node, delete the input terminal by selecting it, then clicking **Delete**.

   Similarly, if you are creating an output node, delete the output terminal.
5. Ensure that **Support dynamic In terminals** and **Support dynamic Out terminals** are cleared.
6. Save the file.

Defining properties for the node

About this task

A message flow developer can add a message flow node to a message flow, then customize that node by setting the available properties. You can define those properties for your user-defined node on the **Properties** tab of the Message Node editor.

For a connector, you must define a hidden property that specifies the connector provider name. You can then add any other relevant properties, such as a database name, host server name, or password. The properties that you set here must match the properties that are used by the connector at run time.

For a connector, table properties are not supported, and you cannot use a custom compiler class or a custom editor class.

Procedure

1. Open the `.msgnode` file for your user-defined node.
2. On the **Properties** tab, click the node name in the property hierarchy to view the properties that are associated with it.
3. Clear **Use integration node default values**.
4. If the node is an input node, select **Input node**.
5. By default, all properties are grouped under the Basic group. You can add new groups in which to place properties. When a flow developer selects your user-defined node in the IBM App Connect Enterprise Toolkit, each group of properties is shown on a separate tab in the **Properties** view. To create more groups of properties, click **Add Property Group**  and enter a suitable name for the group.

6. Add a hidden property to specify the provider name for the connector.
   a) Select the name of a property group, click **Add Simple Property**  , then set the name to `connectorName`.
   b) Select **Built-in** and set it to `String`.
   c) Set the default value to the name of the provider, which must match the **`connectorProvider`** name in the descriptor file of your compiled connector JAR file. This name is used for all interaction types of this particular connector (input, output, or request).
   d) Select **Hidden**.
      This option ensures that this property is associated with the connector, but the message flow developer cannot see or change the value.
   e) Because these properties are hidden, do not select **Read Only**, **Mandatory**, or **Configurable**, and do not specify field-level help.
   f) Do not set **Custom Compiler Class** or **Custom Editor Class**.
7. Add properties to be set by a message flow developer in a similar way.
   Ensure that **Hidden** is cleared for these properties so that the message flow developer can customize them.
8. Optional: Drag the properties in the properties hierarchy to change the order in which they are listed on the properties page.
9. Save and close the `.msgnode` file.
10. Optional: You can customize the text that is displayed in the node properties view for each property. When you define the property in the `.msgnode` file, the name cannot contain spaces. Therefore, you might want to edit the property name so that the name in the Properties view contains spaces.
    To set the text, open the `.properties` file for your user-defined node and edit the following line:
    ```
    Property.propertyName=Property name
    ```
11. Save and close the `.properties` file.

What to do next

Package your user-defined node by following the instructions in "Packaging the user-defined node project for a connector" on page 2368.

User-defined node terminals for connectors

The terminals that you can add to your user-defined node depend on the interaction type.

The following table describes which terminals are available for each type of connector, and how those terminals behave. You cannot use dynamic terminals on a user-defined node that represents a connector.

Interaction type	User-defined node terminals	Behavior
Input	• Output terminal • Failure terminal	The data that is passed through the output terminal includes properties and the body of the message. The properties are copied to the local environment of the message flow at this location: `LocalEnvironment > connectorName > Input > propName = propValue`

Interaction type	User-defined node terminals	Behavior

Output	• Input terminal
	• Output terminal
	• Failure terminal
		The input terminal receives the body of the message, and receives properties from the local environment at this location:
		`LocalEnvironment > Destination > connectorName > Output > propName = propValue`
		The output terminal passes the body of the message without changes. If properties are returned, they are placed in the local environment at this location:
		`LocalEnvironment > WrittenDestination > connectorName > propName = propValue`
		The failure terminal propagates the body of the message and the properties without changes.

Request and response	• Input terminal • Output terminal • Failure terminal	The input terminal receives the body of the message, and it receives properties from the local environment at this location: `LocalEnvironment > Destination > connectorName > Request > propName = propValue` The output terminal passes the body of the message that is returned by the connector. The failure terminal propagates the body of the message and the properties without changes.

Packaging the user-defined node project for a connector

Package the user-defined node project to make it available for other users.

Before you begin

Create the user-defined node for your connector in the IBM App Connect Enterprise Toolkit by following the instructions in "Developing a user-defined node to represent a connector" on page 2364.

Procedure

To package your user-defined node project, complete the following steps in the IBM App Connect Enterprise Toolkit:

1. In the Independent Resources folder of the Application Development view, right-click the user-defined node project that you want to package, then select **Package**.

   The **Package and Distribute User-Defined Nodes** wizard opens.
2. Select **Plug-in jars**, then click **Next**.
3. Select the plug-in that you want to package.

   The appropriate plug-in is selected by default.
4. Select the directory where you want to save the package, then click **Finish**.

Results

The plug-in JAR file is saved in the specified directory, within a folder called `plugins`.

What to do next

You can distribute the plug-in JAR file from your file system to message flow developers who want to use the connector in a message flow. They must install the plug-in by following the instructions in "Installing the user-defined node for a connector in the IBM App Connect Enterprise Toolkit" on page 2370.

Installing a connector in IBM App Connect Enterprise

Install the connector on the integration node on which you want to test its function.

Before you begin

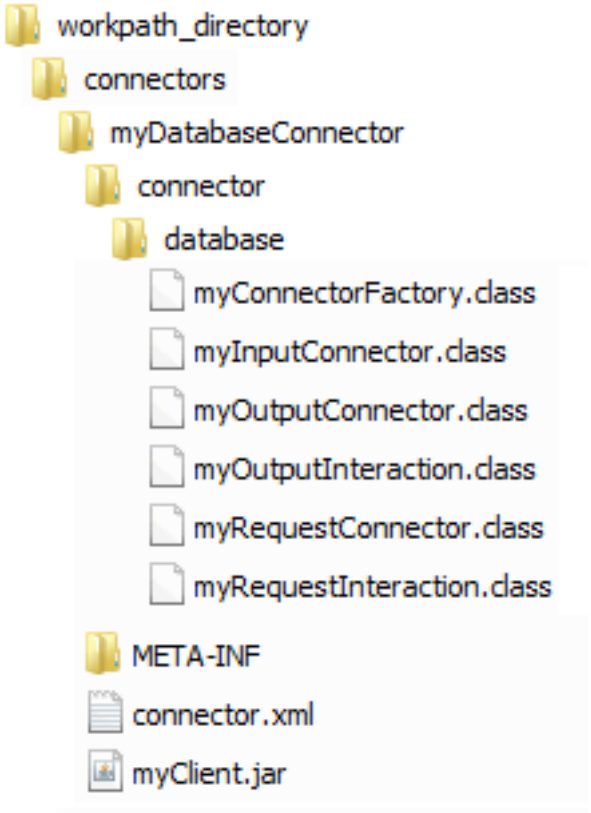
Package your connector. For more information, see "Packaging a connector for the runtime environment" on page 2362.

Procedure

To install the connector on the integration node, complete the following steps:

1. Stop the integration node on which you want to install your connector.
2. Save the JAR file that contains your connector in *workpath*`/connectors`.
   For example, the default workpath directory on Windows is `C:\ProgramData\IBM\MQSI`.

   If the connector JAR file contains other JAR files, extract the connector JAR file to a folder with the same name as the parent JAR file under *workpath*`/connectors`. For example:



3. Restart the integration node to ensure that the integration node picks up the new file.
   The connector is available to all integration servers on that integration node.

Results

The integration node loads the connector files during initialization. After the files are loaded, the integration node calls the registration functions in the connector and records what nodes or parsers the connector supports.

What to do next

Install the user-defined node for your connector by following the instructions in "Installing the user-defined node for a connector in the IBM App Connect Enterprise Toolkit" on page 2370.

Installing the user-defined node for a connector in the IBM App Connect Enterprise Toolkit

Before you can use a user-defined node in a message flow, you must install it into your IBM App Connect Enterprise Toolkit.

Before you begin

Package your user-defined node project by following the instructions in "Packaging the user-defined node project for a connector" on page 2368.

About this task

You can develop message flows by using the user-defined node in the same way as the built-in nodes. To install the user-defined node project, complete the following steps.

Procedure

1. Copy the user-defined node plug-in JAR file into the `dropins` folder in your IBM App Connect Enterprise Toolkit installation location: *`install_dir`*`/tools/dropins`.

   For example, the default installation directory on Windows is `C:\Program Files\IBM\IIB\`*`version`*`\`.
2. To ensure that the new files are available to the IBM App Connect Enterprise Toolkit, restart the Toolkit.

Results

The user-defined node for your connector is displayed in the palette in the Message Flow editor under the category that you specified for the user-defined node project.

What to do next

Test your connector in a message flow by following the instructions in "Testing a connector in IBM App Connect Enterprise" on page 2370.

Testing a connector in IBM App Connect Enterprise

To test the user-defined node that you create for a connector, add your node to a message flow. You can then use one of the debugging tools that are provided with IBM App Connect Enterprise.

Before you begin

- Complete the connector development steps for the runtime environment and IBM App Connect Enterprise Toolkit. For more information, see "Developing connectors" on page 2351.
- Install the user-defined node in the IBM App Connect Enterprise Toolkit. For more information, see "Installing the user-defined node for a connector in the IBM App Connect Enterprise Toolkit" on page 2370.

About this task

After you create a user-defined node for your connector, you can test it by adding it to a message flow in the IBM App Connect Enterprise Toolkit. You add a user-defined node for a connector in the same way that you would add any node to a message flow. You can use debugging and logging tools to ensure that the user-defined node is behaving as expected.

Procedure

To test your user-defined node in the IBM App Connect Enterprise Toolkit, complete the following steps:

1. Create a message flow by following the instructions in "Creating a message flow" on page 574.

2. Add your user-defined node to the message flow by following the instructions in "Adding a message flow node" on page 618. Add other appropriate message flow nodes to complete your message flow logic.
3. Use any of the following methods to test your message flow:

   - **Flow Exerciser**

     To check that your message flow is processing messages as expected, send messages to the flow by using the Flow Exerciser. You can then use the Flow Exerciser to show the path that each message takes, and the structure and content of the logical message tree at any point in a message flow. For more information, see "Testing your message flow by using the Flow Exerciser" on page 648.

   - **Flow debugger**

     You can set breakpoints in a message flow, then step through the flow while you examine and change message variables. To use the flow debugger, you must first deploy your message flow. For more information, see "Testing your message flow by using the flow debugger" on page 659

   - **User trace**

     To view logging output from the connector, enable user trace. Message flow nodes write messages to user trace when they are processing work. These messages show the activity in a message flow, such as which nodes are activated, what code they run, and through which terminals the messages are sent. To use user trace, you must first deploy your message flow.

     Message about your message flow are shown in the trace log file with a name in the following form: *flowName_udnDisplayName*. If the name of your user-defined node contains spaces, the spaces are replaced by underscore characters. For example, if the message flow is called `myDatabaseTestFlow.msgflow`, and the display name of the user-defined node is `My Database Input`, the entry in the trace log file is labeled `myDatabaseTestFlow_My_Database_Input`.

   - **Trace nodes**

     You can add a Trace node to a message flow to write debugging messages to a file, to user trace, or to the system log. You can then review those messages after the message flow processes some data. For more information, see "Testing your message flow by adding Trace nodes" on page 685.

Developing user-defined nodes

You can develop user-defined nodes to extend the function of IBM App Connect Enterprise.

About this task

Your can develop user-defined nodes from a subflow project, or by creating a subflow in a static library.

"Packaging a subflow as a user-defined node provides all the benefits of a subflow, including reusability and maintainability, and the following benefits:

- You can deploy a subflow without the need to compile and inline resources to produce cmf in a BAR file.
- You can use other resources, such as ESQL, maps, subflows, and message models within the function of a subflow user-defined node.
- You can use subflow user-defined nodes within subflows so that you can easily take advantage of both the subflow Use-defined node feature and features such as REST APIs and Integration Services.
- The WebUI can show the true structure of the message flow.
- The flow debugger can step into the subflows.
- The subflow is displayed in the palette in the Message Flow editor.

For more information about developing user-defined nodes, see the following topics:

- "Developing subflow user-defined nodes in a static library" on page 2372
- "Developing user-defined nodes from a subflow project" on page 2382

Developing subflow user-defined nodes in a static library

You can develop a subflow user-defined node in a static library to extend the function of IBM App Connect Enterprise.

About this task

Your installed version of IBM App Connect Enterprise must be 12.0.2.0 or later to be able to develop a subflow user-defined node in a static library.

Two roles of users exist, who can use the capability of subflow user-defined nodes that are developed in a static library: subflow user-defined node authors and subflow user-defined node consumers.

- **Subflow user-defined node authors** are developers of IBM App Connect Enterprise who want to develop, test, and package a subflow user-defined node that is used for a specific purpose. Subflow user-defined node authors do the following tasks:
  - Develop and test subflow user-defined nodes.
  - Package and distribute subflow user-defined nodes.

As a subflow user-defined node author, you develop a subflow user-defined node by first creating a subflow in a static library. Then, add nodes in the subflow so that the subflow serves a specific purpose. You then test the subflow user-defined node by adding the subflow to a message flow and testing the message flow. After you verify the behavior of the subflow user-defined node, you generate a packaged subflow user-defined library from the static library that contains the subflow user-defined node that you developed. The packaged subflow user-defined library is in the form of a `.zip` file, which you distribute to subflow user-defined node consumers who want to install your subflow user-defined node to use in message flows.

As a subflow user-defined node author, if you develop a subflow as a user-defined node within a static library, you have the following benefits:

- You can include other resources, such as ESQL, maps, subflows, and message models within the function of a subflow user-defined node.
- During development, you can use the flow debugger to step into the subflows.
- During development, you can use the IBM App Connect Enterprise web user interface to view the internal structure of the subflow.

Subflow user-defined node consumers are developers of IBM App Connect Enterprise message flows who want to use subflow user-defined nodes in their message flows.

As a subflow user-defined node consumer, if you install a subflow that is packaged as a user-defined node within a static library, you have the following benefits:

- The subflow node icons appear in the palette and you can include them in your message flows.
- The contents of the user-defined-node are hidden. The IBM App Connect Enterprise Toolkit and the IBM App Connect Enterprise web user interface display the subflow as a single node.
- You can deploy message flows that use subflow user-defined nodes as source deploy. It is not necessary to compile them inline to produce a cmf in the BAR file.
- You can use subflow user-defined nodes in subflows, which enables you to use their features, and other features such as REST APIs and integration services, in subflows.
- The contents of the user-defined subflow node are automatically packaged within the BAR file for applications that use the user-defined subflow node.

Procedure

As a subflow user-defined node author, develop, test, package, and distribute a subflow user-defined node by completing step “1” on page 2372 to step “4” on page 2373:

1. “Developing a subflow user-defined node from a subflow in a static library” on page 2373
2. “Testing a subflow user-defined node” on page 2377

3. “Packaging a subflow user-defined node by generating a packaged subflow user-defined library” on page 2379
4. “Distributing a packaged subflow user-defined library” on page 2379

As a subflow user-defined node consumer, install or uninstall a user-defined node by completing step 5 and step 6:

5. “Installing a subflow user-defined node” on page 2380
6. “Uninstalling a subflow user-defined node” on page 2381

Developing a subflow user-defined node from a subflow in a static library

Develop a subflow user-defined node by creating a subflow in a static library.

About this task

Your installed version of IBM App Connect Enterprise must be 12.0.2.0 or later to be able to create a subflow user-defined node by creating a subflow in static library.

As a user-defined subflow author, you can develop, test, package, and distribute a subflow user-defined node that was created as a subflow in static library. Using subflow user-defined nodes that are packaged in a static library provides extra flexibility for creating the subflow user-defined nodes and for how the user-defined nodes are consumed by users. As a user-defined subflow author, you must consider the following factors:

- The static library that contains a subflow user-defined node can also contain resources such as message models, schemas, ESQL, and Java classes. These resources are visible to consumers of the subflow user-defined node when they build their message flow. For example, for a subflow user-defined node that parses an input message that is based on a DFDL message model, the caller of the subflow user-defined node can validate the input message by using a "Rest Content Descriptor" node that specifies the message model from the static library before the subflow user-defined node is started.
- The static library can reference other static libraries that contain non-UDN subflows, ESQL, and schemas, but not message flows. The static library that contains a subflow user-defined node can also reference resources such as message models, non-UDN subflows, ESQL, and schemas (but not message flows) in other static libraries. When the subflow user-defined node library is packaged, the referenced libraries are automatically included in the subflow user-defined node library package.
- You cannot promote properties in subflows that are defined within the referenced library to the user-defined subflow node.
- When a subflow user-defined node uses a subflow from a referenced static library, you must avoid promoting properties from the referenced (nested) subflow to the subflow user-defined node. User-defined subflow consumers cannot set these properties.
- When you define the subflows, you must avoid defining them within the default broker schema. Use an explicit schema to avoid conflicts for consumers of the subflow user-defined nodes.
- When the application or library that uses a subflow user-defined node is packaged into a BAR file, the static library that contains the user-defined node is automatically included within the application or library within the BAR file.
- If you update the subflow user-defined node, the user-defined subflow consumer must install the new version of the user-defined node library into the toolkit and regenerate the BAR file before they can use the new version of the subflow user-defined node.
- When a subflow user-defined node is used by a message flow or subflow, a reference to the subflow user-defined node library is automatically created from the application or library that owns the message flow or subflow. If you later remove the subflow user-defined node, you must manually remove this reference if it is no longer required.

Create a subflow user-defined node by completing the following steps:

Procedure

1. Create a static library by completing the following steps:
   a) Open the **New Library** wizard by using one of the following methods in the IBM App Connect Enterprise Toolkit:
      - Click **File** > **New** > **Library**.
      - In the Application Development view, click **New**, then click **Start by creating a library**.
      - Right-click the white space in the Application Development view, then click **New** > **Library**.
   b) Enter a name for the library. For example, *DeliverFood*.
   c) Select **Static Library**.
   d) Optional: If this library is dependent upon resources in other static libraries, click **Next** and select the existing libraries that you want to reference from the list that is displayed.

      A static library can reference other static libraries only. If you add a reference to a static library that refers to other static libraries, all referenced static libraries are included.

      When you create a subflow user-defined node from a subflow in a static library, the static library must not contain message flows.
   e) Click **Finish**.

   Your new static library with the name *DeliverFood*, appears in the Application Development view.

For more information about libraries, see "Libraries" on page 1945, "Static libraries" on page 1958, and "Creating a library" on page 1964.

2. Add a subflow to the static library that you created in Step 1 by completing the following steps:
   a) Right-click your library in the Application Development view.
   b) Select **New** and then select **subflow** to open the **New Subflow** wizard.

      The name of the static library that you created in Step 1 appears in the `Library name` field.
   c) Enter a name for your subflow in the `Subflow name` field. For example, *HandleOrders*.
   d) Deselect the checkbox for **Use default broker schema**. You must not use the default broker schema when you define user-defined subflow nodes.
   e) In the **Schema** field, enter the name of the schema that you want to use. For example, *my.schema*.

      For more information about creating schemas, see "Creating a broker schema" on page 1966.
   f) Click **Finish**.

      Your new subflow appears under the static library that you created in step 1, and it has the name extension `.subflow`. In this example, the static library name is *Deliver Food*, and the subflow name is *HandleOrders.subflow*. The subflow can be deployed as source, and other subflows and libraries can be added as dependencies.

      Your new subflow also opens in the **Editor** window of the IBM App Connect Enterprise Toolkit, where you must edit it as described in step 3.
3. Add nodes in the subflow so that the subflow serves a specific purpose. From the **Palette**, add message flow nodes to the subflow, and configure and connect them as required. For more information about adding and connecting message flow nodes, see "Defining message flow content" on page 614, "Adding a message flow node" on page 618, "Configuring a message flow node" on page 624, and "Connecting message flow nodes" on page 636.
4. Define the name of the category in which the user-defined subflow nodes that are contained within the library appear on the palette, by completing the following steps:
   a) Right-click the static library to open the menu and select **Subflow user defined node** to open the submenu.
   b) Select **Set palette category** to open the **palette** wizard.
   c) By default, the name of the library is used as the name for the category. If you want to use a different name, for example *Supermarket*, edit the `Specify a category` field in the "Category

settings" section of the wizard. Alternatively, you can set the category to be one of the existing categories that are provided in the palette.

d) Set the icon that is shown in the palette for the subflow user-defined node by selecting **Import from file system** or **Import from workspace** in the "Category icons" section.

You can create icons by using a graphic design application of your own choice and storing them in a convenient location in your file system or workspace. The icon that is shown in the palette for the subflow user-defined node must be 16 x 16 pixels and be of type `.png`.

e) Click **Finish**.

5. Add the subflow to the palette category by completing the following steps:

a) In the Application Development view, right-click the subflow to open the menu and select **Subflow user defined node** to open the submenu.

b) Select **Add to palette** in the submenu to open the **Add subflow to flow editor palette** wizard.

The `Name` field in the "Category settings" section is shown as a read-only field for information only. By default, the name of the library is shown unless you changed the category name at step 4.

c) Optional: If you want the user-defined subflow node to have a different name on the palette from the name in the "Category settings" section, edit the `Name` field in the "Node settings" section.

In this example, the static library was called *Deliver Food* but the category name was changed to *Supermarket* at step 4.

d) Optional: Edit the `Tooltip` field in the "Node settings" section to set the tooltip. The tooltip is shown when you hover over the subflow user-defined node in the palette or in the flow editor.

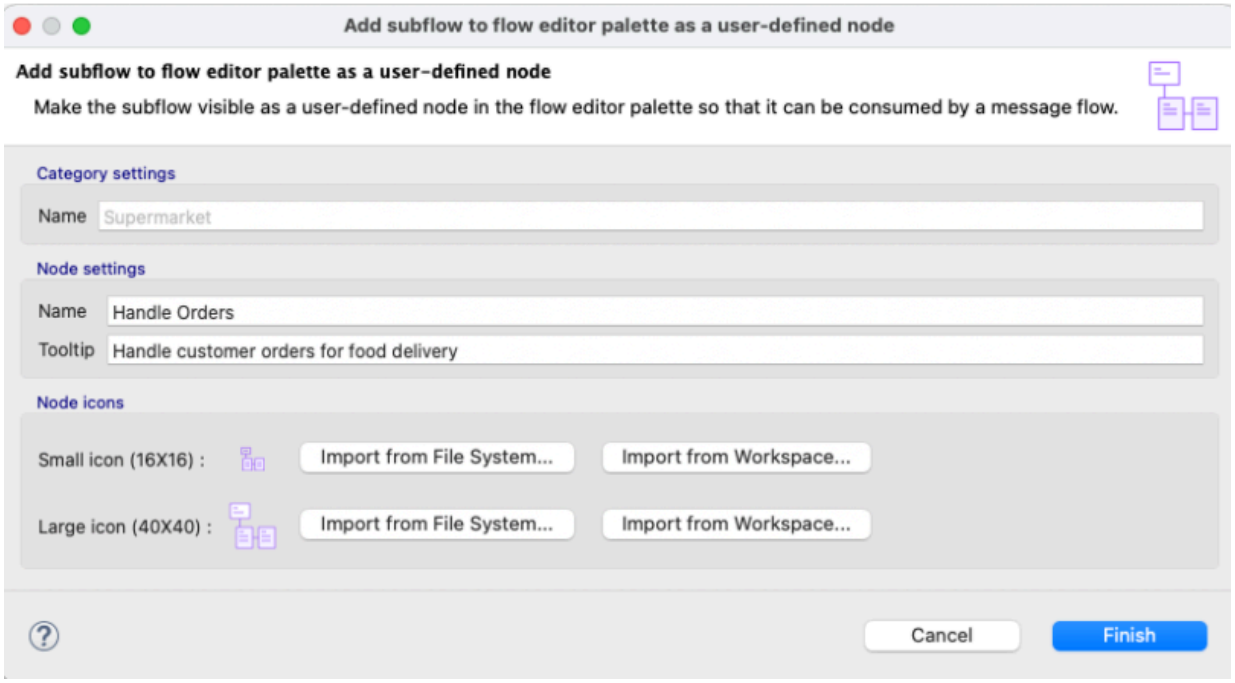
e) Set the small icon that is shown in the palette for the subflow user-defined node by selecting **Import from file system** or **Import from workspace** in the "Node icons" section.

f) Set the large icon that is shown in the flow editor for the subflow user-defined node by selecting **Import from file system** or **Import from workspace** in the "Node icons" section.

You can create icons by using a graphic design application of your own and storing them in a convenient location in your file system or workspace. The small icon that is shown choice in the palette for the subflow user-defined node must be 16 x 16 pixels and be of type `.png`. The small

large icon that is shown in the flow editor for the subflow user-defined node must be 40 x 40 pixels and be of type `.png`.

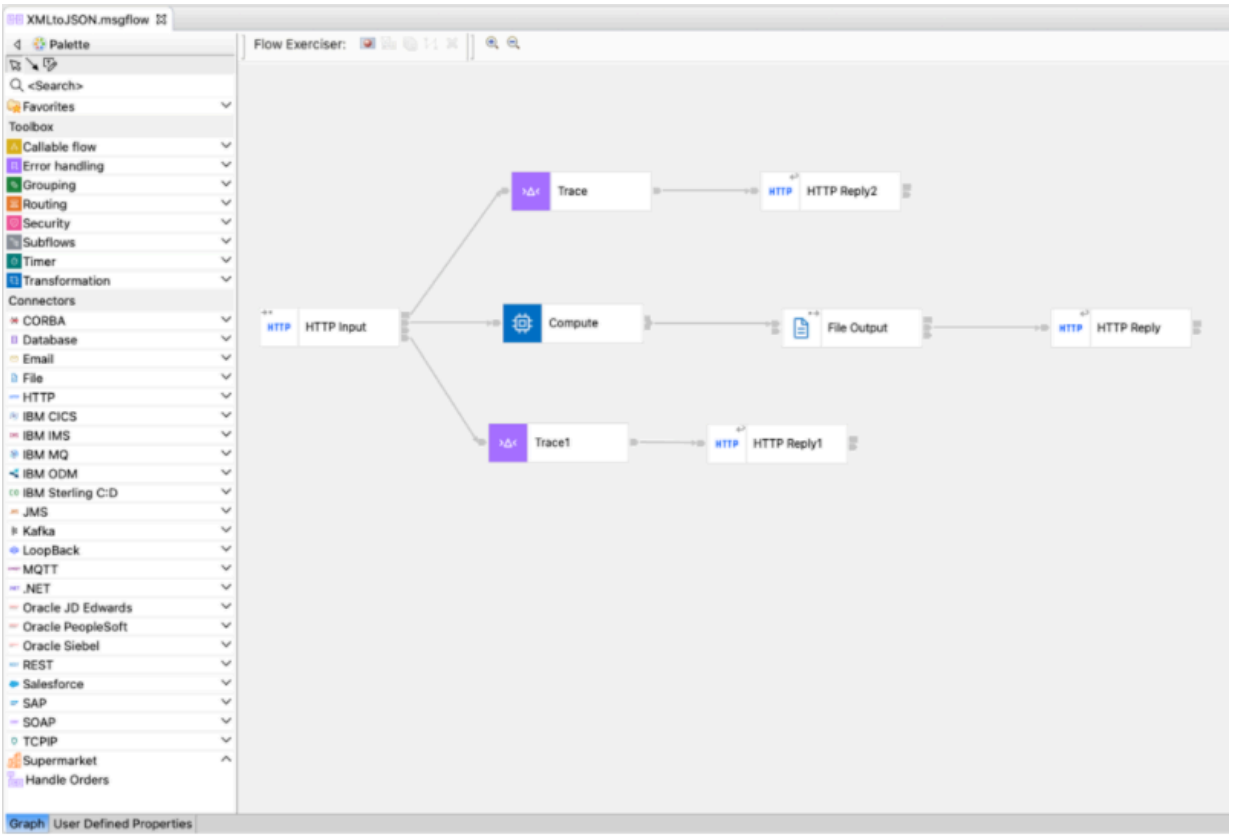
g) Click **Finish**.



Your user-defined node is added to the palette. When you next open a message flow, the new category and subflow user-defined node appear in the palette. In this example, you added a subflow that is called *HandleOrders* to the static library *DeliverFood* and used it to define a subflow user-defined node

called *HandleOrders* under the palette category *Supermarket*. The tooltip is set to *Handle Customer orders for food delivery*.

You can drag a user-defined node from the palette onto the canvas. In this environment, you can continue to update and test your user-defined subflow node in preparation for packaging the subflow user-defined node for delivery to the subflow user-defined node consumers.



What to do next

Before you package and distribute the user-defined node, you can test it as described in "Testing a subflow user-defined node" on page 2377.

Testing a subflow user-defined node

Test your subflow user-defined node before you package and distribute it.

Before you begin

Develop a subflow user-defined node from a subflow in a static library and add it to a message flow as described in "Developing a subflow user-defined node from a subflow in a static library" on page 2373.

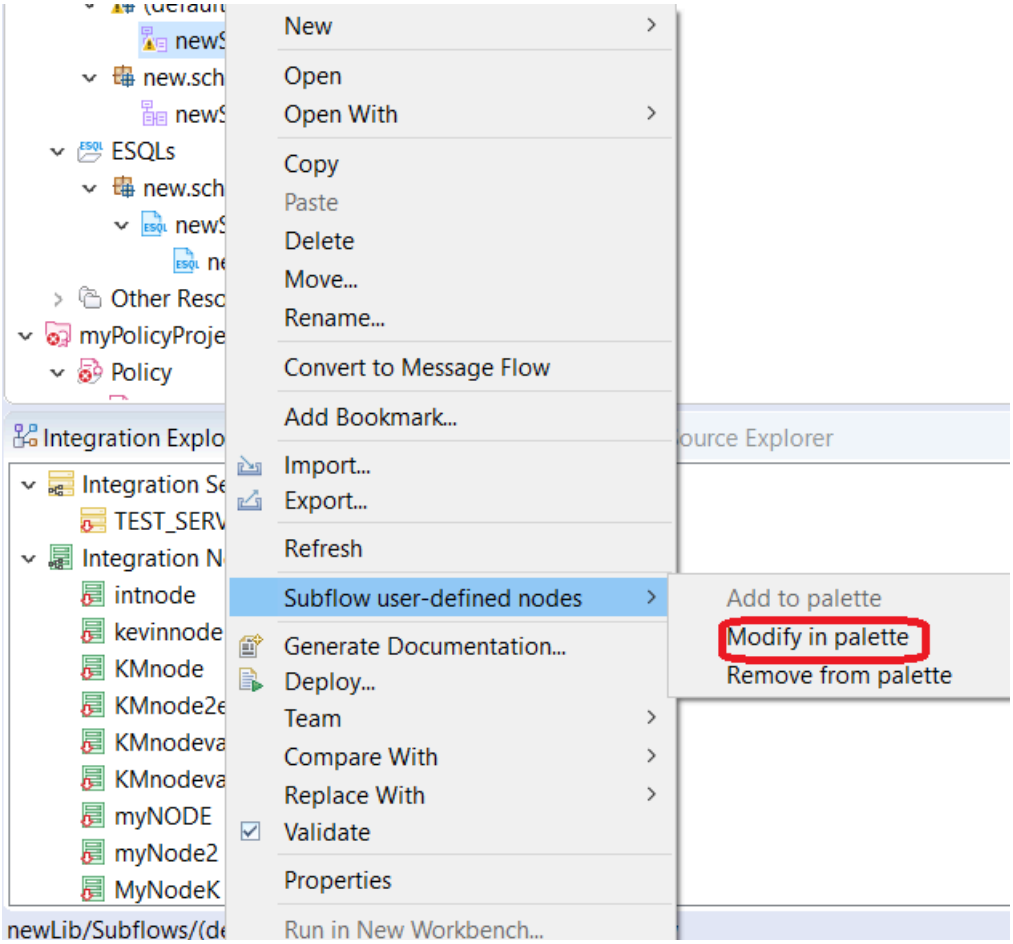
Procedure

Test your subflow user-defined node by completing the following steps:

1. Deploy, test, and if necessary, troubleshoot the message flow to which you added your subflow user-defined node. For more information about deploying and testing message flows, see How do I deploy and test ?

If you need to modify the subflow in the palette category or remove the subflow from the palette category, complete the following steps:

2. Optional: Modify the subflow in the palette category by completing the following steps:
   a) In the Application Development view, right-click the subflow to open the menu and then select **Subflow user defined node**, to open the submenu.
   b) Select **Modify in palette** in the submenu to open the **subflow** wizard.
   c) Modify the settings for the subflow user-defined node as required. If the icons are changed, they are not updated in the palette until you restart the toolkit.



3. Optional: Remove the subflow from the palette category by completing the following steps. If you attempt to delete a subflow that is being used as a subflow user-defined node, you must first use this option to remove the subflow user-defined node from the palette.
   a) In the Application Development view. Right-click the subflow to open the menu and select **Subflow user defined node** to open the submenu.
   b) Select **Remove from palette** in the submenu.

What to do next

When your node behavior is complete and correct, package and distribute the user-defined node, as described in "Packaging a subflow user-defined node by generating a packaged subflow user-defined library" on page 2379 and "Distributing a packaged subflow user-defined library" on page 2379.

Packaging a subflow user-defined node by generating a packaged subflow user-defined library

If you want to distribute your subflow user-defined node to subflow user-defined node consumers, you must package it by generating a packaged subflow user-defined library.

Before you begin

Develop and test a subflow user-defined node as described in "Developing a subflow user-defined node from a subflow in a static library" on page 2373 and "Testing a subflow user-defined node" on page 2377.

About this task

To package a subflow user-defined node by generating a subflow user-defined library, complete the following steps:

Procedure

1. In the Application Development view of the IBM App Connect Enterprise Toolkit, right-click the static library that contains the subflow user-defined node that you want to package. When the menu opens, select **Subflow user defined nodes** to open the submenu.
2. Click **Package subflow user defined nodes** to open the packaging wizard.
3. Enter the name of the .zip file that will contain the packaged subflow user-defined nodes. By default, the library name is used with the extension `.zip`. For example, for the library name *DeliverFood*, the name *DeliverFood.zip* is used as the name of the .zip file.
4. Enter the location of the packaged subflow user-defined library. For example, *C:\myzips*.
5. Click **Finish** to create the .zip file.

   The .zip file is saved to the location that you specified.

What to do next

You can now install the subflow user-defined node, or distribute the packaged subflow user-defined library to enable subflow user-defined node consumers to install the subflow user-defined node. For more information about installing and distributing subflow user-defined nodes, see "Installing a subflow user-defined node" on page 2380 and "Distributing a packaged subflow user-defined library" on page 2379.

Distributing a packaged subflow user-defined library

Distribute the packaged subflow user-defined library to make the subflow user-defined node available for use in a message flow.

About this task

You can distribute the packaged subflow user-defined library by copying the `.zip` file from your file system into a common drive where it can be accessed by subflow user-defined node consumers. Alternatively, you can send it as an email attachment to subflow user-defined node consumers who can download it into their file system.

What to do next

Subflow user-defined node consumers can now install the subflow user-defined node as described in "Installing a subflow user-defined node" on page 2380.

Installing a subflow user-defined node

Install a subflow user-defined node for use to develop message flows.

Before you begin

You can develop message flows by using subflow user-defined nodes in the same way as the built-in nodes. Before you begin, you must develop, test, and package a subflow user-defined node as described in Developing a subflow user-defined node from a subflow in a static library, "Testing a subflow user-defined node" on page 2377, and Packaging a subflow user-defined node by generating a packaged subflow user-defined library. You must then install the static library that contains the subflow user-defined node into your IBM App Connect Enterprise Toolkit before you can use the subflow user-defined node in a message flow.

If you install a subflow user-defined library, you cannot create a project in the workspace that has the same name as the installed library. An error is shown if you attempt to create a project that has the same name as the installed project.

Procedure

1. In the IBM App Connect Enterprise Toolkit, click **Project**, and then select **Manage subflow user-defined libraries** from the menu.

   The Manage subflow user-defined Libraries dialog opens. From this dialog, you can see a list of the installed libraries and install or uninstall a library.
2. Click **Install** to open a dialog where you can use **Windows Explorer** to find the package `.zip` file that you want to install.
3. Select the package `.zip` file that you want to install.
4. Click **Open** to open a dialog that displays details of the library contents.

5. Click **Yes** to confirm that you want to install the library.

   The library is installed. The currently installed library list is updated with the new library.

   The subflow now appears in the palette when you open a message flow. In this example, the subflow is *JavaSubflow* under the library *StaticLibWithJava*.

   You can drag the node onto the canvas. When you package the application or library that uses a subflow user-defined node into a BAR file, the static library that contains the user-defined node is automatically included within the application or library within the BAR file.

6. If a subflow user-defined node is updated, you must install the new version of the user-defined node library into the toolkit. You must regenerate the BAR file before you can use the updated version.

What to do next

When you no longer require the subflow user-defined node, you can uninstall it. For more information, see "Uninstalling a subflow user-defined node" on page 2381.

Uninstalling a subflow user-defined node

Uninstall a packaged subflow user-defined library that was used to develop message flows.

About this task

If you installed a packaged subflow user-defined library that you no longer require, you can uninstall it by completing the following steps:

Procedure

1. In the IBM App Connect Enterprise Toolkit, click **Project** and then select **Manage subflow user-defined libraries** from the menu.

   The Manage subflow user-defined libraries dialog is displayed, containing a list of all subflow user-defined libraries that have been installed.
2. Select the library that you want to uninstall.
3. Click **Uninstall**.

   A dialog opens where you are asked to confirm that you want to uninstall the subflow user-defined library.
4. Click **Yes**.

   The library is removed, and the list of currently installed subflow user-defined libraries is updated.

   The library is no longer available in the workspace, and any flows that use the library now display errors.
5. When a subflow user-defined node is used by a message flow or subflow, a reference to the subflow user-defined node library is automatically created from the application or library that owns the message flow or subflow. If you later remove the subflow user-defined node, you must manually remove this reference.

Developing user-defined nodes from a subflow project

You can develop a user-defined node to extend the function of IBM App Connect Enterprise.

Before you begin

Read the following topics:

- "User-defined extensions overview" on page 2321
- "Why use a user-defined extension?" on page 2322
- "User-defined nodes" on page 2331
- "Which type of user-defined extension to use" on page 2331

About this task

Consider the following restrictions and factors when you develop user-defined nodes:

- Interfacing a C user-defined node to Java and providing a JNI wrapper is not supported. This restriction exists because the integration node internally initializes a JVM, which is not available through the user-defined extension interface. The JVM initializes with various parameters that are specific to the requirements of the integration node. Because only one JVM exists in a process, whoever initializes it first specifies these parameters. If a user-defined node uses Java, and the integration node is initialized first, these parameters might not be suitable for the user-defined node. If the user-defined node creates the JVM before the integration node starts, the integration node might not function correctly.
- User-defined input nodes can support only XML, BLOB, and the WebSphere MQ parsers.
- Avoid functions that are specific to an operating system. If you code in this way, your user-defined extensions can work on various operating systems without requiring changes to the source code.
- Always put a user-defined node into a non-default schema because a user-defined node in a broker schema is known to other message flows by its schema qualified name. For example, if a user-defined node is named `ErrorHandler` and it is in broker schema `com.ibm.mb.toolkit`, it is referenced as `com.ibm.mb.toolkit.ErrorHandler`. If a second provider also has an error handler that is named `ErrorHandler` and it is in broker schema `com.`*`xxx`*`.product`, it is referenced as `com.`*`xxx`*`.product.ErrorHandler`. A user-defined node in a default schema is addressed by its name only. Therefore, if two different providers develop two unrelated error handlers and both are named `ErrorHandler` and both are placed in a default schema, when both user-defined nodes are in the plug-in space for a third user, the reference to `ErrorHandler` is ambiguous.

- If you want to use a subflow to create a user-defined node, read the limitations section in the following topic: "Using a subflow as a user-defined node" on page 2344.

To implement a user-defined node, complete the following tasks in the specified order:

Procedure

1. "Designing a user-defined node" on page 2383
2. "Creating a user-defined node" on page 2383
3. "Packaging and distributing user-defined extensions" on page 2449
4. "Testing a user-defined node" on page 2430
5. "Packaging and distributing a user-defined node project" on page 2452

Designing a user-defined node

Decide what type of node you need to implement the functions that are required by your application.

Before you begin

Read "Deciding which nodes to use" on page 585 to understand the different types of node. You might need more than one node to implement all the functions that you require.

About this task

The functions that you require might not be satisfied by a template that already exists for several reasons:

- The functions that you require do not relate to interacting with external systems. Most of the node design pattern concentrates on communication with external systems, which is the most likely requirement for a user-defined node.
- The functions that are required are not well suited to the IBM App Connect Enterprise architecture, so you should implement them in an end application, or an application server.
- The functions require complex control and state information, which you should not implement as a plug-in.

Creating a user-defined node

You can write user-defined nodes in C, Java, or from a subflow.

Before you begin

Read "Designing a user-defined node" on page 2383.

About this task

When you have created a user-defined node, you can test it, as described in "Testing a user-defined node" on page 2430. If you want to test or use user-defined nodes or parsers on multiple computers, follow the instructions given in "Packaging and distributing user-defined extensions" on page 2449.

Decide whether you want to create a user-defined node in C, Java, or from a subflow, then follow the instructions in the appropriate topic.

- "Creating a user-defined extension in C" on page 2384
- "Creating a user-defined extension in Java" on page 2403
- "Creating a user-defined node from a subflow" on page 2419
- "Creating the user interface representation of a user-defined node in the IBM App Connect Enterprise Toolkit" on page 2421

The following table shows the tasks that are involved in creating the different types of user-defined node.

Objective	Tasks to complete
To create your own Java node by using the IBM App Connect Enterprise Toolkit	1. "Creating an input node in Java" on page 2403 or "Creating a message processing or output node in Java" on page 2409 2. "Using error logging from a user-defined extension" on page 2458 3. "Compiling a Java user-defined node" on page 2418 4. "Testing a user-defined node" on page 2430 5. "Packaging and distributing a user-defined node project" on page 2452 6. Installing a user-defined extension to current and past versions of
To create your own C node:	1. "Creating an input node in C" on page 2385 or "Creating a message processing or output node in C" on page 2392 2. "Using error logging from a user-defined extension" on page 2458 3. "Compiling a C user-defined extension" on page 2400 4. "Installing user-defined extension runtime files on an integration node" on page 2455 5. "Creating the user interface representation of a user-defined node in the IBM App Connect Enterprise Toolkit" on page 2421 6. "Testing a user-defined node" on page 2430 7. "Packaging and distributing a user-defined node project" on page 2452 8. Installing a user-defined extension to current and past versions of
To create your own node from a subflow	1. "Creating a user-defined node from a subflow" on page 2419 2. "Creating the user interface representation of a user-defined node in the IBM App Connect Enterprise Toolkit" on page 2421 3. "Testing a subflow user-defined node project" on page 2433 4. "Packaging and distributing a user-defined node project" on page 2452 5. "Installing a user-defined node" on page 620

Creating a user-defined extension in C
You must complete a series of tasks to create user-defined extensions that use the C language.

About this task

You can write user-defined nodes and user-defined parsers in C.

Complete the appropriate tasks from the following list:

- "Creating an input node in C" on page 2385
- "Creating a message processing or output node in C" on page 2392
- "Developing user-defined parsers" on page 2434
- "Compiling a C user-defined extension" on page 2400

What to do next

When you have completed this set of tasks, continue with the following tasks:

- If you have compiled a user-defined node, "Creating the user interface representation of a user-defined node in the IBM App Connect Enterprise Toolkit" on page 2421

- “Testing a user-defined node” on page 2430
- “Packaging and distributing user-defined extensions” on page 2449

Creating an input node in C
Create a user-defined input node in C to receive messages into a message flow.

Before you begin

Read the following topics:

- “Why use a user-defined extension?” on page 2322
- “User-defined input nodes” on page 2332

About this task

A loadable implementation library, or *LIL*, is the implementation module for a C node. A LIL is implemented as a shared or dynamic link library (DLL), but has the file extension `.lil` not `.dll`.

The implementation functions that you write for the node are listed in C node implementation functions. You can call utility functions, implemented in the runtime integration node, to help with the node operation; these functions are listed in C node utility functions.

IBM App Connect Enterprise provides the source for two sample user-defined nodes called SwitchNode and TransformNode. You can use these nodes in their current state, or you can modify them.

To create an input node in C:

1. “Declaring and defining the node” on page 2385
2. “Creating an instance of the node” on page 2386
3. “Setting attributes” on page 2387
4. “Implementing the node functionality” on page 2388
5. “Overriding the default message parser attributes (optional)” on page 2388
6. “Deleting an instance of the node” on page 2390

Declaring and defining the node

About this task

To declare and define a user-defined node to the integration node, include an initialization function, `bipGetMessageflowNodeFactory`, in your LIL. The following steps outline how the integration node calls your initialization function, and how your initialization function declares and defines the user-defined node:

Procedure

1. The initialization function, `bipGetMessageflowNodeFactory`, is called by the integration node after the operating system has loaded and initialized the LIL. The integration node calls this function to understand what your LIL can do and how the integration node can call the LIL. For example:

   ```
   CciFactory LilFactoryExportPrefix * LilFactoryExportSuffix
   bipGetMessageflowNodeFactory()
   ```

2. The `bipGetMessageflowNodeFactory` function must call the utility function `cniCreateNodeFactory`. This function passes back a unique factory name (or group name) for all the nodes that your LIL supports. Every factory name (or group name) that is passed back must be unique throughout all the LILs in a single runtime integration node.

3. The LIL must call the utility function `cniDefineNodeClass` to pass the unique name of each node, and a virtual function table of the addresses of the implementation functions.

   For example, the following code declares and defines a single node called InputxNode:

```
{
 CciFactory* factoryObject;
 int rc = 0;
 CciChar factoryName[] = L"MyNodeFactory";
 CCI_EXCEPTION_ST exception_st;

 /* Create the Node Factory for this node */
 factoryObject = cniCreateNodeFactory(0, factoryName);
 if (factoryObject == CCI_NULL_ADDR) {

  /* Any local error handling can go here */
 }
 else {
  /* Define the nodes supported by this factory */
  static CNI_VFT vftable = {CNI_VFT_DEFAULT};

 /* Setup function table with pointers to node implementation functions */
 vftable.iFpCreateNodeContext = _createNodeContext;
 vftable.iFpDeleteNodeContext = _deleteNodeContext;
 vftable.iFpGetAttributeName2 = _getAttributeName2;
 vftable.iFpSetAttribute      = _setAttribute;
 vftable.iFpGetAttribute2     = _getAttribute2;
 vftable.iFpRun               = _run;

 cniDefineNodeClass(0, factoryObject, L"InputxNode", &vftable);
 }

 /* Return address of this factory object to the integration node */
 return(factoryObject);
}
```

   A user-defined node identifies itself as providing the features of an input node by implementing the `cniRun` implementation function.

   User-defined nodes have to implement either a `cniRun` or a `cniEvaluate` implementation function. If they do not, the integration node does not load the user-defined node, and the `cniDefineNodeClass` utility function fails, returning CCI_MISSING_IMPL_FUNCTION.

   For example:

```
int cniRun(
  CciContext* context,
  CciMessage* localEnvironment,
  CciMessage* exceptionList,
  CciMessage* message
){
  ...
  /* Get data from external source */
  return CCI_SUCCESS_CONTINUE;
}
```

   Use the return value periodically to return control to the integration node.

   When a message flow that contains a user-defined input node is deployed successfully, the `cniRun` function of the node is called repeatedly to enable the node to retrieve messages and propagate them to the rest of the message flow.

   For the minimum code required to compile a C user-defined node, see the C skeleton code.

Creating an instance of the node

About this task

To instantiate your node:

Procedure

1. When the integration node has received the table of function pointers, it calls the function `cniCreateNodeContext` for each instantiation of the user-defined node. For example, if three message flows are using your user-defined node, your `cniCreateNodeContext` function is called for each of them. This function must allocate memory for that instantiation of the user-defined node to hold the values for the configured attributes. For example:

   a) Call the `cniCreateNodeContext` function:

   ```
   CciContext* _createNodeContext(
     CciFactory* factoryObject,
     CciChar*    nodeName,
     CciNode*    nodeObject
   ){
     static char* functionName = (char *)"_createNodeContext()";
     NODE_CONTEXT_ST* p;
     CciChar          buffer[256];
   ```

   b) Allocate a pointer to the local context and clear the context area:

   ```
     p = (NODE_CONTEXT_ST *)malloc(sizeof(NODE_CONTEXT_ST));

     if (p) {
        memset(p, 0, sizeof(NODE_CONTEXT_ST));
   ```

   c) Save the node object pointer in the context:

   ```
      p->nodeObject = nodeObject;
   ```

   d) Save the node name:

   ```
    CciCharNCpy((CciChar*)&p->nodeName, nodeName, MAX_NODE_NAME_LEN);
   ```

   e) Return the node context:

   ```
   return (CciContext*) p;
   ```

2. An input node has a number of output terminals associated with it, but typically does not have any input terminals. Use the utility function `cniCreateOutputTerminal` to add output terminals to an input node when the node is instantiated. These functions must be invoked within the `cniCreateNodeContext` implementation function. For example, to define an input node with three output terminals:

   ```
   {
      const CciChar* ucsOut = CciString("out", BIP_DEF_COMP_CCSID) ;
      insOutputTerminalListEntry(p, (CciChar*)ucsOut);
      free((void *)ucsOut) ;
    }
    {
      const CciChar* ucsFailure = CciString("failure", BIP_DEF_COMP_CCSID) ;
      insOutputTerminalListEntry(p, (CciChar*)ucsFailure);
      free((void *)ucsFailure) ;
    }
    {
      const CciChar* ucsCatch = CciString("catch", BIP_DEF_COMP_CCSID) ;
      insOutputTerminalListEntry(p, (CciChar*)ucsCatch);
      free((void *)ucsCatch) ;    }
   ```

   For the minimum code required to compile a C user-defined node, see C skeleton code.

Setting attributes

About this task

Attributes are set whenever you start the integration node, or when you redeploy the message flow with new values.

Following the creation of output terminals, the integration node calls the `cniSetAttribute` function to pass the values for the configured attributes of the user-defined node. For example:

```
    {
      const CciChar* ucsAttr = CciString("nodeTraceSetting", BIP_DEF_COMP_CCSID) ;
      insAttrTblEntry(p, (CciChar*)ucsAttr, CNI_TYPE_INTEGER);
      _setAttribute(p, (CciChar*)ucsAttr, (CciChar*)constZero);
      free((void *)ucsAttr) ;
    }
    {
      const CciChar* ucsAttr = CciString("nodeTraceOutfile", BIP_DEF_COMP_CCSID) ;
      insAttrTblEntry(p, (CciChar*)ucsAttr, CNI_TYPE_STRING);
      _setAttribute(p, (CciChar*)ucsAttr, (CciChar*)constSwitchTraceLocation);
      free((void *)ucsAttr) ;
    }
```

The number of configuration attributes that a node can have is unlimited. However, a user-defined node must not implement an attribute that is already implemented as a base configuration attribute. The base attributes are:

- label
- userTraceLevel
- traceLevel
- userTraceFilter
- traceFilter

Implementing the node functionality

About this task

When the integration node knows that it has an input node, it calls the `cniRun` function of this node at regular intervals. The `cniRun` function must then decide what course of action it must take. If data is available for processing, the `cniRun` function can propagate the message. If no data is available for processing, the `cniRun` function must return with CCI_TIMEOUT so that the integration node can continue configuration changes.

For example, to configure the node to call `cniDispatchThread` and process the message, or return with CCI_TIMEOUT:

```
If ( anything to do )
 CniDispatchThread;

   /* do the work */

 If ( work done O.K.)
  Return CCI_SUCCESS_CONTINUE;
 Else
  Return CCI_FAILURE_CONTINUE;
Else
  Return CCI_TIMEOUT;
```

Overriding the default message parser attributes (optional)

About this task

An input node implementation typically determines what message parser initially parses an input message. For example, the MQInput node dictates that an MQMD parser is required to parse the MQMD header. A user-defined input node can select an appropriate header or message parser, and the mode in which the parsing is controlled, by using or overriding the following attributes that are included as default:

rootParserClassName
: Defines the name of the root parser that parses message formats that are supported by the user-defined input node. It defaults to `GenericRoot`, a supplied root parser that causes the integration node to allocate and chain parsers together. It is unlikely that a node would need to modify this attribute value.

firstParserClassName
Defines the name of the first parser, in what might be a chain of parsers that are responsible for parsing the bit stream. It defaults to XML.

messageDomainProperty
An optional attribute that defines the name of the message parser that is required to parse the input message. The supported values are the same as the values that are supported by the MQInput node. (See node for more information.)

messageSetProperty
An optional attribute that defines the message set identifier, or the message set name, in the `Message Set` field, only if the MRM parser was specified by the `messageDomainProperty` attribute.

messageTypeProperty
An optional attribute that defines the identifier of the message in the `MessageType` field, only if the MRM parser was specified by the `messageDomainProperty` attribute.

messageFormatProperty
An optional attribute that defines the format of the message in the `Message Format` field, only if the MRM parser was specified by the `messageDomainProperty` attribute.

If you have written a user-defined input node that always begins with data of a known structure, you can ensure that a specific parser handles the start of the data. For example, the MQInput node reads data only from IBM MQ queues, therefore this data always has an MQMD at the beginning, and the MQInput node sets firstParserClassName to MQHMD. If your user-defined node always handles data that begins with a structure that can be parsed by a specific parser, for example "MYPARSER", set firstParserClassName to MYPARSER in the following way::

1. Declare the implementation functions:

```
CciFactory LilFactoryExportPrefix * LilFactoryExportSuffix bipGetMessageflowNodeFactory()
{
  ....
  CciFactory*      factoryObject;
  ....
  factoryObject = cniCreateNodeFactory(0, (unsigned short *)constPluginNodeFactory);
  ...
  vftable.iFpCreateNodeContext = _createNodeContext;
  vftable.iFpSetAttribute      = _setAttribute;
  vftable.iFpGetAttribute      = _getAttribute;
  ...
  cniDefineNodeClass(&rc, factoryObject, (CciChar*)constSwitchNode, &vftable);
  ...
  return(factoryObject);
}
```

2. Set the attribute in the `cniCreateNodeContext` implementation function:

```
CciContext* _createNodeContext(
  CciFactory* factoryObject,
  CciChar*    nodeName,
  CciNode*    nodeObject
){
  NODE_CONTEXT_ST* p;
  ...

    /* Allocate a pointer to the local context */
    p = (NODE_CONTEXT_ST *)malloc(sizeof(NODE_CONTEXT_ST));
    /* Create attributes and set default values */
    {
      const CciChar* ucsAttrName  = CciString("firstParserClassName", BIP_DEF_COMP_CCSID);
      const CciChar* ucsAttrValue = CciString("MYPARSER", BIP_DEF_COMP_CCSID) ;
      insAttrTblEntry(p, (CciChar*)ucsAttrName, CNI_TYPE_INTEGER);
      /*see sample BipSampPluginNode.c for implementation of insAttrTblEntry*/

      _setAttribute(p, (CciChar*)ucsAttrName, (CciChar*)ucsAttrValue);
      free((void *)ucsAttrName) ;
      free((void *)ucsAttrValue) ;
```

```
    }
```

In the code example above, the `insAttrTblEntry` method is called. This method is declared in the SwitchNode and TransformNode sample user-defined nodes.

Deleting an instance of the node

About this task

Nodes are destroyed when a message flow is redeployed, or when the integration server process is stopped (using the **mqsistop** command). When a node is destroyed, you must call the `cniDeleteNodeContext` function to free all used memory and release all held resources. For example:

```
void _deleteNodeContext(
  CciContext* context
){
  static char* functionName = (char *)"_deleteNodeContext()";

  return;
}
```

Extending the capability of a C input node
When you have created a user-defined node, you can extend its capability.

Before you begin

Read "Creating an input node in C" on page 2385.

About this task

After you have created a user-defined node, the following options are available:

1. "Receiving external data into a buffer" on page 2390
2. "Controlling threading and transactions" on page 2391
3. "Propagating the message" on page 2392

Receiving external data into a buffer

About this task

An input node can receive data from any type of external source, such as a file system or FTP connection, provided that the output from the node is in the correct format. For connections to queues or databases, use the built-in nodes and the API calls supplied, principally because the built-in nodes are already set up for error handling. Do not use the MQGET or MQPUT calls for direct access to IBM MQ queues.

You must provide an input buffer (or bit stream) to contain input data, and associate it with a message object. In the C API, the buffer is attached to the CciMessage object that represents the input message by using the `cniSetInputBuffer` utility function. For example:

```
{
  static char* functionName = (char *)"_Input_run()";
  void*        buffer;
  CciTerminal* terminalObject;
  int          buflen = 4096;
  int          rc = CCI_SUCCESS;
  int          rcDispatch = CCI_SUCCESS;

  buffer = readFromDevice(&buflen);
  cniSetInputBuffer(&rc, message, buffer, buflen);
}
/*propagate etc*/
```

About this task

An input node must perform appropriate end-of-message processing when a message has been propagated through a message flow. Specifically, the input node needs to cause any transactions to be committed or rolled back, and return threads to the thread pool.

Each message flow thread is allocated from a pool of threads that is maintained for each message flow, and starts execution in the `cniRun` function. You determine the behavior of a thread using the `cniDispatchThread` utility function, together with the appropriate return value.

From the `cniRun` function, you can call the `cniDispatchThread` utility function to cause another thread to start executing the `cniRun` function. The most appropriate time to execute another thread is directly after you have established that data could be available for the function to process on the new thread.

The term *transaction* is used generically to describe either a globally coordinated transaction, or a transaction controlled by an integration node. Globally coordinated transactions are coordinated by either IBM MQ as an XA-compliant Transaction Manager, or Resource Recovery Service (RRS) on z/OS. IBM App Connect Enterprise controls transactions by committing (or rolling back) any database resources, and then committing any IBM MQ units of work. However, if a user-defined node is used, the integration node cannot automatically commit any resource updates. The user-defined node uses return values to indicate whether a transaction has been successful, and to control whether transactions are committed or rolled-back. The integration node infrastructure catches any unhandled exceptions, and rolls back the transaction.

The following table describes each of the supported return values, the effect that each one has on any transactions, and what the integration node does with the current thread.

Return value	**Affect on transaction**	**Integration node action on the thread**
CCI_SUCCESS_CONTINUE	Committed	Calls the same thread again in the `cniRun` function.
CCI_SUCCESS_RETURN	Committed	Returns the thread to the thread pool.
CCI_FAILURE_CONTINUE	Rolled back	Calls the same thread again in the `cniRun` function.
CCI_FAILURE_RETURN	Rolled back	Returns the thread to the thread pool.
CCI_TIMEOUT	Not applicable. The function periodically times out while it is waiting for an input message.	Calls the same thread again in the `cniRun` function.

The following code is an example of using the SUCCESS_RETURN return code with the `cniDispatchThread` function:

```
{
  ...
  cniDispatchThread(&rcDispatch, ((NODE_CONTEXT_ST *)context)->nodeObject);
  ...
  if (rcDispatch == CCI_NO_THREADS_AVAILABLE) return CCI_SUCCESS_CONTINUE;
  else return CCI_SUCCESS_RETURN;
}
```

Propagating the message

About this task

Before you propagate a message, decide what message flow data you want to propagate, and which terminal is to receive the data.

The terminalObject is derived from a list that the user-defined node maintains.

For example, to propagate the message to the output terminal, use the `cniPropagate` function:

```
if (terminalObject) {
  if (cniIsTerminalAttached(&rc, terminalObject)) {
    if (rc == CCI_SUCCESS) {
      cniPropagate(&rc, terminalObject, localEnvironment, exceptionList, message);
    }
  }
```

In the above example, the `cniIsTerminalAttached` function is used to test whether the message can be propagated to the specified terminal. If you do not use the `cniIsTerminalAttached` function, and the terminal is not attached to another node by a connector, the message is not propagated and no warning message is returned. Use the `cniIsTerminalAttached` function to prevent this error occurring.

Creating a message processing or output node in C
A message processing node is used to process a message in some way, and an output node is used to produce a message as a bit stream.

Before you begin

Read the following topics:

- "Why use a user-defined extension?" on page 2322
- "User-defined message processing nodes" on page 2336
- "User-defined output nodes" on page 2343

About this task

When you code a message processing node or an output node, the nodes provide essentially the same services. You can perform message processing in an output node, and you can send a message to a bit stream by using a message processing node. For simplicity, this topic refers mainly to the node as a message processing node but it does also contain information about the functions of both types of node.

A loadable implementation library (LIL), is the implementation module for a C node. A LIL is implemented as a shared or dynamic link library (DLL), but has the file extension `.lil` not `.dll`.

For more information about the C node implementation functions that you write for the node, see C node implementation functions. You can call C node utility functions, implemented in the runtime integration node, to help with the node operation; see C node utility functions.

IBM App Connect Enterprise provides the source for two sample user-defined nodes called SwitchNode and TransformNode. You can use these nodes in their current state, or you can modify them.

To create either type of node complete the following tasks:

1. "Declaring and defining your node" on page 2393
2. "Creating an instance of the node" on page 2394
3. "Setting attributes" on page 2396
4. "Implementing the node functionality" on page 2397
5. "Deleting an instance of the node" on page 2397

About this task

To declare and define a user-defined node to the integration node, include an initialization function, `bipGetMessageflowNodeFactory`, in your LIL. The following steps take place on the configuration thread and outline how the integration node calls your initialization function and how your initialization function declares and defines the user-defined node:

Procedure

1. The integration node calls the initialization function `bipGetMessageflowNodeFactory` after the operating system has loaded and initialized the LIL. The integration node calls this function to understand what your LIL can do and how the integration node can call the LIL. For example:

```
CciFactory LilFactoryExportPrefix * LilFactoryExportSuffix
bipGetMessageflowNodeFactory()
```

2. The `bipGetMessageflowNodeFactory` function must call the utility function `cniCreateNodeFactory`. This function passes back a factory name (or group name) for all the nodes that your LIL supports. The factory name (or group name) must be unique throughout all the LILs in a single runtime integration node.
3. The LIL must call the utility function `cniDefineNodeClass` to pass the unique name of each node and a virtual function table of the addresses of the implementation functions.

   For example, the following code declares and defines a single node called MessageProcessingxNode:

```
{
 CciFactory* factoryObject;
 int rc = 0;
 CciChar factoryName[] = L"MyNodeFactory";
 CCI_EXCEPTION_ST exception_st;

 /* Create the Node Factory for this node */
 factoryObject = cniCreateNodeFactory(0, factoryName);
 if (factoryObject == CCI_NULL_ADDR) {
  /* Any local error handling can go here */
 }
 else {
  /* Define the nodes supported by this factory */
 static CNI_VFT vftable = {CNI_VFT_DEFAULT};

 /* Setup function table with pointers to node implementation functions */
 vftable.iFpCreateNodeContext = _createNodeContext;
 vftable.iFpDeleteNodeContext = _deleteNodeContext;
 vftable.iFpGetAttributeName2 = _getAttributeName2;
 vftable.iFpSetAttribute      = _setAttribute;
 vftable.iFpGetAttribute2     = _getAttribute2;
 vftable.iFpEvaluate          = _evaluate;

 cniDefineNodeClass(0, factoryObject, L"MessageProcessingxNode", &vftable);

 }

 /* Return address of this factory object to the integration node */
 return(factoryObject);
}
```

   A user-defined node identifies itself as a message processing or output node by implementing the `cniEvaluate` function. User-defined nodes must implement either a `cniEvaluate` or a `cniRun`

implementation function, otherwise the integration node does not load the user-defined node, and the `cniDefineNodeClass` utility function fails, returning CCI_MISSING_IMPL_FUNCTION.

When a message flow containing a user-defined message processing node is deployed successfully, the node's `cniEvaluate` function is called for each message propagated to the node.

Message flow data is received at the input terminal of the node, that is, the message, Environment, LocalEnvironment, and ExceptionList.

For example:

```
void cniEvaluate(
  CciContext* context,
  CciMessage* localEnvironment,
  CciMessage* exceptionList,
  CciMessage* message
){
  ...
}
```

For the minimum code required to compile a C user-defined node, see C skeleton code.

Creating an instance of the node

About this task

To instantiate your node:

Procedure

1. When the integration node has received the table of function pointers, it calls the function `cniCreateNodeContext` for each instantiation of the user-defined node. For example, if three message flows are using your user-defined node, your `cniCreateNodeContext` function is called for each of them. This function allocates memory for that instantiation of the user-defined node to hold the values for the configured attributes. For example:
   a) The user function `cniCreateNodeContext` is called:

   ```
   CciContext* _Switch_createNodeContext(
     CciFactory* factoryObject,
     CciChar*    nodeName,
     CciNode*    nodeObject
   ){
     static char* functionName = (char *)"_Switch_createNodeContext()";
     NODE_CONTEXT_ST* p;
     CciChar          buffer[256];
   ```

   b) Allocate a pointer to the local context and clear the context area:

   ```
     p = (NODE_CONTEXT_ST *)malloc(sizeof(NODE_CONTEXT_ST));

     if (p) {
        memset(p, 0, sizeof(NODE_CONTEXT_ST));
   ```

   c) Save the node object pointer in the context:

   ```
      p->nodeObject = nodeObject;
   ```

   d) Save the node name:

   ```
    CciCharNCpy((CciChar*)&p->nodeName, nodeName, MAX_NODE_NAME_LEN);
   ```

   e) Return the node context:

   ```
   return (CciContext*) p;
   ```

2. The integration node calls the appropriate utility functions to find out about the node's input terminals and output terminals. A node has a number of input terminals and output terminals associated with it. Within the user function `cniCreateNodeContext`, calls must be made to `cniCreateInputTerminal` and `cniCreateOutputTerminal` to define the user node's terminals. These functions must be started within the `cniCreateNodeContext` implementation function.

   For example, to define a node with one input terminal and two output terminals:

```
{
  const CciChar* ucsIn = CciString("in", BIP_DEF_COMP_CCSID) ;
  insInputTerminalListEntry(p, (CciChar*)ucsIn);
  free((void *)ucsIn) ;
}
{
  const CciChar* ucsOut = CciString("out", BIP_DEF_COMP_CCSID) ;
  insOutputTerminalListEntry(p, (CciChar*)ucsOut);
  free((void *)ucsOut) ;
}
{
  const CciChar* ucsFailure = CciString("failure", BIP_DEF_COMP_CCSID) ;
  insOutputTerminalListEntry(p, (CciChar*)ucsFailure);
  free((void *)ucsFailure) ;
}
```

   The previous code starts the `insInputTerminalListEntry` and `insOutputTerminalListEntry` functions. You can find these functions in the sample code `Common.c`; see Sample node files. These functions define the terminals to the integration node and store handles to the terminals. Handles are stored in the structure referenced by the value returned in `CciContext*`. The node can then access the terminal handles from within the other implementation functions (for example `CciEvaluate`) because `CciContext` is passed to those implementation functions.

   The following code shows the definition of `insInputTerminalListEntry`:

```
TERMINAL_LIST_ENTRY *insInputTerminalListEntry(
  NODE_CONTEXT_ST* context,
  CciChar*         terminalName
){
  static char* functionName = (char *)"insInputTerminalListEntry()";
  TERMINAL_LIST_ENTRY* entry;
  int                  rc;

  entry = (TERMINAL_LIST_ENTRY *)malloc(sizeof(TERMINAL_LIST_ENTRY));
  if (entry) {

    /* This entry is the current end of the list */
    entry->next = 0;

    /* Store the terminal name */
    CciCharCpy(entry->name, terminalName);

    /* Create terminal and save its handle */
    entry->handle = cniCreateInputTerminal(&rc, context->nodeObject, (CciChar*)terminalName);

    /* Link an existing previous element to this one */
    if (context->inputTerminalListPrevious) context->inputTerminalListPrevious->next = entry;
    else if ((context->inputTerminalListHead) == 0) context->inputTerminalListHead = entry;

    /* Save the pointer to the previous element */
    context->inputTerminalListPrevious = entry;
  }
  else {
    /* Error: Unable to allocate memory */
  }

  return(entry);
}
```

   The following example shows the code for `insOutputTerminalListEntry`:

```
TERMINAL_LIST_ENTRY *insOutputTerminalListEntry(
  NODE_CONTEXT_ST* context,
  CciChar*         terminalName
){
  static char* functionName = (char *)"insOutputTerminalListEntry()";
  TERMINAL_LIST_ENTRY* entry;
```

```
  int                 rc;

  entry = (TERMINAL_LIST_ENTRY *)malloc(sizeof(TERMINAL_LIST_ENTRY));
  if (entry) {

    /* This entry is the current end of the list */
    entry->next = 0;

    /* Store the terminal name */
    CciCharCpy(entry->name, terminalName);

    /* Create terminal and save its handle */
    entry->handle = cniCreateOutputTerminal(&rc, context->nodeObject, (CciChar*)terminalName);

    /* Link an existing previous element to this one */
    if (context->outputTerminalListPrevious) context->outputTerminalListPrevious->next = entry;
    else if ((context->outputTerminalListHead) == 0) context->outputTerminalListHead = entry;

    /* Save the pointer to the previous element */
    context->outputTerminalListPrevious = entry;
  }
  else {
    /* Error: Unable to allocate memory */
  }

  return(entry);
}
```

For the minimum code required to compile a C user-defined node, see C skeleton code.

Setting attributes

About this task

Attributes are set whenever you start the integration node, or when you redeploy a message flow with new values. Attributes are set by the integration node calling user code on the configuration thread. Your code needs to store these attributes in its node context area, for later use when processing messages.

Following the creation of input and output terminals, the integration node calls the `cniSetAttribute` function to pass the values for the configured attributes for this instantiation of the user-defined node. For example:

```
    {
      const CciChar* ucsAttr = CciString("nodeTraceSetting", BIP_DEF_COMP_CCSID) ;
      insAttrTblEntry(p, (CciChar*)ucsAttr, CNI_TYPE_INTEGER);
      _setAttribute(p, (CciChar*)ucsAttr, (CciChar*)constZero);
      free((void *)ucsAttr) ;
    }
    {
      const CciChar* ucsAttr = CciString("nodeTraceOutfile", BIP_DEF_COMP_CCSID) ;
      insAttrTblEntry(p, (CciChar*)ucsAttr, CNI_TYPE_STRING);
      _setAttribute(p, (CciChar*)ucsAttr, (CciChar*)constSwitchTraceLocation);
      free((void *)ucsAttr) ;
    }
```

The number of configuration attributes that a node can have is unlimited. However, a node must not implement an attribute that is already implemented as a base configuration attribute. The following list shows base attributes:

- label
- userTraceLevel
- traceLevel
- userTraceFilter
- traceFilter

Implementing the node functionality

About this task

When the integration node retrieves a message from the queue, and that message arrives at the input terminal of your user-defined message processing or output node, the integration node calls the implementation function `cniEvaluate`. This function is called on the message processing thread and it must decide what to do with the message. This function might be called on multiple threads, especially if additional instances are used.

Deleting an instance of the node

About this task

If a node is deleted, the integration node calls the `cniDeleteNodeContext` function. This function is started on the same thread as `cniCreateNodeContext`. Use this function to release resources used by your user-defined node. For example:

```
void _deleteNodeContext(
  CciContext* context
){
  static char* functionName = (char *)"_deleteNodeContext()";
  free ((void*) context);
  return;
}
```

Extending the capability of a C message processing or output node
When you have created a user-defined message processing or output node in C, you can extend its capability.

Before you begin

Read the topic "Creating a message processing or output node in C" on page 2392.

About this task

After you have created a user-defined node, the following options are available:

1. "Accessing message data" on page 2397
2. "Transforming a message object" on page 2398
3. "Accessing ESQL" on page 2399
4. "Propagating a message" on page 2399
5. "Writing to an output device" on page 2400

Accessing message data

About this task

In many cases, the user-defined node must access the contents of the message that is received on its input terminal. The message is represented as a tree of syntax elements. Groups of utility functions are provided for message management, message buffer access, syntax element navigation, and syntax element access. (See C node utility functions for details of the utility functions.)

The types of query that you are likely to want to perform include:

- Obtaining the root element of the required message object
- Accessing the bit stream representation of an element tree
- Navigating or querying the tree by asking for child or sibling elements by name
- Getting the type of the element

- Getting the value of the element

For example, to query the name and type of the first child of body:

```
void cniEvaluate( ...
){
  ...
/* Navigate to the target element */
  rootElement = cniRootElement(&rc, message);
  bodyElement = cniLastChild(&rc, rootElement);
  bodyFirstChild = cniFirstChild(&rc, bodyElement);

/* Query the name and value of the target element */
  cniElementName(&rc, bodyFirstChild, (CciChar*)&elementname, sizeof(elementName));
  bytes = cniElementCharacterValue(
  &rc, bodyfirstChild, (CciChar*)&eValue, sizeof(eValue));
  ...
}
```

To access the bit stream representation of an element tree you can use the `cniElementAsBitstream` function. Using this function, you can obtain the bit stream representation of any element in a message. See cniElementAsBitstream for details of how to use this function, and sample code.

Transforming a message object

About this task

The received input message is read-only, therefore before a message can be transformed, you must write it to a new output message using the `cniCreateMessage` function. You can copy elements from the input message, or you can create new elements and attach them to the message. New elements are typically in a parser's domain.

For example:

1. To write the incoming message to a new message:

   ```
   {
     ...
     context = cniGetMessageContext(&rc, message));
     outMsg = cniCreateMessage(&rc, context));
     ...
   }
   ```

2. To make a copy of the new message:

   ```
   cniCopyElementTree(&rc, sourceElement, targetElement);
   ```

3. To modify the value of a target element:

   ```
     cniSetElementIntegerValue(&rc, targetElement, L"newValue", 8);
   ```

4. After finalizing and propagating the message, you must delete the output message using the `cniDeleteMessage` function:

   ```
    cniDeleteMessage(&rc, outMsg);
   ```

As part of the transformation, you might want to create a new message body. To create a new message body, use one of the following functions, which assign a parser to a message tree folder:

```
cniCreateElementAsFirstChildUsingParser
cniCreateElementAsLastChildUsingParser
cniCreateElementAfterUsingParser
cniCreateElementBeforeUsingParser
```

When creating a message body, do not use the following functions because they do not associate an owning parser with the folder:

```
cniCreateElementAsFirstChild
cniCreateElementAsLastChild
```

```
cniCreateElementAfter
cniCreateElementBefore
```

Accessing ESQL

About this task

Nodes can invoke ESQL expressions using Compute node ESQL syntax. You can create and modify the components of the message using ESQL expressions, and you can refer to elements of both the input message and data from an external database using the `cniSqlCreateStatement`, `cniSqlSelect`, `cniSqlDeleteStatement`, and `cniSqlExecute` functions.

For example, to populate the Result element from the contents of a column in a database table:

```
{
  ...
  sqlExpr = cniSqlCreateStatement(&rc,
   (NODE_CONTEXT_ST *)context->nodeObject,
   L"DB", CCI_SQL_TRANSACTION_AUTO,
   L"SET OutputRoot.XMLNS.Result[] = (SELECT T.C1 AS Col1 FROM Database.TABLE AS T;");
  ...
  cniSqlSelect(&rc, sqlExpr, localEnvironment, exceptionList, message, outMsg);
  cniSqlDeleteStatement(&rc, sqlExpr);
  ...
}
```

For more information about ESQL, see “ESQL overview” on page 1608.

If your user-defined node primarily uses ESQL, consider using a node.

Propagating a message

About this task

Before you propagate a message, decide what message flow data you want to propagate, and which terminal is to receive the data.

1. If the message has changed, finalize the message before you propagate it using the `cniFinalize` function. For example:

   ```
         cniFinalize(&rc, outMsg, CCI_FINALIZE_NONE);
   ```

2. The terminalObject is derived from a list that the user-defined node maintains itself. To propagate the message to the output terminal, use the `cniPropagate` function:

   ```
   if (terminalObject) {
     if (cniIsTerminalAttached(&rc, terminalObject)) {
       if (rc == CCI_SUCCESS) {
         cniPropagate(&rc, terminalObject, localEnvironment, exceptionList, outMsg);
       }
     }
   ```

   In the above example, the `cniIsTerminalAttached` function is used to test whether the message can be propagated to the specified terminal. If you do not use the `cniIsTerminalAttached` function and the terminal is not attached to another node by a connector, the message is not propagated and no warning message is returned. Use the `cniIsTerminalAttached` function to prevent this error occurring.

3. If you created a new output message using `cniCreateMessage`, after propagating the message, delete the output message using the `cniDeleteMessage` function:

   ```
   cniDeleteMessage(&rc, outMsg);
   ```

Writing to an output device

About this task

A transformed message must be serialized to a bit stream; a message can be serialized only once.

The bit stream can then be accessed and written to an output device. Write the message to a bit stream using the `cniWriteBuffer` function. For example:

```
{
  ...
  cniWriteBuffer(&rc, message);
  writeToDevice(cniBufferPointer(&rc, message), cniBufferSize(&rc, message));
  ...
}
```

In this example, the method `writeToDevice` is a user-written method which writes a bit stream to an output device.

Do not write a user-defined output node to write messages to IBM MQ queues; use the supplied MQOutput node in this scenario. The integration node internally maintains an IBM MQ connection and open queue handles on a thread-by-thread basis, and these are cached to optimize performance. In addition, the integration node handles recovery scenarios when certain IBM MQ events occur; this recovery would be adversely affected if IBM MQ MQI calls are used in a user-defined output node.

Compiling a C user-defined extension
Compile user-defined extensions in C for all supported operating systems.

Before you begin

If you create your own user-defined nodes, parsers, and user exits in C, compile them on the operating system on which the target integration node is running. Samples are provided for both nodes and parsers, and are described in Sample node files and Sample parser files. Use the instructions here to compile the samples. If you want to create your own extensions, see the following topics:

- “Creating a user-defined extension in C” on page 2384
- “Developing user-defined parsers” on page 2434
- “Developing user-defined exits” on page 2443

About this task

These instructions use the file names of the supplied samples. If you are compiling your own user-defined extensions, substitute your own file names.

When you compile a user-defined extension that is written in C, you need a compatible compiler. For details of supported compilers, see IBM App Connect Enterprise system requirements.

Header files

About this task

The following header files define the C interfaces:

BipCni.h
Message processing nodes

BipCpi.h
Message parsers

BipCci.h
Interfaces common to both nodes and parsers

BipCos.h
Platform-specific definitions

Compiling

About this task

Compile the source for your user-defined extension on each of the supported operating systems to create the executable file that the integration node calls to implement your user-defined extension. On Linux and AIX and systems, this file is a loadable implementation library (LIL) file; on Windows systems, it is a dynamic load library (DLL) file.

The libraries that you build to contain user-defined nodes or parsers must have the extension `.lil` on all operating systems so that the integration node can load them. Libraries that contain user exits must have the extension `.lel` on all operating systems. The examples in this topic show libraries with the extension `.lil`

All extensions must be compiled as 64-bit libraries.

Refer to the documentation for the compiler that you are using for full details of available compile and link options that might be required for your programs.

Navigate to the directory where your user-defined extension source code is located, and follow the instructions for your operating system:

- AIX
- Linux
- Windows

Compiling on AIX

About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

The following instructions are for compiling an extension:

```
xlc_r -q64 \
   -I. \
   -I/install_dir/server/include/plugin \
   -c SwitchNode.c \
   -o SwitchNode.o

xlc_r -q64 \
   -I. \
   -I/install_dir/server/include/plugin \
   -c TransformNode.c \
   -o TransformNode.o

xlc_r -q64 \
   -I. \
   -I/install_dir/server/include/plugin \
   -c BipSampPluginUtil.c \
   -o BipSampPluginUtil.o

xlc_r -q64 \
   -I. \
   -I/install_dir/server/include/plugin \
   -c Common.c \
   -o Common.o

xlc_r -q64 \
   -I. \
   -I/install_dir/server/include/plugin \
   -c NodeFactory.c \
   -o NodeFactory.o

xlc_r -q64 \
      -qmkshrobj \
      -bM:SRE \
      -bexpall \
      -bnoentry \
      -o SwitchNode.lil SwitchNode.o \
         BipSampPluginUtil.o Common.o NodeFactory.o \
```

```
      -L /install_dir/server/lib \
      -l imbdfplg

chmod a+r SwitchNode.lil
```

Compiling on Linux

About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

When you compile programs on Linux on POWER, replace the option `-fpic` with `-fPIC` if you want to use dynamic linking and avoid any limit on the size of the global offset table.

The following instructions are for compiling an extension on Linux on x86-64, Linux on POWER, and Linux on Z. To compile the extension for Linux on POWER, include the **-02** parameter in the compile and link examples, and include the **-fexceptions** parameter in the compile examples.

```
g++ -c -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/server/include \
   -I/install_dir/server/include/plugin \
   -DLINUX -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   TransformNode.c

g++ -c -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/server/include \
   -I/install_dir/server/include/plugin \
   -DLINUX -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   SwitchNode.c

g++ -c -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/server/include \
   -I/install_dir/server/include/plugin \
   -DLINUX -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   BipSampPluginUtil.c

g++ -c -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/server/include \
   -I/install_dir/server/include/plugin \
   -DLINUX  -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   Common.c

g++ -c -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/server/include \
   -I/install_dir/server/include/plugin \
   -DLINUX -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   NodeFactory.c

g++ -m64 -o samples.lil \
   TransformNode.o \
   SwitchNode.o \
   BipSampPluginUtil.o \
   Common.o NodeFactory.o \
   -shared -lc -lnsl -ldl \
   -L/install_dir/server/lib -limbdfplg
```

These commands create the file `samples.lil` that provides TransformNode and SwitchNode objects.

Compiling on Windows

About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

Ensure that you include a space between `SwitchNode.c` and `BipSampPluginUtil.c`, and also between `-link` and `/DLL`.

Enter the command as a single line of input; in the following example the lines are split to improve readability.

```
cl /VERBOSE /LD /MD /Zi /EHsc /I.
   /Iinstall_dir\server\include\plugin
   SwitchNode.c BipSampPluginUtil.c Common.c
   NodeFactory.c TransformNode.c

```

If you have correctly set the *LIB* environment variable, you do not have to specify the full paths to the LIB files.

Creating a user-defined extension in Java
You must complete a series of tasks to create user-defined nodes that use the Java language.

About this task

Complete the appropriate tasks from the following list:

- “Creating an input node in Java” on page 2403
- “Creating a message processing or output node in Java” on page 2409
- “Compiling a Java user-defined node” on page 2418
- “Packaging a Java user-defined node ” on page 2450

You can write only user-defined nodes in Java: you must write user-defined parsers in C.

What to do next

When you have completed this set of tasks, continue with the following tasks:

- “Creating the user interface representation of a user-defined node in the IBM App Connect Enterprise Toolkit” on page 2421
- “Testing a user-defined node” on page 2430
- “Packaging and distributing user-defined extensions” on page 2449

Restrictions when creating Java nodes
In Java user-defined nodes and the JavaCompute node, calling the `System.exit(...)` method is not supported. Calling this method results in a `SecurityException`.

Creating an input node in Java
An input node is used to receive a message into a message flow, typically from a source that is not supported by the built-in input nodes.

Before you begin

Read the following topics:

- “Why use a user-defined extension?” on page 2322
- “User-defined input nodes” on page 2332

About this task

To create an input node in the Java language:

1. “Creating a Java project” on page 2404
2. “Declaring the input node class” on page 2404
3. “Defining the node constructor” on page 2405
4. “Receiving external data into a buffer” on page 2405
5. “Propagating the message” on page 2406

6. “Controlling threading and transactionality” on page 2406
7. “Declaring the node name” on page 2407
8. “Declaring attributes” on page 2407
9. “Implementing the node functionality” on page 2408
10. “Overriding default message parser attributes (optional)” on page 2408
11. “Deleting an instance of the node” on page 2409

A Java user-defined node is distributed as a `.jar` file.

Creating a Java project

About this task

Before you can create Java nodes in the IBM App Connect Enterprise Toolkit, you must create a Java project:

Procedure

1. Click **File** > **New** > **Project**, select **Java Project** then click **Next**.
2. Give the project a name, then click **Next**.
3. On the **Java Settings** pane, select the **Libraries** tab, and click **Add External JARs**.
4. Select *install_dir*`\server\classes\jplugin2.jar`, where *install_dir* is the home directory of your IBM App Connect Enterprise installation.
5. Follow the prompts on the other tabs to define any other build settings.
6. Click **Finish**.

What to do next

You can now develop the source for your Java node in this project.

Declaring the input node class

About this task

Every class that implements `MbInputNodeInterface` and is contained in the integration node LIL path is registered with the integration node as an input node. When you implement `MbInputNodeInterface`, you must also implement a `run` method for this class. The `run` method represents the start of the message flow, contains the data that formulates the message, and propagates it down the flow. The integration node calls the `run` method when threads become available in accordance with your specified threading model.

The class name must end with the word "Node". For example, if the name is BasicInput in the IBM App Connect Enterprise Toolkit, the class name must be BasicInputNode.

For example, to declare the input node class:

```
package com.ibm.jplugins;

import com.ibm.broker.plugin.*;

public class BasicInputNode extends MbInputNode implements MbInputNodeInterface
{
...
```

Follow these steps to complete this action in the IBM App Connect Enterprise Toolkit:

Procedure

1. Click **File** > **New** > **Other**, select **Class**, then click **Next**.

2. Set the package and class name fields to appropriate values.
3. Delete the text in the **Superclass** text field and click the **Browse** button.
4. Select **MbInputNode**.
5. Click the **Add** button next to Interfaces text field, and select **MbInputNodeInterface**.
6. Click **Finish**.

Defining the node constructor

About this task

When the node is instantiated, the constructor of the node class is called. This class is where you create the terminals of the node, and initialize the default values for the attributes.

An input node has a number of output terminals associated with it, but does not typically have any input terminals. Use the `createOutputTerminal` method to add output terminals to a node when the node is instantiated. For example, to create a node with three output terminals:

```
public BasicInputNode() throws MbException
{
 createOutputTerminal ("out");
 createOutputTerminal ("failure");
 createOutputTerminal ("catch");
 setAttribute ("firstParserClassName","myParser");
 attributeVariable  = "none";
}
```

Receiving external data into a buffer

About this task

An input node can receive data from any type of external source, such as a file system, a queue, or a database, in the same way as all other Java programs, if the output from the node is in the correct format.

Provide an input buffer (or bit stream) to contain input data, and associate it with a message object. Create a message from a byte array by using the `createMessage` method of the **MbInputNode** class, and then generate a valid message assembly from this message. For example, to read the input data from a file:

Procedure

1. Create an input stream to read from the file:

   ```
   FileInputStream inputStream = new FileInputStream("myfile.msg");
   ```

2. Create a byte array the size of the input file:

   ```
   byte[] buffer = new byte[inputStream.available()];
   ```

3. Read from the file into the byte array:

   ```
   inputStream.read(buffer);
   ```

4. Close the input stream:

   ```
   inputStream.close();
   ```

5. Create a message to put on the queue:

   ```
   MbMessage msg = createMessage(buffer);
   ```

6. Create a message assembly to hold this message:

   ```
   msg.finalizeMessage(MbMessage.FINALIZE_VALIDATE);
   MbMessageAssembly newAssembly =
   ```

```
      new MbMessageAssembly(assembly, msg);
```

Propagating the message

About this task

After creating a message assembly, you can propagate it to one of the output terminals that are defined on the node.

For example, to propagate the message assembly to the terminal named **out**:

```
MbOutputTerminal out = getOutputTerminal("out");
out.propagate(newAssembly);
```

To delete the message:

```
msg.clearMessage();
```

To clear the memory that is allocated for the message tree, call the `clearMessage()` function within the finally block of `try/catch`.

Controlling threading and transactionality

About this task

The integration node infrastructure handles transaction issues such as controlling the commit of an IBM MQ or database unit of work when message processing has completed. However, resources modified from within a user-defined node are not necessarily under the transactional control of the integration node.

Each message flow thread is allocated from a pool of threads maintained for each message flow, and starts in the `run` method.

The user-defined node uses return values to indicate whether a transaction is successful, to control whether transactions are committed or rolled back, and to control when the thread is returned to the pool. The integration node infrastructure catches all unhandled exceptions, and rolls back the transaction.

You determine the behavior of transactions and threads by using the appropriate return value:

MbInputNode.SUCCESS_CONTINUE
: The transaction is committed and the integration node calls the `run` method again by using the same thread.

MbInputNode.SUCCESS_RETURN
: The transaction is committed and the thread is returned to the thread pool, assuming that it is not the only thread for this message flow.

MbInputNode.FAILURE_CONTINUE
: The transaction is rolled back and the integration node calls the `run` method again by using the same thread.

MbInputNode.FAILURE_RETURN
: The transaction is rolled back and the thread is returned to the thread pool, assuming that it is not the only thread for this message flow.

MbInputNode.TIMEOUT
: The `run` method must not block indefinitely while waiting for input data to arrive. While the flow is blocked by user code, you cannot shut down or reconfigure the integration node. The `run` method must yield control to the integration node periodically by returning from the `run` method. If input data is not received after a certain period (for example, 5 seconds), the method must return with the TIMEOUT return code. Assuming that the integration node does not need to reconfigure or shut down, the `run` method of the input node gets called again immediately.

To create multithreaded message flows, you call the `dispatchThread` method after a message is created, but before the message is propagated to an output terminal. This action ensures that only one thread is waiting for data while other threads are processing the message. New threads are obtained

from the thread pool up to the maximum limit specified by the `Additional Instances` property of the message flow. For example:

```
public int run( MbMessageAssembly assembly ) throws MbException
{
  byte[] data = getDataWithTimeout();  // user supplied method
                                       // returns null if timeout
  if( data == null )
    return TIMEOUT;

  MbMessage msg = createMessage( data );
  msg.finalizeMessage( MbMessage.FINALIZE_VALIDATE );
  MbMessageAssembly newAssembly =
       new MbMessageAssembly( assembly, msg );

  dispatchThread();

  getOutputTerminal( "out" ).propagate( newAssembly );

  return SUCCESS_RETURN;
}
```

Declaring the node name

About this task

You must declare the name of the node for use and identification by the IBM App Connect Enterprise Toolkit. All node names must end with the characters "Node". Declare the name by using the following method:

```
public static String getNodeName()
{
   return "BasicInputNode";
}
```

If this method is not declared, the Java API framework creates a default node name by using the following rules:

- The class name is appended to the package name.
- The periods are removed, and the first letter of each part of the package and class name is capitalized.

For example, by default, the following class is assigned the node name "ComIbmPluginsamplesBasicInputNode":

```
package com.ibm.pluginsamples;
public class BasicInputNode extends MbInputNode implements MbInputNodeInterface
{
   ...
```

Declaring attributes

About this task

Declare node attributes by using the same method that you use for Java bean properties. You are responsible for writing `get` and `set` methods for the attributes; the API framework infers the attribute names by using the Java bean introspection rules. For example, if you declare the following two methods:

```
private String attributeVariable;

public String getFirstAttribute()
{
  return attributeVariable;
}

public void setFirstAttribute(String value)
{
```

```
  attributeVariable = value;
}
```

The integration node infers that this node has an attribute called firstAttribute. This name is derived from the names of the `get` or `set` methods, not from the variable names of any internal class members. Attributes can be exposed only as strings, so convert numeric types to and from strings in the `get` or `set` methods. For example, the following method defines an attribute called timeInSeconds:

```
int seconds;

public String getTimeInSeconds()
{
  return Integer.toString(seconds);
}

public void setTimeInSeconds(String value)
{
  seconds = Integer.parseInt(value);
}
```

Implementing the node functionality

About this task

As already described, the `run` method is called by the integration node to create the input message. This method must provide all the processing function for the input node.

Overriding default message parser attributes (optional)

About this task

An input node implementation normally determines which message parser initially parses an input message. For example, the built-in MQInput node dictates that an MQMD parser is required to parse the MQMD header. A user-defined input node can select an appropriate header or message parser, and the mode in which the parsing is controlled, by using the following default attributes that are included, which you can override:

rootParserClassName
: Defines the name of the root parser that parses message formats supported by the user-defined input node. It defaults to `GenericRoot`, a supplied root parser that causes the integration node to allocate and chain parsers together. It is unlikely that a node would have to modify this attribute value.

firstParserClassName
: Defines the name of the first parser, in what might be a chain of parsers that are responsible for parsing the bit stream. It defaults to `XML`.

messageDomainProperty
: An optional attribute that defines the name of the message parser required to parse the input message. The supported values are the same as the values that are supported by the MQInput node.

messageSetProperty
: An optional attribute that defines the message set identifier, or the message set name, in the `Message Set` field, only if the MRM parser was specified by the `messageDomainProperty` attribute.

messageTypeProperty
: An optional attribute that defines the identifier of the message in the `MessageType` field, only if the MRM parser was specified by the `messageDomainProperty` attribute.

messageFormatProperty
: An optional attribute that defines the format of the message in the `Message Format` field, only if the MRM parser was specified by the `messageDomainProperty` attribute.

Deleting an instance of the node

About this task

An instance of the node is deleted when either:

- You shut down the integration node.
- You remove the node or the message flow that contains the node, and redeploy the configuration.

When the node is deleted, it can perform cleanup operations, such as closing sockets, if it implements the optional `onDelete` method. This method, if present, is called by the integration node just before the node is deleted.

Implement the `onDelete` method as follows:

```
public void onDelete()
{
  // perform node cleanup if necessary
}
```

Creating a message processing or output node in Java
A message processing node is used to process a message, and an output node is used to output a message as a bit stream.

Before you begin

Read the following topics:

- “Why use a user-defined extension?” on page 2322
- “User-defined message processing nodes” on page 2336
- “User-defined output nodes” on page 2343
- “Restrictions when creating Java nodes” on page 2403

About this task

IBM App Connect Enterprise provides the source for two sample user-defined nodes called SwitchNode and TransformNode. You can use these nodes in their current state, or you can modify them.

When you code a message processing node or an output node, the two types provide essentially the same functions. You can perform message processing within an output node, and likewise you can propagate an output message to a bit stream from a message processing node. For simplicity, this topic refers mainly to the node as a message processing node, but it does discuss the functionality of both types of node.

Complete the following steps:

1. “Creating a new Java project” on page 2410
2. “Declaring the message processing node class” on page 2410
3. “Defining the node constructor” on page 2410
4. “Accessing message data” on page 2411
5. “Transforming a message object” on page 2411
6. “Propagating the message” on page 2412
7. “Declaring the node name” on page 2413
8. “Declaring attributes” on page 2413
9. “Implementing the node functionality” on page 2414
10. “Deleting an instance of the node” on page 2414

A Java user-defined node is distributed as a `.jar` file.

Creating a new Java project

About this task

Before you can create Java nodes in the IBM App Connect Enterprise Toolkit, you must create a new Java project:

1. Click **File** > **New** > **Project**. Select **Java** and click **Next**.
2. In the **Project name** field, enter a project a name, then click **Next**.
3. On the **Java Settings** pane, select the **Libraries** tab, and click **Add External JARs**.
4. Select *install_dir*`\server\classes\jplugin2.jar`.
5. Follow the prompts on the other tabs to define any other build settings.
6. Click **Finish**.

You can now develop the source for your Java node within this project.

Declaring the message processing node class

About this task

Any class that implements `MbNodeInterface`, and is contained in the integration node's LIL path, is registered with the integration node as a message processing node. When you implement `MbNodeInterface`, you must also implement an `evaluate` method for this class. The `evaluate` method is called by the integration node for each message that passes through the flow.

The class name must end with the word "Node". For example, if you have assigned the name as Basic in the IBM App Connect Enterprise Toolkit, the class name must be BasicNode.

For example, to declare the message processing node class:

```
package com.ibm.jplugins;

import com.ibm.broker.plugin.*;

public class BasicNode extends MbNode implements MbNodeInterface
```

Declare the class in the IBM App Connect Enterprise Toolkit:

1. Click **File** > **New** > **Other**, select **Class**, then click **Next**.
2. Set the package and class name fields to appropriate values.
3. Delete the text in the Superclass text field and click **Browse**.
4. Select **MbNode** and click **OK**.
5. Click the **Add** button next to Interfaces text field, and select **MbNodeInterface**.
6. Click **Finish**.

Defining the node constructor

About this task

When the node is instantiated, the constructor of the user's node class is called. Create the terminals of the node, and initialize any default values for attributes in this constructor.

A message processing node has a number of input terminals and output terminals that are associated with it. Use the methods `createInputTerminal` and `createOutputTerminal` to add terminals to a node when the node is instantiated.

For example, to create a node with one input terminal and two output terminals:

```
public MyNode() throws MbException
{
  // create terminals here
```

```
  createInputTerminal ("in");
  createOutputTerminal ("out");
  createOutputTerminal ("failure");
}
```

Accessing message data

About this task

In many cases, the user-defined node needs to access the contents of the message received on its input terminal. The message is represented as a tree of syntax elements. Use the supplied utility function to `evaluate` methods for message management, message buffer access, syntax element navigation, and syntax element access.

The `MbElement` class provides the interface to the syntax elements.

For example:

Procedure

1. To navigate to the relevant syntax element in the XML message:

```
MbElement rootElement = assembly.getMessage().getRootElement();
MbElement switchElement =
rootElement.getLastChild().getFirstChild().getFirstChild();
```

2. To select the terminal indicated by the value of this element:

```
String terminalName;
String elementValue = (String)switchElement.getValue();
if(elementValue.equals("add"))
  terminalName = "add";
else if(elementValue.equals("change"))
  terminalName = "change";
else if(elementValue.equals("delete"))
  terminalName = "delete";
else if(elementValue.equals("hold"))
  terminalName = "hold";
else
  terminalName = "failure";

MbOutputTerminal out = getOutputTerminal(terminalName);
```

Results

Transforming a message object

About this task

The received input message is read-only, so before you can transform a message, you must write it to a new output message. You can copy elements from the input message, or you can create new elements in the output message.

The `MbMessage` class provides the copy constructors, and the methods to get the root element of the message. The `MbElement` class provides the interface to the syntax elements.

For example, if you have an incoming message assembly with embedded messages, you could have the following code in the `evaluate` method of your user-defined node:

1. To create a new copy of the message assembly and its embedded messages:

```
MbMessage newMsg = new MbMessage(assembly.getMessage());
MbMessageAssembly newAssembly = new MbMessageAssembly(assembly, newMsg);
```

2. To navigate to the relevant syntax element in the XML message:

```
MbElement rootElement = newAssembly.getMessage().getRootElement();
```

```
    MbElement switchElement =
   rootElement.getFirstElementByPath("/XML/data/action");
```

3. To change the value of an existing element:

```
  String elementValue = (String)switchElement.getValue();
    if(elementValue.equals("add"))
      switchElement.setValue("change");
    else if(elementValue.equals("change"))
      switchElement.setValue("delete");
    else if(elementValue.equals("delete"))
      switchElement.setValue("hold");
    else
      switchElement.setValue("failure");
```

4. To add a new tag as a child of the switch tag:

```
    MbElement tag = switchElement.createElementAsLastChild(MbElement.TYPE_NAME,
                                                           "PreviousValue",
                                                           elementValue);
```

5. To add an attribute to this new tag:

```
    tag.createElementAsFirstChild(MbElement.TYPE_NAME_VALUE,
                                  "NewValue",
                                  switchElement.getValue());

    MbOutputTerminal out = getOutputTerminal("out");
```

As part of the transformation, you might need to create a new message body. To create a new message body, use one of the following methods, which specifically assigns a parser to a message tree folder:

```
createElementAfter(String)
createElementAsFirstChild(String)
createElementAsLastChild(String)
createElementBefore(String)
createElementAsLastChildFromBitstream(byte[], String, String, String, String, int, int, int)
```

Do not use the following methods, which do not associate an owning parser with the folder:

```
createElementAfter(int)
createElementAfter(int, String, Object)
createElementAsFirstChild(int)
createElementAsFirstChild(int, String, Object)
createElementAsLastChild(int)
createElementAsLastChild(int, String, Object)
createElementBefore(int)
createElementBefore(int, String, Object)
```

Propagating the message

About this task

Before you propagate a message, decide what message flow data you want to propagate, and whether to propagate to a node terminal, or to a Label node.

For example:

1. To propagate the message to the output terminal "out":

```
MbOutputTerminal out = getOutputTerminal("out");
        out.propagate(newAssembly);
```

2. To propagate the message to a Label node:

```
MbRoute label1 = getRoute ("label1");
Label1.propagate(newAssembly);
```

Call the `clearMessage()` function within the finally block of try/catch to clear the memory that is allocated for the message tree.

To propagate the same MbMessage object multiple times, call the `finalizeMessage()` method on the MBMessage object, so that any changes made to the message are reflected in the bit stream that is generated downstream of the Java node; for example:

```
MbMessage newMsg = new MbMessage(assembly.getMessage());
MbMessageAssembly newAssembly = new MbMessageAssembly(assembly, newMsg);
...
newMsg.finalizeMessage(MbMessage.FINALIZE_NONE);
out.propagate(newAssembly;
...
newMsg.finalizeMessage(MbMessage.FINALIZE_NONE);
out.propagate(newAssembly);
```

Declaring the node name

About this task

The name of the node must be the same as the one that is used in the IBM App Connect Enterprise Toolkit. All node names must end with "Node". Declare the name using the following method:

```
public static String getNodeName()
{
   return "BasicNode";
}
```

If this method is not declared, the Java API framework creates a default node name using the following rules:

- The class name is appended to the package name.
- The dots are removed, and the first letter of each part of the package and class name are capitalized.

For example, by default, the following class is assigned the node name "ComIbmPluginsamplesBasicNode":

```
package com.ibm.pluginsamples;
public class BasicNode extends MbNode implements MbNodeInterface
{
   ...
```

Declaring attributes

About this task

Declare node attributes in the same way as Java Bean properties. You must write getter and setter methods for the attributes. The API framework infers the attribute names using the Java Bean introspection rules. For example, if you declare the following two methods:

```
private String attributeVariable;

public String getFirstAttribute()
{
  return attributeVariable;
}

public void setFirstAttribute(String value)
{
  attributeVariable = value;
}
```

the integration node infers that this node has an attribute called firstAttribute. This name is derived from the names of the get or set methods, not from any internal class member variable names. Attributes can

only be exposed as strings, therefore, you must convert any numeric types to and from strings in the get or set methods. For example, the following method defines an attribute called timeInSeconds:

```
int seconds;

public String getTimeInSeconds()
{
  return Integer.toString(seconds);
}

public void setTimeInSeconds(String value)
{
  seconds = Integer.parseInt(value);
}
```

Implementing the node functionality

About this task

The `evaluate` method, defined in `MbNodeInterface`, is called by the integration node to process the message. All the processing function for the node is included in this method.

The `evaluate` method has two parameters that are passed in by the integration node:

1. The `MbMessageAssembly`, which contains the following objects that are accessed using the appropriate methods:
   - The incoming message
   - The LocalEnvironment
   - The global Environment
   - The ExceptionList
2. The input terminal on which the message has arrived.

For example, the following code extract shows how you might write the evaluate method:

```
public void evaluate(MbMessageAssembly assembly, MbInputTerminal inTerm) throws MbException
  {
    // add message processing code here

    getOutputTerminal("out").propagate(assembly);
  }
```

The message flow data, which consists of the message, Environment, LocalEnvironment, and ExceptionList, is received at the input terminal of the node.

Deleting an instance of the node

About this task

An instance of the node is deleted when either:

- You shut down the integration node.
- You remove the node or the message flow that contains the node, and redeploy the configuration.

If you want the node to perform any cleanup operations, for example closing sockets, include an implementation of the `onDelete` method:

```
public void onDelete()
{
  // perform node cleanup if necessary
}
```

This method is called by the integration node immediately before it deletes the node.

Extending the capability of a Java message processing or output node
Within a message processing or output node, you can add extended functions to your Java node.

Before you begin

Read "Creating a message processing or output node in Java" on page 2409.

About this task

You can add one or more of the following functions:

- "Accessing ESQL" on page 2415
- "Interacting with databases" on page 2416
- "Handling exceptions" on page 2416
- "Writing to an output device" on page 2417

Accessing ESQL

About this task

Nodes can invoke ESQL expressions using Compute node ESQL syntax. You can create and modify the components of the message using ESQL expressions, and you can refer to elements of both the input message and data from an external database.

The following procedure demonstrates how to use ESQL to control transactions from the `evaluate` method in your user-defined node:

1. Set the name of the ODBC data source to use. For example:

```
String dataSourceName = "myDataSource";
```

2. Set the ESQL statement to run:

```
String statement =
   "SET OutputRoot.XMLNS.data =
          (SELECT Field2 FROM Database.Table1 WHERE Field1 = 1);";
```

   Or, if you want to run a statement that returns no result:

```
String statement = "PASSTHRU(
                        'INSERT INTO Database.Table1 VALUES(
                             InputRoot.XMLNS.DataField1,
                             InputRoot.XMLNS.DataField2)');";
```

3. Select the transaction you want from the following types:

   MbSQLStatement.SQL_TRANSACTION_COMMIT
   Immediately commit the transaction after the ESQL statement has completed.

   MbSQLStatement.SQL_TRANSACTION_AUTO
   Commit the transaction when the message flow has completed. (Rollbacks are performed if necessary.)

   For example:

```
int transactionType = MbSQLStatement.SQL_TRANSACTION_AUTO;
```

4. Get the ESQL statement. For example:

```
MbSQLStatement sql =
       createSQLStatement(dataSourceName, statement, transactionType);
```

   You can use the method `createSQLStatement(data source, statement` to default the transaction type to MbSQLStatement.SQL_TRANSACTION_AUTO).

5. Create the new message assembly to be propagated:

```
MbMessageAssembly newAssembly =
       new MbMessageAssembly(assembly, assembly.getMessage());
```

6. Run the ESQL statement:

```
sql.select(assembly, newAssembly);
```

   Or, if you want to run an ESQL statement that returns no result:

```
sql.execute(assembly);
```

Interacting with databases

About this task

You can interact with databases from the Java code in your message processing node. The support that is provided is identical to the support for Java code that you write for the JavaCompute node; for details of the available options, and the advantages and restrictions that apply, see “Interacting with databases by using the JavaCompute node” on page 1785.

Handling exceptions

About this task

Use the `MbException` class to catch and access exceptions. The `MbException` class returns an array of exception objects that represent the children of an exception in the integration node exception list. Each element returned specifies its exception type. An empty array is returned if an exception has no children. The following code sample shows an example of how you might use the `MbException` class in the `evaluate` method of your user-defined node.

```
public void evaluate(MbMessageAssembly assembly, MbInputTerminal inTerm) throws MbException
  {
    try
      {

        // plug-in functionality

      }
    catch(MbException ex)
      {
        traverse(ex, 0);

        throw ex; // if re-throwing, it must be the original exception that was caught
      }
  }

  void traverse(MbException ex, int level)
  {
    if(ex != null)
      {
        // Do whatever action here
        System.out.println("Level: " + level);
        System.out.println(ex.toString());
        System.out.println("traceText:  " + ex.getTraceText());

        // traverse the hierarchy
        MbException e[] = ex.getNestedExceptions();
        int size = e.length;
        for(int i = 0; i < size; i++)
          {
            traverse(e[i], level + 1);
          }
      }
  }
```

You can develop a user-defined message-processing or output node in such a way that it can access all current exceptions. For example, to catch database exceptions you can use the `MbSQLStatement` class.

This class sets the value of the 'throwExceptionOnDatabaseError' attribute, which determines integration node behavior when it encounters a database error. When it is set to true, if an exception is thrown it can be caught and handled by the `evaluate` method in your user-defined extension.

The following code sample shows an example of how to use the `MbSQLStatement` class.

```
public void evaluate(MbMessageAssembly assembly, MbInputTerminal inTerm) throws MbException
  {
    MbMessage newMsg = new MbMessage(assembly.getMessage());
    MbMessageAssembly newAssembly = new MbMessageAssembly(assembly, newMsg);

    String table =
       assembly.getMessage().getRootElement().getLastChild().getFirstChild().getName();

    MbSQLStatement state = createSQLStatement( "dbName",
       "SET OutputRoot.XMLNS.integer[] = PASSTHRU('SELECT * FROM " + table + "');" );

    state.setThrowExceptionOnDatabaseError(false);
    state.setTreatWarningsAsErrors(true);

    state.select( assembly, newAssembly );

    int sqlCode = state.getSQLCode();
    if(sqlCode != 0)
      {
        // Do error handling here

        System.out.println("sqlCode = " + sqlCode);
        System.out.println("sqlNativeError = " + state.getSQLNativeError());
        System.out.println("sqlState = " + state.getSQLState());
        System.out.println("sqlErrorText = " + state.getSQLErrorText());
      }

    getOutputTerminal("out").propagate(newAssembly);
  }
```

Writing to an output device

About this task

To write to an output device, the logical (hierarchical) message must be converted back into a bit stream in your `evaluate` method. Use the `getBuffer` method in **MbMessage** to perform this task:

```
public void evaluate( MbMessageAssembly assembly, MbInputTerminal in)
                                                        throws MbException
{
  MbMessage msg = assembly.getMessage();
  byte[] bitstream = msg.getBuffer();

  // write the bitstream out somewhere
  writeBitstream( bitstream );   // user method

 }
```

Typically, for an output node the message is not propagated to any output terminal, therefore you can just return at this point.

You must use the supplied MQOutput node when writing to IBM MQ queues, because the integration node internally maintains an IBM MQ connection and the open queue handles on a thread-by-thread basis. These handles are cached to optimize performance. In addition, the integration node handles exception scenarios when certain IBM MQ events occur, and this recovery is adversely affected if IBM MQ MQI calls are used in a user-defined output node.

Getting and setting the specific type of an Mb element
Two methods are provided for handling the specific type of an Mb syntax element.

About this task

The following methods are available:

- `getSpecificType`
- `setSpecificType`

Use these methods to access or set the specific type of an XML element. For example, to update the current value:

Procedure

1. Call `getSpecificType` on the syntax element.

   The `getSpecificType` method does not take any parameters, but returns the specific type of the element as an int value.
2. Call `setSpecificType` on the syntax element.

   The `setSpecificType` method takes one parameter of the type int, which is the specific type that you want the Mb element to be. This method has no return value.

Results

Specific type values for the XML and MRM parsers are listed in XML, MRM, and XMLNSC parser constants.

Compiling a Java user-defined node

When you have created the code for your Java user-defined node, you must compile it for your operating system.

Before you begin

You must have a user-defined node written in Java. This node can be one of the provided sample nodes that are described in Sample node files, or a node that you have created yourself by using the instructions in either “Creating a message processing or output node in Java” on page 2409 or “Creating an input node in Java” on page 2403.

About this task

You can compile a Java user-defined node either from the command line, or from within the project in the IBM App Connect Enterprise Toolkit. Both options are described later in this section.

When you compile a Java user-defined node from the command line, you must have a compatible IBM Software Developer Kit for Java on the current operating system. For details of supported Java versions, see the IBM App Connect Enterprise system requirements; see IBM App Connect Enterprise system requirements.

Compiling a Java user-defined node from the IBM App Connect Enterprise Toolkit

About this task

Use the following procedure to compile your Java user-defined node from the IBM App Connect Enterprise Toolkit:

Procedure

1. Switch to the Java perspective, and in the Package Explorer, select the `/src` directory inside your node project, and click **File** > **Export**.
2. From the list displayed, select **JAR file**. Click **Next**.

   The resources that are available for you to export as a JAR file are listed.
3. Verify that **Export generated class files and resources** is selected.

4. Specify a name and location for your JAR file.

   Place the file inside the root directory of your node project, and give the file the same name as the name of the project (with a `.jar` extension). You can use the default values for the rest of the options. Click **Finish**.

Results

The `.jar` file that you have created is displayed in your node project, and is ready for you to install on one or more integration nodes (see "Installing user-defined extension runtime files on an integration node" on page 2455), or to package for distribution (see "Packaging and distributing a user-defined node project" on page 2452).

Compiling a Java user-defined node from the command line

About this task

Use the following procedure to compile your Java user-defined node from the command line:

Procedure

1. Add the location of `jplugin2.jar` to the CLASSPATH for your current platform:

   Windows *install_dir*`\server\classes\jplugin2.jar`

   Linux UNIX z/OS *install_dir*`/server/classes/jplugin2.jar`
2. Put your Java user-defined node class into the following directory:

   Windows *install_dir*`\server\sample\extensions\nodes`

   Linux UNIX z/OS *install_dir*`/server/sample/extensions/nodes`
3. Change to the directory that now contains your user-defined node class.
4. Compile the `.java` file by using the **javac** command; for example:

   ```
   javac nodename.java
   ```
5. Package the resulting `.class` file into a `.par` file. See "Packaging a Java user-defined node " on page 2450.

Results

The `.par` file that you have created is ready for you to install on one or more integration nodes (see "Installing user-defined extension runtime files on an integration node" on page 2455), or to package for distribution (see "Packaging and distributing a user-defined node project" on page 2452).

Creating a user-defined node from a subflow
Create user-defined nodes either from scratch, or by using an existing subflow.

About this task

Complete the appropriate tasks from the following list:

- "Creating a user-defined node from a subflow from scratch" on page 2420
- "Creating a user-defined node from an existing subflow" on page 2420
- "Choosing the location of a user-defined node in the palette" on page 2430

Video: Creating and using a subflow user-defined node

This video demonstrates the capability to create a subflow user-defined node using the toolkit. After creating the subflow user-defined node, it is used in another installation of App Connect Enterprise in a message flow to deploy and test the flow.

Creating a user-defined node from a subflow from scratch
Create a user-defined node that packages a subflow by creating a user-defined node project, then creating the user-defined node.

About this task

After you have created a user-defined node, you can edit its properties in the **Palette** editor.
You can define as many user-defined nodes as you want in the same user-defined node project.

To create any type of user-defined node, use the following steps:

Procedure

1. Create a user-defined node project:
   a) To open the **New User-defined Node Project** wizard, click **File** > **New** > **User-defined Node Project**.
   b) Either choose an existing category, or create a category by clicking **Create a new category**.
      Your user-defined nodes are displayed in the palette in the Message Flow editor under the category you specify for the project. You can have only one category in each user-defined node project.
   c) Enter the details for the remainder of the fields as required, then click **Finish**.
   A user-defined node project is created.
2. Create a user-defined node:
   a) To open the **New User-defined Node** wizard, click **File** > **New** > **User-defined Node**.
   b) Select the user-defined node project that you created previously.
   c) Select the schema location that you want to host the user-defined node.
      Use a fully qualified schema. Do not use a default or `mqsi` schema.
   d) Enter the details for the remainder of the fields as required.
   e) Select **Implemented as a subflow**. The **Message Flow** editor opens.
   f) Click **Finish**.
3. Decide on the location of your user-defined node in the palette.
   See “Choosing the location of a user-defined node in the palette” on page 2430.

What to do next

You can now define the reusable logic and the terminals and properties of the user-defined node.

Creating a user-defined node from an existing subflow
Create a user-defined node by converting the project for an existing subflow into a user-defined node project, and then creating the user-defined node.

About this task

To create a user-defined node from an existing subflow, use the following steps:

Procedure

1. To convert existing subflows into user-defined nodes, you must convert the project for the subflow into a user-defined node project:
   a) Right-click the existing project, click **Convert to User-defined Node Project**.
      The **Convert to User-defined Node Project** wizard is displayed.
   b) Choose a category from the following options.
      Your user-defined nodes are displayed in the palette in the Message Flow editor under the category you specify for the project.
      - To use an existing category, select a category from the list provided.
      - To create a new category, select **Create a new category**, enter a name for the category for the nodes that you want to create in the new project.
   c) Enter the details for the remainder of the fields as required.
   d) Click **Finish**.
2. Select the subflow that you want to convert to a user-defined node:
   a) Right-click the subflow to display the menu.
   b) Click **Convert to User-defined Node**.
      The **Convert to User-defined Node** wizard opens.
   c) Enter the details for the remainder of the fields as required.
   d) Click **Finish**.
3. Decide on the location of your user-defined node in the palette.
   See "Choosing the location of a user-defined node in the palette" on page 2430.

Creating the user interface representation of a user-defined node in the IBM App Connect Enterprise Toolkit

When you are developing a user-defined node in Java or C only, you must create the user interface representation of the node in the IBM App Connect Enterprise Toolkit.

Before you begin

- Perform the steps in "Creating a user-defined node" on page 2383.

About this task

The following topics describe the steps that you must complete:

1. "Creating a user-defined node project" on page 2421
2. "Creating a user-defined node in the IBM App Connect Enterprise Toolkit" on page 2422

What to do next

When you have created the IBM App Connect Enterprise Toolkit representation, test your user-defined node, see "Testing a user-defined node" on page 2430.

Creating a user-defined node project

When you create user-defined nodes, you must first create a user-defined node project to contain the nodes and their supporting files.

About this task

To create a new project for your user-defined node, complete the following steps:

Procedure

1. Click **File** > **New** > **User-defined Node Project**.

   The **New User-defined Node Project** wizard starts.
2. Either select an existing category, or select **Create a new category** and specify the name of a new category for the nodes that you are creating.

   Your user-defined nodes are displayed in the palette in the Message Flow editor under the category you specify for the project.
3. Specify a name for your project.
4. Specify a name for your plug-in identifier. To be consistent with the supplied nodes, and to avoid conflict with the names of node projects that are supplied by other independent software vendors, use your Internet domain name for your organization as part of the name and plug-in identifier. For example, the name and plug-in identifier must be of the form *com.xyz.nodegroup*, where *com.xyz* is the company Internet domain name.

   You can save any number of nodes in a single project.
5. Accept all default values and click **Finish**.

Results

A project folder that contains all the supporting files that are required for your user-defined node is shown in the Application Development view under Independent Resources.

What to do next

Create the user-defined node plug-ins, see "Creating a user-defined node in the IBM App Connect Enterprise Toolkit" on page 2422.

Creating a user-defined node in the IBM App Connect Enterprise Toolkit

Create the representation of a user-defined node created in Java and C only, in the IBM App Connect Enterprise Toolkit.

Before you begin

Complete the following task: "Creating a user-defined node project" on page 2421.

About this task

To create the visual representation of your user-defined node in the IBM App Connect Enterprise Toolkit, complete the following tasks:

1. "Creating the user-defined node plug-in files" on page 2422
2. "Defining the node properties" on page 2423
3. Optional: "Adding help to the node" on page 2427
4. Optional: "Creating node icons" on page 2428
5. Optional: "Adding a property editor or compiler" on page 2428

When you have created the representation of the node, you cannot move it to another folder.

Creating the user-defined node plug-in files

Create the files that contain the message processing logic, for user-defined nodes created in Java and C only.

Before you begin

Complete the task following task: "Creating a user-defined node project" on page 2421.

About this task

Procedure

1. Launch the wizard by clicking **File** > **New** > **User-defined Node**.

   The **New User-defined Node** window opens.
2. Select the parent folder for the node from the list of names that are displayed.

   This folder is the project that you created to contain this node.
3. Specify a schema for this node.

   You must not use the default schema or any other common schema, such as `mqsi`.
4. Specify a name for the node.

   The name must be the name of the node, excluding the `Node` at the end.

   For example, if you have created a node called `BasicNode`, the node name must be `Basic`.
5. Click **Finish**.

   A `.msgnode` file for the new node is created and is added to the project in the Application Development view. The `.msgnode` file is opened in the **Message Node** editor.

What to do next

When you have completed this task, define the node properties, see "Defining the node properties" on page 2423.

Defining the node properties

Define the properties for a user-defined node created in Java or C only, and add input and output terminals so that you can connect it to other nodes in a message flow.

Before you begin

Complete the following tasks:

1. "Creating a user-defined node project" on page 2421
2. "Creating the user-defined node plug-in files" on page 2422

About this task

When you complete the task described in "Creating the user-defined node plug-in files" on page 2422, a `.msgnode` file is created for the new node, and is opened in the **Message Node** editor of the Integration Development perspective. You can now add terminals and properties to the node.

Adding terminals to the node

Procedure

1. If the **Terminals** page is not already displayed, click the **Terminals** tab at the bottom of the **Message Node** editor.
2. Click **Add** to the right of the **In Terminals** or **Out Terminals** fields to add an input or output terminal.

   You must define at least one input terminal, but output terminals are optional.
3. To rename a terminal, click the terminal name so that it is highlighted and shows a flashing cursor after the name, and enter a new name.
4. If your node supports dynamic input or output terminals, select the appropriate check box.

   Dynamic terminals are terminals that you can add to certain nodes after you have added them to a message flow in the **Message Flow** editor. For more information, see "Message flow node terminals" on page 497.

Procedure

1. Click the **Properties** tab at the bottom of the **Message Node** editor.

   On the **Properties** page, you can set the properties for the node, for example, a database name, a host server name, or a password. The properties that you set here must match the properties that you specified in the user-defined node itself by using the `get` and `set` methods.
2. If the node is an input node, click the node name in the hierarchy to highlight it, and select **Input node**. Select **Use integration node default values** if you want the node to initialize with the default values for the integration node.
3. By default, all properties are grouped under the Basic group. You can add new groups in which to place properties. When your custom node is selected in the IBM App Connect Enterprise Toolkit, each group of properties is rendered as a separate tab in the **Properties** view. To create additional groups of properties, click **Add Property Group**  .
4. To add a simple property, click the name of a property group in the hierarchy to highlight it, and click **Add Simple Property** 

   The new property is added to the hierarchy as a child of the property group. Its name is highlighted so that you can change it. A number of fields are displayed in the **Details** section, where you can configure the property.

   a) Select the correct attribute type: one of the built-in types, or a type to match the list of values that the property can have.

   b) Enter any default values, which are shown in the **Properties** view when the node is included in a message flow.

   c) Optional: If you want to use a custom property compiler, in the **Custom Compiler Class** field, click **Import** and select the class you want to use for your custom compiler. The class must implement the IRuntimePropertyCompiler interface. For more information, see "Adding a property editor or compiler" on page 2428.

   d) Optional: If you want to use a custom property editor, in the **Custom Editor Class** field, click **Import** and select the class you want to use for your custom editor. The class must implement the IPropertyEditor interface. For more information, see "Adding a property editor or compiler" on page 2428.

   e) Specify the system property for each attribute that you define:

   Hidden
   The property is not displayed in the **Properties** view or the **Promote Property** dialog box.

   Read only
   The property is displayed, but cannot be changed.

   Mandatory
   A value is required. The field cannot be left blank. Boolean and enum properties are always mandatory.

   Configurable
   The property can be configured at deployment time
5. To add a table property, select the name of a property group in the **Properties** view and click **Add Table Property**  .

   In addition to simple properties, a node can also have complex properties. A table property represents a repeating property of a complex type. The new property is added to the hierarchy as a child of the

property group. A number of fields are displayed in the **Details** section where you can configure the table property.

6. To add a column to an existing table, select the name of the table property in the hierarchy, and click **Add Simple Property**  .

   For example, the following figure shows the Property Hierarchy of the usernode, where Filter and Route columns have been added.

   A number of fields are displayed in the **Details** section where you can configure the properties of the column. Define table columns, where each column is assigned to a type.

   a) Select the correct attribute type in the **Type** field: one of the built-in types, or enumeration.

   b) Enter the default value, in the **Default Value** field. This value is shown in the **Properties** view when the node is included in a message flow.

   c) Specify a qualified class name in the **Custom Compiler Class** field for a property compiler. To create a custom compiler, use the IRuntimePropertyCompiler interface.

      For more information about custom property editors and property compilers, see “Adding a property editor or compiler” on page 2428.

   d) Specify a qualified class name in the **Custom Editor Class** field to generate a custom property editor. The property editor specified in this field implements the IColumnPropertyEditor interface responsible for cell editing behavior. Leaving the **Custom Editor Class** field blank means that a

property editor matching-column type is used. Specify your own IColumnPropertyEditor only if you need custom cell editing behavior.

e) Specify the following attributes for each column that you define:

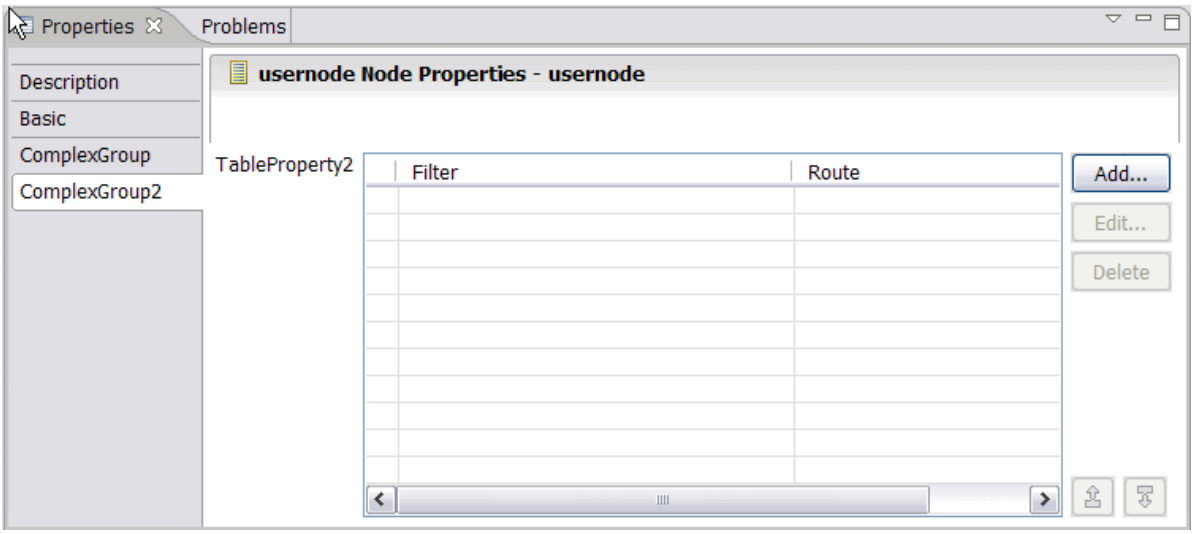
Hidden
Use a hidden column when you want to store, for each row, metadata that is not being displayed.

Read only
The column is displayed, but cannot be changed.

Mandatory
A value is required. The field cannot be left blank. Boolean and enum properties are always mandatory.

Leave the **Custom Editor Class** field of the Details section of a table property blank, unless you want to overwrite the behavior of the entire table. For example, if the table becomes disabled in response to a change in another property editor.

The following figure shows how the Table properties are rendered as a table in the **Properties** view, where you can add, edit, and delete values, and change the order of the values in the table.



7. Optional: Drag the properties in the properties hierarchy to change the order in which they are listed on the properties page.
8. Close the *nodename*`.msgnode` file.
9. Optional: You can customize the text that is displayed in the node properties view for each property.
   To set the text, open the *nodename*`.properties` file and edit the line:

```
Property.propertyName = your descriptive text
```

What to do next

The following tasks are optional:

- “Adding help to the node” on page 2427
- “Creating node icons” on page 2428
- “Adding a property editor or compiler” on page 2428

You can now test your node, see “Testing a user-defined node” on page 2430.

Adding help to the node
Add help information by adding an HTML file to the message flow node that you have created.

Before you begin

Complete the following tasks:

1. “Creating a user-defined node project” on page 2421
2. “Creating the user-defined node plug-in files” on page 2422
3. “Defining the node properties” on page 2423

About this task

Add help information for the message flow node that you have created to explain why and when to use the node, and how it must be configured:

- Topic information that is displayed in the product documentation
- Context-sensitive help that is displayed when you press F1
- Hover help that is displayed when you hold the mouse pointer over the node

All three forms of help are optional; you can create any one or more of the three resources described in the following section.

Procedure

1. Create a `help.html` file in the project to contain the online help that explains what the node does and how you can use it.

   If you have several files, create a separate doc subdirectory in the plug-in project, and store the online help files in that directory.

   You can make the online help for the node look like it is integrated with the product-supplied product documentation, under the leaf node called "User-defined nodes", which you can find in **Reference** > **Message flow development** > **User-defined extensions** > **User-defined nodes**. To make the online help for your node show at that point:

   a) Modify the `plugin.xml` file to include the following extension point to the product documentation:

   ```
   <extension point="org.eclipse.help.toc">
   <toc file="toc.xml"/>
   </extension>
   ```

   b) Create a `toc.xml` file in your user-defined node project, and modify the `link_to` attribute to link to the "UDNodes" anchor that is already defined in the information center contents views:

   ```
   <toc label="My Plugin Node" topic="my_node.htm"
    link_to="../com.ibm.etools.mft.doc/toc.xml#UDNodes">
   <topic label="Mytopic 1" href="topic1.htm>
   </toc>
   ```

   Your help topic is now displayed in the contents views under **Reference** > **Message flow development** > **User-defined extensions** > **User-defined nodes**.

   The sample nodes that are provided with the product demonstrate this option.

   For further explanation of extension points and how to use them, see the PDE guide at Eclipse documentation.

2. Add context sensitive (F1) help to the node. Context-sensitive help is displayed when you click a node in the Integration Development perspective and press F1.

   When a node is created, a `HelpContexts.xml` file is created. This file assigns a context identifier based on the name of the node. Modify the `HelpContexts.xml` file for your node by changing the text in the description field. The name of the `HelpContexts.xml` file must be unique within the

project, but can contain multiple context entries; for example, if you have several nodes within a single project, each node can have its context-sensitive help in the file.

Context-sensitive help is limited in length. A useful way of providing more help to the user is to link from the F1 help to an HTML file that contains further information; for example, to the online help for the node, described previously. Use the following code for the link:

```
<topic href"../plug-in directory/html file" label="Link title">
```

3. Add hover help (known as ToolTip help on Windows) to the node. When you create a user-defined node, a `palette.properties` file is created. Modify this file to contain the hover help for your node, which shows the node name when the palette is not wide enough to display it all.

What to do next

You can add another optional feature, a node icon or a property editor or compiler, or you can test your node, see “Creating node icons” on page 2428, “Adding a property editor or compiler” on page 2428, and “Testing a user-defined node” on page 2430.

Creating node icons
Create the icons that are displayed in the IBM App Connect Enterprise Toolkit when your user-defined node is present.

Before you begin

You must complete the following tasks:

1. “Creating a user-defined node project” on page 2421
2. “Creating the user-defined node plug-in files” on page 2422
3. “Defining the node properties” on page 2423

About this task

You can choose the icon when you create your user-defined node, or you can use the Palette editor to change the icon, see “Choosing the location of a user-defined node in the palette” on page 2430.

What to do next

You can add help, a property editor or compiler, or you can test your node, see “Adding help to the node” on page 2427 or “Adding a property editor or compiler” on page 2428, and “Testing a user-defined node” on page 2430.

Adding a property editor or compiler
Create a property editor by using the IPropertyEditor interface to control how the properties of your user-defined node created in Java or C only, are displayed in the IBM App Connect Enterprise Toolkit. Create a custom compiler by using the IRuntimePropertyCompiler interface; for example, to encrypt a value before sending it to the server.

Before you begin

You must complete the following tasks:

1. “Creating a user-defined node project” on page 2421
2. “Creating the user-defined node plug-in files” on page 2422
3. “Defining the node properties” on page 2423

About this task

The IPropertyEditor interface is used as the basis for all the node property editors in the IBM App Connect Enterprise Toolkit. You can customize the property editor to contain different kinds of controls, such as

text fields and lists. See the IPropertyEditor and IRuntimePropertyCompiler interfaces in the Property editor API.

If you create a custom compiler for your user-defined node, you must install both the compiled runtime files and the user-defined node plug-ins on the integration node to which you want to deploy the node; see "Packaging and distributing user-defined extensions" on page 2449.

If you create a message flow or a subflow that includes a user-defined node and your user-defined node has a custom compiler, be aware of the following information about adding your flow to a BAR file:

- If you want to add your flow to a BAR file as a `.msgflow` file or a `.subflow` file, you must ensure that your custom compiler code implements the IRuntimePropertyCompiler interface. Custom property compilers in versions of WebSphere Message Broker earlier than Version 8.0 use the IPropertyCompiler interface.
- If you want to add your flow to a BAR file as a `.cmf` file, you can continue to use custom compiler code that implements the IPropertyCompiler interface.

For more information about how to add files to a BAR file, see "Adding resources to a BAR file" on page 2470.

Creating a Java class

About this task

To create a Java class for your property editor or compiler, complete the following steps.

Procedure

1. Switch to the Java perspective.
2. Right-click your user-defined node project and click **New** > **Class**. If **Class** is not shown, click **Other**, select **Class** and click **Next**.
3. Type a name for your class in the **Name** field.
4. Complete the following steps, according to whether you are creating a property editor or a property compiler:
   - If you are creating a property editor:

   a) Delete any text in the **Superclass** text field, and click **Browse**.

   b) In the **Choose a type** field, type `AbstractPropertyEditor` and click **OK**.
   AbstractPropertyEditor implements the IPropertyEditor interface.

   - If you are creating a property compiler:

   a) Click **Add** next to the **Interfaces** field.

   b) In the **Choose interfaces** field, type `IRuntimePropertyCompiler` and click **OK**.
5. Click **Finish**.

Testing your property editor or compiler

About this task

To test your property editor, see "Testing a user-defined node" on page 2430.

To test your property compiler, deploy to an integration node the flow that contains your user-defined node.

A custom property editor can use Rational Application Developer or Eclipse APIs. When you migrate to a new version of IBM App Connect Enterprise, your custom property editor might not work if the Rational Application Developer or Eclipse APIs change. Update your property editor code to comply with the changed API.

Choosing the location of a user-defined node in the palette

Use the Palette editor to edit palette-specific information for user-defined nodes, add and delete separators, and rearrange user-defined nodes in the palette.

About this task

- If you change the details for a user-defined node in the Palette editor, save the changes before you add or remove another user-defined node or the changed details will be lost.
- Do not confuse the Palette editor and Customize functions:

  Palette editor
  The Palette editor is started from the Navigator when you select a user-defined node project or the user-defined node virtual folder. The Palette editor is used to set the category, node names, and icons that you want to export so that the user can see the modified node.

  Customize action
  The Customize action is started from the palette in the Message Flow editor when you select a node. The Customize action is used to change the way that the nodes are displayed in the workspace of the current user.

Procedure

1. To open the **Palette** editor use one of the following options:
   - In the Application Development view, under the user-defined node project, select **User Defined Nodes**, click **Edit and Arrange Palette**.
   - In the Application Development view, in the **Other Resources** folder of the user-defined node project, right-click **palette.xmi**. Click **Open With** and select **Palette Editor**.
2. To edit palette-specific information:
   a) In the left side of the **Palette** editor under the Category folder, click the user-defined node that you want to edit. The details about the user-defined node are displayed in the right side of the **Palette** editor.
   b) You can change the details in the **Display Name**, **Tooltip on palette**, and **Node Icons** fields, but you cannot change the **Node Implementation** section.
   c) You can change the category by selecting the Category folder on the left side of the Palette editor, and on the right side either choose an existing category, or rename your own category.
3. To group the user-defined nodes you can add or delete a separator:
   - To add a separator in a user-defined node:
     a. In the left side of the **Palette** editor, right-click the node.
     b. Select **Add Separator Below**. A separator is added below the node in the left side of the **Palette** editor.
   - To delete a separator:
     a. In the left side of the **Palette** editor, right-click **Separator**.
     b. Click **Delete Separator**.
4. To rearrange your user-defined nodes, in the left side of the **Palette** editor either drag the node to its new position, or right-click the node and select **Move Up** or **Move Down**.

Testing a user-defined node

When you have created and installed the required resources, you can test your user-defined node.

Before you begin

Complete the following tasks:

- “Creating a user-defined extension in C” on page 2384 or “Creating a user-defined extension in Java” on page 2403
- “Creating the user interface representation of a user-defined node in the IBM App Connect Enterprise Toolkit” on page 2421
- “Installing user-defined extension runtime files on an integration node” on page 2455

This topic is for user-defined nodes created in Java and C only.

For user-defined nodes created from a subflow, see “Testing a subflow user-defined node project” on page 2433.

Procedure

Use the following steps to test your user-defined node:

1. To test these projects and resources you must launch a second IBM App Connect Enterprise Toolkit by using the following steps:
   a) Right-click the user-defined node project.
      The menu opens.
   b) Click **Run in New Workbench**.
      - If the project contains errors, you receive an error message that gives you the option to continue, or to cancel the action.
      - If the project is error-free, the **Workspace Launcher** window opens.
        i) You can choose to use a new or an existing workspace. To choose an existing workspace, click **Browse**. The second workspace opens.
        ii) You can now test by using the user-defined nodes in all error-free user-defined node projects in your first workbench.
2. Open the Message Flow editor in the second instance of the IBM App Connect Enterprise Toolkit.
   Your new nodes are displayed in the node palette.
3. Create a message flow that includes your node.
   See “Adding a message flow node” on page 618.
4. Deploy the message flow to an integration node.
   See “Deployment rules and guidelines” on page 2465.
5. Send a test message through the flow and look for the results that you expect (for example, a message put to a target queue).
   You might have to write an application to send the test message to the message flow.

6. Use the diagnostic tools that are provided to determine whether your node works, or if not, what went wrong:
   a) For a description of some common problems and their solutions.
      See “Resolving problems with user-defined extensions” on page 3017.
   b) Write entries to the Administration log from your node.
      See “Using error logging from a user-defined extension” on page 2458.
   c) Switch on user trace at debug level.
      See “Using trace” on page 3026.

      The following debug messages are generated by a user trace to help you to understand the execution of your user-defined nodes and parsers:

      - BIP2233 and BIP2234: A pair of messages traced before and after a user-defined extension implementation function is started. These messages report the input parameters and the returned value.

        In these messages, an "implementation function" can be interpreted as either a C implementation function or a Java implementation method.
      - BIP3904: A message traced before starting the Java `evaluate()` method of a user-defined node.
      - BIP3905: A message traced before starting the C `cniEvaluate()` implementation function (iFpEvaluate member of CNI_VFT) of a user-defined node.
      - BIP4142: A debug message that is traced when starting a user-defined node utility function, where the utility function alters the state of a syntax element. All utility functions that start with `cniSetElement*`, where * represents all nodes with that stem, are included.
      - BIP4144 and BIP4145: A pair of messages traced by certain implementation functions that, when started by a user-defined extension, can modify the internal state of an object in the integration node. Possible integration node objects include syntax element, node, and parser.

        In these messages, an "implementation function" can be interpreted as either a C implementation function or a Java implementation method.
      - BIP4146: A debug message that is traced when starting a user-defined parser utility function, where the utility function alters the state of a syntax element. All utility functions that start with `cpiSetElement*`, where * represents all nodes with that stem, are included.
      - BIP4147: An error message that is traced when a user-defined extension passes an invalid input object to a user-defined extension utility API function.
      - BIP4148: An error message that is traced when a user-defined extension damages an object in an integration node.
      - BIP4149: An error message that is traced when a user-defined extension passes an invalid input data pointer to a user-defined extension utility API function.
      - BIP4150: An error message that is traced when a user-defined extension passes invalid input data to a user-defined extension utility API function.
      - BIP4151: A debug message that is traced when `cniGetAttribute2` or `cniGetAttributeName2` sets the return code to an unexpected value. Expected values are

CCI_SUCCESS, CCI_ATTRIBUTE_UNKNOWN, and CCI_BUFFER_TOO_SMALL. Any other value is an unexpected value.

- BIP4152: A debug message that is traced in the following situations:

  i) `cniGetAttribute2` or `cniGetAttributeName2` sets the return code to CCI_BUFFER_TOO_SMALL.

  ii) `cniGetAttribute2` or `cniGetAttributeName2` is called again with the correct size buffer, however the return code is set to CCI_BUFFER_TOO_SMALL.

d) Add a Trace node to your message flow, and check the output that is generated.

e) Use the flow debugger to debug the flow that contains your node.

See "Testing and troubleshooting message flows" on page 647.

What to do next

When your node behavior is complete and correct, add the new node into your normal palette of nodes in the **Message Flow** editor, see "Packaging and distributing a user-defined node project" on page 2452. Until you complete this task, the new nodes are available only in your test IBM App Connect Enterprise Toolkit session on your local system.

Testing a subflow user-defined node project
Test how the user-defined node is displayed, and how it behaves in your environment.

About this task

You can test how the user-defined node is displayed, and how it behaves in your environment by simulating the node. The user-defined node is displayed in the palette in the **Message Flow** editor, and any change to the plug-in during the simulation is effective immediately; you are not required to restart the simulation.

- To start the simulation of a user-defined node:

  1. Right-click the user-defined node project, click **Start Simulation**. This action adds all the user-defined nodes that are in the project to the palette in the **Message Flow** editor under the category that you defined for the project.
  2. You can drag these nodes from the palette onto the **Message Flow** editor canvas in the same way as the built-in nodes.

- To stop the simulation of a user-defined node:

  1. Right-click the user-defined node project, click **Stop Simulation**.
  2. If any message flows are using the user-defined node, an error is generated because the node is no longer available, and the following message is displayed:

     ```
     User-defined nodes that are contributed by the user-defined node
     project Varname will be removed from the Message Flow editor palette.
     If a copy of these nodes is not available from the plug-in space,
     any message flows that use these nodes might get unresolved node
     errors.
     ```

- If you are using custom editors, compilers, or Java code, these resources cannot be tested in simulation mode. To test and debug these projects and resources you must launch a second IBM App Connect Enterprise Toolkit by using the following steps:
  1. Right-click the user-defined node project. The menu opens.
  2. Click **Run in New Workbench**.
     - If the project contains errors, you receive an error message that gives you the option to continue, or to cancel the action.
     - If the project is error-free, the **Workspace Launcher** window opens.
       a. You can choose to use a new or an existing workspace. To choose an existing workspace, click **Browse**. The second workspace opens.
       b. You can now test and debug by using the user-defined nodes in all error-free user-defined node projects in your first workbench.
- In previous versions of the IBM App Connect Enterprise Toolkit, you were able to use launch configurations to test custom editors, compilers, or Java code. However, launch configurations are not supported with user-defined nodes that are created from a subflow. To test custom editors, compilers, and Java code with user-defined nodes that are created from a subflow, right-click the user-defined node project and click **Run in New Workbench**.

Debugging the message flow in simulation mode
Compile, deploy, test, and debug the message flow that includes your user-defined node.

About this task

You can compile, deploy, test, and debug the message flow that includes your user-defined node in the same way that you test any regular subflow. However, you must set a breakpoint so that the debugger stops at that point, see "Working with breakpoints in the flow debugger" on page 669.

You can debug the message flow only if the following constraints are met:

- The user-defined node project must be in the workspace.
- The user-defined node project must be in the simulation mode.
- The subflow cannot be debugged after it has been exported as a plug-in, unless the source code is in your workspace.

Developing user-defined parsers

Create a user-defined parser to interpret messages with a different format and structure.

Before you begin

Read the following topics:

- "Why use a user-defined extension?" on page 2322
- "User-defined parsers" on page 2345

About this task

A loadable implementation library, or a *LIL*, is the implementation module for a C parser (or node). A LIL is a Linux or UNIX shared object or Windows dynamic link library (DLL), that does not have the file extension `.dll` but `.lil`.

The implementation functions that you must write are listed in C parser implementation functions. The utility functions that are provided by IBM App Connect Enterprise to help you are listed in C parser utility functions.

IBM App Connect Enterprise provides the source for a sample user-defined parser called BipSampPluginParser.c. This example is a simple pseudo-XML parser that you can use in its current state, or you can modify.

The task of writing a parser varies considerably according to the complexity of the bit stream to be parsed. Only the basic steps are described here:

1. “Declaring and defining the parser” on page 2435
2. “Creating an instance of the parser” on page 2436
3. “Deleting an instance of the parser” on page 2437

Declaring and defining the parser

About this task

To declare and define a user-defined parser to the integration node, you must include an initialization function, `bipGetParserFactory`, in your LIL. The following steps outline how the integration node calls your initialization function and how your initialization function declares and defines the user-defined parser:

The following procedure shows you how to declare and define your parser to the integration node:

Procedure

1. The initialization function, `bipGetParserFactory`, is called by the integration node after the LIL has been loaded and initialized by the operating system. The integration node calls this function to understand what your LIL is able to do, and how it must be called. For example:

```
CciFactory LilFactoryExportPrefix * LilFactoryExportSuffix
bipGetParserFactory()
```

2. The `bipGetParserFactory` function calls the utility function `cpiCreateParserFactory`. This function passes back a unique factory name (or group name) for all the parsers that your LIL supports. Every factory name (or group name) passed back must be unique throughout all the LILs in the integration node.
3. The LIL calls the utility function `cpiDefineParserClass` to pass the unique name of each parser, and a virtual function table of the addresses of the implementation functions.

   For example, the following code declares and defines a single parser called InputxParser:

```
{
 CciFactory* factoryObject;
 int rc = 0;
 CciChar factoryName[] = L"MyParserFactory";
 CCI_EXCEPTION_ST exception_st;

 /* Create the Parser Factory for this parser */
 factoryObject = cpiCreateParserFactory(0, factoryName);
 if (factoryObject == CCI_NULL_ADDR) {

  /* Any local error handling can go here */
 }
 else {
  /* Define the parsers supported by this factory */
  static CNI_VFT vftable = {CNI_VFT_DEFAULT};

 /* Setup function table with pointers to parser implementation functions */
 vftable.iFpCreateContext            = cpiCreateContext;
 vftable.iFpParseBufferEncoded       = cpiParseBufferEncoded;
 vftable.iFpParseFirstChild          = cpiParseFirstChild;
 vftable.iFpParseLastChild           = cpiParseLastChild;
 vftable.iFpParsePreviousSibling     = cpiParsePreviousSibling;
 vftable.iFpParseNextSibling         = cpiParseNextSibling;
 vftable.iFpWriteBufferEncoded       = cpiWriteBufferEncoded;
 vftable.iFpDeleteContext            = cpiDeleteContext;
 vftable.iFpSetElementValue          = cpiSetElementValue;
 vftable.iFpElementValue             = cpiElementValue;
 vftable.iFpNextParserClassName      = cpiNextParserClassName;
```

```
 vftable.iFpSetNextParserClassName   = cpiSetNextParserClassName;
 vftable.iFpNextParserEncoding       = cpiNextParserEncoding;
 vftable.iFpNextParserCodedCharSetId = cpiNextParserCodedCharSetId;

 cpiDefineParserClass(0, factoryObject, L"InputxParser", &vftable);
 }

 /* Return address of this factory object to the integration node */
 return(factoryObject);
}
```

The initialization function must create a parser factory by starting `cpiCreateParserFactory`. The parser classes supported by the factory are defined by calling `cpiDefineParserClass`. The address of the factory object (returned by `cpiCreateParserFactory`) must be returned to the integration node as the return value from the initialization function.

For example:

a. Create the parser factory using the `cpiCreateParserFactory` function:

```
   factoryObject = cpiCreateParserFactory(&rc, constParserFactory);
```

b. Define the classes of message supported by the factory using the `cpiDefineParserClass` function:

```
if (factoryObject) {
   cpiDefineParserClass(&rc, factoryObject, constPXML, &vftable);
  }
else {
    /* Error: Unable to create parser factory */
  }
```

c. Return the address of this factory object to the integration node:

```
  return(factoryObject);
}
```

Creating an instance of the parser

About this task

When the integration node has received the table of function pointers, it calls the function `cpiCreateContext` for each instantiation of the user-defined parser. If you have three message flows that use your user-defined parser, your `cpiCreateContext` function is called for each of them. This function allocates memory for that instantiation of the user-defined parser to hold the values for the configured attributes. For example:

Procedure

1. Call the `cpiCreateContext` function:

```
CciContext* _createContext(
  CciFactory* factoryObject,
  CciChar*    parserName,
  CciNode*    parserObject
){
  static char* functionName = (char *)"_createContext()";
  PARSER_CONTEXT_ST* p;
  CciChar          buffer[256];
```

2. Allocate a pointer to the local context and clear the context area:

```
  p = (PARSER_CONTEXT_ST *)malloc(sizeof(PARSER_CONTEXT_ST));

  if (p) {
     memset(p, 0, sizeof(PARSER_CONTEXT_ST));
```

3. Save the parser object pointer in the context:

```
   p->parserObject = parserObject;
```

4. Save the parser name:

```
 CciCharNCpy((CciChar*)&p->parserName, parserName, MAX_NODE_NAME_LEN);
```

5. Return the parser context:

```
return (CciContext*) p;
```

Deleting an instance of the parser

About this task

Parsers are destroyed when a message flow is deleted or redeployed, or when the integration server process is stopped (using the **mqsistop** command). When a parser is destroyed, it must free any used memory and release any held resources using the `cpiDeleteContext` function. For example:

```
void cpiDeleteContext(
  CciParser*  parser,
  CciContext* context
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc = 0;

  return;
}
```

Extending the capability of a C user-defined parser

When you have created a C parser, you can extend its capability.

Before you begin

Ensure that you have read and understood the following topic:

- “Developing user-defined parsers” on page 2434

About this task

You can extend the capability of a C parser in the following ways:

- “Implementing the parser functionality” on page 2437
- “Implementing input functions” on page 2438
- “Implementing parse functions” on page 2439
- “Implementing output functions” on page 2439
- “Implementing a message header parser” on page 2440

Implementing the parser functionality

About this task

A parser needs to implement the following types of implementation function:

1. Input functions
2. Parse functions
3. Output functions

Implementing input functions

About this task

Your parser must implement one, and only one, of the following input functions:

- cpiParseBuffer
- cpiParseBufferEncoded
- cpiParseBufferFormatted

The integration node invokes the *input* function when your user-defined parser is required to parse an input message. The parser must tell the integration node how much of the input bitstream buffer that it claims to own. In the case of a fixed-size header, the parser claims the size of the header. If the parser is intended to handle the whole message, it claims the remainder of the buffer.

For example:

1. The integration node invokes the `cpiParseBufferEncoded` input function:

```
int cpiParseBufferEncoded(
  CciParser*  parser,
  CciContext* context,
  int         encoding,
  int         ccsid
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc;
```

2. Get a pointer to the message buffer and set the offset using the `cpiBufferPointer` utility function:

```
  pc->iBuffer = (void *)cpiBufferPointer(&rc, parser);
  pc->iIndex = 0;
```

3. Save the format of the buffer:

```
  pc->iEncoding = encoding;
  pc->iCcsid = ccsid;
```

4. Save the size of the buffer using the `cpiBufferSize` utility function:

```
  pc->iSize = cpiBufferSize(&rc, parser);
```

5. Prime the first byte in the stream using the `cpiBufferByte` utility function:

```
  pc->iCurrentCharacter = cpiBufferByte(&rc, parser, pc->iIndex);
```

6. Set the current element to the root element using the `cpiRootElement` utility function:

```
  pc->iCurrentElement = cpiRootElement(&rc, parser);
```

7. Reset the flag to ensure parsing is reset correctly:

```
  pc->iInTag = 0;
```

8. Claim ownership of the remainder of the buffer:

```
  return(pc->iSize);
}
```

Implementing parse functions

About this task

General parse functions (for example, **cpiParseFirstChild**) are those invoked by the integration node when the syntax element tree needs to be created in order to evaluate an ESQL or Java expression. For example, a Filter node uses an ESQL field reference in an ESQL expression. This field reference must be resolved in order to evaluate the expression. Your parser's general parse function is called, perhaps repeatedly, until the requested element is either created, or is known by the parser not to exist.

For example:

```
void cpiParseFirstChild(
  CciParser*  parser,
  CciContext* context,
  CciElement* element
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc;

  if ((!cpiElementCompleteNext(&rc, element)) &&
      (cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_NAME)) {

    while ((!cpiElementCompleteNext(&rc, element))     &&
           (!cpiFirstChild(&rc, element)) &&
           (pc->iCurrentElement))
    {
      pc->iCurrentElement = parseNextItem(parser, context, pc->iCurrentElement);
    }
  }
  return;
}
```

Implementing output functions

About this task

Your parser must implement one, and only one, of the following output functions:

- cpiWriteBuffer
- cpiWriteBufferEncoded
- cpiWriteBufferFormatted

The integration node invokes the *output* function when your user-defined parser is required to serialize a syntax element tree to an output bit stream. For example, a Compute node might have created a tree in the domain of your user-defined parser. When a node, such as an MQOutput node, needs to serialize this tree, the parser is responsible for appending the output bitstream buffer with data that represents the tree that has been built.

For example:

```
int cpiWriteBufferEncoded(
  CciParser*  parser,
  CciContext* context,
  int         encoding,
  int         ccsid
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                initialSize = 0;
  int                rc = 0;
  const void* a;
  CciByte b;

  initialSize = cpiBufferSize(&rc, parser);
  a = cpiBufferPointer(&rc, parser);
  b = cpiBufferByte(&rc, parser, 0);

  cpiAppendToBuffer(&rc, parser, (char *)"Some test data", 14);

  return cpiBufferSize(0, parser) - initialSize;
```

```
}
```

Implementing a message header parser

About this task

Typically, the incoming message data is of a single message format, therefore one parser is responsible for parsing the entire contents of the message. The class name of the parser that is needed is defined in the `Format` field in the MQMD or the MQRFH2 header of the input message.

However, the message might consist of multiple formats, for example where there is a header in one format followed by data in another format. In this case, the first parser has to identify the class name of the parser that is responsible for the next format in the chain, and so on. In a user-defined parser, the implementation function `cpiNextParserClassName` is invoked by the integration node when it navigates down a chain of parser classes for a message that is composed of multiple message formats.

If your user-defined parser supports parsing a message format that is part of a multiple message format, the user-defined parser *must* implement the `cpiNextParserClassName` function.

For example:

1. Call the **`cpiNextParserClassName`** function:

```
void cpiNextParserClassName(
  CciParser*  parser,
  CciContext* context,
  CciChar*    buffer,
  int         size
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc = 0;
```

2. Copy the name of the next parser class to the integration node:

```
  CciCharNCpy(buffer, pc->iNextParserClassName, size);

  return;
}
```

Compiling a C user-defined extension

Compile user-defined extensions in C for all supported operating systems.

Before you begin

If you create your own user-defined nodes, parsers, and user exits in C, compile them on the operating system on which the target integration node is running. Samples are provided for both nodes and parsers, and are described in Sample node files and Sample parser files. Use the instructions here to compile the samples. If you want to create your own extensions, see the following topics:

- “Creating a user-defined extension in C” on page 2384
- “Developing user-defined parsers” on page 2434
- “Developing user-defined exits” on page 2443

About this task

These instructions use the file names of the supplied samples. If you are compiling your own user-defined extensions, substitute your own file names.

When you compile a user-defined extension that is written in C, you need a compatible compiler. For details of supported compilers, see IBM App Connect Enterprise system requirements.

Header files

About this task

The following header files define the C interfaces:

BipCni.h
Message processing nodes

BipCpi.h
Message parsers

BipCci.h
Interfaces common to both nodes and parsers

BipCos.h
Platform-specific definitions

Compiling

About this task

Compile the source for your user-defined extension on each of the supported operating systems to create the executable file that the integration node calls to implement your user-defined extension. On Linux and AIX and systems, this file is a loadable implementation library (LIL) file; on Windows systems, it is a dynamic load library (DLL) file.

The libraries that you build to contain user-defined nodes or parsers must have the extension `.lil` on all operating systems so that the integration node can load them. Libraries that contain user exits must have the extension `.lel` on all operating systems. The examples in this topic show libraries with the extension `.lil`

All extensions must be compiled as 64-bit libraries.

Refer to the documentation for the compiler that you are using for full details of available compile and link options that might be required for your programs.

Navigate to the directory where your user-defined extension source code is located, and follow the instructions for your operating system:

- AIX
- Linux
- Windows

Compiling on AIX

About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

The following instructions are for compiling an extension:

```
xlc_r -q64 \
   -I. \
   -I/install_dir/server/include/plugin \
   -c SwitchNode.c \
   -o SwitchNode.o

xlc_r -q64 \
   -I. \
   -I/install_dir/server/include/plugin \
   -c TransformNode.c \
   -o TransformNode.o

xlc_r -q64 \
   -I. \
   -I/install_dir/server/include/plugin \
```

```
   -c BipSampPluginUtil.c \
   -o BipSampPluginUtil.o

xlc_r -q64 \
   -I. \
   -I/install_dir/server/include/plugin \
   -c Common.c \
   -o Common.o

xlc_r -q64 \
   -I. \
   -I/install_dir/server/include/plugin \
   -c NodeFactory.c \
   -o NodeFactory.o

xlc_r -q64 \
      -qmkshrobj \
      -bM:SRE \
      -bexpall \
      -bnoentry \
      -o SwitchNode.lil SwitchNode.o \
         BipSampPluginUtil.o Common.o NodeFactory.o \
      -L /install_dir/server/lib \
      -l imbdfplg

chmod a+r SwitchNode.lil
```

Compiling on Linux

About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

When you compile programs on Linux on POWER, replace the option `-fpic` with `-fPIC` if you want to use dynamic linking and avoid any limit on the size of the global offset table.

The following instructions are for compiling an extension on Linux on x86-64, Linux on POWER, and Linux on Z. To compile the extension for Linux on POWER, include the **-02** parameter in the compile and link examples, and include the **-fexceptions** parameter in the compile examples.

```
g++ -c -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/server/include \
   -I/install_dir/server/include/plugin \
   -DLINUX -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   TransformNode.c

g++ -c -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/server/include \
   -I/install_dir/server/include/plugin \
   -DLINUX -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   SwitchNode.c

g++ -c -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/server/include \
   -I/install_dir/server/include/plugin \
   -DLINUX -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   BipSampPluginUtil.c

g++ -c -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/server/include \
   -I/install_dir/server/include/plugin \
   -DLINUX  -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   Common.c

g++ -c -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/server/include \
   -I/install_dir/server/include/plugin \
   -DLINUX -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   NodeFactory.c

g++ -m64 -o samples.lil \
```

```
   TransformNode.o \
   SwitchNode.o \
   BipSampPluginUtil.o \
   Common.o NodeFactory.o \
   -shared -lc -lnsl -ldl \
   -L/install_dir/server/lib -limbdfplg
```

These commands create the file `samples.lil` that provides TransformNode and SwitchNode objects.

Compiling on Windows

About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

Ensure that you include a space between `SwitchNode.c` and `BipSampPluginUtil.c`, and also between `-link` and `/DLL`.

Enter the command as a single line of input; in the following example the lines are split to improve readability.

```
cl /VERBOSE /LD /MD /Zi /EHsc /I.
   /Iinstall_dir\server\include\plugin
   SwitchNode.c BipSampPluginUtil.c Common.c
   NodeFactory.c TransformNode.c
   -link /DLL install_dir\server\lib\imbdfplg.lib
   /OUT:SwitchNode.lil
```

If you have correctly set the *LIB* environment variable, you do not have to specify the full paths to the LIB files.

Developing user-defined exits

You can develop and deploy a user-defined exit.

Before you begin

- Read "User exits" on page 2349.

About this task

The following topics describe the steps required to develop and deploy a user-defined exit.

Procedure

1. "Developing a user exit" on page 2443
2. "Deploying a user exit" on page 2444
3. "Transaction tracking user exit sample" on page 2446

Developing a user exit

You can develop a user exit by declaring it, implementing its behavior, and then compiling it.

About this task

A user exit is user-provided custom software, which is written in C, which can be used to track data that passes through message flows. For an example of how you might implement a user exit, see "Transaction tracking user exit sample" on page 2446.

Procedure

To develop a user exit, complete the following steps:

1. Declare the user exit.

   Declare a user exit by using the `bipInitializeUserExits` function to specify the following properties:

   a) Name (used to register and control the active state of the exit)

   b) User context storage

   c) A function to be invoked (for one or more Event Types)

2. Implement the user exit behavior.

   When the user exit is declared, a set of functions is registered, and these functions are invoked when specific events occur. The behavior of the user exit is provided by implementing these functions. The following table lists the events and their associated functions:

Event	Function
A message is dequeued from the input source.	`cciInputMessageCallback`
A message is propagated to the node for processing.	`cciPropagatedMessageCallback`
A request message is sent to the output node's transport, and transport-specific destination information is written to "WrittenDestination" in the LocalEnvironment.	`cciOutputMessageCallback`
The node completes processing.	`cciNodeCompletionCallback`
The transaction ends	`cciTransactionEventCallback`

3. Your user exit code must implement the cleanup function.

   The user exit library must implement the `bipTerminateUserExits` function. This function is invoked as the integration server's process is ending, and your user exit must clear up any resources that are allocated during the `bipInitializeUserExits` function.

4. Compile.

   Use your existing process for your environment to compile your user exit. See “Compiling a C user-defined extension” on page 2400 for more details.

   For more information about supported C compilers, see IBM App Connect Enterprise system requirements.

5. Link the compiled code to a library with the extension `.lel` that exports the `bipInitializeUserExits` and `bipTerminateUserExits` functions.

What to do next

Deploy the user exit by following the instructions in “Deploying a user exit” on page 2444.

Deploying a user exit

Deploy your user exit to the integration node.

Before you begin

- Write and compile the user exit code. See “Developing a user exit” on page 2443.
- Ensure that the exit:

  1. Is in a library that has the extension `.lel`
  2. Exports the functions `bipInitializeUserExits` and `bipTerminateUserExits`

About this task

You can set the state of the user exit dynamically to active, or inactive, on a per-message flow basis without restarting the integration node.

You can set the state of the user exit dynamically to active, or inactive, for an independent integration server or an integration server that is managed by an integration node. You do not have to restart the integration node.

You can set the state of the user exit dynamically to active, or inactive, for an integration node. You must start the integration node.

To deploy the user exit:

Procedure

1. Install the user exit code on an integration node.

   The library that contains the user exit code must be installed on a file system that can be accessed by the integration node. For example, the file must have read and execute authority for the user ID under which the integration node runs. The integration node looks in the following places for libraries that contain user exits:

   - The `userExitPath` property of the integration node.

     The integration node property `userExitPath` defines a list of directories that are separated by colons (semicolons on Windows). You can set this property by using one of the following methods:

     – Set the `userExitPath` property when you create a new integration node, use the `-x` flag on the **mqsicreatebroker** command.

     – Set the `userExitPath` property for an existing integration node, use the `-x` flag on the **mqsichangeflowuserexits** command.

     – Set the `userExitPath` property for an existing integration node by modifying the entry in the `node.conf.yaml` file for the integration node.

   - The environment variable *MQSI_USER_EXIT_PATH*.

     Append the directory that contains extension files to the environment variable *MQSI_USER_EXIT_PATH* associated with the environment in which the integration node is running.

   If the `userExitPath` property and the environment variable *MQSI_USER_EXIT_PATH* are both set, the environment variable takes precedence. All the directories in the environment variable are searched in the order in which they appear in the variable. Then, all the directories in the integration node property are searched in the order in which they appear in the property.

2. Load the user exit library into the integration node's processes.

   When the user exit library is installed on the integration node, you must load it in one of the following ways:

   - Stop and restart the integration node.
   - Run the **mqsireload** command to restart the integration server processes.

3. Activate the user exit.

   User exits can be active or inactive, and are inactive by default. You can change the state of a user exit dynamically by updating the node.conf.yaml file, or by using the **mqsichangeflowuserexits** command. You must restart the integration node.

   To set the default user exit state for an integration node:

   a) Stop the integration node.

   b) Set the `--active-user-exit-list` property of the integration node by using one of the following methods:

      - Modify the `activeUserExitList` property in the `node.conf.yaml` file.
      - Use the `-x` flag on the **mqsichangeflowuserexits** command.

   c) Start the integration node and check the system log to ensure that all integration servers start without error.

      If you specify any user exit names that are not provided by any library that is loaded by the integration server, a BIP2314 message is written to the system log. All flows that are in the integration servers fail to start.

   d) Optional: If a BIP2314 message is written to the system log and the flows in the integration servers fail to start, take one of the following actions:

      - Provide a library in the user exit path that implements the exit. Then, run the **mqsireload** command, or restart the integration node, to load an exit from the library.
      - Run the **mqsichangeflowuserexits** command to remove the exit from both the active and inactive lists.

   You can also override the default user exit state for an integration node. You can use the **mqsichangeflowuserexits** command to activate, or deactivate, user exits on a per-integration node, per-integration server, or per-message flow basis. The order of precedence is message flow then integration server, then integration node. When multiple exits are active for a flow, the integration node starts them in the order that is defined by the **mqsichangeflowuserexits** command.

Transaction tracking user exit sample

The AceSpanTraceExample user exit sample demonstrates how you can use a user exit to capture flow context information, which could then be used to implement a simple span trace for message flows that contain HTTP, Kafka, or MQ transport nodes.

A span trace can be used to track transactions across multiple components, so that you can see how the transactions have been routed through the components. This approach typically passes a span identifier from one component to another, through transport headers, to allow the transaction to be correlated; this enables you to see a broader view of the transactions than you could see if you used a separate trace for each individual component.

If you run an integration server with this sample user exit enabled, an MQ queue on the integration server's default queue manager (`AceSpanTraceExample`) is used to write a span summary message each time a flow with an MQ, Kafka, or HTTP transport input node processes a message. The user exit reads or writes a span identifier when the flow inputs or outputs an MQ, Kafka, or HTTP message.

The AceSpanTraceExample sample is in the *`install_dir`*`\sample\extensions\userexits\transports` directory, and the loadable exit library is called `AceSpanTraceExample.lel`.

The AceSpanTraceExample is a C++ implementation that uses the App Connect Enterprise interface defined through the MqsiTransportUserExitBase class, which uses C user exit callbacks to show how a message flow span trace might be implemented. The logic of the exit is implemented in the `AceSpanTraceExample.hpp/cpp`.

The sample implements the following transport-specific callback functions, which are invoked by IBM App Connect Enterprise when HTTP, Kafka, and MQ transport nodes process messages:

- `onTransportInputMessage`

  This callback informs the user exit that an MQInput, HTTPInput, SOAPInput, HTTPAsyncResponse, SOAPAsyncResponse, or KafkaConsumer node has received a message, and signals the start of a message flow processing span. The callback provides the message flow and node context and any requested headers, such as MQ MQRFH2 header fields, HTTP headers, or Kafka properties.

- `beforeTransportOutputMessage`

  This callback informs the user exit that an MQOutput, HTTPRequest, HTTPAsyncRequest, SOAPRequest, SOAPAsyncRequest, RESTRequest, RESTAsyncRequest, or KafkaProducer node is about to emit a message. This callback allows the user exit to set any required headers in the output message, such as MQ MQRFH2 header fields, HTTP headers, or Kafka properties.

- `afterTransportOutputMessage`

  This callback informs the user exit that an MQOutput, HTTPRequest, HTTPAsyncRequest, SOAPRequest, SOAPAsyncRequest, RESTRequest, RESTAsyncRequest, or KafkaProducer node has emitted a message. This callback allows the user exit to receive details of the message emitted and its destination, such as MQ `MQMD.msgid`.

- `onTransportResponseMessage`

  This callback informs the user exit that an HTTPRequest, SOAPRequest, or RESTRequest node has received a response message. The callback provides the message flow and node context and any requested headers.

- `beforeTransportGetMessage`

  This callback informs the user exit that an MQGet or KafkaRead node is about to start a read operation to attempt to get a message.

- `onTransportGetMessage`

  This callback informs the user exit that an MQGet or KafkaRead node has received a message. The callback allows the user exit to obtain required headers from the received message, such as MQ MQRFH2 header fields or Kafka properties.

- `onTransportTransactionComplete`

  This callback informs the user exit that a message flow processing span, which started at an `onTransportInputMessage`, is complete. The callback allows the user exit to access the completion status and any last exception code.

For more information, see the functional description in the `AceSpanTraceExample.hpp` header file.

Note: The following class files, which are in the `Base` subfolder, must **not** be modified:

- MqsiTransportUserExitBase
- MqsiUserExitWrapper

If the transaction tracking exit is enabled for a message flow that includes any of the following message flow nodes, and the output terminal of these nodes has multiple direct connections to downstream message flow nodes (rather than using a FlowOrder node), the `onTransportResponseMessage` or `onTransportGetMessage` callback is invoked each time a message is propagated to the directly connected output connections:

- HTTPRequest
- RESTRequest
- SOAPRequest
- MQGet
- KafkaRead

If you need to include multiple downstream connection branches in the message flow, use a FlowOrder node to control the order in which the connection branches are invoked.

The sample source code is also precompiled into the loadable exit library, `AceSpanTraceExample.lel`, which can be used by the integration server if it is specified in the `UserExits` section of the integration server's `server.conf.yaml` file:

```
UserExits:
  activeUserExitList: 'AceSpanTraceExample'
  userExitPath: '<path>'
```

The user exit path defines the directory or set of directories that the integration server's exit manager inspects to see whether there are any loadable exit library files.

When an integration server starts and finds the sample loadable exit library, it calls its `onStartServer` function and passes context information including the name of the integration server and the version at which the integration server is running, and also allows the sample to register the name of a span trace example. If that name matches an entry in the `activeUserExitList`, the transport-specific callback functions in this library are invoked by the integration server when messages are processed by the message flows.

The `onStartServer` callback in this example also provides a data structure of transports for which it should be called (either HTTP, Kafka, or MQ) and field names and locations that the functions in the user exit library will be passed (on an input message) or set (on an output message).

The exit callbacks in the sample are called from message flow nodes that interact with the MQ, Kafka, or HTTP transport. All these transports receive message flow context information including server name, application name, library name, message flow name, and message flow node name and type. Additionally, they are passed data from fields as defined in the example data structure table. For example, the following table defines the data structure for HTTP:

Table 77. Example data structure for HTTP

Transport	**Location**	**Field name**
HTTP	HTTPHeader	traceparent
HTTP	HTTPHeader	tracestate
HTTP	HTTPHeader	x-remote-addr

With the data structures defined in this table, the transport-specific callback functions implemented in the sample carry out the following processing:

- The `onTransportInputMessage` receives any headers that are found in the input, such as `traceparent`, `tracestate`, and `x-remote-addr`. It sets a new value for `traceparent` and then saves the values in the environment, which can then be accessed from other message flow nodes that are involved in the trace.

  For example, you could have a message flow containing an HTTPInput node, and the `onStartServer` function has registered the data structure and specified that it should be called for HTTP transport messages. When the HTTPInput node receives a message, it checks to see whether it needs to invoke the user exit, based on the information in the transport section. If it does need to invoke the user exit, it performs a lookup in the message assembly to extract the values that are available, then calls the `onTransportInputMessage` function that is implemented in the user exit library. In addition to the data structure, it also passes some flow context information, such as the name of the integration server, the application, the message flow name, the message flow node name and type, and the transport type of the message flow node that has called this user exit.

  The sample implements this user exit interface. The sample receives the headers and sets a new value for `traceparent` (`traceParent = TraceStartedinACE`), which appears in the span context. The sample also sets a value for the `AceTrace` environment variable by using `setEnvironmentValue(`*`name`*`)`, which provides an audit trail of the nodes that have called the user exit.

- The `beforeTransportOutputMessage` function retrieves the value of `traceparent` from the environment by using `getEnvironmentValue(name)`, and appends the name of the current message flow node to the `AceTrace` environment variable. The outbound HTTPOutputHeader is then set (`traceparent=traceparent+"flow-context"`) and the returned values are updated into the output message header.

  For example, you could have an HTTPRequest node that is about to send an output message. The transport type has been checked, and it has been determined that the callback function in the user exit library needs to be invoked. The data that is relevant to the HTTP transport is passed over, and the message flow exit is invoked with the flow context information. The sample then appends the information about the current message flow (such as the message flow name, application name, and message flow node name) into the `AceTrace` environment variable, which is recording the audit trail of nodes that have caused the user exit to be invoked. The sample also retrieves the `traceparent` that was set by the HTTPInput node, and concatenates that with the flow context information. The HTTPRequest node has now been added onto the end of the `traceparent` in the environment, which was previously set by the HTTPInput node. The information in the data structure is updated into the message assembly and set into the outbound HTTP header.
- The `onTransportResponseMessage` allows the user exit to record the arrival of a response message from an HTTP request.
- The `beforeTransportGetMessage` signals that a mid-flow Get or Read message flow node is about to start a get or read operation on the transport.
- The `onTransportGetMessage` signals that a mid-flow Get or Read message flow node has received a message from a transport and provides trace data from it.
- The `onTransportTransactionComplete` message is used by the user exit to complete the span trace and issue a summary message to an MQ queue on the integration server's default queue manager (`AceSpanTraceExample`).
- The `afterTransportOutputMessage` retrieves information from the transport relating to the message that has been transmitted. For HTTP, this would include the HTTP `RequestURL`.

Packaging and distributing user-defined extensions

When you have created and tested a user-defined extension, you can package and distribute it.

Before you begin

Complete the following tasks:

- “Developing user-defined extensions” on page 2321
- “Testing a user-defined node” on page 2430

About this task

When you have created and tested your user-defined extension, you can distribute these resources to other computers.

For user-defined extensions created in Java or C:

1. Package and install the user-defined extensions. To package and install the resources that make up the workbench representation of your user-defined node, see “Packaging and distributing a user-defined node project” on page 2452.
2. Copy the files generated by the compilation step to all the computers on which you have created integration nodes that might need these resources. If you have created a user-defined node in Java or C that uses a custom property compiler, you must also install the user-defined node project on integration nodes to which you want to deploy the node. See “Installing user-defined extension runtime files on an integration node” on page 2455. For a more automated approach, see Installing a user-defined extension to current and past versions of.

For user-defined nodes created from subflows:

- Package and install the user-defined nodes implemented as a subflow, see "Packaging and distributing a user-defined node project" on page 2452.

Packaging a Java user-defined node

How to package a Java user-defined node.

Before you begin

You must have a user-defined node written in Java. This node can be one of the provided sample nodes that are described in Sample node files, or a node that you have created yourself by using the instructions in either "Creating a message processing or output node in Java" on page 2409 or "Creating an input node in Java" on page 2403.

About this task

You can package a user-defined node in two ways:

- **PAR**

  A Plug-in Archive (PAR) is the deployment unit for Java user-defined nodes. The PAR contains the user-defined node classes and, if required as dependencies, can contain JAR files. A PAR file is a compressed file with a `.par` file extension. The directory structure in the `.par` file has the following format:

  - `/classes`

    The user-defined node classes are stored in this location.

  - `/lib`

    JAR files that are required by the user-defined node are stored in this location. This directory is optional because it might not be necessary to include JAR files.

  The following procedure describes how to package an example user-defined node, *parexamplenode*. In this example, the PAR is to be contained in *par.example.parexamplenode.class* with a JAR file dependency *dependency.jar*.

  1. Create the directory structure; for example:
     - `/classes/par/example/parexamplenode.class`
     - `/lib/dep.jar`
  2. Issue a file compression command to create the PAR; for example:

     ```
     jar cvf parexample.par classes lib
     ```

  The PAR must be placed in the LIL path that is specified in "Installing user-defined extension runtime files on an integration node" on page 2455.

- **JAR**

  User-defined nodes can be packaged by using a simple JAR. For example, if your node is defined in `example/jarexamplenode.class`, create the JAR by using the `jar cvf jarexample.jar example` command.

  The preferred way to package a Java user-defined node is to use a PAR file, because all dependencies can be packaged with the node, and each node is loaded in a separate class loader. For information about loading classes, see "User-defined node class loading" on page 2451.

  The JAR must be placed in the LIL path that is specified in "Installing user-defined extension runtime files on an integration node" on page 2455.

Deployment dependencies

About this task

If a user-defined node requires an external package, the package can be deployed in one of following ways:

- The external packages can be added to the `/lib` directory in the deployed PAR.
- For external packages that are shared between several node types, the packages can be added to one of the following locations:
  - One of the `shared-classes` directories. For more details of these directories, see "Java shared classloader" on page 1752.
  - The CLASSPATH environment variable, where all user-defined nodes that are in the integration node installation can access the packages

User-defined node class loading

Details the Java classes packaging options and loading order precedence for user-defined nodes.

Java user-defined node classes can be packaged and loaded in two ways:

- Plug-in Archive (PAR) file; an integration node defined format - Each PAR file is given it's own class loader which isolates any classes it loads from any other part of the IBM App Connect Enterprise, including nodes in other PAR files.
- Standard Java archive (JAR) file - All JAR files containing plug-in nodes are loaded into the same classloader and can access classes in JAR files containing other user-defined nodes.

For both packaging mechanisms, if the classloader cannot find a required class within the package it defers to the shared class loader to find the required class. The shared classloader looks in a set of directories on the integration node machine and loads any JAR files found. It can be used to install any required JAR files that do not need to be repeatedly deployed, such as client libraries that the Java compute nodes need to use. For more details, see "Java shared classloader" on page 1752.

If the required class cannot be found in any of the deployed JAR files, or in the JAR files installed in the shared classes directories, a classloader containing all of the integration node supplied classes is checked (for example: this classloader contains the `jplugin2.jar`), followed by the classpath, and then finally the Java virtual machine (JVM) system classloader.

Two key points must be considered when deciding which of the above mechanisms are used to load a class:

- Isolation between different applications (for example: adding classes to the classpath makes them available to every part of IBM App Connect Enterprise and can cause conflicts).
- Delegation from one classloader to another can only occur in one direction. If a class is resolved in the shared classloader, then it cannot directly create classes in the PAR classloader.

User-defined nodes class loading search paths

User-defined nodes package in a PAR file

The integration node uses the following search path to find user-defined node classes:

1. `/classes` to locate classes in the deployed PAR file.
2. `/lib` to locate any JAR files in the deployed PAR file.
3. *workpath*`/config/`*<my_int_node_name>*`/`*<my_int_server_label>*`/shared-classes` to locate any JAR files in the integration server `shared-classes` directory.
4. *workpath*`/config/`*<my_int_node_name>*`/shared-classes` to locate any JAR files in the integration node `shared-classes` directory.
5. *workpath*`/shared-classes/` to locate any JAR files in the top level `shared-classes` directory.
6. CLASSPATH environment variable.

User-defined nodes package in a JAR file

The integration node uses the following search path to find user-defined node classes:

1. The deployed JAR file.
2. *workpath*/config/*<my_int_node_name>*/*<my_int_server_label>*/shared-classes to locate any JAR files in the integration server shared-classes directory.
3. *workpath*/config/*<my_int_node_name>*/shared-classes to locate any JAR files in the integration node shared-classes directory.
4. *workpath*/shared-classes/ to locate any JAR files in the top level shared-classes directory.

Packaging and distributing a user-defined node project

Export the user-defined node project to make it available for other users.

About this task

To export the user-defined node project, you can package the user-defined node project as plug-in JAR files or as an update site:

- "Packaging as plug-in JAR files" on page 2452
- "Packaging as an update site" on page 2453

What to do next

You can now install the plug-in on all the computers on which your IBM App Connect Enterprise Toolkit users might want to use them, following the instructions in "Installing a user-defined node" on page 620.

If you have created a user-defined node in Java or C that uses a custom property compiler, you must also install the user-defined node plug-in on the integration nodes or independent integration servers onto which you want to deploy the user-defined node; see the following topics:

- "Installing user-defined extension runtime files on an integration server" on page 2456
- "Installing user-defined extension runtime files on an integration node" on page 2455

Packaging as plug-in JAR files

Export the user-defined node project as plug-in JAR files to make it available for other users.

About this task

If you use this option, the user-defined node user must copy the user-defined node plug-ins into the plug-ins folder in the IBM App Connect Enterprise Toolkit. However, the user-defined node user can write a script to automate the copying process, so that the user-defined nodes are deployed automatically.

To package your user-defined node projects so that they are available in the environment of the user, complete the following tasks:

Procedure

1. Right-click the project that you want to package, select **Package**.
   The **Package and Distribute User-Defined Nodes** wizard opens.
2. Select **Plug-in jars**. Click **Next**.
3. Select the plug-ins and fragments that you want to use.
   Projects upon which the subflow user-defined node depends, such as message set projects, are automatically included and are not shown in the list.
4. Navigate through the wizard, completing the fields as required. Click **Finish**.

Packaging as an update site

Create an installation site for Web page distribution of the user-defined node projects that includes or references other projects or plug-ins. You can either create a new update site, or use an existing one.

About this task

To package your user-defined node projects so that they are available in the environment of the user, complete the following tasks:

Procedure

1. Right-click the project that you want to package, select **Package**.
   The **Package and Distribute User-Defined Nodes** wizard opens.
2. Select **Installation package**.
   You can either create a new installation site or use an existing installation site in the workspace.
   - To create a new installation site:
     a. Select **Create a new package**, and in the **Create a new package** field, enter a name for the package. If a project with that name exists in the workspace, you are asked if you want to delete the project so that you can continue with packaging.
     b. Click **Next**.
     c. Optional: Select any projects and plug-ins that you want to include in your package:
        i) The top section shows the user-defined node projects that are available in your workspace. Select the projects that you want to include in your package.
        ii) The bottom section shows all the Eclipse plug-ins that the selected user-defined node projects require. IBM App Connect Enterprise Toolkit built-in plug-ins that have a plug-in identifier that starts with `com.ibm.etools.mft` are not shown. The Eclipse plug-ins that are required are a combination of the following plug-ins:
           – All Eclipse plug-ins that are listed as the dependency plug-ins in the plug-in manifest for the user-defined node project
           – All Eclipse plug-ins that contributed user-defined nodes that are being used by one of your selected user-defined node projects
        iii) Click **Next**.
     d. Optional: Further customize your user-defined node package by adding in any detailed information that you want to include. Click **Next**.
     e. Click **Finish**. When you click **Finish**, the selected user-defined node project and its dependent user-defined node projects in the workspace are packaged into an Eclipse feature, and an Eclipse Update Site is built. The Eclipse feature and Eclipse update site project use the name that you have given to the package appended with `.feature` or `.site`. Any space in the package name is replaced by a dot (.).
     f. The **Distribution** window opens. To save the instructions to the clipboard, click **Save the instruction above to clip board**.
     g. To select a destination for your user-defined node package, in the "**Web distribution**" section, click **Copy project *Your project name*.** . The "**Copy package**" window opens. Select the location, click **OK**.
   - To use an existing installation site you must have already created an installation site.
     a. Select **Update user-defined nodes in an existing package**, select an installation site from the list. Click **Finish**. When you click **Finish**, the selected user-defined node project and its dependent user-defined node projects in the workspace are packaged into an Eclipse feature, and an Eclipse Update Site is built. The Eclipse feature and Eclipse update site project use the

name that you have given to the package appended with `.feature` or `.site`. Any space in the package name is replaced by a dot (.).

b. The **Distribution** window opens. To save the instructions to the clipboard, click **Save the instruction above to clip board**.

c. To select a destination for your user-defined node package, in the "**Web distribution**" section, click **Copy project *Your project name*.** . The "**Copy package**" window opens. Select the location, click **OK**.

Installing from an update site

If you have packaged your user-defined nodes into an update site, use the software update mechanism to install the user-defined nodes.

About this task

To install your user-defined nodes from an update site, use the following steps:

Procedure

1. Click **Help** > **Software Updates**.
   The **Software Updates and Add-ons** window opens.
2. Click the **Available Software** tab.
   A list of available sites is displayed. If the update site that you want to use is not listed, click **Add Site**. The **Add Site** window opens. Select the location that you want to use, click **OK**.
3. In the **Available Software** tab, select the site that you want to use, click **Install**.

Updating and uninstalling from an update site

You can update, uninstall, or revert the configuration of any user-defined node plug-ins that have been previously installed from an update site.

About this task

To update, uninstall, or revert the configuration of any user-defined node plug-ins, complete the following steps:

Procedure

1. Click **Help** > **Software Updates**.
   The **Software Updates and Add-ons** window opens.
2. Click the **Installed Software** tab.
3. Select the previously installed user-defined node plug-in.
4. Click **Update**, **Uninstall**, or **Revert Configuration** depending on the action you want to perform.

Installing user-defined extension runtime files on an integration node

Install the compiled runtime files for your user-defined extension on the integration node on which you want to test its function. If your user-defined node uses a custom compiler, install the user-defined node plug-in to the integration node on which you want to deploy the node.

Before you begin

- Create and compile your user-defined extension using the procedure described in "Compiling a Java user-defined node" on page 2418 or "Compiling a C user-defined extension" on page 2400.
  - The files that have been created for extension created in C depend on the underlying integration node operating system:

    Windows A dynamic link library (DLL), named with a file type of `.lil`.

    Linux A shared object, again with a file type of `.lil`.
  - For Java nodes, a Java Archive file (JAR), with a file type of `.jar` (on all operating systems).
- If you have created a user-defined node, you must also complete the task that is described in "Creating the user interface representation of a user-defined node in the IBM App Connect Enterprise Toolkit" on page 2421.
- If your user-defined node contains a custom compiler, you must package your user-defined node project; see "Packaging and distributing a user-defined node project" on page 2452.

About this task

This task instructs you to stop and restart integration nodes. This action is required in all but the two circumstances described in step "4" on page 2455 later in this section, although if you do stop and restart the integration node, you can ensure that anyone with an interest in a particular integration server is made aware that recent changes have been made.

This task is applicable to user-defined nodes written in Java or C only. If your user-defined node contains a custom compiler, you must install the compiled runtime files and the user-defined node plug-in to the integration node. If your user-defined node does not contain a custom compiler, install only the compiled runtime files to the integration node.

To install runtime and user-defined node plug-in files on the integration node:

Procedure

1. Stop the integration node on which you want to install your compiled or packaged user-defined extension file (files with extension `.lil`, `.jar`, `.par`, `.pdb`, or `.lel`)
2. Create a directory if you do not already have one for this purpose. Add the directory to the LILPATH: set LILPATH=<directory>

   CAUTION: Do not put the `.lil`, `.jar`, `.par`, `.pdb`, or `.lel` files in the IBM App Connect Enterprise installation directory, because they might be overwritten by the integration node.
3. Put your user-defined file in the directory, and make sure that the integration node has access to it.

   For example, on Linux use the **chmod 755*** command on the file. If your user-defined node contains a custom compiler, put your user-defined plug-in file in the same directory.
4. Stop and restart the integration node to implement the change and to ensure that the existence of the new file is detected.

   An integration node restart is not necessary in the following circumstances:

   - If you have created an integration server in the IBM App Connect Enterprise Toolkit, and nothing is yet deployed to it, you can add the `.lil`, `.pdb`, `.jar`, `.par`, or `.lel` file to your selected directory.
   - If something has already been deployed to the integration server that you want to use, add the `.lil`, `.pdb`, `.jar`, `.par`, or `.lel` file to your selected directory, and issue the **mqsireload** command to

restart the group. You cannot overwrite an existing file on the Windows system when the integration node is running, because of the file lock that is put in place by the operating system.

Use these two approaches with care, because any integration server that is connected to the same integration node also detects the new `.lil`, `.pdb`, `.jar`, `.par`, or `.lel` files when that integration server restarts, or when something is first deployed to that integration server.

5. Repeat the previous steps for every integration node that needs the user-defined extension file and user-defined node plug-in file. If all of your integration nodes are on the same operating system type, you can build the user-defined extension file once and distribute it to each of your systems.

   If you have a cluster that includes Linux and Windows integration nodes, you must build the user-defined extension files separately on each operating system type.

   Windows On Windows, the `.pdb` file provides symbolic information that is used when stack diagnostic information is displayed in the event of access violations or other software malfunctions.
6. For C user-defined extensions, store the `.pdb` file in the same directory as the `.lil` file to which it corresponds.
7. Use the **`mqsicreatebroker`** command, to specify to the integration node the directory that contains the user-defined extension file.

   When you have installed a user-defined extension, it is referred to by its schema and name, just like a message flow.

Results

The integration node loads the user-defined extension files during initialization. After loading the files, the integration node calls the registration functions in the user-defined extension and records what nodes or parsers the user-defined extension supports.

A C user-defined extension implements a node or parser factory that can support multiple nodes or parser types. For more information, see "Node and parser factory behavior" on page 2327. Java users are not required to write a node factory.

Installing user-defined extension runtime files on an integration server

Install the compiled runtime files for your user-defined extension on the integration server on which you want to test its function. If your user-defined node uses a custom compiler, install the user-defined node plug-in to the integration server on which you want to deploy the node.

Before you begin

- Create and compile your user-defined extension using the procedure described in "Compiling a Java user-defined node" on page 2418 or "Compiling a C user-defined extension" on page 2400.
  - The files that have been created for extension created in C depend on the operating system:

    Windows A dynamic link library (DLL), named with a file type of `.lil`.

    Linux A shared object, again with a file type of `.lil`.
  - For Java nodes, a Java Archive file (JAR), with a file type of `.jar` (on all operating systems).
- If you have created a user-defined node, you must also complete the task that is described in "Creating the user interface representation of a user-defined node in the IBM App Connect Enterprise Toolkit" on page 2421.
- If your user-defined node contains a custom compiler, you must package your user-defined node project; see "Packaging and distributing a user-defined node project" on page 2452.

About this task

This task instructs you to stop and restart integration servers. This action is required in all cases, although if you do stop and restart an integration server, you should ensure that anyone with an interest in a particular integration server is made aware that recent changes have been made.

This task is applicable to user-defined nodes written in Java or C only. If your user-defined node contains a custom compiler, you must install the compiled runtime files and the user-defined node plug-in to the integration server. If your user-defined node does not contain a custom compiler, install only the compiled runtime files to the integration server.

To install runtime and user-defined node plug-in files on the integration server:

Procedure

1. Stop the integration server on which you want to install your compiled or packaged user-defined extension file (files with extension `.lil`, `.jar`, `.par`, `.pdb`, or `.lel`)
   This is required in all cases, there are no exceptions.
2. Create a directory if you do not already have one for this purpose.

   For example:

   ```
   C:\Work\Development\Demo\Plugins\bin
   ```

   CAUTION: Do not put the `.lil`, `.jar`, `.par`, `.pdb`, or `.lel` files in the IBM App Connect Enterprise installation directory, because they might be overwritten.
3. Put your user-defined file in the directory, and make sure that the integration server has access to it.

   For example, on Linux use the **chmod 755*** command on the file. If your user-defined node contains a custom compiler, put your user-defined plug-in file in the same directory.
4. Restart the integration server to implement the change and to ensure that the existence of the new file is detected.
5. Repeat the previous steps for every integration server that needs the user-defined extension file and user-defined node plug-in file. If all of your integration servers are on the same operating system type, you can build the user-defined extension file once and distribute it to each of your systems.

   If you have a cluster that includes Linux and Windows integration servers, you must build the user-defined extension files separately on each operating system type.

   
   On Windows, the `.pdb` file provides symbolic information that is used when stack diagnostic information is displayed in the event of access violations or other software malfunctions.
6. For C user-defined extensions, store the `.pdb` file in the same directory as the `.lil` file to which it corresponds.
7. Add the directory to the LILPATH by updating the `server.conf.yaml` configuration file.

   For example:

   ```
   lilPath: C:\Work\Development\Demo\Plugins\bin
   ```

Results

The integration server loads the user-defined extension files during initialization. After loading the files, the integration server calls the registration functions in the user-defined extension and records what nodes or parsers the user-defined extension supports.

A C user-defined extension implements a node or parser factory that can support multiple nodes or parser types. For more information, see “Node and parser factory behavior” on page 2327. Java users are not required to write a node factory.

Updating a user-defined extension

On all systems, you can change a user-defined extension file.

About this task

You must stop and restart the integration node for your changes to show, However, you are not required to stop and restart the integration node in the following two scenarios:

- If you have created an integration server in the IBM App Connect Enterprise Toolkit, but have not yet deployed to it, you can add the `.lil`, `.pdb`, and `.jar` files to your chosen directory.
- If an object has already been deployed to the integration server that you want to use, add the `.lil`, `.pdb`, and `.jar` files to your chosen directory and use the **mqsireload** command to restart the group. You cannot overwrite an existing file on the Windows system when the integration node is running because a file lock is put in place by the operating system.

These two scenarios must be used with caution, because any integration server that is connected to the same integration node also detects the new `.lil`, `.pdb`, and `.jar` files when that integration server is restarted, or when an object is first deployed to it. If you restart the integration node, you must ensure that anyone with an interest in a particular integration server is made aware that recent changes have been made to the integration node.

These two scenarios assume that you have used the **mqsicreatebroker** command to notify the integration node of the directory in which the user-defined extension files have been placed.

Procedure

To change a user-defined extension file:

1. Stop the integration node by using the **mqsistop** command.
2. Update or overwrite the `.lil` or `.jar` file.
3. Restart the integration node by using the **mqsistart** command.

Uninstalling a user-defined extension from the integration node

Remove a user-defined extension file from the integration node.

About this task

1. Stop the integration node by using the **mqsistop** command.
2. Delete the `.lil` or `.jar` file from the directory you created when installing the user-defined extension. See “Installing user-defined extension runtime files on an integration node” on page 2455.
3. Restart the integration node by using the **mqsistart** command.

Using error logging from a user-defined extension

Program user-defined extensions to write entries in the local error log.

About this task

In most circumstances, user-defined extensions should use exceptions to report errors. However, you can provide information about significant events, error or otherwise, for problem determination and operational purposes. The details that you supply are included in predefined message text that is extracted from a message source or catalog.

- In C code, use the utility function `CciLog` or `CciLogW` to report events. Two of the arguments that you pass to this function, `messageSource` and `messageNumber`, define the event source (catalog) and the integer representation of a message within that source, respectively.

  You can also write trace information, using `CciUserTrace`, `CciUserTraceW`, `CciUserDebugTrace`, and `CciUserDebugTraceW` when tracing and debugging is active.
- In Java code, use the class `MbService`, which provides static methods to log information to the event log. To log messages to the event log, package your messages into a standard Java resource bundle. You can use one of the three logging methods, passing in the resource bundle name and the message key. The message is fully resolved, and is then inserted as a single insert into the appropriate integration node message as shown:
  - logInformation(...) - BIP4360 Java user-defined node information: *user message*
  - logWarning(...) - BIP4361 Java user-defined node warning: *user message*
  - logError(...) - BIP4362 Java user-defined node error: *user message*

You can write messages that are defined in the product message catalog (`BIPmsgs`), to which you can add your own text as an argument. If you prefer, you can create your own message catalog, so that you can create more complex messages, or share a message catalog with other applications. If you want to create your own message catalog, see "Creating message catalogs" on page 2459.

- Windows On Windows systems, messages are written to the Windows event log.
- Linux On Linux systems, messages are written to the SYSLOG facility.

The description here covers exceptions that are raised during normal message flow processing. You must also provide for exceptions that are raised when you deploy and configure a message flow. Messages that result from these configuration exceptions are reported back to the IBM App Connect Enterprise Toolkit for display to the IBM App Connect Enterprise Toolkit user. Create an appropriately-named Java properties file to contain your messages, then copy the file to each computer on which you are running the IBM App Connect Enterprise Toolkit, so that your messages can be displayed.

Creating message catalogs

Create your own message catalogs to write tailored entries to the local error log.

About this task

In some error and other situations, you might choose to write information to the error log so that you can track what is happening in a message flow. You can use the Throw and Trace built-in nodes to generate entries in the log, or you can create your own nodes and user exits, and write entries in the log from your user-defined extensions.

You can write either or both of the following sets of messages:

- A fixed set of messages that are provided in the product message catalog. This set provides a range of numbers for Throw nodes (BIP3001 to BIP3049), and a second range for Trace nodes (BIP3051 to BIP3099). A third range (BIP2951 to BIP2999) is provided for the ESQL statements LOG and THROW.

  When you use these messages, you can also provide additional text that is displayed in the message text.
- Your own messages, created in your own message catalog. You can use this additional catalog to define specialized message content, and you can include variables or inserts that are determined by the code that generates the message. You can also share your own message catalog with other applications that are not associated with IBM App Connect Enterprise.

When you throw an exception from ESQL by using a THROW statement, the ESQL code adds an extra leading insert that contains the name of the current component. The rest of the inserts that are provided by the ESQL script follow this leading insert. Therefore, you must consider this insert when you are writing your own message catalog.

The instructions in this topic describe how to create message catalogs for C programs. If you want to create a Java resource bundle, refer to the documentation for the Java 2 Platform, Standard Edition.

Read the section appropriate to your integration node operating system:

- "Building and installing a Windows message source" on page 2460
- "Creating an XPG/4 catalog for Linux, UNIX, and z/OS" on page 2461

Building and installing a Windows message source

About this task

On Windows, you must create your additional message catalog as a DLL file. The DLL file contains definitions of your event messages, which the event viewer can display in a readable format, based on the event message written by your application. When you compile a message catalog, a header file is created that defines symbolic values for each event message number you have created. You must include the header file in your application.

To create an event source for the Windows Event Log Service:

Procedure

1. Create a message compiler input (`.mc`) file with the source for your event messages.

   Refer to the Microsoft Developer Network Web site, and search on `.mc file` for details on the format of this input file.
2. Compile the message file to create a resource compiler input file:

   ```
   mc -v -w -s -h c:\mymessages -r c:\mymessages mymsg.mc
   ```

   where `c:\mymessages` is the location of the output files and *mymsg.mc* is the name of the input file.

   The message compiler produces an output header (`.h`) file that contains symbolic `#defines` that map to each message number that is coded in the input `.mc` file. Include this header file when you compile a user-defined extension source file that uses a utility function (for example, `CciLog`) to write an event message that you have defined. The `messageNumber` argument to utility function must use the appropriate value that is hash-defined in the output header file.
3. Compile the output file (`.rc`) from the message compiler to create a resource file (`.res`):

   ```
   RC /v output_file.rc
   ```
4. Create a resource DLL file from the `.res` file:

   ```
   LINK /DLL /NOENTRY resource_file.res
   ```
5. Append the location of the resource DLL file to the *MQSI_CONSOLE_NLSPATH* environment variable, for example:

   ```
   set MQSI_CONSOLE_NLSPATH=%MQSI_CONSOLE_NLSPATH%;c:\messages
   ```

   You can do this by creating a custom environment script in your working directory. The default location is `C:\ProgramData\IBM\MQSI\Common\profiles`.

6. Install the event source into the Windows Event Log Service:

   a) Start the Windows Registry Editor:

   ```
   regedit
   ```

   b) Create a new registry subkey for your user-defined extension under the existing structure:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\EventLog\Application
```

   Right-click **Application** and select **New** > **Key**. The new key is created immediately under the Application key (not under the IBM App Connect Enterprise key). You must give the key the name that you specify for the `messageSource` on a utility function in your user-defined extension (for example, `CciLog`) or as the property of the built-in node that you have included in your message flow.

   Create the following values for this entry:

   EventMessageFile
   Set the value of this string to contain the fully qualified path for the DLL file that you have created to contain your messages. This entry represents the message catalog.

   TypesSupported
   Set the DWORD value to "7".

Creating an XPG/4 catalog for Linux, UNIX, and z/OS

About this task

On Linux, UNIX, and z/OS systems, messages are written to the SYSLOG facility. If you want to use your own message catalog, you must create an XPG/4 message catalog.

The process for creating a message catalog (a `.cat` file) depends on the operating system on which you are creating it. The commands that you use are typically **gencat** (create or modify a message catalog) and **dspcat** (to display all or part of a message catalog). The **gencat** command merges text files that contain your message text, to create or modify a formatted catalog. The text files typically have a file extension of `.msg`.

You must append the location of the message catalog to the *MQSI_CONSOLE_NLSPATH* environment variable. You can use %L and %N to represent the locale and the catalog name, for example:

```
export MQSI_CONSOLE_NLSPATH=${MQSI_CONSOLE_NLSPATH}:${MY_INST_PATH}/messages/%L/%N:
${MY_INST_PATH}/messages/En_US/%N
```

In this example, the English version is hardcoded later in the search path, ensuring that messages are displayed even in locales for which no `.cat` file exists.

The messages that you define in the `.msg` files can include variables that are substituted at run time. Such variables must be of the format *{number}*, where *{number}* is the message insert number, surrounded by braces. The first message insert is numbered 0. For example:

```
1234 "MSG1234E: \
Syntax Error. \n
The value '{0}' is not valid for property '{1}'.\n
Correct it and then reissue the command.\n"
```

If you create a message catalog on one operating system, you cannot port it to another operating system because the catalogs are binary-encoded. However, you can use the same `.msg` files as input to the **gencat** command on another system.

See the relevant information in the documentation for your operating system. For example:

- AIX For AIX, see the *Commands Reference* in the product documentation.

- z/OS For z/OS, see the *UNIX System Services Command Reference* in the z/OS product documentation online.

You must also check the information about additional supported locales, if you want to use messages in locales other than US English.

Chapter 7. Deploying integration solutions

Deployment is the process of transferring the development resources for an integration solution to the runtime environment. The development resources are deployed to an integration server or to the cloud. To deploy an integration solution to a production environment, you can package your development resources into a single file for transfer to the production environment.

About this task

To develop an integration solution, you might need to create a number of resources such as message flows, subflows, message models, maps, Java code, and ESQL files.

You can store your development resources in applications or libraries. If some of your resources are used by multiple applications, you can store those resources in a static library or a shared library. To understand the difference between static libraries and shared libraries, see “Libraries” on page 1945. You can then deploy the resources by deploying the applications and libraries that contain the resources.

During the development of a solution, you can deploy the development resources directly to an integration server by using options in the IBM App Connect Enterprise Toolkit. By using this approach, you can quickly verify changes as you develop your solution; see “Deploying integration solutions during development” on page 2464.

When you are ready to deploy your solution to a production environment, you can package the resources into a BAR file. You can add applications and libraries to the BAR file. If your solution contains message flows or other resources that are in an integration project, you can add these resources individually to the BAR file. If you use policies to override the properties that are set on the message flows and message flow nodes, you also add these policies to the BAR file.

You can also include version information in your resources so that you can match the packaged or deployed resources with the resources that you maintain in a source control system.

For more information, see “Packaging integration solutions” on page 2465.

Before you deploy your solution to a production environment, you can customize the BAR file to configure the solution for any differences between the development environment and the production environment.

You can also choose to precompile the resources that the BAR file contains (such as XML schema, DFDL schema, and graphical data maps), so that they are ready to run when the integration server starts. This reduces the time that it takes for the deployed application to start processing messages. For more information, see the command.

When your BAR file is configured, you can deploy it to a production environment; see “Deploying integration solutions to a production environment” on page 2480. Your production environment could be IBM App Connect Enterprise or IBM App Connect on IBM Cloud.

When an integration solution is no longer required, you can remove the integration solution from your environment; see “Deleting deployed resources” on page 319. If you want to redeploy your solution, you must first delete the existing deployed solution and then deploy again.

You can also deploy IBM App Connect Enterprise to IBM Cloud Private, by using Helm Charts. For more information, see IBM App Connect in containers.

Deploying integration solutions during development

During development, you can deploy a solution directly to an integration server by using options in the IBM App Connect Enterprise Toolkit.

Before you begin

You must have an integration server in the IBM App Connect Enterprise Toolkit that you can deploy resources to. For more information, see "Configuring an integration server by modifying the server.conf.yaml file" on page 172.

About this task

The mode in which IBM App Connect Enterprise is running can affect the number of integration servers and message flows that you can deploy. For more information, see "Restrictions that apply in each operation mode" on page 5.

If you are developing a solution and you want to test the solution or some of the solution resources quickly, you can deploy the resources that you want to test directly to an integration server. You can deploy the following resources:

- An application or library
- A message flow that is contained in an integration project
- A subflow that is defined in a `.subflow` file and contained in an integration project
- One or more policies that are contained in a policy project

For prerequisites and guidelines that are associated with the deployment of integration solutions, see "Deployment rules and guidelines" on page 2465.

Procedure

In the IBM App Connect Enterprise Toolkit, deploy your resources by using one of the following methods:

- Use drag-and-drop:
  a) In the **Application Development** pane, select the resources that you want to deploy.
  b) Drag the resources onto an integration server in the **Integration Explorer** pane.
- Use menu options that are associated with the resource:
  a) In the **Application Development** pane, right-click the resource that you want to deploy and click **Deploy**.
  b) In the **Integration Explorer** pane, select the integration server where you want to deploy the resource and click **Finish**.

  Repeat these steps to deploy any other resources that you want to deploy.
- Use menu options that are associated with the integration server:
  a) In the **Integration Explorer** pane, right-click the integration server where you want to deploy your resources, and click **Deploy**.
  b) Select the type of resource that you want to deploy to see a list of available resources of that type that can be deployed.
  c) Select the resource that you want to deploy and click **OK**.

  Repeat these steps to deploy any other resources that you want to deploy.

Results

Your solution resources are deployed. One or more BAR files are generated automatically, and deployed to the integration server. You can find these BAR files in the **GeneratedBarFiles** folder in the Application Development view. If you deploy an application that refers to a static library, the static library is added to

the same BAR file as the application. If you deploy an application that refers to a shared library, you must first deploy the shared library; a separate BAR file is generated for the shared library.

Deployment rules and guidelines

When you deploy all or part of an integration solution to an integration server, you must adhere to a number of rules.

Check the following list for any rules or guidelines for deploying all or part of your integration solution:

- If you are deploying an application that depends on a shared library, you must deploy the shared library with the application or before you deploy the application.
- If you deploy a message flow that is contained in an application or static library, the whole application or library is deployed; you cannot deploy a message flow on its own if the message flow belongs to an application or static library. You cannot store a message flow in a shared library.
- If you deploy a message flow that contains a subflow that is defined in a `.subflow` file, you must deploy the subflow to the same integration server. You must deploy the subflow with the message flow or before you deploy the message flow.
- If you redeploy a subflow that is defined in a `.subflow` file to an integration server, any message flows that use the subflow in that integration server are stopped and restarted. When the message flows restart, they use the updated subflow.
- If you deploy an application or library to an integration server where the application or library already exists, the existing application or library and its contents are removed, before the new application or library is deployed.
- If you are deploying a message flow that uses one or more Mapping nodes, see Deploying message maps.
- If you are deploying a message flow that uses WebSphere Adapters, see “WebSphere Adapters resources” on page 2475.
- Windows If your message flows call .NET code from a .NETCompute node or from ESQL, you must distribute the assemblies to every integration server that uses these message flows. For more information, see “Deploying .NET assemblies” on page 1793.
- If your BAR file contains a mixture of resources that are compiled and resources that are not compiled, you might see unexpected results. For example, if you select the **Compile and in-line resources** option to create a BAR file that contains an ESQL file and a message flow, the ESQL is embedded in the compiled message flow (`.cmf`) file. If you then update the ESQL and add it to the BAR file with the **Compile and in-line resources** option cleared, the ESQL file is added as an individual resource, but the `.cmf` file uses the original ESQL because the original ESQL remains embedded in the `.cmf` file. To avoid confusion, select one of the following deployment options:

  1. Deploy all the resources (for example `.msgflow`, `.subflow`, and `.esql`) as source code.
  2. Deploy all the resources in the compiled form. This deployment method requires that all the subflows are implemented in `.msgflow` files. As a result, all the flow, subflow, and ESQL code is in-lined into the parent CMF file. This method does not allow the same flexibility as the source code deployment, but it does provide an unambiguous runtime behavior.

  For other limitations when using CMF files, see BAR file contents: Message flows.

Packaging integration solutions

If you package your integration solution, you can control the deployment of the solution into your production environment. You package integration solutions by adding the required resources to a BAR file.

Before you begin

Develop and test the integration solutions that you want to deploy; see Chapter 6, “Developing integration solutions,” on page 481 and “Testing and troubleshooting message flows” on page 647.

About this task

You can deploy some individual resources without packaging them manually; see “Deploying integration solutions during development” on page 2464.

However, you can deploy all your integration solution resources together if you package them in a single BAR file, then deploy the BAR file.

You can also include version information in your resources so that you can match the packaged or deployed resources with the resources that you maintain in a source control system; see “Version and keyword information for deployable resources” on page 2466.

Procedure

To package resources into a BAR file, complete the following steps:

1. Create a BAR file; see “Creating a BAR file” on page 2469.
2. Add resources to the BAR file; see “Adding resources to a BAR file” on page 2470.

What to do next

1. Optional: Prepare your packaged solution for deployment by configuring properties with the appropriate values for your production environment.
2. Deploy your BAR file to an integration server, to IBM Integration Bus on Cloud, or to IBM App Connect on IBM Cloud; see “Deploying integration solutions to a production environment” on page 2480.

Version and keyword information for deployable resources

You can add a version and other custom keyword values to deployable resources during development and then check the versions of resources that are packaged in BAR files, or deployed to an integration server.

The ability to add version information to your resources is particularly useful if you use a source control system to manage your resources. The version information that you add to your resources can be viewed when the resources are packaged into a BAR file ready for deployment, and when the resources are deployed to an integration server. You can use the version information to match the versions of the packaged or deployed resources with the versions of the resources that you store in your source control system.

For information about adding and viewing version and keyword information in your deployable resources, see the following topics:

- “Adding version information and custom keyword values to your development resources” on page 2466
- “Viewing version information and custom keyword values in your packaged solutions” on page 2468
- “Viewing version information and custom keyword values in your deployed solutions” on page 319

Adding version information and custom keyword values to your development resources

You can add a version and other custom keyword values to deployable resources during development.

About this task

Version information is assigned to a development resource by including the following string in the source code of the resource:

```
$MQSI_VERSION=VersionIdentifier MQSI$
```

For example:

```
$MQSI_VERSION=v1.0 MQSI$
```

Custom keywords are assigned to a development resource by including the following string in the source code of the resource:

```
$MQSI KeywordName=KeywordValue MQSI$
```

For example:

```
$MQSI Author=John Smith MQSI$
```

Note: Do not use BAR as a keyword name. The BAR keyword is associated with each object automatically when it is deployed and it contains the full path name of the BAR file that deployed the object.

Note: Do not use the following characters within keywords because they cause unpredictable behavior:

```
^ $ . | \ < > ? + * = & [ ] ( )
```

You can use these characters in the values that are associated with keywords; for example:

- `$MQSI RCSVER=$id$ MQSI$` is acceptable (`RCSVER` is a valid keyword name).
- `$MQSI $name=Fred MQSI$` is not acceptable (`$name` is not a valid keyword name).

The method for adding version information, custom keywords, and custom keyword values to the source code varies depending on the resource type. The following table describes a method that you can use to add version and custom keyword information to each type of resource:

Resource type	Method to add version and custom keywords
Message flows	Add the *VersionIdentifier* to the Version field in the message flow properties. Information added to the Version field does not need to be encased in `$MQSI` tags. Add custom keyword strings to the Short Description or Long Description fields in the message flow properties by using the IBM App Connect Enterprise Toolkit or the web user interface.
Subflows	Add the *VersionIdentifier* to the Version field in the subflow properties. Information added to the Version field does not need to be encased in `$MQSI` tags. Add custom keyword strings to the Short Description or Long Description fields in the subflow properties by using the IBM App Connect Enterprise Toolkit or the web user interface. **Note:** If you use `Compile and in-line resources` when you build your BAR file, you must use a different keyword in each instance of a subflow. Only the first recorded instance of each keyword within the message flow `.cmf` file is available to applications that use the IBM Integration API, which includes the IBM App Connect Enterprise Toolkit. The order that subflows appear in the `.cmf` file is not guaranteed.
Applications and Libraries	It is not possible to add version or custom keyword strings to an application or library during development. Instead, you must complete the following steps: 1. Create a `keywords.txt` file. 2. Add the version or custom keyword strings to the `keywords.txt` file. 3. Package the application or library in a BAR file. 4. Add the `keywords.txt` file to the `META-INF` directory within the `.appzip`, `.libzip`, or `.shlibzip` file that is in the BAR file.

For information about viewing version or custom keyword information in your packaged or deployed resources, see the following topics:

- "Viewing version information and custom keyword values in your packaged solutions" on page 2468
- "Viewing version information and custom keyword values in your deployed solutions" on page 319

Viewing version information and custom keyword values in your packaged solutions

You can view version and custom keyword information in your packaged resources.

About this task

If version or custom keyword information was added to your resources during development, you can view the values in a BAR file by using the following methods:

- "Viewing version information by using the BAR file editor" on page 2468
- "Viewing version and custom keyword information by using the mqsireadbar command" on page 2468

Viewing version information by using the BAR file editor

Procedure

To view the version that is associated with the resources that are packaged in a BAR file by using the BAR file editor, complete the following steps:

1. Open the BAR file in the IBM App Connect Enterprise Toolkit.

   The BAR file opens in the BAR file editor.
2. Expand the entries in the **Name** column to see all the resources in the BAR file.

Results

If any of the resources have a version, the value is displayed in the **Version** column. It is not possible to view custom keywords and values by using the BAR file editor.

Viewing version and custom keyword information by using the `mqsireadbar` command

Procedure

From the command environment (on Linux) or the IBM App Connect Enterprise Console (on Windows), type the following command:

```
mqsireadbar -b BARFileName -r
```

where *BARFileName* is the fully qualified name of your BAR file.

Results

The content of the BAR file is listed. If a resource has a version or custom keyword value, the values are listed under the resource name. For example, in the following system output, you can see that the ESQL resource has an associated version (`esql2.0`) and custom keyword and value (`Author = John Smith`).

```
BIP1052I: Reading Bar file using runtime mqsireadbar...
Error Handler Message Flowsproject.generated.bar:
  Error Handler Message Flows.appzip (12/06/15 17:46):
    Error_Handler.esql (12/06/15 17:46):
    application.descriptor (12/06/15 17:46):
    Main_Flow.msgflow (12/06/15 17:46):
    Error_Handler.subflow (12/06/15 17:46):
    Main_Flow.esql (12/06/15 17:46):
```

```
      Author = John Smith
      VERSION = esql2.0
    Deployment descriptor:
      startMode
      javaIsolation
      Error_Handler#Check Backout Count.dataSource
      Error_Handler#Check Backout Count.connectDatasourceBeforeFlowStarts
      Error_Handler#Copy Message.dataSource
...
```

What to do next

For information about adding version or custom keyword information to your development resources, or viewing version or custom keyword information in your deployed resources, see the following topics:

- "Adding version information and custom keyword values to your development resources" on page 2466
- "Viewing version information and custom keyword values in your deployed solutions" on page 319

Creating a BAR file

Create a separate BAR file for each configuration that you want to deploy.

About this task

When you are ready to deploy your solution to a production environment, you can package the resources into a BAR file. You can add applications and libraries to the BAR file. If your solution contains message flows or other resources that are in an integration project, you can add these resources individually. If you have policies that can be used to override message flow and message flow node properties at run time, you also add them to the BAR file. When you have added all the resources that are required by your solution to your bar file, you can deploy the BAR file to an integration server.

The following instructions describe how to create a BAR file.

Creating a BAR file with the IBM App Connect Enterprise Toolkit

About this task

When you create a BAR file by using the IBM App Connect Enterprise Toolkit, by default it is created in an integration project called **BARfiles**. In the Application Development view, the new BAR file is shown under the **BARfiles** integration project, in a folder called BARs. You can customize the default location of BAR files by setting a preference (**Window** > **Preferences** > **Integration Development** > **Build BAR**).

To create a BAR file by using the IBM App Connect Enterprise Toolkit, complete the following steps:

Procedure

1. Click **File** > **New** > **BAR file**.
2. Select the location for your BAR file.

   You can select an existing application, library, or integration project, or you can create a new integration project by clicking **New**.
3. Enter a name for the BAR file that you are creating.
4. Click **Finish**.

Results

A file with a `.bar` extension is created and is displayed under the application, library, or integration project, in a folder called BARs. The BAR File editor opens. All BAR files are also shown in a separate category in the Application Development view called BARs. Each BAR file that is listed here displays information about the project in which the BAR file is stored.

What to do next

Add files to the BAR file by following the instructions in "Adding resources to a BAR file" on page 2470.

Adding resources to a BAR file

To deploy a group of related resources to an integration server, include them in a BAR file.

Before you begin

Create a BAR file for each configuration that you want to deploy. For more information, see "Creating a BAR file" on page 2469.

About this task

You can add any deployable resources from the workspace to a BAR file. If you select **Add workspace project source files**, the source and project files for all message flows, message model schema files, message sets, or other deployable resources in the BAR file are included. If you do not add the source and project files to the BAR file, make sure that you keep a copy of the source and project files because you cannot regenerate the development resources from the compiled resources that are in the BAR file. If you add the source and project files to the BAR file, make sure that you keep a copy of the BAR file because you cannot regenerate the BAR file or from the deployed resources on an integration server.

For more information about the files that you can include in a BAR file, see "BAR file contents" on page 2472.

To add files to a BAR file by using the IBM App Connect Enterprise Toolkit, complete the following steps.

Procedure

1. Open the BAR file by double-clicking it.

   The contents of the BAR file are shown in the BAR File editor. (If the BAR file is new, this view is empty.)
2. On the **Prepare** tab of the BAR File editor, select deployable workspace resources to add to the BAR file:

   - Click **Applications, shared libraries, services, and REST APIs** to see a list of these resources that can be deployed. If you select an application, shared library, or service, all the contained resources are deployed with that container.
   - Click **Policies** to see a list of policy projects that can be deployed. You can add multiple policy projects to the BAR file. Properties that are set in these policies override the properties that are set on deployed message flows, message flow nodes, and the integration server at run time.
   - Click **Message flows, static libraries, and other message flow dependencies** to see the individual resources that you can deploy directly to the integration server. After these resources are deployed, they are visible to all other deployed resources in the same integration server.

   Note:

   - If an application refers to a shared library, that library must be deployed before or with the application. A shared library can be deployed in the same BAR file as an application that refers to it, or the application and referenced shared library can be deployed in separate BAR files.
   - If an application that you select refers to one or more static libraries, those libraries are added to the application `.appzip` file as nested `.libzip` files. These referenced static libraries are private and are not accessible to resources outside the application. Therefore, those static libraries are not selected on the **Prepare** tab by default. However, if you want to deploy a static library as an integration server-level library, which is accessible to other resources, select the static library to

deploy it separately. A `.libzip` file is created for that static library and added to the BAR file at root level.

- If you select a static library that refers to other static libraries, those referenced libraries are also added to the BAR file as `.libzip` files.
- If the application that you select refers to one or more .NET application domains, those application domains are added to the BAR file at root level as a `.appdomainzip` file.
- You cannot add an integration project to a BAR file. Instead, add the individual resources that are contained in the integration project to the BAR file.
- If your solution contains Java code or message sets, you must compile these resources and add the compiled resources to the BAR file; see "Packaging resources that include Java code or message sets" on page 2474.
- If a message flow that you select contains one or more WebSphere Adapters nodes, a dialog box opens so that you can identify the following resources:
  - One or more WebSphere Adapters components to be used by the WebSphere Adapters nodes.
  - One or more libraries that contain an XSD for the business objects that are used by the WebSphere Adapters nodes

  For more information about including WebSphere Adapters in a BAR file, see "Including WebSphere Adapters resources in a BAR file" on page 2475.

3. Optional: To include source files, select **Add workspace project source files**.

   If you select **Add workspace project source files**, source projects for all applications, libraries, and other compiled resources are added to the `src` folder of the BAR file.
4. Optional: To remove existing content from the BAR file before you build the new BAR file, select **Remove contents of BAR before building**.
5. Optional: If you are adding a message flow to a BAR for a second time, and used the **Manage** tab to change flow parameters, select **Override configurable property values** to reset configuration settings.

   If this control is cleared, existing settings are left in place when a flow is replaced.
6. Optional: To include message flows as compiled message flow (`.cmf`) files, and to include ESQL code directly in the `.cmf` file of each message flow that references an ESQL file, select **Compile and in-line resources**. By default, when you add a message flow to a BAR file, it is added as a `.msgflow` file. By default, each ESQL file that is referenced by one or more of your message flows is deployed as an individual resource, and can be accessed by multiple `.msgflow` files.

   If any of the flows that you add to your BAR file contain a subflow that is defined in a `.msgflow` file, you must select **Compile and in-line resources**.
7. Click **Build and Save**.

Results

The **Manage** tab lists the files that are now in your BAR file. Expand your applications and libraries to view their contents. Compiled resources in the BAR file are shown in alphabetical order in the tree. You can edit only root elements. For example, if you added an application to the BAR file, you can rename the `.appzip` file or add comments to it. You cannot edit the resources inside the `.appzip` file, but you can edit the configurable properties for those resources.

You cannot remove individual resources from `.appzip`, `.appdomainzip`, `.libzip`, or `.shlibzip` files. To remove these resources, you must remove the application, .NET application domain, or library.

You can choose not to display your source files by selecting **Built resources** or **Configurable properties** from the list in the **Filter by** menu.

What to do next

Complete one or both of the following tasks:

- Deploy the BAR file; see "Deploying integration solutions to a production environment" on page 2480.

BAR file contents

The BAR file is a compressed file to which you can add a number of deployable resources.

When you select resources to add to the BAR file, the following files are added for each resource type:

Applications

A `.appzip` file for each application.

The `.appzip` file contains all resources that belong to the application, such as `.msgflow`, `.cmf`, `.esql`, `.map`, `.xsd`, and any message set `.dictionary` and `.xsdzip` files. If an application refers to one or more libraries, `.libzip` or `.shlibzip` files for the referenced libraries are also added to the BAR file.

Static libraries

A `.libzip` file for each static library.

This file contains all resources that belong to the static library, such as `.msgflow`, `.cmf`, `.esql`, `.map`, `.xsd`, and any message set `.dictionary` and `.xsdzip` files. If a static library refers to other static libraries, `.libzip` files for the referenced libraries are also added to the BAR file.

Shared libraries

A `.shlibzip` file for each shared library.

This file contains all resources that belong to the shared library, such as `.cmf`, `.esql`, `.map`, `.xsd`, and any message set `.dictionary` and `.xsdzip` files. If a shared library refers to other shared libraries, `.shlibzip` files for the referenced libraries are also added to the BAR file.

Message flows

- If you select **Compile and in-line resources** in the BAR File editor, a `.cmf` file is added to the BAR file for each message flow. This file is a compiled version of the message flow.

  The following limitations apply when you are testing compiled message flows:

  – You cannot use the Flow Exerciser with compiled message flows.

  – You cannot set debugger breakpoints on connections in compiled message flows.

  – The flow diagram that is shown in the web user interface does not match how the flow is shown in the IBM App Connect Enterprise Toolkit.

  – Monitoring events and statistics records do not match the points in the original flow diagram.

- If you do not select **Compile and in-line resources** in the BAR File editor, a `.msgflow` file is added to the BAR file for each message flow. This file contains a definition for the message flow. This file is not compiled.

You cannot add the same message flow to a BAR file as both a `.cmf` file and a `.msgflow` file. If your flow contains one of the following nodes, you cannot add the flow as a `.msgflow` file:

- A user-defined node that is created from a subflow
- A subflow node that represents a subflow that is defined in a `.msgflow` file
- A WebSphere Message Broker Version 7.0 Mapping node

Subflows

A `.subflow` file for each subflow that is contained in an integration project. This file is not compiled.

Subflows that are defined in `.msgflow` files are not displayed in the BAR file as separate items, and are added to the BAR file automatically when the BAR file is built. To include these subflows, you must add only the parent flow. Subflows that are defined in `.subflow` files are displayed in the BAR file as separate items and can be deployed as individual resources.

.NET assemblies

A `.appdomainzip` file for each AppDomain that contains .NET assemblies that are used by a message flow in the BAR file.

.NET assemblies that are required by .NETCompute nodes in message flows are added to the BAR file from your integration project automatically when you add the message flow.

Message set dictionaries
A `.dictionary` file for each message set dictionary.

DFDL, XML schema, or WSDL files
The following files are added:

- A `.xsd` file for each DFDL or XML schema file that is defined in an application or library.
- XSD compressed files (`.xsdzip`) for each XML schema and WSDL that is defined in a message set.

XML files, stylesheets, and XSLT files
XML files (`.xml`), stylesheets (`.xsl`), and XSLT files (`.xslt`), if required by nodes in the message flows that you added to this BAR file. For example, the XSLTransform node might require these files.

XML and XSL files are added to the BAR file automatically if they are required by the flow

JAR files
JAR files (`.jar`), if required by JavaCompute nodes in the message flows that you added to this BAR file.

JAR files that are required by JavaCompute nodes in message flows are added to the BAR file from your Java project or integration project automatically when you add the message flow.

JAR files that are available to the integration server include JAR files that you deployed and JAR files that exist in the `classes` directories in the installation directory. For example, the files `IntegrationAPI.jar`, `jplugin2.jar`, and `javacompute.jar` are always visible to the integration server, and do not have to be deployed separately.

WebSphere Adapter files
Inbound or outbound adapter files (`.inadapter` or `.outadapter`), if required by WebSphere Adapter nodes (for example, the SiebelInput node) in the message flows that you added to this BAR file.

ESQL files

- If you select **Compile and in-line resources** in the BAR File editor, ESQL code is embedded in the `.cmf` file that references it.
- If you do not select **Compile and in-line resources** in the BAR File editor, ESQL files (`.esql`) are added to the BAR file as individual resources.

If your BAR file contains a mixture of resources that are compiled and resources that are not compiled, you might see unexpected results. For example, if you select the **Compile and in-line resources** option to create a BAR file that contains an ESQL file and a message flow, the ESQL is embedded in the compiled message flow (`.cmf`) file. If you then update the ESQL and add it to the BAR file with the **Compile and in-line resources** option cleared, the ESQL file is added as an individual resource, but the `.cmf` file uses the original ESQL because the original ESQL remains embedded in the `.cmf` file. To ensure that all your resources are either compiled or not compiled, when you change the **Compile and in-line resources** option, also select **Remove contents of BAR before building**, and rebuild the BAR file.

Graphical maps
A `.map` file for each graphical data mapping routine.

Policies
A `.policyxml` file for each policy.

The `.policyxml` file contains a list of property values that override, at run time, properties that are set on deployed message flows, message flow nodes, or the integration server.

Other files that you might want to associate with this BAR file
You might want to include Java source files, `.msgflow` files, or `.wsdl` files for future reference. BAR files can contain all files types. If you choose to include source files in the BAR file, source projects for all applications, libraries, and other compiled resources are added to the `src` folder of the BAR file.

Packaging resources that include Java code or message sets

Compile Java code and message sets so that you can add them to a BAR file.

About this task

You can use the **mqsipackagebar** command to create BAR files on computers that do not have IBM App Connect Enterprise Toolkit installed. This command adds only deployable resources to the BAR file, so if you want to add message sets or Java code you must first compile them to create deployable resources. For more information about the **mqsipackagebar** command, see command.

You can compile resources by using the **mqsicreatebar** command, or by using the IBM App Connect Enterprise Toolkit. If you use the IBM App Connect Enterprise Toolkit, you can either compile resources in the current workspace or you can compile resources in selected projects.

If you want to use the **mqsipackagebar** command to create BAR files from source files that are stored in a version control system, use one of the following processes to ensure that your message sets and Java code are compiled before you create a BAR file:

- Use the **mqsicreatebar** command to compile message sets and Java code that are stored in the version control system. You might use this command as part of an automated process.
- Ensure that your message sets and Java code are compiled before you add them to the version control system by using the IBM App Connect Enterprise Toolkit.

Procedure

To compile your message sets and Java code, complete one of the following steps:

- To compile message sets and Java code by using the **mqsicreatebar** command, complete the following steps. For more information about the **mqsicreatebar** command, see command.
  a) Open a command window that is configured for your environment.
  b) Enter the following command:

  ```
  mqsicreatebar -data workspace -compileOnly
  ```

  where *workspace* is the fully qualified path to the workspace that contains the message set projects or Java projects that you want to compile.

  Your message sets are compiled into `.dictionary`, or `.xsdzip` files. Your Java code is compiled into `.jar` files.
- To compile all message sets and Java code in the current workspace by using the IBM App Connect Enterprise Toolkit, complete the following steps:
  a) Click **Project** > **Build for mqsipackagebar**.

  The **Build Information** window shows the directories in which the compiled resources are created. Your message sets are compiled into `.dictionary`, or `.xsdzip` files. Your Java code is compiled into `.jar` files.
  b) Click **OK**.
- To compile message sets and Java code in selected projects by using the IBM App Connect Enterprise Toolkit, complete the following steps:
  a) In the Application Development view, right-click the message set project or Java project that you want to compile. Click **Build for mqsipackagebar**.

  The **Build Information** window shows the directories in which the compiled resources are created. Your message sets are compiled into `.dictionary`, or `.xsdzip` files. Your Java code is compiled into `.jar` files.
  b) Click **OK**.

What to do next

Run the **mqsipackagebar** command to create your BAR file, see "Creating a BAR file" on page 2469.

Including WebSphere Adapters resources in a BAR file

Deploy the resources that are generated when you run the **Adapter Connection** wizard by adding them to a BAR file.

Before you begin

- Read "WebSphere Adapters nodes" on page 1050.

About this task

To deploy the message flow successfully, you must deploy the WebSphere Adapters component in the same application, static library, or BAR file as your message flow. If the WebSphere Adapters component is not available, deployment of the message flow fails. The following list includes the file extensions of the resources that you deploy:

- `.msgflow` (the message flow)
- `.inadapter` (the inbound WebSphere Adapters component)
- `.outadapter` (the outbound WebSphere Adapters component)
- Optional: `.appzip` (an application)
- Optional: `.libzip` (a static library)
- Optional: `.shlibzip` (a shared library)

For more information, see "WebSphere Adapters resources" on page 2475.

The mode in which IBM App Connect Enterprise is running can affect the number of integration servers and message flows that you can deploy. For more information, see "Restrictions that apply in each operation mode" on page 5.

Procedure

1. For details of the steps that you must complete before you can deploy a message flow, see "Deployment rules and guidelines" on page 2465.
2. Add the message flow to the BAR file.

   When you add a message flow that contains one or more WebSphere Adapters nodes to a BAR file, a dialog box opens so that you can identify the following resources:

   - One or more WebSphere Adapters components to be used by the WebSphere Adapters nodes
   - One or more libraries that contain an XSD for the business objects that are used by the WebSphere Adapters nodes
3. When you have added the message flow, WebSphere Adapters components, and library, deploy the BAR file.

WebSphere Adapters resources

After you run the **Adapter Connection** wizard and create a message flow, you must deploy the resources that are generated by adding them to an application, library, or BAR file.

To build an IBM App Connect Enterprise solution that integrates with an Enterprise Information System (EIS), such as SAP, Siebel, JD Edwards, or PeopleSoft, you need the following resources:

- A message flow that contains at least one WebSphere Adapters node
- A library (created by the **Adapter Connection** wizard) that describes the logical model of the data, as defined by the EIS

- An adapter, which includes two sets of information that are used by the WebSphere Adapters node in the message flow:
  - Connection information
  - Interface information

    The interface information contains a list of methods. For outbound adapters, methods define the operations or services that can be run on the EIS by the WebSphere Adapters request node. For inbound adapters, the method defines callout functions or events from the EIS that cause the WebSphere Adapters input node to propagate a message through the message flow.

    For each method, the information consists of the name of the method, and the name and namespaces of the message types that are used for input and output. To run the method successfully, the message types must be defined in the library.

Iterative deployment

The message flow can be coded with knowledge of the logical model of the data that is exchanged with the EIS (for example, where Mapping nodes are used to transform the data), but it can also act as a gateway to the EIS, where no transformation of data takes place. When the flow acts as a gateway, you need to be able to run new operations or respond to new events in the EIS without changing or reloading the resources that are already deployed.

You can use iterative deployment to deploy the resources that are required to support the new methods, without affecting any resources that are already deployed. Iterative deployment is possible by using primary and secondary adapters. The primary adapter for a WebSphere Adapters node contains its connection information and part of its interface; the secondary adapters contain the rest of the interface.

You can store a secondary adapter in the same library as the primary adapter, or a different library. If the library that contains the primary adapter is referenced by an application or library, you can reference the project that contains the secondary adapter from the same application or library, or from a different application or library.

You must stop any message flow that references a primary adapter before you redeploy the primary adapter. However, you do not need to stop the message flow when you deploy the secondary adapter. During deployment of the secondary adapter, the primary adapter provides connection information, and the secondary adapter supplies additional interface information.

Preparing packaged solutions for deployment

You can configure properties on the resources in your BAR file to match the properties or requirements of your production environment.

About this task

You can configure the following properties that are associated with your message flows:

- The name of the consumer and provider policies that are used to authenticate, encrypt, and sign messages for SOAP nodes.
- Whether the message flow is processed as an XA coordinated transaction that is coordinated by IBM MQ.
- The name of the security profile that a message flow uses to complete authorization with Security Profiles policy (SecurityProfiles)
- The Workload Management policy that is used to manage the message flow. If you do not have a Workload Management policy, you can set the workload management properties directly in the BAR file.

For information on how to set these properties; see “Editing configurable properties in a BAR file” on page 2477.

You can configure the value of user-defined properties that were configured on your message flows during the development of your solution; see “Configuring a message flow at deployment time with user-defined properties” on page 1749.

You can add additional instances of a message flow to your solution; see “Adding multiple instances of a message flow to a BAR file” on page 2479.

Editing configurable properties in a BAR file

An administrator can use configurable properties to update target-dependent properties that are associated with a solution, such as queue names, queue manager names, and database connections.

Before you begin

Create a BAR file and add resources to it. For more information, see “Creating a BAR file” on page 2469 and “Adding resources to a BAR file” on page 2470.

About this task

By changing configurable properties, you can customize a BAR file for a new integration node (for example, a test system) without editing and rebuilding the message flows or the resources that they use, such as message mappings, ESQL code, and Java code. For example, if you select an application, you can set the start mode for that application. If you select a message flow, you can change properties for policy sets, monitoring, and the security profile. You can also expand a message flow and set the properties for the nodes in that flow. For information about the configurable properties that you can set, see Configurable properties in a file.

Properties that you define are contained in the deployment descriptor file (`META-INF/broker.xml`). The deployment descriptor is parsed when the BAR file is deployed.

You can edit configurable properties in the following ways:

- “Editing configurable properties with the IBM App Connect Enterprise Toolkit” on page 2477
- “Editing configurable properties with the mqsiapplybaroverride command” on page 2478

Editing configurable properties with the IBM App Connect Enterprise Toolkit

About this task

To edit properties by using the IBM App Connect Enterprise Toolkit, complete the following steps.

Procedure

1. Open the BAR file.

   The resources in your BAR file are listed on the **Manage** tab.
2. Optional: You can view the properties that can be configured for your message flows and subflows by selecting **Built resources that are configurable** from the **Filter by** list.
3. Optional: If you migrated the BAR file from a previous version, refresh the contents so that you can see and configure all the available properties. For more information, see “Refreshing the contents of a BAR file” on page 2488.
4. Select the resource that you want to configure.

   You can expand resources to show individual message flow nodes.

   The values that you can configure for the selected resource are displayed in the **Properties** view, on the **Configure** and **Workload Management** tabs.
5. Update the appropriate values in the **Properties** view; see Configurable properties in a file.
6. Save the BAR file.

What to do next

Deploy the BAR file by following the instructions in “Deploying integration solutions to a production environment” on page 2480.

Editing configurable properties with the `mqsiapplybaroverride` command

About this task

To edit properties by using the **mqsiapplybaroverride** command, complete the following steps.

Procedure

1. Open a command window that is configured for your environment.
2. Run the **mqsireadbar** command to see which properties you can configure; see command.
   For example, the following command reads the file `c:\myBarFile.bar` and lists the properties for all applications and libraries in the file, including libraries inside applications:

   ```
   mqsireadbar -b c:\myBarFile.bar -r
   ```

3. Create a text file, and list the properties that you want to change in the following format:

   ```
   property=newValue
   ```

   For example, the following text file sets the value of the `queueName` property on the node `MQ Input` in the message flow `sampleFlow`, to `NEW_INPUT_QUEUE`, and clears the value of the `queueName` property on the subflow `sampleSubflow1`:

   ```
   # override.properties file
   sampleFlow#MQ Input.queueName=NEW_INPUT_QUEUE
   sampleSubflow1#queueName
   ```

4. Run the **mqsiapplybaroverride** command, and specify the location of your BAR file, and the text file that lists the properties to change.
   For example, the following command reads the BAR file `c:\myBarFile.bar`, uses the `c:\override.properties` file to change the property values set in `c:\myBarFile.bar` and creates a new BAR file, `c:\myNewBarFile.bar`, with the resources you configured to use the new properties:

   ```
   mqsiapplybaroverride -b c:\myBarFile.bar -p c:\override.properties -o c:\myNewBarFile.bar
   ```

   For more information about the **mqsiapplybaroverride** command, see command.

What to do next

Deploy the BAR file by following the instructions in “Deploying integration solutions to a production environment” on page 2480.

Configuring a message flow at deployment time with user-defined properties

Use user-defined properties (UDPs) to configure message flows at deployment and run time, without modifying program code. You can give a UDP an initial value when you declare it in your program, or when you use the Message Flow editor to create or modify a message flow.

Before you begin

For an overview of user-defined properties, see “User-defined properties” on page 569.

For an example of how to code a UDP statement, see DECLARE statement.

About this task

In ESQL, you can define UDPs at the module or schema level. After a UDP has been defined in the Message Flow editor, you can modify the value before you deploy it. You can also modify the value of a

UDP dynamically at run time by using the administration REST API, as described in "Setting message flow user-defined properties at run time by using the administration REST API" on page 436.

To configure UDPs, complete the following steps.

Procedure

1. Open the BAR file.

   The contents of the BAR file are shown on the **Manage** tab of the BAR File editor. On this tab, you can expand a flow to show the individual nodes that it contains.
2. Click the relevant message flow or subflow (not the `.cmf` compiled message flow file).

   The UDPs that are defined in that flow are displayed with their values in the **Properties** view.
3. If the value of the UDP is unsuitable for your current environment or task, change it to an appropriate value.

   The value of the UDP is set at the flow level, and is the same for all eligible nodes that are contained in the flow.

   Note: If a subflow includes a UDP that has the same name as a UDP in the main flow, the value of the UDP in the subflow is not changed.
4. Save your BAR file.

What to do next

Deploy the message flow by following the instructions in "Deploying integration solutions to a production environment" on page 2480.

Adding multiple instances of a message flow to a BAR file

Add more than one instance of a message flow to a BAR file and use configurable properties to customize each instance.

About this task

You can deploy multiple instances of the same message flow with different values for configurable properties. By using the same flow with different configurable property values, you can reuse a flow but customize each instance to your requirements. For example, you might use one flow with a particular value for an output queue, then add a second instance of the same flow and use a configurable property to set a different value for the output queue.

If you want to create multiple instances of a message flow to improve performance, see "Optimizing message flow throughput" on page 2763.

Procedure

To deploy multiple instances of a message flow with different values for the configurable properties, complete the following steps:

1. In the Application Development view, create a copy of the message flow of which you want to deploy multiple instances; see "Copying a message flow or subflow by using copy" on page 580.
2. Add the original message flow and the copy of the message flow to your BAR file; see "Adding resources to a BAR file" on page 2470.
3. Open the BAR file.

   The resources in your BAR file are listed on the **Manage** tab.
4. On the **Manage** tab, you can now edit the configurable properties for both message flows.

   For more information, see "Editing configurable properties in a BAR file" on page 2477.

Results

Tip: The names that are assigned in the BAR file are also used on the command line when you run the **mqsilist** command on the integration server, or the **mqsichangeflowstats** command for a message flow.

What to do next

Deploy the BAR file by following the instructions in "Deploying integration solutions to a production environment" on page 2480. Both message flows are deployed and use the values for the configurable properties that you set in the BAR file.

Deploying integration solutions to a production environment

After you create and populate a BAR file with the development resources, you can deploy the integration solution to an integration server.

Before you begin

Complete the following steps:

- Review the deployment rules and guidelines; see "Deployment rules and guidelines" on page 2465.
- Package your integration solution in a BAR file; see "Packaging integration solutions" on page 2465.

Note:

The mode in which IBM App Connect Enterprise is running can affect the number of integration servers and message flows that you can deploy. For more information, see "Restrictions that apply in each operation mode" on page 5.

About this task

Choose one of the following methods to deploy a BAR file:

- "Deploying a BAR file by using the web user interface" on page 2480
- "Deploying a BAR file by using the IBM App Connect Enterprise Toolkit" on page 2481
- "Precompiling and deploying a BAR file by using the mqsibar command" on page 2481
- "Deploying a BAR file by using the mqsideploy command" on page 2482
- "Deploying a BAR file by using the IBM Integration API" on page 2483
- "Deploying a BAR file to IBM App Connect on IBM Cloud" on page 2484
- "Deploying a BAR file to IBM App Connect in containers" on page 2484

If you change a BAR file and want to propagate those changes to one or more integration servers, you must delete the existing BAR file from the integration server and deploy the new one.

Deploying a BAR file by using the web user interface

About this task

You can select a BAR file and deploy it to an integration server by using the web user interface.

You can also select an *overrides file*, which defines the BAR file properties that you want to change for a specific deployment. For more information, see command.

Procedure

1. Start the web user interface for your integration node or independent integration server, as described in "Accessing the web user interface" on page 89.

   For an integration node, the web user interface displays the node's integration servers. For an integration server, the web user interface displays the server's deployed message flows and other resources.
2. Select the **Deploy** action.

   For example:

   - In the web user interface for an integration node, select the required integration server (where you want to deploy the BAR file), and then click **Deploy**.
   - In the web user interface for an independent integration server, click **Deploy**.
3. Follow the instructions that are displayed.

Results

The contents of the BAR file are deployed to the integration server, and the deployed resources are shown.

Deploying a BAR file by using the IBM App Connect Enterprise Toolkit

About this task

To deploy a BAR file by using the IBM App Connect Enterprise Toolkit, complete the following steps. You can deploy to only one integration server at a time.

Procedure

1. Optional: Typically, an incremental BAR file deployment is done. To do a complete BAR file deployment, right-click the target integration server in the Integration Explorer view and click **Delete** > **All Flows and Resources**.

   Wait for the operation to complete before you continue.

   To refresh only some of the resources with the contents of the BAR file, do not click **Delete** > **All Flows and Resources**.
2. Deploy a BAR file to an integration server by using one of the following methods.

   - Drag the BAR file onto your target integration server in the Integration Explorer view.
   - Right-click the BAR file, then click **Deploy** and select the target integration server.
   - Right-click the target integration server, click **Deploy**, select **BAR from workspace** or **BAR from file system**, select the BAR file that you want to deploy, and click **OK**.
3. If the BAR file has changed since you last edited it, you are asked whether you want to save the file before deployment. If you click **Cancel**, the BAR file is not saved and deployment does not take place.

Results

The contents of the BAR file (for example, message flows and message sets) are deployed to the integration server. In the Integration Explorer view, the deployed resources are added to the appropriate integration server.

Precompiling and deploying a BAR file by using the `mqsibar` command

About this task

You can use the **`mqsibar`** command to deploy a BAR file to an integration server, by unpacking the contents directly into the integration server's `run` directory. You can also choose to precompile the

resources that the BAR file contains (such as XML schema, DFDL schema, and graphical data maps), so that they are ready to run when the integration server starts.

You can use the **mqsibar** command in a script, as part of an automated process that might include commands to test, tune, deploy, and run the application, as an alternative to deploying through the toolkit or web user interface. This method can be particularly useful if you are running IBM App Connect Enterprise in a cloud container.

Deploy a BAR file by using the **mqsibar** command, by completing the following steps.

Procedure

1. Open a command window that is configured for your environment.

   For information about configuring your command environment in preparation for running commands, see "Setting up a command environment" on page 64.
2. Run the **mqsibar** command, as shown in the following example:

   On Windows and Linux:

   Unpack the BAR file and compile resources into the integration server work directory, ready to be run when the integration server starts:

   ```
   mqsibar -a myAppAndShLibs.bar -c -w /sis01Wrk
   ```

   where:

   - **-a** specifies the name of the input BAR file to be processed.

     The BAR file must contain all referenced resources. If an application in the BAR file references a library that is contained by a different BAR file, an error occurs.
   - **-c** specifies that the contents of the BAR file will be compiled.

     Resources that are included in the BAR file, such as DFDL schema, XML schema, and graphical data maps, are compiled as a result of specifying this parameter.
   - **-w** specifies the integration server work directory.

     The integration server work directory is created by the **mqsicreateworkdir** command, which you run when you are configuring the integration server. When the work directory is created, a `run` subdirectory is also created, and it is this directory that the contents of the BAR file are unpacked into when the **mqsibar** command is run. For more information about configuring and starting an integration server, see "Configuring an integration server by modifying the server.conf.yaml file" on page 172 and "Starting an integration server" on page 250.

   For more information about using the **mqsibar** command, see command.
3. Start (or restart) the integration server, for the changes to take effect.

Results

The command reports when responses are received from the integration server. If the command completes successfully, it returns 0 (zero).

Deploying a BAR file by using the `mqsideploy` command

About this task

To deploy a BAR file by using the **mqsideploy** command, complete the following steps.

Procedure

1. Open a command window that is configured for your environment.

2. Enter the appropriate command for your operating system and configuration, by using the following examples as a guide.

```
mqsideploy -i ipAddress -p port -a barfile
```

```
mqsideploy --admin-host ipAddress --admin-port port --bar-file barfile
```

The command completes an incremental deployment. To do a complete BAR file deployment, add the **-m** parameter.

The **-i** (IP address) and **-p** (port) parameters represent the connection details for the independent integration server or the integration node.

If deploying to an integration node, you must also specify the **-e** (integration server name) parameter. If you want to run this command against an integration node on the same computer, you can specify the integration node name instead of -i and -p, as in the following example:

```
mqsideploy integrationNodeName -e integrationServerName
-a barfile
```

If you have a `.broker` file that contains the connection details for an independent integration server or integration node, you can specify this file instead of -i and -p by using the **-n** parameter, as in the following example:

```
mqsideploy -n integrationNodeFileName -e integrationServerName
-a barfile
```

where *integrationNodeFileName* is the path and file name of the `.broker` file.

For alternative long names for parameters, and for more information about the command, see command.

Results

The command reports when responses are received from the integration node or independent integration server. If the command completes successfully, it returns 0 (zero).

Deploying a BAR file by using the IBM Integration API

About this task

To deploy a BAR file by using the IBM Integration API, use the `deploy` method of the `ExecutionGroupProxy` class.

The following code shows how an application can do an incremental deployment:

```
import
com.ibm.broker.config.proxy.*;
public class DeployBAR {

  public static void main(String[] args) {
    BrokerConnectionParameters bcp =
       new IntegrationNodeConnectionParameters("localhost",
4414);
    try {
      BrokerProxy b = BrokerProxy.getInstance(bcp);
      ExecutionGroupProxy eg = b.getExecutionGroupByName("default");
      DeployResult dr = eg.deploy("MyBAR.bar", true, 30000);
      System.out.println("Result = "+dr.getCompletionCode());
    } catch (Exception e) {
      e.printStackTrace();
    }
  }
}
```

By default, the `deploy` method completes an incremental deployment. To do a complete deployment, use a variant of the method that includes a `false` value for the Boolean `isIncremental` parameter. For example, `eg.deploy("MyBAR.bar", false, 30000)`.

Deploying a BAR file to IBM App Connect on IBM Cloud

With IBM App Connect on IBM Cloud (IBM App Connect on IBM Cloud - with the Lite plan or an Enterprise plan), you can also deploy and manage integration solutions that were developed in the App Connect Toolkit.

Before you begin

Before you can deploy an integration solution to IBM App Connect on IBM Cloud, you must sign up for an account with enterprise capabilities (the Lite plan or an Enterprise plan); see IBM App Connect in IBM Cloud.

About this task

App Connect on IBM Cloud provides a fully managed environment that you can use to deploy integration solutions to the cloud without the need to acquire and maintain an IT infrastructure.

You deploy a solution to App Connect on IBM Cloud by uploading the BAR file to the cloud. When you upload your BAR file to the cloud, an integration server is created in the cloud, and the contents of the BAR file are unpackaged and run on that integration server. Each integration server in App Connect on IBM Cloud contains the contents of a single BAR file. You can see your integration servers on the App Connect on IBM Cloud dashboard, where you can start and stop them. You can also configure authentication and secure connectivity between your resources in the cloud and on premises.

For detailed instructions about how to upload BAR files to the cloud, see Running enterprise integration solutions in App Connect on IBM Cloud.

What to do next

You can check the results of your deployment; see “Checking the results of deployment” on page 2485.

Deploying a BAR file to IBM App Connect in containers

Using IBM Cloud Pak for Integration or the App Connect Enterprise, you can deploy an IBM App Connect Enterprise Toolkit integration to run in an integration server in the container.

Before you begin

Before you can deploy an integration solution to IBM App Connect in containers, you must have installed IBM App Connect by using the IBM App Connect Operator, and created an instance of the App Connect Dashboard into which you want to deploy the BAR file.

- Ensure that you have access to the App Connect Dashboard.

About this task

You create the integration server by uploading your IBM App Connect Enterprise Toolkit integration in the form of a broker archive (BAR) file by using the App Connect Dashboard.

After you have uploaded your BAR file, you can create configurations that can be applied to the integration server when you deploy it, and can configure the integration server details.

The integration server is displayed as a tile on the **Servers** page of the dashboard, with an initial status of `Unavailable`, which then changes to `Started` when the deployment completes.

For detailed instructions about how to deploy BAR files to IBM App Connect in containers, see the following documentation:

- Deploying Toolkit integrations to IBM App Connect in containers (Continuous delivery)

- Deploying Toolkit integrations to IBM App Connect in containers (Extended Update Support)

What to do next

You can click the integration server tile to view the deployed integration. From the **Servers** page, you can also view the integrations for all listed integration servers by clicking **Integrations** to open the **Integrations** page.

Checking the results of deployment

After you deploy a BAR file, you can check that the operation completed successfully.

About this task

You can check the results of a deployment by using any of the following methods:

- "Checking deployment by using the IBM App Connect Enterprise Toolkit" on page 2485
- "Checking deployment by using the mqsideploy command" on page 2485
- "Checking deployment by using the IBM Integration API" on page 2486
- "Checking deployment to IBM Integration Bus on Cloud" on page 2486
- "Checking deployment to IBM App Connect on IBM Cloud" on page 2487

Also, check the system log on the target system where the integration node was deployed to make sure that the integration node did not report any errors.

If version or custom keyword information was included in the resources, you can also check the version of the resources that are deployed to your integration server; see "Viewing version information and custom keyword values in your deployed solutions" on page 319.

Checking deployment by using the IBM App Connect Enterprise Toolkit

About this task

Follow these steps to check a deployment by using the IBM App Connect Enterprise Toolkit:

Procedure

1. In the Integration Development perspective, open the Deployment Log view:
   a) Click **Window** > **Show View** > **Other**.
   b) In the **Show View** window expand **Integration Development**, and click **Deployment Log**.
2. View the messages that relate to each deployment in the Deployment Log view.

Results

The Deployment Log is updated only after a deployment is processed completely by the integration node. If a deployment fails, the reasons for the failure are shown here.

Checking deployment by using the `mqsideploy` command

About this task

If you use the **`mqsideploy`** command to deploy, the command displays the results of the deployment. For example, if you type the following command for the default integration server of the integration node:

```
mqsideploy INODE -e default -a my.bar
```

the following response indicates that the deployment was successful:

```
BIP1039I: Deploying BAR file 'my.bar' to integration node 'INODE' (integration
server 'default') ...
BIP1092I: The integration node successfully processed the deployment request.
```

The command also returns a numeric completion code value to indicate the outcome. If the deployment completes successfully, the command returns 0. For details of other values that you might see returned, see command.

Checking deployment by using the IBM Integration API

About this task

Code your application to test the results of the deployment actions that it takes. For example:

```
import com.ibm.integration.admin.model.common.LogEntry;
import com.ibm.integration.admin.model.server.DeployResult;
import com.ibm.integration.admin.proxy.IntegrationAdminException;
import com.ibm.integration.admin.proxy.IntegrationNodeProxy;
import com.ibm.integration.admin.proxy.IntegrationServerProxy;

public class DeployExample {

  public static void main(String[] args) {
    IntegrationNodeProxy node = new IntegrationNodeProxy("localhost",4414,"","",false);
    try {
      IntegrationServerProxy server = node.getIntegrationServerByName("server1");
      DeployResult result  = server.deploy("C:\\temp\\mybarfile.bar");
      int deployStatus = server.getLastHttpResponse().getStatusCode();
      if (deployStatus >= 400)
      {
        System.out.println("Http response error: " + deployStatus );
      }
      else
      { // deploy worked, check for any Log entries
        LogEntry[] logEntries  = result.getLogEntry();
        if (logEntries != null)
        {
          for (LogEntry logEntry: logEntries)
          {
            System.out.println("Deploy log entry: "+logEntry.getDetailedText());
          }
        }
      }
    } catch (IntegrationAdminException e) {
      System.out.println("Error deploying: "+e);
    }
  }
}
```

If the deployment message could not be sent to the integration node, an `IntegrationAdminException` exception is thrown at the time of the deployment. If the integration node receives the deployment message, log messages for the overall deployment are displayed, followed by completion codes specific to each integration node that is affected by the deployment.

Checking deployment to IBM Integration Bus on Cloud

About this task

When you upload BAR files into IBM Integration Bus on Cloud, a list of integrations is created. You can then start and stop those integrations, and view information about them.

To check the status of your integrations on the cloud, complete the following steps.

Procedure

1. Log in to IBM Integration Bus on Cloud.
   For more information, see Getting started.

2. Click **Integrations** to open the Integrations view.
3. Look at the status for the relevant integration.
   - If the status is `Started`, the BAR file has been deployed, and the integration is running.
   - If the status is `Stopped`, the BAR file has been deployed, but the integration has not yet been started.
   - If the status is `Preparing`, the BAR file is being deployed.

Checking deployment to IBM App Connect on IBM Cloud

About this task

When you upload a BAR file into IBM App Connect on IBM Cloud, an integration server is created to run the contents of that BAR file. The integration server is represented by a tile on the App Connect on IBM Cloud dashboard. You can start and stop the integration servers, and view information about them.

To check the status of your integrations on the cloud, complete the following steps.

Procedure

1. Log in to App Connect on IBM Cloud.
2. The App Connect on IBM Cloud dashboard should open automatically, but if it does not, click **Dashboard**.
3. Look at the status for the relevant integration server:
   - If the status is `Preparing`, the BAR file is being deployed.
   - If the status is `Stopped`, the BAR file has been deployed, but the integration server has not yet been started.
   - If the status is `Started`, the BAR file has been deployed, and the integration server is running.

What to do next

You can administer your integration node, integration server, and deployed resources; see Chapter 5, "Administering IBM App Connect Enterprise," on page 243.

Redeploying integration solutions to a production environment

If you change an integration solution, you can redeploy the updated solution to the same integration servers.

About this task

You can package an updated integration solution for redeployment by using one of the following methods:

- You can repackage the updated integration solution in the BAR file editor, and generate a new BAR file; see "Preparing packaged solutions for deployment" on page 2476.
- You can refresh the existing BAR file; see "Refreshing the contents of a BAR file" on page 2488.

You can redeploy the updated BAR file to one or more integration servers by using one of the deployment methods that are described in "Deploying integration solutions to a production environment" on page 2480. You do not have to stop the message flows that you deployed previously. All the resources in the integration server that are also in the redeployed BAR file are replaced.

You do not have to redeploy JAR files unless you updated them. If one or more JAR files in your BAR file are present on the computer where the integration node is running, you can remove them from your BAR file before you deploy the BAR file again.

If your updates to the BAR file include the deletion of resources, a redeployment does not result in their deletion from the integration node. For example, assume that your BAR file contains applications A1, A2,

and A3. Update the file by removing A2 and adding application A4. If you redeploy the BAR file, all four applications are available in the integration server when the redeployment completes. A1 and A3 are replaced by the contents of the redeployed BAR file.

To clear previously deployed resources from the integration server before you redeploy (for example, if you are deleting resources), use one of the methods that are described in "Deleting deployed resources" on page 319.

- To use the IBM App Connect Enterprise Toolkit, follow the instructions for a new deployment, making sure that you select **Delete** > **All Flows and Resources** before you deploy resources.
- To use the **mqsideploy** command, follow the instructions for a new deployment, making sure that you add the **-m** parameter to perform a complete BAR file deployment.
- To use the IBM Integration API, follow the instructions for a new deployment.

If your message flows are not transactional, stop the message flows before you redeploy resources to ensure that all the applications complete cleanly and are in a known and consistent state. You can stop individual message flows, integration servers, or integration nodes.

If your message flows are transactional, the processing logic that handles commitment or rollback ensures that resource integrity and consistency are maintained.

What to do next

Check the results of the redeployment by following the instructions in "Checking the results of deployment" on page 2485.

Refreshing the contents of a BAR file

Refresh the contents of a BAR file by rebuilding it in the BAR file editor.

Before you begin

You must have created a BAR file and added files to it. For more information, see "Creating a BAR file" on page 2469 and "Adding resources to a BAR file" on page 2470.

About this task

If you change resources that you added to your BAR file, the BAR file is inconsistent, and is shown with an "out-of-sync" icon in the Application Development view. The BAR file is also inconsistent if any changes are made to the container (integration project, application, or library) to which the resources belong. For example, the BAR file is inconsistent if a new message flow is added to an application where existing resources from the application are in the BAR file.

If you want to rename a deployed resource, see "Renaming resources that are deployed to integration servers" on page 2489.

To refresh the contents of a BAR file before you deploy it, complete the following steps.

Procedure

1. Open the BAR file.
   The contents of the BAR file are shown on the **Manage** tab of the BAR File editor.

2. To refresh all the resources in the BAR file on the **Manage** tab, click **Rebuild existing BAR entries**  .

   A dialog box opens, showing progress. When the operation is complete, click **Details** to see information about what was refreshed.

   Alternatively, you can refresh the archive contents by right-clicking a BAR file in the Application Development view and selecting **Build and Save BAR**. The BAR file is rebuilt in the background.

   You can view the user and service logs on the **User Log** and **Service Log** tabs of the BAR File editor.

   Clear the contents of logs by clicking **Remove** ().
3. Optional: To view details about the build of an individual deployable resource on the **Manage** tab, right-click the resource and click **Details**.

   The Properties view opens and the **Details** tab is displayed. The **Details** tab shows the following details about the deployable resource:

   - The workspace resource, with references to the linked workspace resources (for example, `.msgflow` `.mset`, `.xml`, and `.xslt` files).
   - The status of the last compilation, which shows the user log entry for the last compilation.

What to do next

Deploy the BAR file by following the instructions in "Deploying integration solutions to a production environment" on page 2480 or "Redeploying integration solutions to a production environment" on page 2487.

Renaming resources that are deployed to integration servers

You cannot rename a resource while it is still deployed to an integration server. You must change the name of the resource that is in the BAR, then redeploy the BAR file.

Before you begin

You must have deployed resources to an integration server.

About this task

To rename a deployed resource, complete the following steps.

Procedure

1. Remove the deployed resource from the integration server.

   For more information, see "Deleting deployed resources" on page 319.
2. Right-click the development resource.
3. Optional: If you rename a resource that is referenced by another resource, you might need to update the references to the renamed resource.
   For example, suppose you rename a library that is referenced by an application. Renaming the library breaks the reference between the application and library. To fix the reference, right-click the application, click **Manage library references**, and select the renamed library.
4. Refresh the contents of the BAR file by clicking **Rebuild and save BAR**  on the **Manage** tab of the BAR File editor.
5. Redeploy the BAR file.

Chapter 8. Security

Security is an important consideration for both developers of IBM App Connect Enterprise applications, and for system administrators configuring IBM App Connect Enterprise authorities.

When you are designing an IBM App Connect Enterprise application, it is important to consider the security measures that are needed to protect the information in the system.

The “Security overview” on page 2491 introduces the concepts that you need to understand before you set up security for IBM App Connect Enterprise.

The following topics explain the different aspects of security that you need to consider when you are designing your applications:

Security overview

When you are designing an IBM App Connect Enterprise application it is important to consider the security measures that are needed to protect the information in the system.

An important aspect of securing an enterprise system is the ability to protect the information that is passed from third parties. This capability includes restricting access to IBM MQ and JMS queues. For information about the steps involved, refer to the documentation supplied by your transport provider. If you are using HTTPS, you need to set specific properties in the HTTP nodes. For information about this option, see node, node, and node.

In addition to securing the transport, you can secure individual messages based on their identity. For more information about securing messages in a message flow, see “Message flow security” on page 2550.

Some security configuration is required to enable IBM App Connect Enterprise to work correctly and to protect the information in the system. For example, you can secure the messaging transport with SSL connections, restrict access to queues, apply WS-Security to web services, and secure access to message flows.

The following topics introduce the concepts that you need to understand before you set up security for IBM App Connect Enterprise:

Authorization for configuration tasks

Authorization is the process of granting or denying access to a system resource.

For IBM App Connect Enterprise, authorization is concerned with controlling who has permission to access the integration server and its resources, and ensuring that users who attempt to work with them have the necessary permissions to do so.

Examples of tasks that require authorization are:

- Configuring an integration server; for more information, see "Configuring an integration server by modifying the server.conf.yaml file" on page 172.
- Accessing queues; for example, putting a message to the input queue of a message flow.
- Taking actions within the IBM App Connect Enterprise Toolkit; for example, deploying a message flow to an integration server.

Security exits

Use security exit programs to verify that the partner at the other end of a connection is genuine.

When you connect from the IBM App Connect Enterprise Toolkit to an integration server on another computer, a security exit is not started by default to monitor the connection. If you want to protect access to the integration server from client programs, you can use the IBM MQ security exit facility.

You can enable a security exit at each end of the connection between your client session and the integration server :

- Set up a security exit on the channel at the integration server end. This security exit has no special requirements; you can provide a standard security exit.
- Set up a security exit in the IBM App Connect Enterprise Toolkit. Identify the security exit properties when you connect to the integration server . The security exit is a standard IBM MQ security exit, written in Java.

For an overview of security exits and details of their implementation, see "Channel security exit programs" in the *Intercommunication* section of the IBM MQ product documentation online.

Public key cryptography

All encryption systems rely on the concept of a key. A key is the basis for a transformation, usually mathematical, of an ordinary message into an unreadable message. For centuries, most encryption systems have relied on private key encryption. Public key encryption is the only challenge to private key encryption that has appeared in the last 30 years.

Private key encryption

Private key encryption systems use a single key that is shared between the sender and the receiver. Both must have the key; the sender encrypts the message by using the key, and the receiver decrypts the message with the same key. Both the sender and receiver must keep the key private to keep their communication private. This kind of encryption has characteristics that make it unsuitable for widespread general use:

- Private key encryption requires a key for every pair of individuals who need to communicate privately. The necessary number of keys rises dramatically as the number of participants increases.
- Keys must be shared between pairs of communicators, therefore the keys must be distributed to the participants. The need to transmit secret keys makes them vulnerable to theft.
- Participants can communicate only by prior arrangement. You cannot send a usable encrypted message to someone spontaneously. You and the other participant must make arrangements to communicate by sharing keys.

Private key encryption is also called symmetric encryption because the same key is used to encrypt and decrypt the message.

Public key encryption

Public key encryption uses a pair of mathematically-related keys. A message that is encrypted with the first key must be decrypted with the second key, and a message that is encrypted with the second key must be decrypted with the first key.

Each participant in a public key system has a pair of keys. One key is nominated as the private key and is kept secret. The other key is distributed to anyone who wants it; this key is the public key.

Anyone can encrypt a message by using your public key, but only you can read it. When you receive the message, you decrypt it by using your private key.

Similarly, you can encrypt a message for anyone else by using their public key, and they decrypt it by using their private key. You can then send the message safely over an unsecured connection.

This kind of encryption has characteristics that make it very suitable for general use:

- Public key encryption requires only two keys per participant.
- The need for secrecy is more easily met: only the private key needs to be kept secret, and because it does not need to be shared, it is less vulnerable to theft in transmission than the shared key in a symmetric key system.
- Public keys can be published, which eliminates the need for prior sharing of a secret key before communication. Anyone who knows your public key can use it to send you a message that only you can read.

Public key encryption is also called asymmetric encryption, because the same key cannot be used to encrypt and decrypt the message. Instead, one key of a pair is used to undo the work of the other.

With symmetric key encryption, beware of stolen or intercepted keys. In public key encryption, where anyone can create a key pair and publish the public key, the challenge is in verifying the identity of the owner of the public key. Nothing prevents a user from creating a key pair and publishing the public key under a false name. The listed owner of the public key cannot read messages that are encrypted with that key because the owner does not have the corresponding private key. If the creator of the false public key can intercept these messages, that person can decrypt and read messages that are intended for someone else. To counteract the potential for forged keys, public key systems provide mechanisms for validating public keys and other information with digital certificates and digital signatures.

Public Key Infrastructure (PKI)

PKI is an infrastructure that uses public key technology to allow applications to interact securely. PKI uses public key encryption to provide privacy. In practice, only a small amount of data is encrypted in this way. Typically, a *session key* is used with a symmetric algorithm to transmit the bulk of the data efficiently.

In business transactions, trust is even more important than privacy. PKI uses the private key to allow an application to sign a document. For the recipient to authenticate the sender, it needs a reliable way to obtain the public key for the sender. This public key is provided in the form of a digital certificate, which is mediated by a trusted third party certificate authority (CA).

Digital certificates

Certificates provide a way of authenticating users. Instead of requiring each participant in an application to authenticate every user, third-party authentication relies on the use of digital certificates.

A digital certificate is equivalent to an electronic ID card. The certificate serves two purposes:

- Establishes the identity of the owner of the certificate
- Distributes the owner's public key

Certificates are issued by trusted third parties, called certificate authorities (CAs). These authorities can be commercial ventures or local entities, depending on the requirements of your application. The CA is trusted to adequately authenticate users before issuing certificates. A CA issues certificates with digital signatures. When a user presents a certificate, the recipient of the certificate validates it by using the digital signature. If the digital signature validates the certificate, the certificate is recognized

as intact and authentic. Participants in an application need to validate certificates only; they do not need to authenticate users. The fact that a user can present a valid certificate proves that the CA has authenticated the user. The designation, "trusted third parties", indicates that the system relies on the trustworthiness of the CAs.

The certificates and private keys are stored in files called *keystores* and *truststores*.

- A keystore holds the private keys and public key certificates for an application.
- A truststore contains the CA certificates required to authenticate certificates that are presented by another application.

Contents of a digital certificate

A certificate contains several pieces of information, including information about the owner of the certificate and the issuing CA. Specifically, a certificate includes:

- The distinguished name (DN) of the owner. A DN is a unique identifier, a fully qualified name including not only the common name (CN) of the owner but also the owner's organization and other distinguishing information.
- The public key of the owner.
- The date on which the certificate is issued.
- The date on which the certificate expires.
- The distinguished name of the issuing CA.
- The digital signature of the issuing CA. The message-digest function creates a signature based upon all the previously listed fields.

The idea of a certificate is that a CA takes the public key of the owner, signs the public key with its own private key, and returns the information to the owner as a certificate. When the owner distributes the certificate to another party, it signs the certificate with its private key. The receiver can extract the certificate that contains the CA signature with the public key of the owner. By using the CA public key and the CA signature on the extracted certificate, the receiver can validate the CA signature. If valid, the public key that is used to extract the certificate is considered good. The owner signature is validated, and if the validation succeeds, the owner is successfully authenticated to the receiver.

The additional information in a certificate helps an application to determine whether to honor the certificate. With the expiration date, the application can determine if the certificate is still valid. With the name of the issuing CA, the application can check that the CA is considered trustworthy by the site.

An application that needs to authenticate itself must provide its personal certificate, the one containing its public key, and the certificate of the CA that signed its certificate, called a signer certificate. In cases where chains of trust are established, several signer certificates can be involved.

Requesting certificates

To get a certificate, send a certificate request to the CA. The certificate request includes:

- The distinguished name of the owner or the user for whom the certificate is requested
- The public key of the owner
- The digital signature of the owner

The message digest function creates a signature based on all the previously listed fields.

The CA verifies the signature with the public key in the request to ensure that the request is intact and authentic. The CA then authenticates the owner. Exactly what the authentication consists of depends on a prior agreement between the CA and the requesting organization. If the owner in the request is authenticated successfully, the CA issues a certificate for that owner.

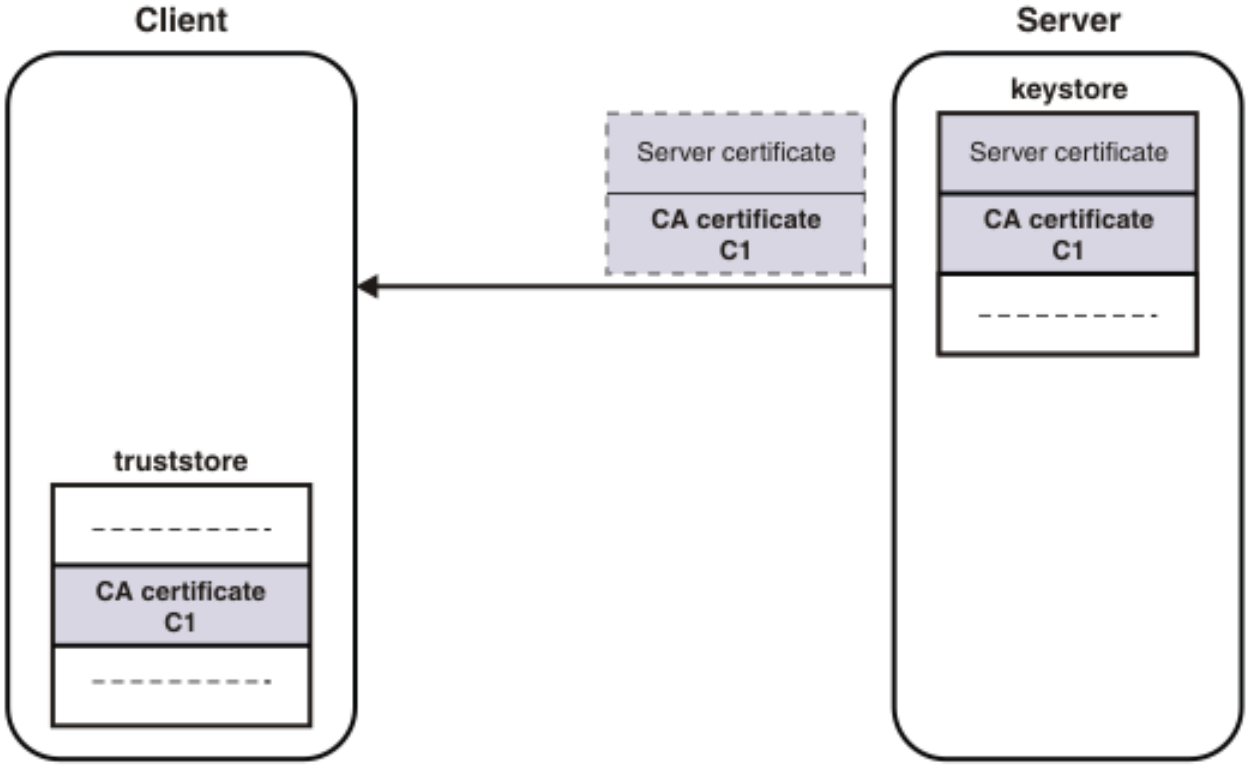
Using certificates: Chain of trust and self-signed certificate

To verify the digital signature on a certificate, you must have the public key of the issuing CA. Public keys are distributed in certificates, therefore you must have a certificate for the issuing CA that is signed by the issuer. One CA can certify other CAs, so a chain of CAs can issue certificates for other CAs, all of whose public keys you need. Eventually, you reach a root CA that issues itself a self-signed certificate. To validate a user certificate, you need certificates for all of the intervening participants back to the root CA. You then have the public keys that you need to validate each certificate, including the user certificate.

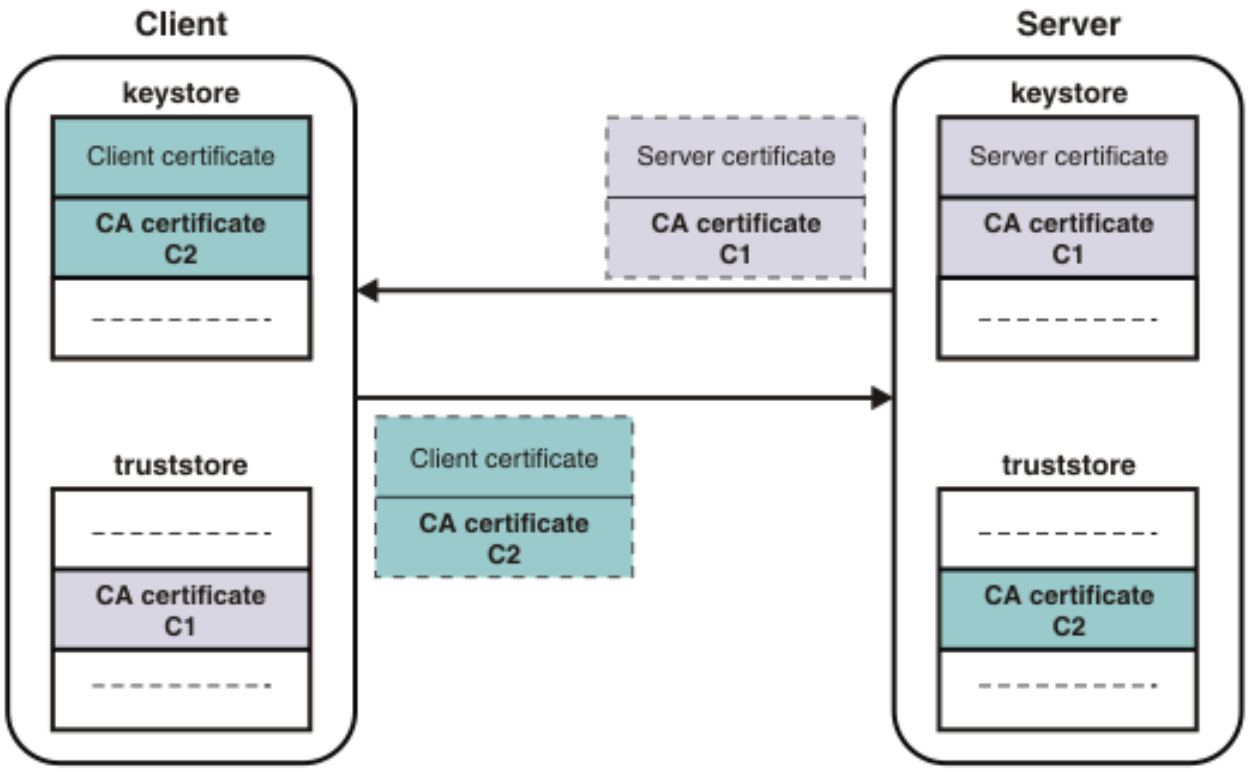
A self-signed certificate contains the public key of the issuer and is signed with the private key. The digital signature is validated like any other, and if the certificate is valid, the public key it contains is used to check the validity of other certificates issued by the CA. However, anyone can generate a self-signed certificate. In fact, you can probably generate self-signed certificates for testing purposes before installing production certificates. The fact that a self-signed certificate contains a valid public key does not mean that the issuer is a trusted certificate authority. To ensure that self-signed certificates are generated by trusted CAs, such certificates must be distributed by secure means; for example, hand-delivered on floppy disks, downloaded from secure sites, and so on.

Applications that use certificates store these certificates in a keystore file. This file typically contains the necessary personal certificates, its signing certificates, and its private key. The private key is used by the application to create digital signatures. Servers always have personal certificates in their keystore files. A client requires a personal certificate only if the client must authenticate to the server when mutual authentication is enabled.

To allow a client to authenticate a server, a server keystore file contains the private key and the certificate of the server and the certificates of its CA. A client truststore file must contain the signer certificates of the CAs of each server, which the client must authenticate. The following diagram illustrates how a client authenticates a server.



If mutual authentication is needed, the client keystore file must contain the client private key and certificate. The server truststore file requires a copy of the certificate of the client CA. The following diagram illustrates mutual authentication.



Digital signatures

A digital signature is a number that is attached to a document. For example, in an authentication system that uses public-key encryption, digital signatures are used to sign certificates.

This signature establishes the following information:

- The integrity of the message: Is the message intact? That is, has the message been modified between the time it was digitally signed and now?
- The identity of the signer of the message: Is the message authentic? That is, was the message signed by the user who claims to have signed it?

A digital signature is created in two steps. The first step distills the document into a large number. This number is the digest code or fingerprint. The digest code is then encrypted, which results in the digital signature. The digital signature is appended to the document from which the digest code is generated.

Several options are available for generating the digest code. This process is not encryption, but a sophisticated checksum. The message cannot regenerate from the resulting digest code. The crucial aspect of distilling the document to a number is that if the message changes, even in a trivial way, a different digest code results. When the recipient gets a message and verifies the digest code by recomputing it, any changes in the document result in a mismatch between the stated and the computed digest codes.

To stop someone from intercepting a message, changing it, recomputing the digest code, and retransmitting the modified message and code, you need a way to verify the digest code as well. To verify the digest code, reverse the use of the public and private keys. For private communication, it makes no sense to encrypt messages with your private key; these keys can be decrypted by anyone with your public key. However, this technique can be useful for proving that a message came from you. No one can create it because no-one else has your private key. If some meaningful message results from decrypting a document by using someone's public key, the decryption process verifies that the holder of the corresponding private key did encrypt the message.

The second step in creating a digital signature takes advantage of this reverse application of public and private keys. After a digest code is computed for a document, the digest code is encrypted with the sender's private key. The result is the digital signature, which is attached to the end of the message.

When the message is received, the recipient follows these steps to verify the signature:

1. Recomputes the digest code for the message.
2. Decrypts the signature by using the sender's public key. This decryption yields the original digest code for the message.
3. Compares the original and recomputed digest codes. If these codes match, the message is both intact and authentic. If not, something has changed and the message is not to be trusted.

Administration security

Administration security controls the rights of users to complete administrative tasks for integration nodes, integration servers, and other IBM App Connect Enterprise resources.

The following topics introduce the concepts that you need to understand before you can set up administration security for IBM App Connect Enterprise, and explain the steps involved in securing integration nodes and their resources:

- “Administration security overview” on page 2497
- “Setting up administration security” on page 2504

You can also control access to independent integration servers and integration nodes by using either HTTP basic authentication or by using SSL or TLS. The following topics explain how to configure basic authentication and SSL or TLS:

- “Configuring HTTP basic authentication for an integration node or server” on page 2548
- “Configuring SSL or TLS for an integration node or server” on page 2548

Administration security overview

Administration security controls users' permissions to access integration nodes, integration servers, and their resources, and to complete administrative tasks.

Administration security is an optional feature of IBM App Connect Enterprise; it is not enabled by default. You can enable authentication and select the required authorization mode, either by using the **mqsichangeauthmode** command or by setting properties in the `server.conf.yaml` or `node.conf.yaml` configuration files. For more information, see “Enabling administration security” on page 2504.

You can control users' access to integration nodes, integration servers, and their resources by associating users with roles. A role is a set of security permissions that control access to runtime components and resources, and each user account is associated with a particular role. The permissions are checked to determine a user's authorization to perform tasks through the web user interface, REST API, IBM App Connect Enterprise Toolkit, and IBM App Connect Enterprise commands. For more information about roles, see “Role-based security” on page 2503, and for information about how to create and assign roles to web users, see “Managing web user accounts” on page 2510.

The following aspects of administration security are supported by IBM App Connect Enterprise:

- Authentication
- Authorization

Authentication

Authentication is the process of establishing the identity of a user or system and verifying that the identity is valid. IBM App Connect Enterprise provides authentication support for the following administration interfaces:

- IBM App Connect Enterprise web user interface

- IBM App Connect Enterprise RESTful application programming interface (API)
- IBM App Connect Enterprise Toolkit
- IBM App Connect Enterprise commands. You can use some commands to provide security credentials when you are connecting to a remote host, by providing an ID and password as a URI, on the **-i** *URI* parameter.

For these administration interfaces, authentication is done by App Connect Enterprise. To use App Connect Enterprise to authenticate a user, you create a web user account with a local password. The user ID and password are then checked against the credentials that are held in the system.

Alternatively, you can use an external LDAP server to authenticate a user. To use an LDAP server, you must configure your integration node to use an LDAP server for authentication. Credentials are checked against the username and password set in the LDAP server. When LDAP is enabled, local passwords are ignored. Unless you intend to use file-based authorization, you do not need to create a web user account with a local password.

For more information about the authentication support that is provided by IBM App Connect Enterprise, see "Authenticating users for administration" on page 2507.

Authorization

Authorization is the process of controlling users' access to resources, by verifying that they have the necessary permissions to complete the requested actions against the specified resources.

When administration security is enabled, you can control users' access to integration nodes, integration servers, and resources. Control the access by setting permissions that allow user IDs associated with specified roles to complete actions on specified resources. App Connect Enterprise checks the authorizations when it receives a request to view or change its properties or resources. If the user ID associated with the request is not authorized, the request is denied. Permissions are checked for all actions that are attempted by users of the following interfaces:

- IBM App Connect Enterprise
- IBM App Connect Enterprise Toolkit sessions
- IBM App Connect Enterprise RESTful application programming interface (API)
- Java programs that use the IBM Integration API to complete operations on the integration node.
- All the following commands:
  - **mqsichangeresourcestats**
  - **mqsicreateexecutiongroup**
  - **mqsideleteexecutiongroup**
  - **mqsideploy**
  - **mqsilist**
  - **mqsimode**
  - **mqsireloadsecurity**
  - **mqsireportresourcestats**
  - **mqsistartmsgflow**
  - **mqsistopmsgflow**
  - **mqsiwebuseradmin**

  For more information about authorization that is required for these commands, see Commands and authorizations for administration security.

  You can run all commands that are not stated here only on the computer on which the integration node or server is running. When you run any unlisted commands, the user ID that is used to run the commands must be a member of the security group mqbrkrs. Alternatively, it must be the same user ID that is running the integration node or server.

Users of the web user interface and the IBM App Connect Enterprise Toolkit who do not have read, write, and execute permissions for the integration node or integration servers, have only restricted access to those resources.

For **integration nodes** and their managed integration servers, three modes of authorization are supported: file-based authorization (*file* mode), queue-based authorization (*mq* mode), and LDAP authorization mode. You can enable administration security for an integration node and specify file-based authorization or queue-based authorization mode, by using either of the following methods:

- Use the **mqsichangeauthmode** command, as described in "Configuring authorization by using the mqsichangeauthmode command" on page 2528.
- Set the properties in the integration node's `node.conf.yaml` configuration file, as described in "Configuring authorization for an integration node by modifying the node.conf.yaml file" on page 2523.

You can specify LDAP authorization by setting properties in the integration node's configuration file, as described in "Configuring authorization by using LDAP groups" on page 2537.

For independent **integration servers**, file-based authorization (*file* mode), and LDAP authorization are supported. You can enable file-based authorization for an independent integration server (which is not managed by an integration node), by using one of the following methods:

- Use the **mqsichangeauthmode** command as described in "Configuring authorization by using the mqsichangeauthmode command" on page 2528.
- Set the properties in the integration server's `server.conf.yaml` configuration file, as described in "Configuring authorization for an integration server by modifying the server.conf.yaml file" on page 2526.

You can enable LDAP authorization for an independent integration server (which is not managed by an integration node), by setting properties in the integration server's `server.conf.yaml` configuration file, as described in "Configuring authorization by using LDAP groups" on page 2537.

File-based authorization (*file* mode)

File-based authorization can be configured for integration nodes (and their managed integration servers) and for independent integration servers.

If an integration node or server is configured to use file-based authorization, you can grant permissions to a role by using the command, or by setting permissions in the `node.conf.yaml` or `server.conf.yaml` configuration file. For more information, see and "Setting file-based permissions" on page 2530.

If no permissions are found for the role name, a check is conducted to see if the role name matches a system user ID. If a matching system user ID exists, and if it is a member of the mqbrkrs group, full permissions are given.

Queue-based authorization (*mq* mode)

Queue-based authorization can be configured for integration nodes (and their managed integration servers).

If the queue-based mode of authorization is set for an integration node, you specify permissions on authorization queues, which are defined on the queue manager that is specified on the integration node:

- SYSTEM.BROKER.AUTH. This queue represents the integration node and its properties. Only one queue exists of this name for each integration node. This queue is defined as a local queue.
- One SYSTEM.BROKER.AUTH.*EG* for each integration server that you define on the integration node, where *EG* is the name of the integration server. These queues are defined as alias queues.

Read, write, and execute authorities are granted automatically to the user group mqbrkrs on the SYSTEM.BROKER.AUTH queue.

When you create an integration server on an integration node for which security is enabled, the integration server authorization queue SYSTEM.BROKER.AUTH.*EG* is created, where *EG* is the name of the integration server. Read, write, and execute authorities are automatically granted to the user group mqbrkrs on this queue.

If the integration node is configured to use queue-based authorization, you must create a system user ID on the operating system on which your integration node is running. You then assign permissions to the system user ID, and this set of permissions represents a role with a name that corresponds to the name of the system user ID. For example, the set of permissions that you define for a system user who is called `ibmuser` for a role that is called `ibmuser`. For more information about setting permissions for queue-based authorization, see "Setting queue-based permissions" on page 2533.

LDAP authorization mode

LDAP authorization can be configured for integration nodes (and their managed integration servers) and for independent integration servers. If an integration node or server is configured to use LDAP authorization, you can grant permissions to a role by setting permissions in the `node.conf.yaml` or `server.conf.yaml` configuration file. For more information, see "Configuring authorization by using LDAP groups" on page 2537.

For more information about the authorization support provided by IBM App Connect Enterprise, see "Authorizing users for administration" on page 2516 and "Role-based security" on page 2503.

For more information about security permissions, see the following topics:

- "Permissions for acting on integration nodes, integration servers, and resources" on page 2518
- "Permissions for connecting to a queue manager" on page 2521
- "Setting file-based permissions" on page 2530
- "Setting queue-based permissions" on page 2533
- "Authorization queues for queue-based administration security" on page 2501
- "Role-based security" on page 2503

IBM App Connect Enterprise permissions and equivalent IBM MQ permissions and LDAP permissions

If you have enabled integration node administration security, you can give different permissions to user IDs to allow them to complete various actions against an integration node or its resources.

When a user requests an action against an integration node or an integration server, the integration node accesses the stored authorization information to check whether the user ID has the required permissions for that action against the target resource.

If queue-based administration security is enabled on the integration node, permissions are specified on authorization queues. Permission to perform an integration node administration task is mapped to an IBM MQ authority associated with the relevant authorization queue, and is created and maintained by the integration administrator.

If file-based security is enabled on the integration node, permissions are specified using the **`mqsichangefileauth`** command, and can be created and maintained by user IDs that are members of the mqbrkrs group.

If LDAP security is enabled on the integration node, permissions are specified by setting properties in the `node.conf.yaml` configuration file.

The mapping from integration node permission to IBM MQ permission, file-based permission and LDAP permission is shown in the following table.

Integration node permission	**IBM MQ permission**	**MQ queue-based permission (using `setmqaut`)**	**File-based permission (using `mqsichangefileauth`) or LDAP permission (using .conf.yaml configuration file)**
Read	Inquire	+INQ	read+
Write	Put	+PUT	write+

Integration node permission	IBM MQ permission	MQ queue-based permission (using `setmqaut`)	File-based permission (using `mqsichangefileauth`) or LDAP permission (using .conf.yaml configuration file)
Execute	Set	+SET	set+

For information about the authorizations that are required for specific tasks, see Tasks and authorizations for administration security.

IBM MQ specific and generic profiles

IBM MQ supports both specific and generic profiles to manage IBM MQ permissions. When you enable queue-based administration security, you can create specific profiles to define IBM MQ permissions on SYSTEM.BROKER.AUTH and on one or more SYSTEM.BROKER.AUTH.*EG* queues (where *EG* is the name of a specific integration server).

You might want to grant a user, or group of users, authority to a number of integration servers, or perhaps all integration servers. You can use an IBM MQ generic profile to grant authority in this way. A generic profile defines authority to an existing set of integration servers, and all additional groups, that match the profile. A generic profile is one that uses special characters (wildcard characters) in the profile name, such as asterisks (*).

For example, if you want to create a generic profile to authorize access to all integration servers defined on the integration node, you can specify SYSTEM.BROKER.AUTH.**. If you want a profile for a set of integration servers with names that all start with the same character string, you can specify SYSTEM.BROKER.AUTH.TEST**.

For more information about IBM MQ generic profile wildcard characters, see Wildcards used in generic profiles, and for information about IBM MQ generic profile priorities, see Profile priorities in the IBM MQ product documentation online.

Authorization queues for queue-based administration security

If the queue-based mode of administration security is enabled, the integration node examines specific queues to determine whether a user has the required permissions to complete a particular task against the integration node or its resources.

If a queue manager is specified on the integration node, the queue-based mode of administration security (*mq* mode) is specified by default. For more information about authorization modes, see “Configuring administration security to use file-based, queue-based, or LDAP authorization” on page 2523.

You set security permissions on the following authorization queues:

SYSTEM.BROKER.AUTH
: The queue SYSTEM.BROKER.AUTH is created when you use the **mqsichangeauthmode** command to enable queue-based administration security (`mq` mode) on the integration node. Read, write, and execute permissions are granted automatically to the user group mqbrkrs on this queue. The SYSTEM.BROKER.AUTH queue is created as a local queue, and is used to define which users are authorized to perform actions on the integration node and its properties.

  If the **mqsichangeauthmode** command fails to create the queue for any reason, you can create it manually; see “Creating the default system queues on an IBM MQ queue manager” on page 99.

SYSTEM.BROKER.AUTH.*integrationServerName*
: When you create an integration server on an integration node for which you have enabled queue-based administration security, the integration server authorization queue SYSTEM.BROKER.AUTH.*integrationServerName* is created (if it did not already exist), where *integrationServerName* is the name of the integration server. If the queue already exists, check that the permissions are appropriate. Read, write, and execute permissions are automatically granted to

the user group mqbrkrs on this queue. The dedicated integration server queues are created as aliases to the queue SYSTEM.BROKER.AUTH.

If the integration node fails to create the queue for any reason, you can create it manually; see "Creating the default system queues on an IBM MQ queue manager" on page 99.

SYSTEM.BROKER.DC.AUTH

When you use the **mqsicreatebroker** command to create an integration node with an associated queue manager, the SYSTEM.BROKER.DC.AUTH queue is created automatically. If you create the integration node without specifying a queue manager, and subsequently modify it to specify a queue manager and enable queue-based administration security (`mq` mode), you must also create the SYSTEM.BROKER.DC.AUTH queue; see "Creating the default system queues on an IBM MQ queue manager" on page 99.

SYSTEM.BROKER.DC.AUTH.*integrationServerName*

When you create an integration server on an integration node for which you have enabled queue-based administration security, the integration server authorization queue SYSTEM.BROKER.DC.AUTH.*integrationServerName* is created (if it did not already exist), where *integrationServerName* is the name of the integration server. If the queue already exists, check that the permissions are appropriate. Read, write, and execute permissions are automatically granted to the user group *mqbrkrs* on this queue. The dedicated integration server queues are created as aliases to the queue SYSTEM.BROKER.DC.AUTH.

If the integration node fails to create the queue for any reason, you can create it manually; see "Creating the default system queues on an IBM MQ queue manager" on page 99.

If you create an integration node without enabling administration security, you can change it later by using the **mqsichangeauthmode** command. If you have defined one or more integration servers on that integration node when you change its security setting, the required integration server authorization queues are defined.

A queue can be created only by a user ID that is a member of the IBM MQ security group mqm. Therefore, the user ID that is used to create or change an integration node, and the ID under which the integration node is running when an integration server is created, must be a member of that security group. If the user ID does not have the required permissions, a message is returned to the command , or written to the system log, with the error and the name of the queue. You must create the queue yourself, or ask your IBM MQ administrator to create it for you.

IBM MQ restricts the length of a queue name to 48 characters. Queue name characters must be in the En_US ASCII character set, and contain only uppercase and lowercase letters, digits, and the following special characters: period (.), forward slash (/), underscore (_), and percent (%). If the name of your integration server includes a character that is not valid, that character is replaced in the IBM MQ queue name by an underscore character. For example, if you create an integration server with the name `test@environment`, the authorization queue is created with the name SYSTEM.BROKER.AUTH.test_environment.

If you are running a secure environment, limit the names of your integration servers to 26 characters. This limit ensures that the authorization queue names generated, which include the prefix SYSTEM.BROKER.AUTH, do not exceed the IBM MQ limit of 48 characters.

If your integration server names do not all conform to the length and character requirements, integration servers with similar names might result in a shared authorization queue. If this situation occurs, a warning message is returned to the user that issued the command, or is written to the system log, when the second integration server is created to state that the queue is shared.

When you delete an integration server, its associated authorization queue is retained. The queue is deleted if you specify the appropriate parameter when you delete the integration node. The queue can be reused if you recreate the integration server, but you must check the permissions that you have defined on the queue to ensure that they are still valid.

If you rename an integration server, you must first create an authorization queue with the appropriate name. You must also recreate the IBM MQ permissions associated with the original authorization queue

on this queue before you rename the integration server; the integration node does not perform this task on your behalf. The integration node rejects the rename request if the authorization queue does not exist, to ensure that security is not affected by the renaming. If you do not recreate these permissions, no user IDs are authorized to perform a task against the renamed integration server.

When you delete an integration node, you can specify that all its authorization queues are also deleted; they are not deleted by default.

For more information about setting permissions for queue-based authorization, see "Setting queue-based permissions" on page 2533.

Role-based security

You can control access to integration nodes, integration servers, and their resources through the web user interface, REST application programming interface (API), IBM App Connect Enterprise Toolkit, and App Connect Enterprise commands, by associating users with roles.

A *role* is defined by a set of security permissions that control users' access to an integration node or integration server, and its associated resources.

As an integration administrator, you can control the access that web users have to integration nodes, integration servers, and resources, by assigning each user to a role. You can authorize users with a particular role to complete specific actions; for example, you might allow users with one role to view integration server resources, while allowing users with another role to modify them.

You can grant the same permissions to multiple users by assigning them to the same role, but each user can be assigned to only one role.

You can configure integration nodes (and their associated integration servers) to use file-based authorization, queue-based authorization, or LDAP authorization. You can configure independent integration servers (which are not associated with an integration node) to use file-based authorization or LDAP authorization. For information about how to set the authorization mode, see "Configuring administration security to use file-based, queue-based, or LDAP authorization" on page 2523.

If an integration node or an independent integration server is configured to use file-based authorization (**file** mode), you can grant permissions to a role either by using the **-r** *role* and **-p** *permissions* parameters of the command, or by setting permissions in the `node.conf.yaml` or `server.conf.yaml` configuration files. For more information about file-based authorization, see "Setting file-based permissions" on page 2530.

In **file** mode, if a user is assigned to a role that has no permissions defined, when that user attempts an action, a check is made to see whether the role name matches a local operating system user name. If there is a match (for example, both the role name and operating system user name are `aceadmin`), a check is made to see whether that user name is a member of the mqbrkrs group. If it is a member, permission is granted for all actions on all objects.

If an integration node is configured to use queue-based authorization (**mq** mode), you must create a system user name on the operating system on which your integration node is running. You then assign permissions to the system user name, and this set of permissions represents a role with a name that corresponds to the name of the system user name. For example, the set of permissions that you define for a system user called `ibmuser` form a role called `ibmuser`. For information about setting permissions for queue-based authorization, see "Setting queue-based permissions" on page 2533.

If an integration node or an independent integration server is configured to use LDAP authorization (**ldap** mode), you can grant permissions to a role by setting permissions in the `node.conf.yaml` or `server.conf.yaml` configuration files. For more information about LDAP authorization, see "Configuring authorization by using LDAP groups" on page 2537.

You can create web user accounts and assign them to the appropriate roles by using the command. For more information, see "Managing web user accounts" on page 2510 and "Controlling access to data and resources in the web user interface" on page 2544.

Setting up administration security

Control the actions that users can perform on an integration node or integration server, and its resources.

About this task

You can enable administration security and specify the required authorization mode for an integration node or integration server by using the command or in the node.conf.yaml or server.conf.yaml configuration file. When you have activated administration security, grant users or groups the required permissions to complete their tasks.

You can grant permissions to users of the web user interface by associating the web user account with a predefined role. For more information, see “Role-based security” on page 2503 and “Managing web user accounts” on page 2510.

Procedure

To set up administration security for an integration node or integration server, complete the following steps:

1. Enable administration security and set the required authorization mode.

   For more information, see “Enabling administration security” on page 2504.
2. Control access to the administration interfaces by using the authentication capabilities that are provided with IBM App Connect Enterprise.

   For more information, see “Authenticating users for administration” on page 2507 and “Managing web user accounts” on page 2510.
3. Set the appropriate permissions to authorize users to complete specific tasks.

   For more information, see “Authorizing users for administration” on page 2516.

Enabling administration security

Enable administration security on an integration node or integration server, to control which users can complete specific tasks against that integration node or server and its resources.

About this task

If you do not enable administration security for an integration node, all users are able to complete all actions against the integration node and all its managed integration servers. If you do not enable administration security for an independent integration server (which is not managed by an integration node), all users are able to complete all actions against that integration server and its resources. If administration security is not enabled, web users can access the web user interface as the default user, with unrestricted access to data and resources.

You can enable administration security and specify the authorization mode for an integration node or integration server, either by setting the **`authorizationEnabled`** and **`authorizationMode`** properties in the `node.conf.yaml` or `server.conf.yaml` configuration files, or by using the **`mqsichangeauthmode`** command.

Procedure

Enable administration security for an integration node or integration server by following the steps in one of the following topics:

- “Enabling administration security by using the node.conf.yaml or server.conf.yaml configuration file” on page 2505
- “Enabling administration security by using the mqsichangeauthmode command” on page 2506

What to do next

Set the required permissions to enable users to complete the appropriate tasks on the integration node or integration server and resources. This task is described in "Authorizing users for administration" on page 2516. For more information about specifying authorization modes, see "Configuring administration security to use file-based, queue-based, or LDAP authorization" on page 2523.

Enabling administration security by using the node.conf.yaml or server.conf.yaml configuration file

Enable administration security on an integration node or integration server to control which users can complete specific tasks against it and its resources.

About this task

If you do not enable administration security for an integration node, all users are able to complete all actions against the integration node and all its managed integration servers. If you do not enable administration security for an independent integration server, all users are able to complete all actions against that integration server and its resources. If administration security is not enabled, web users can access the web user interface as the default user, with unrestricted access to data and resources.

You can enable administration security and specify the authorization mode for the integration node or server, by setting properties in the **`Admin Security`** section of the `node.conf.yaml` or `server.conf.yaml` configuration file for the relevant integration node or server.

Procedure

1. Open the `node.conf.yaml` or `server.conf.yaml` configuration file for your integration node or server, by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, because they are not valid characters in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
2. In the relevant `node.conf.yaml` or `server.conf.yaml` file, set the **`basicAuth`**, **`authorizationEnabled`**, and **`authorizationMode`** properties:
   a) Enable basic authentication by setting the **`basicAuth`** property to `true`:

   ```
   basicAuth: true
   ```

   b) Enable authorization by setting the **`authorizationEnabled`** property to `true`:

   ```
   authorizationEnabled: true
   ```

   c) Specify the authorization mode that you require, by setting the **`authorizationMode`** property to `file`, `mq`, or `ldap`.

   For example, to enable administration security with the file-based authorization mode:

   ```
   authorizationMode: file
   ```

3. Optional: If basic authentication is enabled, you can use the following properties to control the maximum number of login attempts that can be made within a specified period before the client is locked out:
   - **authMaxAttempts** - the maximum number of login attempts that can be made during the specified period before being blocked (default is 5)
   - **authAttemptsDuration** - the period of time (in seconds) during which the maximum number of login attempts can be made before being blocked (default is 300)
   - **authBlockedDuration** - the period of time (in seconds) for which the client is blocked from logging in when the maximum number of login attempts has been reached without success (default is 300).

   For example:

```
Admin Security
   Authentication
   #  If basicAuth is enabled, a maximum of authMaxAttempts authentication attempts are
 allowed for a client within period authAttemptsDuration
   #  If authMaxAttempts is reached without success, the client is locked out for period
 authBlockedDuration
      basicAuth: true                # Clients web user name and password will be
 authenticated when set true
      authMaxAttempts: 3             # Max allowed authentication attempts
      authAttemptsDuration: 300      # Authentication attempts period in seconds
      authBlockedDuration: 600       # Authentication blocked period in seconds
```

4. Save the modified `.yaml` file.
5. Restart the integration node or server for the changes to take effect.

What to do next

Set the required permissions to enable users to complete the appropriate tasks on the integration node or server and its resources. This task is described in "Authorizing users for administration" on page 2516. For more information about specifying authorization modes, see "Configuring administration security to use file-based, queue-based, or LDAP authorization" on page 2523.

Enabling administration security by using the `mqsichangeauthmode` command

Enable administration security on an integration node or server to control which users can complete specific tasks against it and its resources.

About this task

If administration security is not enabled, web users can access the web user interface as the default user, with unrestricted access to data and resources.

If you do not enable administration security for an integration node, all users are able to complete all actions against the integration node, the integration servers that it manages, and all associated resources. If you do not enable administration security for an independent integration server, all users are able to complete all actions against the integration server and its resources.

You can enable administration security and specify the authorization mode for the integration node or server by using the **mqsichangeauthmode** command to specify queue-based administration security, or file-based authorization mode. For information about LDAP authorization, see "Configuring authorization by using LDAP groups" on page 2537.

You can set additional administration security properties, such as the maximum number of login attempts that can be made before a client is locked out, by editing the `node.conf.yaml` or `server.conf.yaml` configuration file for the integration node or server. For more information, see "Enabling administration security by using the node.conf.yaml or server.conf.yaml configuration file" on page 2505.

Procedure

To enable administration security by using the **mqsichangeauthmode** command, complete the following steps:

1. Stop the integration node by using the web user interface or by running the command.
2. Enable administration security and specify the authorization mode, by using the command:
   a) Enable administration security by specifying the **-s active** parameter on the **mqsichangeauthmode** command.
   b) Specify the authorization mode that you require by using the **-m** parameter.

      For example, to enable administration security with the file-based authorization mode for the ACE11NODE integration node, enter the following command:

      ```
      mqsichangeauthmode ACE11NODE -s active -m file
      ```

      where `-s active` enables administration security for the integration node, and `-m file` specifies the file-based authorization mode.

      If you have chosen to use queue-based administration security (`mq` mode), ensure that the queue manager specified on the integration node is running.
3. Ensure that the system user ID that runs the **mqsichangeauthmode** command is a member of the mqbrkrs group. Read, write, and execute permissions are granted automatically on the integration node to all user IDs that belong to this group.

   If you have chosen to use queue-based administration security (`mq` mode), ensure that the user ID is a member of the mqm group, with permission to create the required authorization queues. If the queues are not created automatically, you can create them manually; see "Creating the default system queues on an IBM MQ queue manager" on page 99. For more information, see "Authorization queues for queue-based administration security" on page 2501.

   Manage the membership of the mqbrkrs group and mqm group with care, and ensure that this level of authorization is granted only to users who require it.
4. Start the integration node by using the web user interface or the command.

What to do next

Set the required permissions to enable users to complete the appropriate tasks on the integration node and its resources. This task is described in "Authorizing users for administration" on page 2516. For more information about specifying authorization modes, see "Configuring administration security to use file-based, queue-based, or LDAP authorization" on page 2523.

Authenticating users for administration

Authentication is the process of establishing the identity of a user or system and verifying that the identity is valid. You can control access to the IBM App Connect Enterprise administration interfaces by using the authentication capabilities that are provided with the product.

Before you begin

Read the following topics:

- "Administration security overview" on page 2497
- "Setting up administration security" on page 2504
- "Role-based security" on page 2503

About this task

IBM App Connect Enterprise provides authentication support for the following administration interfaces:

- IBM App Connect Enterprise web user interface.

- IBM App Connect Enterprise RESTful application programming interface (REST API).
- IBM App Connect Enterprise Toolkit.
- IBM App Connect Enterprise commands.

If administration security authentication (**basicAuth**) is enabled, users of the web user interface and the REST API must log in with a user ID and password. If LDAP authentication is enabled on the integration node or independent integration server, then all users are authenticated by the LDAP server. Any local passwords are ignored. If LDAP authentication is not configured, then the user ID and password are checked against the credentials that are held in the integration node or independent integration server. Users' access to data and resources is controlled by the permissions that are associated with their role. For more information, see “Role-based security” on page 2503.

If administration security is not enabled, web users can interact with the IBM App Connect Enterprise web user interface without logging on. They interact with the web UI as the 'default' user and can access all data and resources. For users of the REST API, all REST requests are unrestricted if administration security is not enabled.

For the following administration interfaces, authentication is provided only by the system login; no additional authentication is carried out:

- IBM App Connect Enterprise Toolkit
- IBM Integration API
- IBM App Connect Enterprise commands (when they make a local connection, specifying only the integration node name)

For more information about authenticating users for administration, see “Managing web user accounts” on page 2510 and “Accessing the web user interface” on page 89.

For more information about authenticating web user accounts by using LDAP, see “Enabling LDAP authentication” on page 2511.

For more information about authorizing users based on the role to which they are assigned, see “Authorizing users for administration” on page 2516.

You can enable authentication for users of IBM App Connect Enterprise administration interfaces, either by using the **mqsichangeauthmode** command, or by setting security properties in the appropriate `.yaml` configuration file for your integration node or server.

Procedure

Enable authentication by completing the steps in one of the following tasks:

- “Enable authentication by using the mqsichangeauthmode command” on page 2508
- “Enable authentication by modifying the node.conf.yaml or server.conf.yaml file” on page 2509

Enable authentication by using the `mqsichangeauthmode` command

About this task

Complete the following steps to enable authentication for users of the IBM App Connect Enterprise administration interfaces, by using the **mqsichangeauthmode** command:

Procedure

1. Run the **mqsichangeauthmode** command on your integration node or server. Specify the **-b** parameter to enable authentication only, as shown in the following example:

   ```
   mqsichangeauthmode -w myIntegrationServerWorkPath -b active
   ```

   In this example, authentication is enabled on the independent integration server, the work path of which is specified by the **-w** parameter.

   In the following example, authentication is enabled on the integration node ACE11NODE:

   ```
   mqsichangeauthmode ACE11NODE -b active
   ```

   Alternatively, you can specify the **-s** parameter, which configures both authentication and authorization. For more information, see command.
2. Restart your integration node or integration server for the changes to take effect.

Enable authentication by modifying the node.conf.yaml or server.conf.yaml file

About this task

Modify properties in the `.yaml` configuration file for your integration node or integration server to enable authentication for users of the IBM App Connect Enterprise administration interfaces.

Procedure

1. Open the `node.conf.yaml` or `server.conf.yaml` configuration file for your integration node or server, by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor. However, you must ensure that you do not include any tab characters, which are invalid characters in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
2. In the Admin Security Authentication section of the `.yaml` configuration file, set the **basicAuth** property to `true`:

   ```
   basicAuth: true
   ```
3. Optional: If basic authentication is enabled, you can use the following properties to set the maximum number of login attempts that can be made within a specified period before the client is locked out:
   - **authMaxAttempts** - the maximum number of login attempts that can be made during the specified period before the user is blocked from logging in (default is 5)
   - **authAttemptsDuration** - the time (in seconds) during which the maximum number of login attempts can be made before the user is blocked from logging in (default is 300)
   - **authBlockedDuration** - the time (in seconds) for which the client is blocked from logging in when the maximum number of login attempts has been reached without success (default is 300).

   For example,

   ```
   Admin Security
      Authentication
      #  If basicAuth is enabled, a maximum of authMaxAttempts authentication attempts are
    allowed for a client within period authAttemptsDuration
      #  If authMaxAttempts is reached without success, the client is locked out for period
    authBlockedDuration
         basicAuth: true                                                  # Clients web user
    name and password will be authenticated when set true
         authMaxAttempts: 3                                               # Max allowed
    authentication attempts
         authAttemptsDuration: 300                                        # Authentication
    attempts period in seconds
   ```

```
      authBlockedDuration: 600                                          # Authentication
  blocked period in seconds
```

4. Save the `.yaml` configuration file.
5. Restart your integration node or integration server for the changes to take effect.

Managing web user accounts

IBM App Connect Enterprise administrators can use the **mqsiwebuseradmin** command to create a new web user, to set, or change a web user's password, to remove a web user or to assign a web user to a role.

Before you begin

Read the following topics:

- web user interface
- “Accessing the web user interface” on page 89
- “Role-based security” on page 2503

About this task

If administration security is enabled, web users can access the web user interface only when they log on using their web user account. As an administrator, you can create multiple roles, with different permissions assigned to them. You can then assign one or more web users to a role. The web users access to data and resources is controlled by the permissions that are set for their role. For more information, see “Role-based security” on page 2503.

If administration security is not enabled, web users can interact with the web user interface without logging on. They interact with the web user interface as the 'default' user and can access all data and resources.

If the integration node or integration server is configured to use file-based authorization, you assign permissions to the role by using the **mqsichangefileauth** command or in the node.conf.yaml or server.conf.yaml configuration file. Permissions are set for the integration node or integration server, and the data capture object. For more information about setting permissions for file-based authorization, see “Setting file-based permissions” on page 2530.

If the integration node is configured to use queue-based authorization (**mq** mode), you must create a system user ID on the operating system that is running your integration node. This system user is then used as a role, and you assign permissions to it by setting them on the following authorization queues:

- SYSTEM.BROKER.AUTH
- SYSTEM.BROKER.AUTH.*integrationServerName*
- SYSTEM.BROKER.DC.AUTH

For more information about setting permissions for queue-based authorization, see “Setting queue-based permissions” on page 2533.

If the integration node or integration server is configured to use LDAP authorization, you assign permissions to the role by configuring node.conf.yaml or server.conf.yaml configuration file. Permissions are set for the integration node or integration server. For information about setting permissions for LDAP authorization, see “Configuring authorization by using LDAP groups” on page 2537.

For more information about how to set the permissions that are required for using the web user interface, see “Controlling access to data and resources in the web user interface” on page 2544.

When you define your roles and set the required permissions, you can assign web users to the appropriate role, and they acquire permissions through their assigned role.

Procedure

Complete these steps to grant access to web users based on their assigned role:

1. Stop the integration node or integration server for which you are configuring administration security.
2. Enable administration security for the integration node or server by using the **mqsichangeauthmode** command, or in the node.conf.yaml or server.conf.yaml configuration file, specifying your chosen authorization mode.

   For example, to enable administration security with the file-based authorization mode for the ACE11NODE integration node, enter the following command.

   ```
   mqsichangeauthmode ACE11NODE -s active -m file
   ```

   where `-s active` enables administration security for the integration node, and `-m file` specifies the file-based authorization mode.

   The following example enables authentication only (not authorization) on an independent integration server whose work path is specified by the **-w** parameter:

   ```
   mqsichangeauthmode -w myIntegrationServerWorkpath -b active
   ```

   For more information, see command and “Enabling administration security” on page 2504.
3. Define the roles and their associated permissions. You can assign permissions to each role that you identify. For example, you might decide that your web users can be categorized into two main roles: web administrators and web users. Define a role for each of these groups of users (for example, `ACEUsers` and `ACEAdmins`) with permissions that allow them to complete the required tasks, such as viewing or modifying resources:

   - If the integration node or server is configured to use file-based authorization (**file** mode), you define the roles and associated permissions by using the **mqsichangefileauth** command or in the node.conf.yaml or server.conf.yaml configuration file. For more information about setting permissions for file-based authorization, see “Setting file-based permissions” on page 2530.
   - If the integration node is configured to use queue-based authorization (**mq** mode), you must create a system user ID on the operating system for each role that you identify. You must then assign permissions to the system user ID, which is then used as a role. For information about setting permissions for queue-based authorization, see “Setting queue-based permissions” on page 2533.
   - If the integration node or server is configured to use LDAP authorization (**ldap** mode), you define the roles and associated permissions by configuring the node.conf.yaml or server.conf.yaml configuration file. For information about setting permissions for LDAP authorization, see “Configuring authorization by using LDAP groups” on page 2537.

   For more information about setting the appropriate permissions, see “Authorizing users for administration” on page 2516 and “Controlling access to data and resources in the web user interface” on page 2544.
4. Use the **mqsiwebuseradmin** command to create your web user accounts and assign them to the appropriate roles.

   For more information, see command. For more information about roles, see “Role-based security” on page 2503. For more information about authenticating web user accounts by using LDAP, see “Enabling LDAP authentication by using the mqsichangeproperties command” on page 2515.

   If you add a local password by using the **-a** parameter, and LDAP authentication is enabled, the local password is ignored. When LDAP authentication is enabled, all web user logins must be authenticated by using LDAP. Any local passwords are ignored.
5. Restart the integration node or integration server for the changes to take effect.

Enabling LDAP authentication

Web user accounts can be authenticated against a Lightweight Directory Access Protocol (LDAP) or Secure LDAP (LDAPS) server. You can authenticate web users by using the REST API, the web user

interface, the IBM App Connect Enterprise Toolkit, or custom integration applications that use the Integration API.

Before you begin

Ensure that you have an LDAP server that is LDAP Version 3 compliant, for example:

- IBM Tivoli Directory Server
- Microsoft Active Directory
- OpenLDAP

About this task

You can enable LDAP authentication for an integration node. See "Enabling an integration node to use LDAP for authentication" on page 2512. You can also enable LDAP authentication for an integration server. See "Enabling an integration server to use LDAP for authentication" on page 2513.

If a web user account has a local password, and LDAP authentication is enabled, the local password is ignored. When LDAP authentication is enabled, all web user logins must be authenticated by using LDAP. Any local passwords are ignored.

Enabling an integration node to use LDAP for authentication

About this task

You can enable LDAP authentication for an integration node by modifying the `node.conf.yaml` configuration file, by following the steps in the following procedure.
Alternatively, you can enable LDAP authentication for an integration node by running the `mqsichangeproperties` command. For more information, see "Enabling LDAP authentication by using the mqsichangeproperties command" on page 2515.

Procedure

1. Stop the integration node. See "Starting and stopping an integration node on Windows, Linux, and UNIX systems" on page 247.
2. Open the `node.conf.yaml` configuration file for your integration node by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor. However, you must ensure that you do not include any tab characters because they are invalid in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
   The properties that you need to set are in the **`Admin Security`** section of the `node.conf.yaml` configuration file:

```
Admin Security:
#  Authentication
  #basicAuth: true                                                  # Clients web user name
 and password will be authenticated when set true
  #ldapUrl: ldap[s]://server[:port]/baseDN[?[uid_attr][?[base|sub]]]  # ldap authentication
 url
  #ldapBindDn: ldap::adminAuthentication                            # Resource alias or
 full bind dn
  #ldapBindPassword: ldap::adminAuthentication                      # Resource alias or
 bind password
  #  Authorization
  #authorizationEnabled: false     # Clients web user role will be authorized when set true
  #authorizationMode: 'file'       # Set authorization mode. Choose 1 of : ldap, file or mq
```

3. Set the following properties:
   a) Set the **basicAuth** property to `true`.
   b) Set the **ldapUrl** property to the URL of your LDAP server.
   c) Optional: Specify the service credentials to be used by the integration node when it binds to the LDAP server during a query. This information is required if the `sub` option is used in the **ldapUrl** and your LDAP server does not support anonymous bind.

      To specify these credentials, set the **ldapBindDn** and **ldapBindPassword** properties. For example:

      - **ldapBindDn**: *CN=XXXXXXXXX-XXXXXX,OU=PSST,OU=SAUsers,OU=PBS,OU=SS,DC=ent,DC=ds,DC=xxx,DC=xxx*
      - **ldapBindPassword**: *ldap::adminAuthentication*

      Set these properties by using one of the following methods:

      - Set the properties in the `node.conf.yaml` file (which stores the credential in clear text).
      - Set an alias name that you then use with the **mqsisetdbparms** command.
      - Set an alias name that you then use with the **mqsicredentials** command to store the LDAP bind DN and password.
4. Start the integration node. See "Starting and stopping an integration node on Windows, Linux, and UNIX systems" on page 247.
5. Optional: Configure the web user accounts for each user that you want to authorize. This step is not required if you intend to configure authorization by using LDAP groups. See "Configuring authorization by using LDAP groups" on page 2537. The step is required when you use file-based or queue-based authorization. See "Configuring administration security to use file-based, queue-based, or LDAP authorization" on page 2523. Either create new web user accounts or modify existing web user accounts:

   - Create a web user account by using the **mqsiwebuseradmin** command. For example,

     ```
     mqsiwebuseradmin intNode -c -u ldapusername -x -r sysrole
     ```

     where *ldapusername* is the username in the LDAP directory, and *sysrole* is the role to associate with the web user account. For more information about roles, see "Role-based security" on page 2503.
   - Modify an existing web user account to remove any local password. For example,

     ```
     mqsiwebuseradmin intNode -m -u ldapusername -x -r sysrole
     ```

     You can modify an existing web user account to be authenticated by using LDAP only if the existing username matches the username in the LDAP directory. If the usernames do not match, you must create a new web user account.

Enabling an integration server to use LDAP for authentication

Procedure

1. Stop the integration server. See "Stopping an integration server" on page 254.
2. Open the `server.conf.yaml` configuration file for your integration server by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor. However, you must ensure that you do not include any tab characters because they are invalid in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
   The properties that you need to set are in the **Admin Security** section of the `server.conf.yaml` configuration file:

   ```
   Admin Security:
   #  Authentication
   ```

```
 #basicAuth: true                                                    # Clients web user name
and password will be authenticated when set true
 #ldapUrl: ldap[s]://server[:port]/baseDN[?[uid_attr][?[base|sub]]]  # ldap authentication
url
 #ldapBindDn: ldap::adminAuthentication                              # Resource alias or
full bind dn
 #ldapBindPassword: ldap::adminAuthentication                        # Resource alias or
bind password
 #  Authorization
 #authorizationEnabled: false     # Clients web user role will be authorized when set true
 #authorizationMode: 'file'       # Set authorization mode. Choose 1 of : ldap, file or mq
```

3. Set the following properties:
   a) Set the **basicAuth** property to `true`.
   b) Set the **ldapUrl** property to the URL of your LDAP server.
   c) Optional: Specify the service credentials to be used by the integration server when it binds to the LDAP server during a query. This information is required if the sub option is used in the **ldapUrl** and your LDAP server does not support anonymous bind.

      To specify these credentials, set the **ldapBindDn** and **ldapBindPassword** properties. For example:

      - **ldapBindDn**: *CN=XXXXXXXXX-XXXXXX,OU=PSST,OU=SAUsers,OU=PBS,OU=SS,DC=ent,DC=ds,DC=xxx,DC=xxx*
      - **ldapBindPassword**: *ldap::adminAuthentication*

      Set these properties by using one of the following methods: s

      - Set the properties in the `server.conf.yaml` file (which stores the credential in clear text).
      - Set an alias name that you then use with the **mqsisetdbparms** command.
      - Set an alias name that you then use with the **mqsicredentials** command to store the LDAP bind DN and password.
4. Start the integration server. See "Starting an integration server" on page 250.
5. Optional: Configure the web user accounts for each user that you want to authorize. This step is not required if you intend to configure authorization by using LDAP groups. See "Configuring authorization by using LDAP groups" on page 2537. The step is required when you use file-based or queue-based authorization. See "Configuring administration security to use file-based, queue-based, or LDAP authorization" on page 2523. Either create new web user accounts or modify existing web user accounts:

   - Create a web user account by using the **mqsiwebuseradmin** command. For example,

     ```
     mqsiwebuseradmin intNode -c -u ldapusername -x -r sysrole
     ```

     where *intNode* is the name of the integration node, *ldapusername* is the username in the LDAP directory, and *sysrole* is the role to associate with the web user account. For more information about roles, see "Role-based security" on page 2503.
   - Modify an existing web user account to remove any local password. For example,

     ```
     mqsiwebuseradmin intNode -m -u ldapusername -x -r sysrole
     ```

     You can modify an existing web user account to be authenticated by using LDAP only if the existing username matches the username in the LDAP directory. If the usernames do not match, you must create a new web user account.

What to do next

You might want to authorize users for administration. For more information, see "Authorizing users for administration" on page 2516.

*Enabling LDAP authentication by using the **mqsichangeproperties** command*
Web user accounts can be authenticated against a Lightweight Directory Access Protocol (LDAP) or Secure LDAP (LDAPS) server. You can authenticate web users by using the REST API, the web user interface, the IBM App Connect Enterprise Toolkit, or custom integration applications that use the Integration API.

Before you begin

Ensure that you have an LDAP server that is LDAP Version 3 compliant, for example:

- IBM Tivoli Directory Server
- Microsoft Active Directory
- OpenLDAP

Procedure

1. Open a command window that is configured for your environment.
2. To set the LDAP server that you want to use for authentication, enter the following command on the command line.

```
mqsichangeproperties intNode -b RestAdminListener -n ldapUrl
-v "ldapURL"
```

where *intNode* is the name of your integration node and *ldapURL* is the URL for your LDAP.

Enter the *ldapURL* by using the following syntax:

```
ldap[s]://server[:port]/baseDN[?[uid_attr][?[base|sub]]]
```

ldap or ldaps
(Required) Fixed protocol string. Use `ldaps` to specify that SSL is used.

server
(Required) Name or IP address of the LDAP server.

port
(Optional) Port on the LDAP server. If SSL is not enabled, the default port is 389. If SSL is enabled, the default port is 636.

baseDN
(Required) String that defines the base distinguished name (DN) of all users in the directory. If users exist in different subtrees, specify a common subtree under which a search on the username uniquely resolves to the required user entry, and set the sub attribute.

If users who need access to the integration exist in multiple base DNs, you can specify more than one base DN in the *ldapURL* by enclosing each base DN in parentheses. The following syntax shows how to specify the *ldapURL* when users exist in three base DNs:

```
ldap[s]://server[:port]/|(baseDN1)(baseDN2)(baseDN3)[?[uid_attr][?[base|sub]]]
```

uid_attr
(Optional) String that defines the attribute to which the incoming username maps, typically uid, CN, or email address. The default is uid.

base or sub
(Optional) Defines whether to run a base or subtree search. If `base` is selected, the authentication is faster because the DN of the user is constructed from the uid_att, username, and baseDN

values. If sub is selected, a search must be completed before the DN can be resolved. The default is sub.

For example,

```
ldap://ldap.acme.com:389/ou=sales,o=acme.com
```

or

```
ldaps://localhost:636/ou=sales,o=acme?cn?base
```

Put public server certificates in the integration node truststore for use with LDAPS connections; do not put them in the RestAdminListener truststore.

3. Optional: If you want to configure authorization by using LDAP groups, you must set the **authorizationMode** property to `'ldap'`, by using the **mqsichangeauthmode** command, or by setting it in the `.yaml` configuration file.

   If you set the **authorizationMode** property to `'file'`, or `'mq'`, and you enabled LDAP authentication, you must configure the authorization role for web user account for each user that you want to authorize. To configure the role for each web user, either create new web user account or modify any existing web user accounts as follows:

   - Create a web user account by using the **mqsiwebuseradmin** command. For example,

     ```
     mqsiwebuseradmin intNode -c -u ldapusername -x -r sysrole
     ```

     where *ldapusername* is the username in the LDAP directory, and *sysrole* is the role to associate with the web user account. For more information about roles, see “Role-based security” on page 2503.

     If you add a local password by using the **-a** parameter, and LDAP authentication is enabled, the local password is ignored. When LDAP authentication is enabled, all web user logins must be authenticated by using LDAP. Any local passwords are ignored.

   - Modify an existing web user account to remove any local password. For example,

     ```
     mqsiwebuseradmin intNode -m -u ldapusername -x -r sysrole
     ```

     You can modify an existing web user account to be authenticated by using LDAP only if the existing username matches the username in the LDAP directory. If the usernames do not match, you must create a new web user account.

What to do next

You might want to authorize users for administration. For more information, see “Authorizing users for administration” on page 2516.

Authorizing users for administration

Authorize users to complete specific tasks against an integration node or server and its resources.

About this task

Three levels of permission are supported for IBM App Connect Enterprise administration security: read, write, and execute. These permissions can be applied to each role for the following types of objects:

- Integration node resources
- Integration server resources
- Data resources (record-replay)

For more information about roles, see “Role-based security” on page 2503.

You can enable administration security for an integration node or integration server, either by using the **mqsichangeauthmode** command, or by setting the security properties in the `node.conf.yaml` or `server.conf.yaml` configuration files.

If you enable administration security for an integration node, you can also choose which authorization mode (file-based, queue-based, or LDAP authorization) will be used for setting permissions. For independent integration servers (which are not managed by an integration node), you can specify file-based authorization or LDAP authorization.

You control access to an **integration node** (and the integration servers that it manages) by setting file-based or queue-based permissions, or LDAP authorization. You can set file-based permissions either by using the **mqsichangefileauth** command, or by setting properties in the `node.conf.yaml` configuration file. You can set queue-based permissions by using IBM MQ authorization queues on the queue manager that is specified on the integration node. You can set LDAP authorization by setting properties in the `node.conf.yaml` configuration file. For information about the permissions that are required for working with an integration node and its resources, see "Permissions for acting on integration nodes, integration servers, and resources" on page 2518.

When you enable administration security for an **integration node**, the default mode of authorization depends on whether a queue manager is specified on the integration node. If a queue manager has been specified, authorization for the integration node is based on IBM MQ queues by default (`mq` mode), and the required queues used for setting authorization are created automatically when the integration node is created. If you create an integration node without specifying an associated queue manager, file-based authorization (`file` mode) is used by default.

You can control access to an independent **integration server** (which is not managed by an integration node) by using either file-based permissions, or LDAP authorization. You can set file-based permissions either by using the **mqsichangefileauth** command or by setting properties in the `server.conf.yaml` configuration file. You can set LDAP authorization by setting properties in the `server.conf.yaml` configuration file.

If you are using any IBM App Connect Enterprise functions that require access to IBM MQ, you must set the required permissions that enable the connection to be made to the queue manager that is specified on the integration node. For information about these permissions, see "Permissions for connecting to a queue manager" on page 2521. When you have set the required permissions for connecting to the queue manager, you can set the permissions that authorize users to act on the integration node and its resources.

For information about authentication, see "Authenticating users for administration" on page 2507.

Procedure

Complete the following steps to set the required authorization mode and to authorize users to work with an integration node or server and its resources:

1. Ensure that administration security for the integration node or server is enabled and configured to use the required authorization mode, as described in "Configuring administration security to use file-based, queue-based, or LDAP authorization" on page 2523.

   To find out which authorization mode is currently in effect, see "Checking the authorization mode" on page 2529.
2. If you are using queue-based administration security for an integration node, set the required permissions to enable users to connect to the IBM MQ queue manager.

   For information about these permissions, see "Permissions for connecting to a queue manager" on page 2521.
3. Set the required permissions to enable users to complete tasks on an integration node or server and its resources. For information about the permissions that are required, see "Permissions for acting on integration nodes, integration servers, and resources" on page 2518.

   For information about how to set the permissions, see "Setting file-based permissions" on page 2530, "Setting queue-based permissions" on page 2533, and "Configuring authorization by using LDAP groups" on page 2537.

4. You can control web users' access to data and resources by assigning permissions to the role that the users are assigned to. For more information, see “Controlling access to data and resources in the web user interface” on page 2544.

Permissions for acting on integration nodes, integration servers, and resources

Permissions are required for users to act on integration nodes, integration servers, and resources.

Authorization to perform administrative tasks is determined by the permissions that are granted to the role to which the user has been assigned. The following tables show the permissions that are required for the user's assigned role in order for them to carry out specific tasks, depending on whether you are using queue-based, file-based, or LDAP administration security. For information about how to specify an authorization mode, see “Configuring administration security to use file-based, queue-based, or LDAP authorization” on page 2523.

If you are using any IBM App Connect Enterprise functions that require access to IBM MQ, you must also set the required permissions for connecting to the queue manager that is specified on the integration node. For information about the permissions that are required for connecting to the queue manager, see “Permissions for connecting to a queue manager” on page 2521.

Table 78. MQ queue-based permissions required for acting on an integration node

Action	Integration node permission	MQ queue-based security: IBM MQ queue	MQ queue-based security: IBM MQ permission (set on setmqaut command)
View	read	SYSTEM.BROKER.AUTH	+INQ
Create	write	SYSTEM.BROKER.AUTH	+PUT
Delete	write	SYSTEM.BROKER.AUTH	+PUT
Modify	write	SYSTEM.BROKER.AUTH	+PUT
Start	execute	SYSTEM.BROKER.AUTH	+SET
Stop	execute	SYSTEM.BROKER.AUTH	+SET
Inject	execute	SYSTEM.BROKER.AUTH	+SET

Table 79. File-based permissions required for acting on an integration node

Action	Integration node permission	File-based security: Object flag (set on mqsichangefileauth command)	File-based security: File permission (set on mqsichangefileauth command or in a node.conf.yaml file)
View	read		read+
Create	write		write+
Delete	write		write+
Modify	write		write+
Start	execute		execute+
Stop	execute		execute+
Inject	execute		execute+

Where no object flag is specified on the command command, the file-based permissions are set at the level of the integration node.

Table 80. LDAP permissions required for acting on an integration node

Action	Integration node permission	LDAP security: Permission (set in node.conf.yaml configuration file)
View	read	'read+'
Create	write	write+
Delete	write	'write+'
Modify	write	'write+'
Start	execute	'execute+'
Stop	execute	'execute+'
Inject	execute	'execute+'

Table 81. MQ queue-based permissions required for acting on an integration server that is managed by an integration node

Action	Integration node permission	MQ queue-based security: IBM MQ queue	MQ queue-based security: IBM MQ permission (set on setmqaut command)
View	read	SYSTEM.BROKER.AUTH.*integrationServerName*	-INQ
Create	write	SYSTEM.BROKER.AUTH.*integrationServerName*	-PUT
Delete	write	SYSTEM.BROKER.AUTH.*integrationServerName*	-PUT
Modify	write	SYSTEM.BROKER.AUTH.*integrationServerName*	-PUT
Start	execute	SYSTEM.BROKER.AUTH.*integrationServerName*	-SET
Stop	execute	SYSTEM.BROKER.AUTH.*integrationServerName*	-SET

Table 82. File-based permissions required for acting on an integration server that is managed by an integration node

Action	Integration node permission	File-based security: Object flag (set on mqsichangefileauth command)	File-based security: File permission (set on mqsichangefileauth command or in a node.conf.yaml file)
View	read	-e *integration_server*	read+
Create	write	-e *integration_server*	write+
Delete	write	-e *integration_server*	write+
Modify	write	-e *integration_server*	write+
Start	execute	-e *integration_server*	execute+
Stop	execute	-e *integration_server*	execute+

Table 83. LDAP permissions required for acting on an integration server that is managed by an integration node

Action	Integration node permission	LDAP security: Permission (set in the node.conf.yaml configuration file of the integration node that manages the integration server)
View	read	'read+'
Create	write	write+
Delete	write	'write+'
Modify	write	'write+'
Start	execute	'execute+'
Stop	execute	'execute+'

Table 84. File-based permissions required for acting on an independent integration server (not managed by an integration node)

Action	File-based security: Object flag (set on mqsichangefileauth command)	File-based security: File permission (set on mqsichangefileauth command or in a server.conf.yaml file)
View	-e *integration_server*	read+
Create	-e *integration_server*	write+
Delete	-e *integration_server*	write+
Modify	-e *integration_server*	write+
Start	-e *integration_server*	execute+
Stop	-e *integration_server*	execute+
Inject	-e *integration_server*	execute+

Table 85. LDAP permissions required for acting on an independent integration server (not managed by an integration node)

Action	LDAP security: Permission (set in server.conf.yaml configuration file)
View	'read+'
Create	'write+'
Delete	'write+'
Modify	'write+'
Start	'execute+'
Stop	'execute+'
Inject	'execute+'

Table 86. Permissions required for acting on a data object					
Action	**Integration node permission**	**MQ queue-based security: IBM MQ queue**	**MQ queue-based security: IBM MQ permission (set on setmqaut command)**	**File-based security: Object flag (set on mqsichangefileauth command)**	**File-based security: File permission (set on mqsichangefileauth command)**
View	read	SYSTEM.BROKER.DC.AUTH	+INQ	-o *Data*	read+
	read	SYSTEM.BROKER.DC.AUTH.*integrationServerName*	+INQ	-o *Data*	read+
Replay	execute	SYSTEM.BROKER.DC.AUTH.*integrationServerName*	+SET	-o *IntegrationServerName* -o *Data*	execute+

File-based and LDAP-based permissions:

When you create an integration server on an integration node for which either file-based or LDAP security has been enabled, you must explicitly set the permissions for the integration server and then restart the integration node for the changes to take effect. For more information, see "Configuring authorization for an integration node by modifying the node.conf.yaml file" on page 2523.

Queue-based permissions:

If the queue-based mode of administration security (*mq* mode) is enabled when you create an integration node, the queue SYSTEM.BROKER.AUTH is created. Read, write, and execute permissions are granted automatically to the user group mqbrkrs on this queue. The SYSTEM.BROKER.AUTH queue is created as a local queue, and is used to define which users are authorized to perform actions on the integration node and the integration node properties.

When you create an integration server on an integration node for which you have enabled queue-based security, the integration server authorization queue SYSTEM.BROKER.AUTH.*integrationServerName* is created, where *integrationServerName* is the name of the integration server. Read, write, and execute permissions are automatically granted to the user group mqbrkrs on this queue.

When you use the **mqsicreatebroker** command to create an integration node with an associated queue manager, the SYSTEM.BROKER.DC.AUTH queue is created automatically. If you create an integration node without specifying a queue manager, you can modify the integration node afterwards to specify a queue manager and enable administration security in mq mode; however, you must also create the SYSTEM.BROKER.DC.AUTH queue. For information about creating the system queues, see "Creating the default system queues on an IBM MQ queue manager" on page 99.

For more information about the creation of authorization queues, see "Authorization queues for queue-based administration security" on page 2501.

Permissions for connecting to a queue manager

If you are using any IBM App Connect Enterprise functions that require access to IBM MQ, permissions are required for connecting to a queue manager, in addition to the specific permissions that are required for acting on integration nodes and resources.

If you are using any IBM App Connect Enterprise functions that require access to IBM MQ, you must set the required permissions that enable the connection to be made to the queue manager that is specified on the integration node.

The following topics summarize the IBM MQ permissions that are required to connect to the queue manager that is specified on the integration node:

- "Permissions for administrators" on page 2522
- "Permissions for users connecting to the integration node" on page 2522

When you have set the required permissions for connecting to the queue manager, you must also set the permissions that are required to enable users to work with the integration node and its resources. For more information about these permissions, see "Permissions for acting on integration nodes, integration servers, and resources" on page 2518. You can use either queue-based or file-based permissions, or LDAP authorization to authorize users to access resources; for information about how to select the authorization mode and set the permissions, see the following topics:

- "Configuring administration security to use file-based, queue-based, or LDAP authorization" on page 2523
- "Setting file-based permissions" on page 2530
- "Setting queue-based permissions" on page 2533
- "Configuring authorization by using LDAP groups" on page 2537

Permissions for administrators
If you are using any IBM App Connect Enterprise functions that require access to IBM MQ, additional permissions are required by administrators.

About this task

When you activate administration security with the authorization mode set to `mq`, the IBM MQ permissions for inquire, put, and set are granted for the group mqbrkrs for the queue SYSTEM.BROKER.AUTH. These permissions grant read, write, and execute authority on the integration node and its properties to all system user IDs that are members of mqbrkrs, where the system ID is provided by a local command or Toolkit, or corresponds to the configured role for a remote or web user.

If you want additional user IDs to have administrator authorization, either add those IDs to the group mqbrkrs, or add IBM MQ permissions for inquire, put, and set for those user IDs to this queue.

The following table summarizes the IBM MQ permissions that are required in order to connect to the queue manager that is specified on the integration node:

Object	Name	Permissions
Queue manager	The queue manager associated with the integration node; for example, ACEQMGR	Connect Inquire

For information about the permissions that are required to enable users to act on IBM App Connect Enterprise resources, see "Permissions for acting on integration nodes, integration servers, and resources" on page 2518.

Permissions for users connecting to the integration node
If you are using any IBM App Connect Enterprise functions that require access to IBM MQ, additional permissions are required to enable users to connect to the integration node.

About this task

If a user or application wants to connect to an integration node, you must grant them the appropriate permissions. All applications written to the IBM Integration API, and users of the IBM App Connect Enterprise Toolkit, require permissions based on their expected actions. The following table shows the IBM MQ permissions that are required in order to connect to the queue manager that is specified on the integration node:

Object	Name	Permissions
Queue manager	The queue manager associated with the integration node; for example, ACEQMGR	Connect Inquire

Notes:

1. Users and applications can connect to the integration node without this level of authority, but are unable to request actions against the integration node, including viewing properties.

For information about the permissions that are required to enable users to act on IBM App Connect Enterprise resources, see "Permissions for acting on integration nodes, integration servers, and resources" on page 2518.

Configuring administration security to use file-based, queue-based, or LDAP authorization

You can enable administration security for an integration node or integration server, either by using the **mqsichangeauthmode** command, or by setting the security properties in the `node.conf.yaml` or `server.conf.yaml` configuration file. If you enable administration security for an integration node, you can also choose which authorization mode (file-based, queue-based, or LDAP authorization) will be used for setting permissions. For independent integration servers (which are not managed by an integration node), you can specify file-based authorization, or LDAP authorization.

Before you begin

Read the following topics:

- "Administration security overview" on page 2497
- "Authorizing users for administration" on page 2516

About this task

You control access to an integration node (and the integration servers that it manages) by setting file-based, or queue-based permissions, or LDAP authorization. You can set file-based permissions either by using the **mqsichangefileauth** command, or by setting properties in the `node.conf.yaml` configuration file. You can set queue-based permissions by using IBM MQ authorization queues on the queue manager that is specified on the integration node. You can set LDAP authorization by setting properties in the `node.conf.yaml` configuration file.

You can control access to an independent integration server (which is not managed by an integration node) by using file-based permissions or LDAP authorization. You can set file-based permissions either by using the **mqsichangefileauth** command or by setting properties in the `server.conf.yaml` configuration file. You can set LDAP authorization by setting properties in the `server.conf.yaml` configuration file.

To configure authorization for an integration node or integration server, complete the steps in one of the following topics:

- "Configuring authorization for an integration node by modifying the node.conf.yaml file" on page 2523
- "Configuring authorization for an integration server by modifying the server.conf.yaml file" on page 2526
- "Configuring authorization by using the mqsichangeauthmode command" on page 2528
- "Configuring authorization by using LDAP groups" on page 2537

Configuring authorization for an integration node by modifying the node.conf.yaml file

You can configure integration nodes (and the integration servers that they manage) to use either file-based authorization, queue-based authorization, or LDAP authorization, by setting the security properties in the `node.conf.yaml` configuration file.

Before you begin

Read the following topics:

- "Administration security overview" on page 2497
- "Authorizing users for administration" on page 2516
- "Configuring administration security to use file-based, queue-based, or LDAP authorization" on page 2523

About this task

Authorization to perform administrative tasks is determined by the permissions that are granted to the role to which the web user has been assigned. When using LDAP authorization, a web user's role is determined by mapping the LDAP groups that they belong to with a predefined role, as described in "Configuring authorization by using LDAP groups" on page 2537. You can then set file-based permissions for that role. For more information about controlling access by using file-based permissions, see "Setting file-based permissions" on page 2530. For information about controlling access by using queue-based permissions, see "Setting queue-based permissions" on page 2533.

When you enable administration security for an integration node, the default mode of authorization depends on whether a queue manager is specified on the integration node. If a queue manager has been specified, administration security for the integration node is based on IBM MQ queues by default (`mq` mode), and the required queues used for setting authorization are created automatically when the integration node is created. If you create an integration node without specifying an associated queue manager, file-based administration security is used by default (`file` mode).

For information about controlling access to an independent integration server, see "Configuring authorization for an integration server by modifying the server.conf.yaml file" on page 2526.

You configure authorization for an integration node (and its managed integration servers) by setting properties in the Security section of the integration node's `node.conf.yaml` file:

```
# Admin Security
  #  Authentication
  #  If basicAuth enabled, a maximum of authMaxAttempts authentication attempts are allowed for
 a client within period authAttemptsDuration
  #  If authMaxAttempts is reached without success, the client is locked out for period
 authBlockedDuration
  #basicAuth: false                                                    # Clients web user name
 and password will be authenticated when set true
  webUserPasswordHashAlgorithm: PBKDF2-SHA-512                        # Algorithm used to hash
 the password for webuser accounts.
  #authMaxAttempts: 5                                                 # Max allowed
 authentication attempts
  #authAttemptsDuration: 300                                          # Authentication attempts
 period in seconds
  #authBlockedDuration: 300                                           # Authentication blocked
 period in seconds
  #sessionTimeout: 86400                                              # Set the timeout in
 seconds that REST API/Web UI sessions can be inactive before becoming invalid. Default is 86400
 seconds (24 hours).
  #ldapUrl: ldap[s]://server[:port]/baseDN[?[uid_attr][?[base|sub]]]  # ldap authentication url
  #ldapBindDn: ldap::adminAuthentication                              # Resource alias or full
 bind dn
  #ldapBindPassword: ldap::adminAuthentication                        # Resource alias or bind
 password
  #  Authorization
  #authorizationEnabled: false     # Clients web user role will be authorized when set true
  #authorizationMode: 'file'       # Set authorization mode. Choose 1 of : ldap, file or mq
  #ldapAuthorizeUrl: ldap[s]://server[:port]/baseDN[?[attr_name][?[base|sub]][?filter_expr]]  #
 ldap authorization url
  #ldapCheckServerIdentity : true  # Disables hostname verification of ldaps server when set to
 false

Security:
  #dynamicUpdate: false            # If true, changes to security settings will be picked up
 automatically by the Integration Node, after a few seconds.
  LdapAuthorizeAttributeToRoleMap:
    # When 'authorizationMode' is ldap, set the mapping from a matched LDAP authorization
 attribute, as
    # configured in 'ldapAuthorizeUrl' to the ACE web user role name
    # e.g. map the following LDAP group DNs to web user roles 'adminRole', 'viewRole'
    #'cn=admins,cn=group,ou=ace': 'adminRole'
    #'cn=monitors,cn=group,ou=ace': 'viewRole'
  Node:
    Permissions:
      # Set Admin Security Authorization file permissions for the Integration Node by web user
 role using 'read+:write+:execute+' , or 'all+'
      # '+' grants permission, '-' denies permission
      # e.g. define the following web user roles 'viewRole' and 'adminRole'
      #viewRole:  'read+:write-:execute-'
      #adminRole: 'all+'
    DataPermissions:
```

```
      # Set Admin Security Authorization file permissions for Record and Replay web user roles
 using 'read+:write+:execute+' , or 'all+'
      # '+' grants permission, '-' denies permission. Record and Replay roles also require 'read
+' permission to be defined for the
      # Integration Node in the Permissions section above.
      # e.g. define the following web user roles 'dataViewer', 'dataReplayer' and 'adminRole'
      #dataViewer:  'read+:write-:execute-'
      #dataReplayer: 'read+:write-:execute-'
      #adminRole: 'all+'
  Server:
    # Set Admin Security Authorization file permissions for each named Integration Server
    # e.g. define the following web user roles 'viewRole' and 'adminRole' for Integration Server
 'server01'
    #server01:
      #Permissions:
        #viewRole:  'read+:write-:execute-'
        #adminRole: 'all+'
      #DataPermissions:
        # Set Admin Security Authorization file permissions for Record and Replay web user role
 using 'read+:write+:execute+' , or 'all+'
        # '+' grants permission, '-' denies permission.
        # e.g. define the following web user roles 'dataViewer', 'dataReplayer' and 'adminRole'
        #dataViewer:  'read+:write-:execute-'
        #dataReplayer: 'read+:write-:execute+'
        #adminRole: 'all+'
```

You set permissions in the `node.conf.yaml` file for the integration node and for all the integration servers that it manages. When you have added or modified permissions, ensure that you restart the integration node for the changes to take effect.

Procedure

Configure the authorization mode for an integration node by completing the following steps:

1. Open the `node.conf.yaml` configuration file for your integration node, by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, because they are not valid in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
2. If administration security has not already been enabled, enable it now by setting the **authorizationEnabled** property in the Admin Security section of the `node.conf.yaml` file to `true`:

   ```
   authorizationEnabled: true
   ```
3. Specify the authorization mode that you require, by setting the **authorizationMode** property to either `file`, `mq`, or `ldap`.

   For example, to configure the integration node to use file-based authorization, set the following value:

   ```
   authorizationMode: file
   ```
4. Assign permissions to the defined roles, by specifying a combination of `read`, `write`, and `execute`, or `all`, with + to grant permission, and - to deny permission; for example:

   ```
   viewRole:  'read+:write-:execute-'
   adminRole: 'all+'
   ```

   where the `viewRole` has only read permission, and the `adminRole` has permission for all actions.
5. Save the modified `node.conf.yaml` file.
6. Restart the integration node for the changes to take effect, by using the command.

What to do next

For information about specifying the authorization mode for an integration node by using the **mqsichangeauthmode** (instead of modifying the `node.conf.yaml` file), see “Configuring authorization by using the mqsichangeauthmode command” on page 2528. You can then set permissions as described

in “Setting file-based permissions” on page 2530, “Setting queue-based permissions on Linux, AIX, and Windows systems” on page 2534or “Setting file-based permissions” on page 2530.

Configuring authorization for an integration server by modifying the server.conf.yaml file
You can configure integration servers to use file-based authorization, or LDAP authorization, by setting the security properties in the `server.conf.yaml` configuration file.

Before you begin

Read the following topics:

- “Administration security overview” on page 2497
- “Authorizing users for administration” on page 2516

About this task

You can configure authorization for an independent integration server (which is not associated with an integration node) by setting file-based permissions, or LDAP authorization in the Security section of the integration server's `server.conf.yaml` configuration file:

```
# Admin Security
  #  Authentication
  #  If basicAuth enabled, a maximum of authMaxAttempts authentication attempts are allowed for
 a client within period authAttemptsDuration
  #  If authMaxAttempts is reached without success, the client is locked out for period
 authBlockedDuration
  #basicAuth: false                                                    # Clients web user name
 and password will be authenticated when set true
  webUserPasswordHashAlgorithm: PBKDF2-SHA-512                        # Algorithm used to hash
 the password for webuser accounts.
  #authMaxAttempts: 5                                                 # Max allowed
 authentication attempts
  #authAttemptsDuration: 300                                          # Authentication attempts
 period in seconds
  #authBlockedDuration: 300                                           # Authentication blocked
 period in seconds
  #sessionTimeout: -1                                                 # Client-side expiration
 time in seconds for REST API/Web UI sessions.
                                                                      # Negative values or zero
 signify that the session remain active
                                                                      # for the lifetime of the
 browser session. Defaults to -1.
  #serverSessionTimeout: 86400                                        # Server-side expiration
 time in secods for REST API/Web UI sessions. Can
                                                                      # be specified
 independently of the client-side timeout, allowing sessions
                                                                      # to be invalidated on the
 server before they are expired by the client. This
                                                                      # useful in particular
 when the client-side session lifetime is set to that
                                                                      # of the browser session
 ('BROWSER_EXIT' special
  #serverSessionTimeoutCheckInterval: 3600
  #ldapUrl: ldap[s]://server[:port]/baseDN[?[uid_attr][?[base|sub]]]  # ldap authentication url
  #ldapBindDn: ldap::adminAuthentication                              # Resource alias or full
 bind dn
  #ldapBindPassword: ldap::adminAuthentication                        # Resource alias or bind
 password
  #  Authorization
  #authorizationEnabled: false     # Clients web user role will be authorized when set true
  #authorizationMode: 'file'       # Set authorization mode. Choose 1 of : ldap, file
  #ldapAuthorizeUrl: ldap[s]://server[:port]/baseDN[?[attr_name][?[base|sub]][?filter_expr]]  #
 ldap authorization search url
  #ldapCheckServerIdentity : true  # Disables hostname verification of ldaps server when set to
 false

Security:
  LdapAuthorizeAttributeToRoleMap:
    # When 'authorizationMode' is ldap, set the mapping from a matched LDAP authorization
 attribute, as
    # configured in 'ldapAuthorizeUrl' to the ACE web user role name
    # e.g. map the following LDAP group DNs to web user roles 'adminRole', 'viewRole'
    #'cn=admins,cn=group,ou=ace': 'adminRole'
```

```
    #'cn=monitors,cn=group,ou=ace': 'viewRole'
  Permissions:
    # Set Admin Security Authorization file permissions by web user role using 'read+:write
+:execute+' , or 'all+'
    # '+' grants permission, '-' denies permission
    # e.g. define the following web user roles 'viewRole' and 'adminRole'
    #viewRole:  'read+:write-:execute-'
    #adminRole: 'all+'
  DataPermissions:
    # Set Admin Security Authorization file permissions for Record and Replay web user role
 using 'read+:write+:execute+' , or 'all+'
    # '+' grants permission, '-' denies permission.  Record and Replay roles also require 'read
+' permission to be defined
    # in the Permissions section above.
    # e.g. define the following web user roles 'dataViewer', 'dataReplayer' and 'adminRole'
    #dataViewer:  'read+:write-:execute-'
    #dataReplayer: 'read+:write-:execute+'
    #adminRole: 'all+'
```

For information about controlling access to an integration node, see “Configuring authorization for an integration node by modifying the node.conf.yaml file” on page 2523.

Procedure

Configure the authorization mode for an integration server by completing the following steps:

1. Open the `server.conf.yaml` configuration file for your integration server, by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, because they are not valid in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
2. If administration security has not already been enabled, enable it now by setting the **authorizationEnabled** property in the `server.conf.yaml` file to `true`:

   ```
   authorizationEnabled: true
   ```
3. Specify the authorization mode that you require, by setting the **authorizationMode** property to either `file`, or `ldap`.

   For example, to configure the integration node to use file-based authorization, set the following value:

   ```
   authorizationMode: file
   ```
4. Assign permissions to the defined roles, by specifying a combination of `read`, `write`, and `execute`, or `all`, with + to grant permission, and - to deny permission; for example:

   ```
   viewRole:  'read+:write-:execute-'
   adminRole: 'all+'
   ```

   where the `viewOnly` role has only read permission, and the `admin` role has permission for all actions.
5. Save the modified `server.conf.yaml` file.
6. Restart the integration server for the changes to take effect.

What to do next

You can also configure authorization for an integration server by using the **mqsichangeauthmode** command, and then set permissions by using the **mqsichangefileauth** command. For more information, see “Configuring authorization by using the mqsichangeauthmode command” on page 2528 and “Setting file-based permissions” on page 2530.

*Configuring authorization by using the **mqsichangeauthmode** command*
Use the **mqsichangeauthmode** command to enable administration security for an integration node or integration server.

Before you begin

Read the following topics:

- "Administration security overview" on page 2497
- "Authorizing users for administration" on page 2516

About this task

You can use the **mqsichangeauthmode** command to enable administration security for an integration node or integration server, and to configure the authorization mode to be used. If you are configuring administration security for an integration node, you can use the **mqsichangeauthmode** command to configure it to use either a file-based or queue-based mode of authorization. If you are configuring administration security for an independent integration server (which is not managed by an integration node), you can use the **mqsichangeauthmode** command to configure it to use file-based authorization only.

If you want to configure an integration node, or an independent integration server (which is not managed by an integration node) to use LDAP authorization, you can do this only by setting properties in the node.conf.yaml configuration file for the integration node or integration server. For more information, see "Configuring authorization for an integration node by modifying the node.conf.yaml file" on page 2523, and "Configuring authorization for an integration server by modifying the server.conf.yaml file" on page 2526.

Procedure

1. Use the **mqsichangeauthmode** command to enable administration security:
   a) Enable administration security by specifying either **-s active** to enable both authentication and authorization, or **-b active** to enable authentication only.
   For example:

   ```
   mqsichangeauthmode -w myIntegrationServerWorkpath -b active
   ```

   This example enables authentication on an independent integration server, whose work path is specified by the **-w** parameter.
   b) Optional: If you enable both authentication and authorization by setting **-s active**, you must also specify the required authorization mode by using the **-m** parameter:
   - For an integration node:
     - Specify **-m file** to use file-based permissions, which are set using the **mqsichangefileauth** command. If you create an integration node without specifying an associated queue manager, file-based administration security is used by default for the integration node.
     - Specify **-m mq** to use IBM MQ queues for setting permissions. You can use queue-based security only if you have installed IBM MQ and specified a queue manager on the integration node. If a queue manager is specified on the integration node, administration security is

queue-based by default, and the required queues used for setting authorization are created automatically when the integration node is created.

For example:

```
mqsichangeauthmode ACE11NODE -s active -m file
```

- For an integration server:
  - Specify **-m file** to use file-based permissions, which are set using the **mqsichangefileauth** command.

For more information, see command and command.

2. Restart the integration node for the changes to take effect.

What to do next

If you want to check which security mode is currently in effect, you can either check the settings in the `node.conf.yaml` or `server.conf.yaml` configuration files, or you can run the command, as described in "Checking the authorization mode" on page 2529.

Checking the authorization mode

Use the **mqsireportauthmode** command to display the authorization mode that is currently in effect for the integration node or integration server.

Before you begin

Read the following topics:

- "Authorizing users for administration" on page 2516
- "Configuring administration security to use file-based, queue-based, or LDAP authorization" on page 2523

About this task

Administration authority can be controlled by using IBM MQ queues that are owned by a queue manager specified on the integration node, or by file-based permissions that are set using the **mqsichangefileauth** command, or by LDAP authorization that is set by editing the security properties in the `node.conf.yaml` or `server.conf.yaml`configuration file. You can use the **mqsireportauthmode** command to display the administration security status and authorization mode that are currently in effect for the integration node or server.

Procedure

1. Run the **mqsireportauthmode** command to display the current administration security status and authorization mode.
   For example, display the current settings for an integration node called ACE11NODE:

   ```
   mqsireportauthmode ACE11NODE
   ```

   Alternatively, display the current administration security settings for an independent integration server, whose work path is specified by the **-w** parameter:

   ```
   mqsireportauthmode -w myIntegrationServerWorkpath
   ```

2. The output from the command shows whether administration security is active or inactive, and whether the current authorization mode is `file` (file-based), `mq` (queue-based), or ldap (LDAP authorization).

Setting file-based permissions

Grant and revoke administration authority by configuring file-based permissions for working with an integration node and its resources or and integration server and its resources.

Before you begin

Read the following topics:

- "Administration security overview" on page 2497
- "Authorizing users for administration" on page 2516
- "Configuring administration security to use file-based, queue-based, or LDAP authorization" on page 2523

About this task

You can grant and revoke administration authority for an integration node and its managed integration servers, or for an independent integration server, by configuring file-based permissions for specified roles. You can configure these permissions by using the command, or by setting properties in the `node.conf.yaml` file (for an integration node and its managed integration servers) or in the `server.conf.yaml` file (for an independent integration server).

You can use file-based permissions for authorization if the file-based or LDAP-based mode of administration security has been specified for the integration node or server. For LDAP authorization, you must associate a role with the LDAP groups to which the user belongs, and then set file-based permissions for that role. For more information, see "Configuring authorization by using LDAP groups" on page 2537.

To specify an authorization mode for an integration node (and its managed integration servers) or an independent integration server, you can either use the command or set the **`authorizationEnabled`** and **`authorizationMode`** properties in the `node.conf.yaml` or `server.conf.yaml` configuration file.

Three levels of authorization permissions are supported for IBM App Connect Enterprise administration security: read, write, and execute. You can assign permissions to a role by specifying the type of permission followed by a plus (+) to grant permissions, or a minus (-) to revoke permissions:

- *read+/-*
- *write+/-*
- *execute+/-*
- *all+/-*

These permissions can be applied to each role for the following types of objects:

- Integration node resources
- Integration server resources
- Data objects (record-replay and business transaction monitoring)

Note: If you grant permissions to a role at the integration node level, those permissions are not applied to the integration servers that are managed by the integration node; you must also set permissions explicitly for individual integration servers.

Set file-based permissions for your integration node or integration server by completing one of the following tasks:

- "Setting permissions in the node.conf.yaml configuration file or server.conf.yaml configuration file" on page 2531
- "Setting permissions by using the mqsichangefileauth command" on page 2531

Setting permissions in the node.conf.yaml configuration file or server.conf.yaml configuration file

About this task

You can configure authorization for an integration node (and its managed integration servers) or for an independent integration server, by setting permissions for roles in the Security section of the `node.conf.yaml` or `server.conf.yaml` configuration file.

You can define a role and grant or deny permissions to it, by specifying them in the appropriate `.conf.yaml` file. In the following example, the role called `viewRole` has been granted read permission only, and the role called `adminRole` has been granted permission for all actions.

```
Permissions:
    viewRole:  'read+:write-:execute-'
    adminRole: 'all+'
```

Procedure

Configure the authorization mode for an integration node or server by completing the following steps:

1. Open the `node.conf.yaml` file (for an integration node and its managed integration servers) or the `server.conf.yaml` file (for an independent integration server), by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, because they are not valid in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
2. If administration security has not already been enabled, activate authentication and authorization by setting the **basicAuth** and **authorizationEnabled** properties to `true`:

   ```
   basicAuth: true
   authorizationEnabled: true
   ```
3. Specify the file-based authorization mode, by setting the **authorizationMode** property to `file`:

   ```
   authorizationMode: file
   ```
4. Define the role and set its permissions, by specifying a combination of `read`, `write`, and `execute`, or `all`, with + to grant permission, and - to deny permission; for example:

   ```
   viewOnly:  'read+:write-:execute-'
   aceAdmin:     'all+'
   ```

   where the `viewOnly` role has only read permission, and the `aceAdmin` role has permission for all actions.
5. Save the modified file.
6. Restart the integration node or independent integration server, as appropriate, for the changes to take effect.

*Setting permissions by using the **mqsichangefileauth** command*

About this task

You specify the permissions as a comma-separated list of values. A value can be specified for each permission (*read*, *write*, and *execute*) only once in the list of values. For example, you cannot specify *all-,read+* because it would be attempting to set the *read* permission twice (once explicitly, and once as part of *all*). If *all* is specified, it must be the only value. If you specify *all-*, all permission records in the registry are removed.

Procedure

Follow these steps to set permissions for a role:

1. Ensure that administration security has been enabled for the integration node.

   For more information, see “Enabling administration security” on page 2504.
2. Use the **mqsichangefileauth** command to change the permissions that are assigned to a role. For example, the following command shows how to set permissions on an integration server that is associated with an integration node:

   ```
   mqsichangefileauth ACE11NODE -r aceAdmins -e default -p read+,execute+
   ```

   In this example, the role `aceAdmins` is granted execute and read permission on `ACE11NODE.default` (the `default` integration server on the `ACE11NODE` integration node). If this role did not previously exist, the write permission is disabled.

   The following example shows how to set permissions on an independent integration server (which is not managed by an integration node):

   ```
   mqsichangefileauth -w server_workpath -r aceAdmins -e default -p read+,execute+
   ```

   The **mqsichangefileauth** command saves the permissions to the `node.conf.yaml` or `server.conf.yaml` overrides file.
3. Restart the integration node or independent integration server for the changes to take effect.

What to do next

For information about authentication, see “Authenticating users for administration” on page 2507.

Checking file-based permissions
Use the **mqsireportfileauth** command or YAML configuration files to view the file-based administration security permissions that are in effect for the specified integration node.

Before you begin

Read the following topics:

- “Administration security overview” on page 2497
- “Authorizing users for administration” on page 2516
- “Configuring administration security to use file-based, queue-based, or LDAP authorization” on page 2523

About this task

You can display the file-based administration security permissions for the specified integration node by using the **mqsireportfileauth** command or you can view the properties in the `node.conf.yaml` file (for an integration node and its managed integration servers) or the `server.conf.yaml` file (for an independent integration server).

Three levels of authorization are supported for IBM App Connect Enterprise administration security: read, write, and execute. These permissions can be applied to the following types of objects for each role (system user):

- Integration node resources
- Integration server resources
- Data capture objects (record-replay)

Procedure

1. Ensure that the user running the command is a member of the group mqbrkrs.

2. Use the **mqsireportfileauth** command to display the administration security permissions that have been set for a specified role on the integration node.
   For example, display the permissions that are currently in effect for the role `iibAdmins` on the integration node `IB10NODE`:

   ```
   mqsireportfileauth IB10NODE -r iibAdmins
   ```

   The output from the command has a format similar to that shown in the following example:

   ```
   BIP8931I: Role = 'iibAdmins', Resource = '', Permissions = 'read+,write+,execute+'
   ```

3. You can also use the **mqsireportfileauth** command to display all the administration security permissions that have been set for all roles on the integration node. Roles are reported only if they have positive permissions set; any roles that have no permissions set are not reported in the output of this command.
   For example, display all roles for which permissions have been set on the integration node `IB10NODE`:

   ```
   mqsireportfileauth IB10NODE -l
   ```

   The output from the command has a format similar to that shown in the following example:

   ```
   BIP8931I:  Role = 'iibAdmins' Resource = '' Permissions = 'read+,write+,execute+'
   BIP8931I:  Role = 'iibGuests' Resource = '' Permissions = 'read+,write-,execute-'
   ```

   You can also display roles for which permissions have been set on a specified integration server in the integration node; for example:

   ```
   mqsireportfileauth IB10NODE  -e is01  -l
   ```

   The output from the command has a format similar to that shown in the following example:

   ```
   BIP8931I: Role = 'iibAdmins', Resource = 'is01', Permissions = 'read+,write+,execute+'
   BIP8931I: Role = 'iibGuests', Resource = 'is01', Permissions = 'read+,write-,execute-'
   ```

Setting queue-based permissions

You can use IBM MQ queues to authorize users to complete specific tasks against an integration node and its resources.

Before you begin

- Ensure that IBM MQ is installed and that a queue manager is specified on the integration node.
- Read the following topics:
  - “Enabling administration security” on page 2504
  - “Authorizing users for administration” on page 2516

About this task

When you have enabled administration security and specified the queue-based (MQ) authorization mode, you can set the required permissions for users to act on the integration node and its resources. You set the permissions on the following authorization queues:

- SYSTEM.BROKER.AUTH
- SYSTEM.BROKER.AUTH.*EG* (where *EG* is the name of the integration server)
- SYSTEM.BROKER.DC.AUTH

The queue SYSTEM.BROKER.AUTH is created when you use the **mqsichangeauthmode** command to enable queue-based administration security (`mq` mode) on the integration node. When you create an integration server on an integration node for which you have enabled queue-based administration security, the integration server authorization queue SYSTEM.BROKER.AUTH.*EG* is created (if it did not already exist), where *EG* is the name of the integration server.

The SYSTEM.BROKER.DC.AUTH queue is created when you use the **mqsicreatebroker** command to create an integration node with an associated queue manager. For more information about these authorization queues, see "Authorization queues for queue-based administration security" on page 2501.

You can set permissions to individual principals (user IDs), to groups of users, or both, on all platforms:

- If you grant a group or a user ID permissions at the integration node level (on queue SYSTEM.BROKER.AUTH), it does not inherit permissions for integration servers. You must explicitly set permissions for individual integration servers, or for all integration servers.
- On Linux and UNIX, you can authorize both principals and groups. However, when authorizing a principal, IBM App Connect Enterprise additionally authorizes the primary group of that principal. If there are many users who belong to that primary group, they become authorized at the same time. Consider using groups instead of primary groups for authorization, because variants of UNIX use primary groups in different ways.
- If a user ID is a member of the IBM MQ security group mqm, it automatically has permissions to act on all IBM MQ objects.
- On Windows, if a user ID is a member of the security group Administrators, it automatically has permissions to act on all IBM MQ objects.

When you change permissions on a queue, the integration node accesses the updated values the next time that a request is processed. You do not have to stop and restart the integration node.

If you update user ID or group membership by using the operating system facilities on the platform on which the integration node queue manager is running, you must ensure that the queue manager is aware of these changes. Select the option **Refresh Authorization Service** in the IBM MQ Explorer to notify the queue manager of the updated status.

Procedure

1. Ensure that administration security is enabled for the integration node and that the queue-based authorization mode has been set.

   For information about how to enable administration security and set the authorization mode, see "Enabling administration security" on page 2504. For more information about changing the authorization mode, see "Configuring administration security to use file-based, queue-based, or LDAP authorization" on page 2523
2. Follow the steps in one of the following tasks, depending on your platform:
   - "Setting queue-based permissions on Linux, AIX, and Windows systems" on page 2534

Setting queue-based permissions on Linux, AIX, and Windows systems
Use queue-based administration security to grant users permissions to complete specific tasks against an integration node or integration server running on Linux, AIX, or Windows.

Before you begin

Use the command to activate administration security and to specify the queue-based mode of administration security for the integration node or integration server.

About this task

For security reasons, it is important that permissions are set correctly. You can use IBM MQ commands to set up and manage your required security levels. Use the **setmqaut** command to set the required permissions, and the **dspmqaut** command to check which permissions have been set.

The following permissions are required for users to act on the integration node and its resources:

Table 87. Permissions required for acting on an integration node			
Action	**Integration node permission**	**Queue**	**IBM MQ permission (set on setmqaut command)**
View	read	SYSTEM.BROKER.AUTH	+INQ
Create	write	SYSTEM.BROKER.AUTH	+PUT
Delete	write	SYSTEM.BROKER.AUTH	+PUT
Modify	write	SYSTEM.BROKER.AUTH	+PUT
Start	execute	SYSTEM.BROKER.AUTH	+SET
Stop	execute	SYSTEM.BROKER.AUTH	+SET

Table 88. Permissions required for acting on an integration server			
Action	**Integration server permission**	**Queue**	**IBM MQ permission (set on setmqaut command)**
View	read	SYSTEM.BROKER.AUTH.EG	+INQ
Create	write	SYSTEM.BROKER.AUTH.EG	+PUT
Delete	write	SYSTEM.BROKER.AUTH.EG	+PUT
Modify	write	SYSTEM.BROKER.AUTH.EG	+PUT
Start	execute	SYSTEM.BROKER.AUTH.EG	+SET
Stop	execute	SYSTEM.BROKER.AUTH.EG	+SET

Table 89. Permissions required for acting on a record replay and business transaction monitoring object			
Action	**Integration node / integration server permission**	**Queue**	**IBM MQ permission (set on setmqaut command)**
View	read	SYSTEM.BROKER.DC.AUTH	+INQ
	read	SYSTEM.BROKER.DC.AUTH.*integrationServerName*	+INQ
Replay	execute	SYSTEM.BROKER.DC.AUTH.*integrationServerName*	+SET

The **setmqaut** command grants and revokes permissions cumulatively. To avoid retaining unwanted permissions that have been set previously, set them explicitly on each **setmqaut** command by specifying `-all` to remove all existing permissions, followed by the permissions that you want to set.

The following command grants execute permission and retains any permissions that were already set:

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group1 +set
```

The following command grants execute permission and does not retain any existing permissions:

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group1 -all +set
```

You can also set multiple permissions at the same time. For example, the following command removes any existing permissions and then grants execute and write permissions:

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group1 -all +set +put
```

Use the **dspmqaut** command after each **setmqaut** command, to check that the permissions have been set correctly.

For further information about the commands shown in the following examples, and for details of the parameters, see the IBM MQ product documentation online.

Examples

All the examples shown here are for an integration node that is associated with the queue manager `test`.

Grant only execute permission to the integration node to the user IDs that are defined in the group group1:

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group1 -all +set
dspmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group1
```

Grant only execute and write permission to the integration node to the user IDs that are defined in the group group2:

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group2 -all +set +put
dspmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group2
```

Revoke execute permission from the user IDs that are defined in the group group2:

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group2 -set
dspmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group2
```

Using a generic IBM MQ profile on a Linux system, grant only write permission for all integration servers for the user IDs that are defined in the group group3:

```
setmqaut -m test -t queue -n "SYSTEM.BROKER.AUTH.**" -g group3 -all +put
dspmqaut -m test -t queue -n "SYSTEM.BROKER.AUTH.**" -g group3
```

Note: You enclose generic profile names in quotes on AIX and Linux systems. For more information see the IBM MQ product documentation online and search for the "Using OAM generic profiles on UNIX systems and Windows" topic.

Using a generic IBM MQ revoke write permission on a Linux system for all integration servers for the user IDs that are defined in the group group3:

```
setmqaut -m test -t queue -n "SYSTEM.BROKER.AUTH.**" -g group3 -all -put
dspmqaut -m test -t queue -n "SYSTEM.BROKER.AUTH.**" -g group3
```

Grant only read permission for a specific integration server called `default` for group group4:

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH.default -g group4 -all +inq
dspmqaut -m test -t queue -n SYSTEM.BROKER.AUTH.default -g group4
```

Revoke execute and write permission for a specific integration server called `default` for group group5:

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH.default -g group5 -set -put
dspmqaut -m test -t queue -n SYSTEM.BROKER.AUTH.default -g group5
```

Using a generic IBM MQ on a non-Linux system, dump all IBM MQ permissions for all integration servers:

```
dmpmqaut -m test -t queue -n SYSTEM.BROKER.AUTH.**
```

Configuring authorization by using LDAP groups

Authorize roles in App Connect Enterprise against a Lightweight Directory Access Protocol (LDAP) or Secure LDAP (LDAPS) server.

Before you begin

Read the following topics:

- "Administration security overview" on page 2497
- "Authorizing users for administration" on page 2516
- "Configuring administration security to use file-based, queue-based, or LDAP authorization" on page 2523

About this task

You can grant and revoke administration authority for an integration node and for each of its managed integration servers. You can also grant and revoke administration authority for an independent integration server that is not managed by an integration node. You can do these tasks by configuring LDAP authorization for specified groups or attributes in LDAP to specified roles in App Connect Enterprise. You can configure the authorization by setting properties in the `node.conf.yaml` file for the integration node, or the `server.conf.yaml` file for the integration server.

LDAP authorization can be applied only to LDAP authenticated users. LDAP users must belong to one or more LDAP groups, or have one or more LDAP attributes that map to roles in App Connect Enterprise, with appropriate access to the admin REST API. Roles in App Connect Enterprise are granted read, write, or execute permissions for objects in integration nodes or independent integration servers (which are not managed by an integration node). For more information, see "Role-based security" on page 2503. LDAP users can belong to a single LDAP group that can be mapped to a single role in App Connect Enterprise, or multiple LDAP groups that can be mapped to multiple roles in App Connect Enterprise. An LDAP authenticated user's LDAP attributes can also be used to map to roles in App Connect Enterprise.

Configure LDAP authorization by completing the following steps.

Procedure

1. LDAP authorization can be applied only to LDAP authenticated users. If LDAP authentication is not enabled, enable it now as described in "Enabling LDAP authentication" on page 2511.
2. Open the `node.conf.yaml` file for the integration node, or the `server.conf.yaml` file for the integration server by using a YAML editor.

   If you are not able to access a YAML editor, you can edit the file by using a plain text editor. You must ensure that you do not include any tab characters. Tab characters are not valid in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

   If you run commands that modify settings for an integration node, or an integration server that is managed by an integration node, the modified settings are saved in a `.conf.yaml` file. The `.conf.yaml` file is located in the overrides directory. For example, `C:\ProgramData\IBM\MQSI\components\acev11node\overrides\node.conf.yaml` for an integration node, and `C:\ProgramData\IBM\MQSI\components\acev11node\servers\myNodeServer\overrides\server.conf.yaml` for an integration server managed by an integration node. If a property is set in the integration node's base `node.conf.yaml` file, and also in the overrides directory (`\overrides\node.conf.yaml`), the property value that is set in the overrides directory is used. For more information, see "Configuring an integration node by modifying the node.conf.yaml file" on page 118.

   If you have previously run commands that modify the independent integration server, those modified settings are saved in a `.conf.yaml` file in the overrides directory, for example, `<work directory>/overrides/server.conf.yaml`. If a property is set in the integration server's

`server.conf.yaml` file, and also in the overrides directory (`/overrides/server.conf.yaml`), the property value that is set in the overrides directory is used. For more information, see "Configuring an integration server by modifying the server.conf.yaml file" on page 172.

3. Enable authorization by setting the **authorizationEnabled** property value to `true` in the `.yaml` configuration file:

```
  #  Authorization
  authorizationEnabled: true     # Clients web user role will be authorized when set true
```

4. Set the **authorizationMode** property to `'ldap'` in the `.yaml` configuration file:

```
authorizationMode: 'ldap'       # Set authorization mode. Choose 1 of : ldap, file or mq
```

5. Optional: Create roles in App Connect Enterprise by configuring the `.yaml` configuration files.

   The roles **viewRole** and **adminRole** are supplied by default in the `.yaml` configuration file. The `node.conf.yaml` and `server.conf.yaml` files allow free-form names for roles that are not predefined in App Connect Enterprise. In the following example, the roles **supportRole**, **manager**, **administrator** and **developer** are created.

```
Permissions:
    # Set Admin Security Authorization file permissions by web user role using 'read+:write
+:execute+' , or 'all+'
    # '+' grants permission, '-' denies permission
    # e.g. define the following web user roles 'viewRole' and 'adminRole'
    viewRole:  'read+:write-:execute-'
    adminRole: 'all+'

    supportRole:'read+:write-:execute+'
    manager: 'read+:write-:execute-'
    administrator:'all+'
    developer: 'read+:write-:execute+'
```

6. Set admin security authorization file permissions for roles in the `.yaml` configuration file, by specifying a combination of `read`, `write`, and `execute`, or `all`, with + to grant permission, and - to deny permission, for example:

```
Permissions:
    # Set Admin Security Authorization file permissions by web user role using 'read+:write
+:execute+' , or 'all+'
    # '+' grants permission, '-' denies permission
    # e.g. define the following web user roles 'viewRole' and 'adminRole'
    viewRole:  'read+:write-:execute-'
    adminRole: 'all+'
```

   In this example, users with the role `viewRole` are granted read permission only, and users with the role `adminRole` have permission for all actions.

   This step is identical whether you are using LDAP authorization or file-based authorization. For more information, see "Setting file-based permissions" on page 2530.

7. Optional: Set admin security authorization file permissions for roles in the `.yaml` configuration file for each named integration server managed by an integration node. Specify a combination of `read`, `write`, and `execute`, or `all`, with + to grant permission, and - to deny permission, for example:

```
Server:
    # Set Admin Security Authorization file permissions for each named Integration Server
       #server01:
         #Permissions:
            viewRole:  'read+:write-:execute-'
            adminRole: 'all+'
       #server02:
          #Permissions:
            viewRole:  'read+:write-:execute+'
```

```
            adminRole: 'all+'
```

In this example, users with the role `adminRole` have permission for all actions on server01 and server02. Users with the role `viewRole` are granted read permission only on server01, and read and execute permission on server02.

This step is identical whether you are using LDAP authorization or file-based authorization. For more information, see “Setting file-based permissions” on page 2530. By default, integration servers that are managed by an integration node inherit permissions from the integration node.

8. Optional: Map values of LDAP attributes on LDAP objects to names of roles in App Connect Enterprise by configuring the `.yaml` configuration file, as shown in the following example:

```
Security:
  LdapAuthorizeAttributeToRoleMap:
    'graham': 'adminRole'    # (user mapped to role)
    'martin': 'viewRole'    # (user mapped to role)
    'DB_ADMIN':'adminRole'      # (field mapped to role)
    'NETWORK_ADMIN':'viewRole'  # (field mapped to role)
    'o=AceViewersGroup,o=groups,ou=ace': 'viewRole'  # (group mapped to role)
    'o=AceAdminsGroup,o=groups,ou=ace':  'viewRole'  # (group mapped to role)
```

If you have existing LDAP attributes and existing roles in App Connect Enterprise with different names, you must map from one to the other. If LDAP objects have attribute names that do not match names of defined roles in App Connect Enterprise, access is denied. You do not need to map in the following cases:

- If values of LDAP group attributes match the names of roles in App Connect Enterprise.
- If you configure LDAP attribute values to match names of existing roles in App Connect Enterprise.
- If you create roles in App Connect Enterprise with names identical to values of LDAP attributes.

The `node.conf.yaml` and `server.conf.yaml` files allow free-form names for roles that are not predefined in App Connect Enterprise.

LDAP allows free-form names for values of attributes. The names of values of attributes are not predefined in LDAP.

Note:

In LDAP, roles in App Connect Enterprise are derived from LDAP group search attributes. For example, cn, dn, email, location.

Multiple group membership gives the user multiple roles in App Connect Enterprise. For example, AceAdmin, AceViewer, AceDeveloper. When a user tries to perform an action, all roles are tried until permission is granted.

Template syntax allows LDAP to use information about the authenticated user to search for groups. In the **`ldapAuthorizeUrl`** parameters in the `.yaml` configuration file, you can use {{dn}} to substitute the users distinguished name, and {{username}} to substitute the username.

```
#ldapAuthorizeUrl: ldap[s]://server[:port]/baseDN[?[attr_name][?[base|sub]][?filter_expr]]
 # ldap authorization search url
```

ldap:
(Required) An LDAP URL begins with the protocol prefix "ldap." The protocol prefix "ldap" indicates an entry or entries accessible from the LDAP server that is running on the specified hostname at the specified port number.

s:
(Optional) Specifies whether SSL is used. Default is not to use SSL.

server:
(Required) The name or IP address of the LDAP server to contact. You must use the same server that you used for authentication.

port:
(Required) The port to connect to. Default is 389 (non-SSL). For LDAP servers with SSL enabled, the port is typically 636.

baseDN
(Required) The LDAP Distinguished Name. It identifies the base object of the LDAP search.

attr_name:
(Optional) String used to indicate which attributes are returned from the entry. For example, uid, cn, or email address. Default is *uid*.

base|sub:
(Optional) Specifies the scope of the search to run in the specified LDAP server. The allowable scopes are "base" for a base object search, or "sub" for a subtree search. If `base` is defined, the authentication is faster because the DN of the user can be constructed from the *attr_name*, and *baseDN* values. If *sub* is selected, a search must be run before the DN can be resolved. Default is *sub*.

filter_expr:
(Optional) A valid LDAP filter expression that can use template syntax to substitute the details of the authenticated user; for example:

- `{{dn}}` is replaced with the user's distinguished name.
- `{{username}}` is replaced with the user's username attribute value.

Therefore, you can use filters like the following examples.

- `(member={{dn}})` matches groups where the authenticated user's distinguished name is set as a *member* attribute value.
- `(cn={{username}})` matches an entry where the authenticated user's username is set as the *cn* attribute value.

You now have options on how to configure LDAP authorization.

- Authorize a single LDAP group to have a role in App Connect Enterprise. See step “9” on page 2540.
- Authorize multiple LDAP groups to have roles in App Connect Enterprise. See step “10” on page 2541.
- Authorize an LDAP authenticated user's LDAP attributes to have a role in App Connect Enterprise. See step “11” on page 2542.

9. Optional: Authorize a single LDAP group to have a role in IBM App Connect Enterprise by setting values for **`ldapAuthorizeUrl`** in the `.yaml` configuration file.

   Before you do this step, ensure that you set admin security authorization file permissions as required for roles in App Connect Enterprise. Also, ensure that you complete any required mapping of LDAP

attribute names to names of roles in App Connect Enterprise.See step “5” on page 2538, step “6” on page 2538, step “7” on page 2538, and step “8” on page 2539.

In the following example, an LDAP authenticated user, `graham`, is a member of a single group in LDAP, which has the distinguished name (dn) `cn=administrator,ou=groups,o=ace`, as shown in the following LDAP configurations:

```
ObjectClass: Person
dn: cn=graham,ou=users,o=ace
cn: graham

ObjectClass: groupOfNames
dn: cn=administrator,ou=groups,o=ace
cn: administrator
Member: cn=graham,ou=users,o=ace
Member: cn=martin,ou=users,o=ace
```

To authorize the single LDAP group with distinguished name (dn) `cn=administrator,ou=groups,o=ace` to have the role `adminRole` in IBM App Connect Enterprise, set the values for **`ldapAuthorizeUrl`** in the `.yaml` configuration file as shown in the following example:

- `localhost` is the server
- `:10389` is the port
- `o=groups,ou=ace` is the baseDN (Distinguished name)
- `?cn` is the attr_name
- `?sub` indicates that a subset of the LDAP tree structure is to be searched
- `?(member={{dn}})` is the filter_expr

```
ldapAuthorizeUrl: 'ldap://localhost:10389/o=groups,ou=ace?cn?sub?(member={{dn}})'  # ldap
 authorization search url'
```

When the LDAP-authenticated user `graham` attempts to complete an action on the integration node or integration server, a search confirms that the LDAP distinguished name (dn) `cn=administrator,ou=groups,o=ace` is authorized to have the role `adminRole` in App Connect Enterprise. The LDAP-authenticated user `graham` is a member of the LDAP group `cn=administrator,ou=groups,o=ace`, so permission to complete the action is granted.

For more information about the parameters in **`ldapAuthorizeUrl`**, see step “8” on page 2539.

10. Optional: Authorize multiple LDAP groups to roles in App Connect Enterprise by setting values for **`ldapAuthorizeUrl`** in the `.yaml` configuration file.

    Before you do this step, ensure that you set admin security authorization file permissions as required for roles in App Connect Enterprise. Also, ensure that you complete any required mapping of LDAP attribute names to names of roles in App Connect Enterprise. See step “5” on page 2538, step “6” on page 2538, step “7” on page 2538, and step “8” on page 2539.

    In the following example, the LDAP-authenticated user, `martin`, is a member of two groups in LDAP, with the distinguished names (dn) `cn=administrator,ou=groups,o=ace,` and `cn=viewer,ou=groups,o=ace`, as shown in the following LDAP configurations:

```
ObjectClass: Person
dn: cn=martin,ou=users,o=ace
cn: martin

ObjectClass: groupOfNames
dn: cn=administrator,ou=groups,o=ace
cn: administrator
Member: cn=graham,ou=users,o=ace
Member: cn=martin,ou=users,o=ace

ObjectClass: groupOfNames
dn: cn=viewer,ou=groups,o=ace
```

```
cn: viewer
Member: cn=graham,ou=users,o=ace
Member: cn=martin,ou=users,o=ace
```

To authorize the LDAP group with distinguished name (dn) `cn=administrator,ou=groups,o=ace` to have the role `adminRole` in App Connect Enterprise, and authorize the LDAP group with distinguished name (dn) `cn=viewer,ou=groups,o=ace` to have the role, `viewRole` in App Connect Enterprise, configure the .conf.yaml file with the values in the following example:

- `localhost` is the server
- `:10389` is the port
- `o=groups,ou=ace` is the baseDN (Distinguished name)
- `?cn` is the attr_name
- `?sub` indicates that a subset of the LDAP tree structure is to be searched
- `?(member={{dn}})` is the filter_expr

```
ldapAuthorizeUrl: 'ldapAuthorizeUrl: 'ldap://localhost:10389/o=groups,ou=ace?cn?sub?
(member={{dn}})'  # ldap authorization search url'
```

When the LDAP-authenticated user `martin` attempts to complete an action on the integration node or integration server, a search confirms that the LDAP distinguished name (dn) `cn=viewer,ou=groups,o=ace` is authorized to have the role `viewRole` in App Connect Enterprise. The LDAP-authenticated user `martin` is a member of the LDAP group `cn=viewer,ou=groups,o=ace`. Therefore, the user `martin` is granted the permissions that are set for the role `viewRole` in the `.yaml` configuration file of the integration server or integration node. See step “6” on page 2538 and step “7” on page 2538. Each role is checked until permission is either granted or rejected. The LDAP-authenticated user `martin` is also a member of the LDAP group `cn=administrator,ou=groups,o=ace`. Therefore, the user `martin` is granted the permissions that are set for the role `adminRole` in the `.yaml` configuration file of the integration server or integration node.

For more information about the parameters in **`ldapAuthorizeUrl`**, see step “8” on page 2539.

11. Optional: Authorize an authenticated user's LDAP attributes to have a role in App Connect Enterprise by setting values for **`ldapAuthorizeUrl`** in the `.yaml` configuration file.

    Before you do this step, set admin security authorization file permissions as required for roles in App Connect Enterprise. Also, complete any required mapping of LDAP attribute names to names of roles in App Connect Enterprise.See step “5” on page 2538, step “6” on page 2538, step “7” on page 2538, and step “8” on page 2539.

    In the following example, the LDAP attribute `job` has the value `administrator` as shown in the following LDAP configuration:

```
ObjectClass: Person
dn: cn=graham,ou=users,o=ace
cn: graham
```

```
  job:administrator
```

To authorize the LDAP attribute `job` with the value `administrator` to have the role `adminRole` in App Connect Enterprise, configure the `.conf.yaml` file with the values that are shown in the following example:

- `localhost` is the server
- `:10389` is the port
- `o=users,ou=ace` is the baseDN (Distinguished name)
- `?job` is the attr_name
- `?sub` indicates that a subset of the LDAP tree structure is to be searched
- `cn={{username}}` is the filter_expr

```
ldapAuthorizeUrl: 'ldap://localhost:10389/o=users,ou=ace?job?sub?(cn={{username}}) # ldap
 authorization search url'
```

The LDAP-authenticated user `graham` attempts to complete an action on the integration node or integration server. A search confirms that the LDAP attribute name `job`, with the value `administrator` is authorized to have the role `adminRole` in App Connect Enterprise. The LDAP-authenticated user `graham` has an LDAP attribute `job` with the value, `administrator`, so permission to complete the action is granted.

For more information about the parameters in **`ldapAuthorizeUrl`**, see step “8” on page 2539.

12. Save the modified file.
13. Restart the integration node or integration server for the changes to take effect.

Example

The following example shows a `.conf.yaml` file that is configured to enable LDAP authentication and LDAP authorization. It demonstrates the use of free-form names that are allowed by LDAP and App Connect Enterprise. In the section `LdapAuthorizeAttributeToRoleMap`, the LDAP group `developers` is mapped to the role `supportRole` in App Connect Enterprise. The section `Permissions` includes some further examples of roles that are defined in App Connect Enterprise. For example, the role `manager` is defined with read permission.

```
# Admin Security
  #  Authentication
  basicAuth: true
  ldapUrl: 'ldap://localhost:10389/ou=users,o=ace?cn?sub'
  #ldapBindDn: ldap::adminAuthentication
  #ldapBindPassword: ldap::adminAuthentication
  #  Authorization
  authorizationEnabled: true     # Clients web user role will be authorized when set true
  authorizationMode: 'ldap'       # Set authorization mode. Choose 1 of : ldap, file or mq

  ldapAuthorizeUrl: 'ldap://localhost:10389/o=users,ou=ace?description?sub?(member={{dn}})'
  #ldapAuthorizeUrl: 'ldap://localhost:10389/o=groups,ou=ace?employeeType?sub?(cn={{username}})'

Security:
  LdapAuthorizeAttributeToRoleMap:

            adminRole: 'all+'
```

Controlling access to data and resources in the web user interface

Integration administrators can control web users' access to data and integration node resources by assigning permissions to users based on their role.

Before you begin

- Read the following topics:
  - web user interface
  - “Role-based security” on page 2503
- Ensure that the web user interface has been configured. For more information, see “Configuring the IBM App Connect Enterprise web user interface” on page 87.

About this task

Integration administrators can restrict web users' access to data and integration node resources only if administration security is enabled. If administration security is not enabled, web users can interact with the web user interface without logging on, which means that they can access the web user interface as the 'default' user and have access to all data and integration node resources.

To perform any administrative task from the web user interface when administration security is enabled, you must have permission to view properties on the integration node. For a full list administrative tasks and the permissions required, see Tasks and authorizations for administration security.

With administration security enabled, REST users can view only the URIs for which they are authorized. If administration security is disabled, all REST requests are unrestricted.

Note: When queue-based security is enabled, a check is made on all SYSTEM.BROKER.AUTH queues to establish the permissions that the user has. As a result of this check, AMQ8077 messages might be seen.

As an integration administrator, you can set permissions to restrict users' access based on the tasks that they are required to perform. Some example tasks and their associated permissions are shown in the following table:

Example access and actions	IBM MQ queue-based permissions (set on the setmqaut command)	File-based permissions (set on the mqsichangefileauth command)
Allow data technicians to view record and replay data stores under **Data** tab of the integration node or integration server in the web user interface.	• `+inq` permission on SYSTEM.BROKER.DC.AUTH queue • `+inq` permission on SYSTEM.BROKER.AUTH queue	• `read+` permission on the `integration node` • `read+` permission on the `Integration Node Data object`

Example access and actions	IBM MQ queue-based permissions (set on the setmqaut command)	File-based permissions (set on the mqsichangefileauth command)
Allow web users to view and download recorded messages in an integration server's record and replay store.	• +inq permission on SYSTEM.BROKER.DC.AUTH queue • +inq permission on SYSTEM.BROKER.DC.AUTH.*integrationServerName* queue • +inq permission on SYSTEM.BROKER.AUTH queue	• read+ permission on the integration node • read+ permission on the Integration Node Data object • read+ permission on the Integration Server Data object
Allow web users to view, download and replay recorded messages in an integration server's record and replay data store.	• +inq permissions on SYSTEM.BROKER.AUTH queue • +inq permission on the SYSTEM.BROKER.DC.AUTH queue • +inq + set permission on SYSTEM.BROKER.DC.AUTH.*integrationServerName* queue	• read+ permission on the integration node • read+ permission on the Integration Node Data object • read+, execute+ permission on the Integration Server Data object
Allow REST users to request information about messages recorded under an integration server's record and replay data store.	• +inq permission on SYSTEM.BROKER.DC.AUTH.*integrationServerName* queue	read+ permission on the Integration Server Data object
Allow REST users to view and replay messages.	• +inq permission on SYSTEM.BROKER.DC.AUTH.*integrationServerName* queue to view • + set permission on SYSTEM.BROKER.DC.AUTH.*integrationServerName* queue to replay	• read+ permission on the Integration Server Data object to view. • execute+ permission on the Integration Server Data object to replay.
Allow web users to view business transactions on the Business Transactions Monitor tab	• +inq permission on SYSTEM.BROKER.AUTH queue • +inq permission on SYSTEM.BROKER.AUTH.*integrationServerName* queue, where *integrationServerName* is the integration server that hosts the business transaction definition • +inq permission on SYSTEM.BROKER.DC.AUTH queue	• read+ permission on the integration node • read+ permission on the Integration Server that hosts the business transaction definition • read+ permission on the integration node data object

Example access and actions	IBM MQ queue-based permissions (set on the setmqaut command)	File-based permissions (set on the mqsichangefileauth command)
Allow web users to view business transaction definitions on the Business Transactions Configure tab	• +inq permission on SYSTEM.BROKER.AUTH queue • +inq permission on SYSTEM.BROKER.AUTH.*integrationServerName* queue, where *integrationServerName* is the integration server that hosts the business transaction definition • +inq permission on SYSTEM.BROKER.DC.AUTH queue	• read+ permission on the integration node • read+ permission on the integration server that hosts the business transaction definition • read+ permission on the integration node data object
Allow web users to start and stop recording for a business transaction definition on the Business Transactions Configure tab.	• +inq permission on SYSTEM.BROKER.AUTH queue • +inq +set permission on SYSTEM.BROKER.AUTH.*integrationServerName* queue, where *integrationServerName* is the integration server that hosts the business transaction definition • +inq permission on SYSTEM.BROKER.DC.AUTH queue	• read+ permission on the integration node • read+ execute+ permission on the integration server that hosts the business transaction definition • read+ permission on the integration node data object
Allow web users to create or update a business transaction definition or a business transaction policy on the Business Transaction Monitoring Configure tab.	• +inq permission on SYSTEM.BROKER.AUTH queue • +inq +put permission on SYSTEM.BROKER.AUTH.*integrationServerName* queue, where *integrationServerName* is the integration server where the business transaction definition is being defined • +inq permission on SYSTEM.BROKER.AUTH.*integrationServerName* queue, where *integrationServerName* is the integration server from which you want to select business monitoring events to include in the business transaction definition • +inq permission on SYSTEM.BROKER.DC.AUTH queue	• read+ permission on the integration node • read+ write+ permission on the integration server where the business transaction definition is defined • read+ permission on the integration server from which you want to select business monitoring events to include in the business transaction definition • read+ permission on the integration node data object

Example access and actions	IBM MQ queue-based permissions (set on the setmqaut command)	File-based permissions (set on the mqsichangefileauth command)
Allow web users to delete a stopped business transaction definition.	• `+inq` permission on SYSTEM.BROKER.AUTH queue • `+inq +put` permission on SYSTEM.BROKER.AUTH.*integrationServerName* queue, where *integrationServerName* is the integration server where the business transaction definition is defined • `+inq` permission on SYSTEM.BROKER.DC.AUTH queue	• `read+` permission on the integration node • `read+ write+` permission on the integration server where the business transaction definition is defined • `read+` permission on the integration node data object

Integration administrators can also allow web users to start and stop integration servers, applications, and message flows from the web user interface, by granting permissions to the roles with which the web users are associated.

For more information about role-based access, see “Role-based security” on page 2503 and “Managing web user accounts” on page 2510.

Procedure

1. Enable administration security and configure the integration node to use either file-based or queue-based authorization.

   For more information, see “Enabling administration security” on page 2504.
2. Define the roles and their associated permissions. You can assign permissions to each role that you have identified; for example, you might decide that your web users can be categorized into two main roles: web administrators and web users. Define a role for each of these groups of users (for example, `iibUsers` and `iibAdmins`) with permissions that allow them to perform the required tasks, such as viewing or modifying resources:

   - If the integration node is configured to use file-based authorization (**`file`** mode), you define the roles and associated permissions on the integration node, by using the **mqsichangefileauth** command. For information about setting permissions for file-based authorization, see “Setting file-based permissions” on page 2530.
   - If the integration node is configured to use queue-based authorization (**`mq`** mode), you must create a system user ID on the operating system for each role that you have identified. You must then assign permissions to the system user ID, which is then used as a role. For information about setting permissions for queue-based authorization, see “Setting queue-based permissions” on page 2533.
   - If the integration node is configured to use LDAP authorization, you define the roles and associated permissions on the integration node, by setting properties in the `node.conf.yaml` for the integration node. For information about setting permissions for LDAP authorization, see “Configuring authorization by using LDAP groups” on page 2537.

   For more information about setting the appropriate permissions, see “Authorizing users for administration” on page 2516.
3. Use the **mqsiwebuseradmin** command to create your web user accounts and assign them to the appropriate roles.

   For more information, see command. For more information about roles, see “Role-based security” on page 2503.

Configuring HTTP basic authentication for an integration node or server

You configure HTTP basic authentication for your IBM App Connect Enterprise integration node or server by modifying properties in a `node.conf.yaml` or `server.conf.yaml` configuration file. .

Before you begin

- Start an instance of the IBM App Connect Enterprise command console. You can use the console to create a username and password by issuing the **mqsiwebuseradmin** command.

Procedure

1. Use a YAML editor to open the `.yaml` configuration file for your integration node or server.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, which are not accepted in YAML and would cause your configuration to fail. If choose to use a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

   For more information about working with YAML, see http://www.yaml.org/start.html.
2. Uncomment the following line in the `.yaml` file:

   ```
   #basicAuth: true       # Clients require a web username and password
   ```
3. Save the `.yaml` file.

   The properties that you set in the `.yaml` file take effect when the integration node or server is started. If you modify these properties again, you must also restart the integration node or server.
4. In the IBM App Connect Enterprise command console, create a username and password by issuing the **mqsiwebuseradmin** command.
   For example:

   ```
   mqsiwebuseradmin -w c:\workdir\ACEServ1 -u admin -a password -c
   ```

   You can create multiple users; the permissions are identical for all users.
5. Restart the integration node or server for the changes to take effect.

What to do next

When you manage your integration node or server, or the resources that are deployed to it, by using either the IBM App Connect Enterprise Toolkit or web user interface, you are prompted to enter the username and password that you have created in this task in addition to the host name and port number of the integration node or server. When you use the IBM App Connect Enterprise Toolkit to create a connection to the integration node or server, you can optionally save the password to the Eclipse Secure Storage by selecting the **Save Password** check box in the Create connection wizard.

Configuring SSL or TLS for an integration node or server

You configure SSL or TLS for your IBM App Connect Enterprise integration node or server by modifying properties in a `.yaml` configuration file. You also use the **mqsisetdbparms** command to set a password.

Before you begin

- Start an instance of the IBM App Connect Enterprise command console. You can use the console to create a username and password by issuing the **mqsisetdbparms** command.

Procedure

1. Use a YAML editor to open the `.yaml` configuration file for your integration node or server.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, which are not accepted in YAML and would cause your configuration to fail. If choose to use a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

   For more information about working with YAML, see http://www.yaml.org/start.html.
2. Uncomment the following lines in the `.yaml` file:

   ```
   #sslCertificate: '/path/to/serverPKCS.p12'  ...
   #sslPassword: 'adminRestApi::sslpwd'        ...
   ```

   Where `adminRestApi::sslpwd` is the default resource name to be specified on the **mqsisetdbparms** command.

   You can specify values inside or without single quotes[2]. Also note the comments in the `.yaml` file about values to specify for the type of server certificate that you want to use.
3. In the line that starts `SslCertificate`, specify the file path to the server certificate on your system. For example, to use a p12 certificate:

   ```
   sslCertificate: '/Work/ACEv11/certificates/ssl/key.p12'   # See comment below
   ```
4. To use a pem certificate, in the line that starts `SslPassword` specify the file path to the pem file. For example:

   ```
   sslPassword: '/Work/ACEv11/certificates/ssl/cakey.pem'   # See comment below
   ```
5. Save the `.yaml` file.

   The properties that you set in the `.yaml` file take effect when the integration node or server is started. If you modify these properties again, you must also restart the integration node or server.
6. To use a p12/pfx certificate, run the **mqsisetdbparms** command to specify the password for your server certificate.

   - Ensure that you specify the resource name on the **-n** parameter as `adminRestApi::sslpwd` to match the `sslPassword` value in the `.yaml` file.
   - The -u (username) value is ignored.

   For example:

   ```
   mqsisetdbparms -w c:\workdir\ACEServ1 -n adminRestApi::sslpwd -u dummy -p password
   ```
7. Restart the integration node or server for the changes to take effect.

What to do next

When you use the IBM App Connect Enterprise Toolkit to create a connection to the integration node or server, ensure that you select the **Use HTTPS** check box in the Create connection wizard.

Disabling administration security

Disable administration security to remove control over an integration node and its resources.

About this task

You can disable administration security for an integration node by updating the **authorizationEnabled** property in the `node.conf.yaml` configuration file.

[2] To be more explicit about the string values, you should put the values inside quotes.

Procedure

1. Open the `node.conf.yaml` configuration file for your integration node, by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, which are invalid characters in YAML and will cause your integration node configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
2. In the `node.conf.yaml` file, set the **`authorizationEnabled`** property to `false`:

   For example:

   ```
   authorizationEnabled: false
   ```
3. Save the modified `node.conf.yaml` file.
4. Restart the integration node by using the web user interface or the command.

Results

When this command completes, all users are able to complete tasks against the integration node. They can also complete all tasks against all integration servers that have been defined, and that are defined in the future, on this integration node.

Message flow security

Control access to individual messages in a message flow, using the identity of the messages.

The following topics introduce the concepts that you need to understand before you can configure message flow security, and they explain the steps involved in setting up security for your message flows:

- “Message flow security overview” on page 2550
- “Setting up message flow security” on page 2583

Message flow security overview

IBM App Connect Enterprise provides a security manager to control access to individual messages in a message flow, by using the identity of the message.

You can configure an integration server for processing end-to-end an identity that is carried in a message through a message flow by using a security profile. By creating a security profile, you can configure security for a message flow to control access based on the identity that is associated with the message and provide a security mechanism that is independent of both the transport type and message format.

Only a subset of the connectors available in IBM App Connect Enterprise use security profiles to control and vary the identity that is used when the connector interacts with an external system. For other connectors, a fixed identity can be specified, which is used to authorize access to the external system. For those connectors, the integration server has its own repository of identities, which can be updated by using the **`mqsivault`** and **`mqsicredentials`** commands.

If you do not enable message flow security, the default security facilities that are in IBM App Connect Enterprise are based on the security facilities that are provided by the transport mechanism. In this case, the integration server processes all messages that are delivered to it, using the integration server service identity as a proxy identity for all message instances. Any identity that is present in the incoming message is ignored.

The security functions that are associated with a message flow are controlled by using “Security profiles” on page 2552, which are created by the App Connect Enterprise administrator and accessed by the security manager at runtime.

The security manager enables the integration server to:

- Extract the identity from an inbound message

- Authenticate the identity, by using either an external security provider (such as LDAP) or a locally stored identity in the integration server vault
- Map the identity to an alternative identity, by using an external security provider
- Check that either the alternative identity or the original identity is authorized to access the message flow, by using an external security provider
- Propagate either the alternative identity or the original identity with an outbound message.

The following external security providers (also known as Policy Decision Points or PDPs) are supported:

- Tivoli Federated Identity Manager (TFIM) V6.1 for authentication, mapping, and authorization
- WS-Trust V1.3 compliant Security Token Service (including TFIM V6.2) for authentication, mapping, and authorization
- Lightweight Directory Access Protocol (LDAP) for authentication and authorization
- Windows Domain Controllers for authentication
- Kerberos KDCs for authentication

As an alternative to using an external security provider to authenticate an identity, you can use an identity stored locally in the integration server vault. For more information, see "Authenticating incoming requests by using credentials stored in the vault" on page 2597.

You can invoke message flow security by configuring either a security enabled input node or a SecurityPEP node. You can use the SecurityPEP node to invoke the message flow security manager at any point in the message flow between an input node and an output (or request) node.

For an overview of the sequence of events that occur when the message flow security manager is invoked by using either a security enabled input node or a SecurityPEP node, see the following topics:

- "Invoking message flow security using a security enabled input node" on page 2565
- "Invoking message flow security using a SecurityPEP node" on page 2569

The input nodes that support message flow security are:

- MQInput
- HTTPInput
- SOAPInput

The support for treating security exceptions as normal exceptions is provided by only the MQInput and HTTPInput nodes; it is not available in the SOAPInput node.

The output nodes that support identity propagation are:

- CICSRequest
- HTTPRequest
- HTTPAsyncRequest
- IMSRequest
- MQOutput
- MQReply
- RESTRequest
- RESTAsyncRequest
- SAPRequest
- SiebelRequest
- SOAPRequest
- SOAPAsyncRequest
- SOAPReply
- SecurityPEP

If the message flow is a web service that is implemented by using the "SOAP nodes" on page 811, the identity can be taken from the "WS-Security" on page 2650 header tokens that are defined through appropriate "Policy sets" on page 2662 and bindings.

To improve performance, the security manager uses a security cache. Entries are created in the security cache when a message flow with a security profile performs authentication, mapping, or authorization. The entries are valid for the length of time that is specified by the `cacheTimeout` property of the `securitycache` component after which the entries are marked as expired. When an entry is marked as expired, it must be reauthenticated, mapped, or reauthorized with the security provider before it can be reused, and its expiry time is reset. For information about specifying a value for the `cacheTimeout` property, see "Configuring the security cache" on page 2579. You can use the **mqsireloadsecurity** command to force the immediate expiry of some or all of the entries in the security cache.

For a SOAPRequest and SOAPAsyncRequest node, an appropriate policy set and bindings can be defined to specify how the token is placed in the WS-Security header (rather than the underlying transport headers). For more information, see "Policy sets" on page 2662.

The following topics in this section provide more detailed information about message flow security:

- "Identity" on page 2554
- "Security profiles" on page 2552
- "Authentication and validation" on page 2561
- "Authorization" on page 2562
- "Identity mapping" on page 2564
- "Identity and security token propagation" on page 2580
- "Security identities for the integration server connecting to external systems" on page 2582
- "Invoking message flow security using a security enabled input node" on page 2565
- "Invoking message flow security using a SecurityPEP node" on page 2569
- "Authentication, mapping, and authorization with TFIM V6.2 and TAM" on page 2574
- "Authentication, mapping, and authorization with TFIM V6.1 and TAM" on page 2572
- "Configuring the security cache" on page 2579
- "Security exception processing" on page 2582

Security profiles

A security profile defines the security operations that are to be performed in a message flow at SecurityPEP nodes and security enabled input and output nodes.

Security profiles are configured by the integration administrator before deploying a message flow, and are accessed by the security manager at run time.

A security profile allows an integration administrator to specify whether authentication, authorization, mapping, and propagation are to be performed on the identity or security tokens associated with messages in the message flow. You can create a security profile for use with an external security provider (also known as a Policy Decision Point or PDP) to provide security enforcement and mapping. IBM Tivoli Federated Identity Manager (TFIM) V6.1 and WS-Trust v1.3 compliant Security Token Service (including TFIM V6.2) are supported for authentication, authorization, and mapping. Lightweight Directory Access Protocol (LDAP) is supported for authentication and authorization. As an alternative to using an external security provider for authentication, you can create a security profile for authenticating against credentials that are held locally in the integration server's vault, as described in "Authenticating incoming requests by using credentials stored in the vault" on page 2597.

Security profiles apply to the following security-enabled message flow nodes:

- CICSRequest
- HTTPInput
- HTTPRequest

- HTTPAsyncRequest
- IMSRequest
- MQInput
- MQOutput
- MQReply
- RESTRequest
- RESTAsyncRequest
- SAPRequest
- SecurityPEP
- SiebelRequest
- SOAPInput
- SOAPReply
- SOAPRequest
- SOAPAsyncRequest

These nodes have a **Security Profile** property, in which you can specify the name of the security profile that determines the type of security that is configured for the node. If the named security profile does not exist at run time, the message flow fails to deploy. If a specified external security provider does not support the type of token configured on the node for the security operation, an error is reported and the message flow fails to deploy. If the security profile specifies local authentication, but the credentials have not been created or the alias name is not matching, the deployed message flow will fail to start. For more information, see "Authenticating incoming requests by using credentials stored in the vault" on page 2597.

Security profiles can be configured by the administrator at deployment time in the BAR file editor. The security-enabled nodes have a **Security Profile** property in the BARfile editor, which can be left blank, set to *No Security*, or set to a specific security profile name. Set *No Security* to explicitly turn off security for the message flow node. If the **Security Profile** property is blank, the node inherits the **Security Profile** property that is set at the message flow level. If the **Security Profile** property is left blank at both levels, security is turned off for the message flow node.

The security profile also specifies whether propagation is required. A pre-configured profile that specifies propagation is provided for use by output and request nodes. This profile is the *Default Propagation* security profile. This profile can also be used on an input node to extract tokens and put them into the message tree ready for propagation or processing in a SecurityPEP node.

Security profiles contain values for the following properties:

alternateServers

Defines the comma-separated list of LDAP servers to failover when the primary server is not available. The list has the following format:

```
ldap[s]://host1:[port1], ldap[s]://host2:[port2], ldap[s]://host3:[port3]
```

After failover, the newly connected LDAP server becomes the primary server.

authentication

Defines the type of authentication that is performed on the source identity. For more information, see "Authentication and validation" on page 2561.

authenticationConfig

Defines the information that the integration server needs to authenticate the identity, and can be one of the following values:

- The configured alias name of the locally stored credentials in the integration server's vault. These credentials are used for basic authentication when the **Authentication** type is `Local`. For more

information, see “Authenticating incoming requests by using credentials stored in the vault” on page 2597.

- The information that the integration server needs to connect to the external security provider and look up identity tokens. This property is in the form of a provider-specific configuration string.

mapping
Defines the type of mapping that is performed on the source identity. For more information, see “Identity mapping” on page 2564.

mappingConfig
Defines how the integration node connects to the provider, and contains additional information required to look up the mapping routine. It is a provider-specific configuration string.

authorization
Defines the types of authorization checks that are performed on the mapped or source identity. For more information, see “Authorization” on page 2562.

authorizationConfig
Defines how the integration node connects to the provider, and contains additional information that can be used to check access (for example, a group that can be checked for membership). It is a provider-specific configuration string.

passwordValue
Defines how passwords are treated when they enter a message flow. If *PLAIN* is selected, the password appears in the Properties folder in plain text. If *OBFUSCATE* is selected, the password appears in the Properties folder in base64 encoding. If *MASK* is selected, the password appears in the Properties folder as four asterisks (****).

propagation
Enables or disables identity propagation on output and request nodes. On the security enabled input nodes, you can choose to select only identity propagation, without specifying any other security operations, to make the extracted incoming identity or security token available for use in the other nodes in the message flow, such as output or request nodes. For more information, see “Identity and security token propagation” on page 2580.

idToPropagateToTransport
Enables the use of a specific security identity for propagation. Set the value to `STATIC ID`, and set the security identity by using the **`transportPropagationConfig`** parameter.

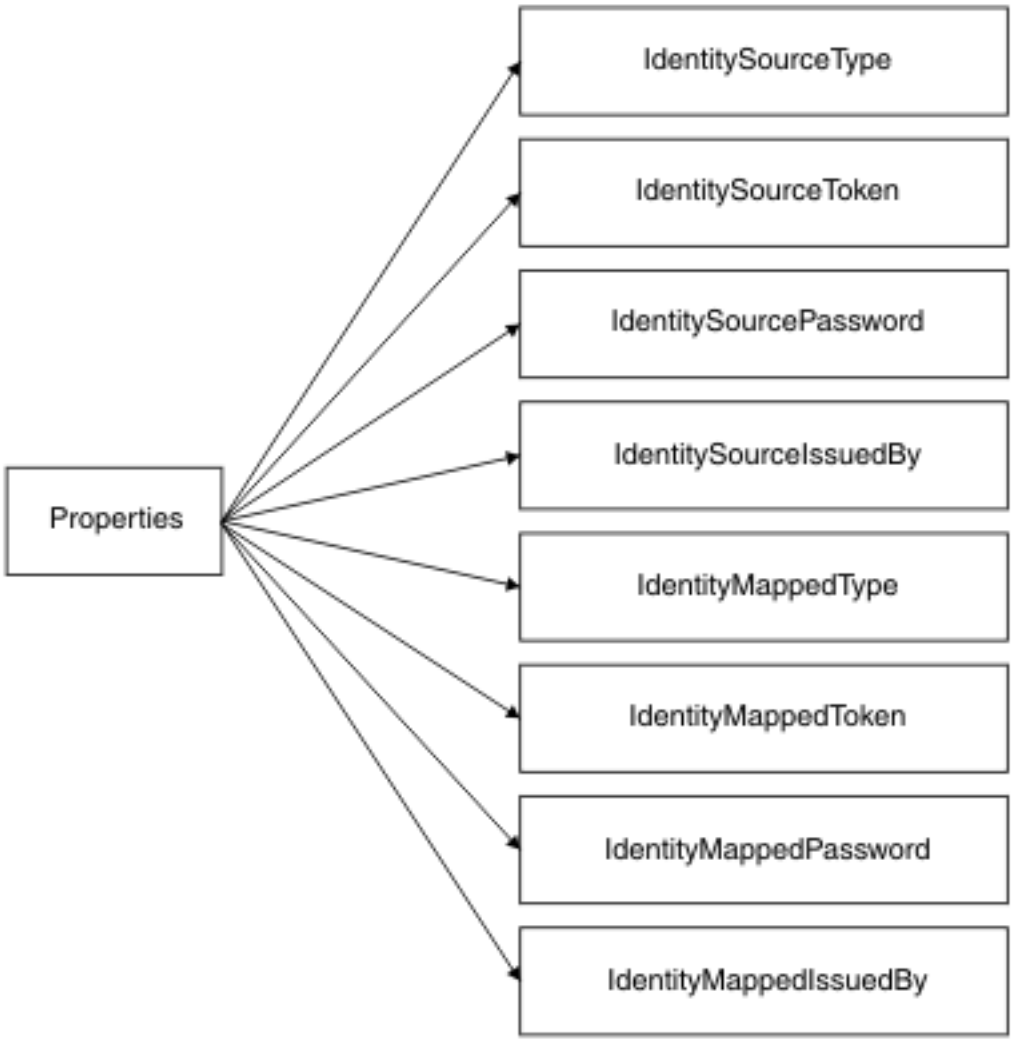
transportPropagationConfig
Provides a specific security identity to propagate when **`idToPropagateToTransport`** is set to `STATIC ID`. Set the value to the name that you associate with the static user name and password identity when you run the **`mqsisetdbparms`**. For more information, see “Configuring a message flow for identity propagation” on page 2613.

For information about configuring settings for the security profile, see “Creating a security profile” on page 2584.

Identity

In IBM App Connect Enterprise, an identity is a security token that uniquely identifies an individual, or that provides a set of assertions that can be validated.

When a SecurityPEP node or a supported input node is configured with a security profile, the extracted identity is held in the integration node as eight properties in the Properties folder of the message tree structure. These properties define two identities in the integration node: source and mapped. For both the source and mapped identities, values are held for **Type**, **Token**, **`Password`**, and **`IssuedBy`** properties:



The **Identity token type** property on the security-enabled input nodes can be set to a value of *Transport Default*, which causes the token type to be created from the default identity header or fields of the transport. For WebSphere MQ, *Transport Default* provides an identity type of *Username*. For HTTP, *Transport Default* provides an identity type of *Username and Password*. The Identity token type property on the SecurityPEP node can be set to *Current Token*, which enables it to use the identity in the Properties folder fields instead of extracting a new identity from the message.

The following table shows the support that is provided (by the message flow security manager and external security providers) for the extraction of different types of security token. For information about the token types that are supported for identity propagation, see "Identity and security token propagation" on page 2580.

Table 90. Support for security token types - token extraction

Token type (format)	Integration node security manager support for token extraction	External security provider support
Username	Username tokens are supported for extraction by the following message flow nodes: • HTTPInput • MQInput • SecurityPEP • SOAPInput The token is obtained from one of the following transport headers: • MQ – From MQMD user ID • HTTP – From HTTP BasicAuth header containing only a username part • SOAP – From a WS-Security UsernameToken header. The policy set and binding (associated with the SOAP node) must define a username profile, and the wsse:UsernameToken must contain only a `wsse:Username` element. – From the Kerberos subject in a WS-Security header. The policy set and binding (associated with the SOAP node) must define a Kerberos profile. – From the HTTP BasicAuth header containing only a username part if no policy set is defined on the SOAP node. Alternatively, the token can be taken from any part of the message tree when the token location is specified (on the node) using an XPath expression or ESQL field path. The literal string value used by the integration node (and which you can use to specify the token type in an ESQL or Java program) is *username*.	LDAP: Authorization WS-Trust V1.3 STS (including TFIM V6.2): • Authentication • Mapping • Authorization **Note:** To prevent the use of a username token (rather than a username and password token) with these security providers, consider setting the **`Reject Empty Password`** security profile property to TRUE. The security manager then rejects a user name during authentication if the user name has an empty password token, and the user name is not authenticated with the external security provider.

Table 90. Support for security token types - token extraction (continued)

Token type (format)	Integration node security manager support for token extraction	External security provider support
Username and password or Username and RACF PassTicket	Username and password tokens are supported for extraction by the following message flow nodes: • HTTPInput • MQInput • SecurityPEP • SOAPInput The token is obtained from one of the following transport headers: • HTTP – From HTTP BasicAuth header containing both a username and password part • SOAP – From a WS-Security UsernameToken header. The policy set and binding (associated with the SOAP node) must define a username profile and the wsse:UsernameToken must contain both `wsse:Username` and `wsse:Password` elements. – From the HTTP BasicAuth header containing only a username part if no policy set is defined on the SOAP node Alternatively, the token can be obtained from any part of the message tree when the token location is specified (on the node) using an XPath expression or ESQL path. The password token can carry either a clear text password or a RACF PassTicket. If you are using a WS-Trust V1.3 STS (such as TFIM V6.2), you can use it to map (issue) or validate RACF PassTickets, by specifying the token type as *Username and password*. This support is available with security enabled input nodes and SecurityPEP nodes. The literal string value used by the integration node (and which you can use to specify the token	LDAP: • Authentication • Authorization TFIM V6.1: • Authentication • Mapping • Authorization WS-Trust V1.3 STS (including TFIM V6.2): • Authentication • Mapping • Authorization IWA: • Authentication

Table 90. Support for security token types - token extraction (continued)

Token type (format)	**Integration node security manager support for token extraction**	**External security provider support**
SAML assertion	SAML tokens are supported for extraction by the following message flow nodes: • SecurityPEP • MQInput • HTTPInput • SOAPInput The token is obtained from one of the following places: • SOAP – From a WS-Security header. The policy set and binding (associated with the SOAP node) must define a SAML profile. • Any part of the message tree when the token location is specified using an XPath expression or ESQL path. The literal string value used by the integration node (and which you can use to specify the token type in an ESQL or Java program) is *SAML*.	WS-Trust V1.3 STS (including TFIM V6.2): • Authentication • Mapping • Authorization

Table 90. Support for security token types - token extraction (continued)

Token type (format)	Integration node security manager support for token extraction	External security provider support
Kerberos GSS v5 AP_REQ	Kerberos tickets are supported for processing by the message flow security manager from the SecurityPEP node. A WS-Security Kerberos token profile is supported by the following SOAP nodes, but in this case, the Kerberos Key Distribution Center is communicated with directly, and the properties folder is populated with a Username token representing the Kerberos subject: • SOAPInput The token is obtained from any part of the message tree at a SecurityPEP node, if the token location is specified using an XPath expression or ESQL path. The literal string value used by the integration node (and which you can use to specify the token type in an ESQL or Java program) is *kerberosTicket*.	WS-Trust V1.3 STS (including TFIM V6.2): • Authentication • Mapping • Authorization
LTPA v2 token	LTPA tokens are supported for extraction by the following nodes: • SecurityPEP • SOAPInput The token is obtained from any part of the message tree at a SecurityPEP node, if the token location is specified using an XPath expression or ESQL path. The literal string value used by the integration node (and which you can use to specify the token type in an ESQL or Java program) is *LTPA*.	WS-Trust V1.3 STS (including TFIM V6.2): • Authentication • Mapping • Authorization

Table 90. Support for security token types - token extraction (continued)

Token type (format)	Integration node security manager support for token extraction	External security provider support
X.509 Certificate	X.509 tokens are supported for extraction by the following message flow nodes: • SecurityPEP • MQInput • HTTPInput • SOAPInput The token is obtained from one of the following places: • SOAP – From a WS-Security header. The policy set and binding (associated with the SOAP node) must define an X.509 profile. • Any part of the message tree when the token location is specified using an XPath expression or ESQL path. The literal string value used by the integration node (and which you can use to specify the token type in an ESQL or Java program) is *X.509*.	TFIM V6.1: • Authentication • Mapping • Authorization. WS-Trust V1.3 STS (including TFIM V6.2): • Authentication • Mapping • Authorization.
Universal WSSE token	Universal WSSE tokens are supported for extraction by the SecurityPEP node only. The token is obtained from any part of the message tree at a SecurityPEP node, if the token location is specified using an XPath expression or ESQL path. The literal string value used by the integration node (and which you can use to specify the token type in an ESQL or Java program) is *UniversalWsse*.	WS-Trust V1.3 STS (including TFIM V6.2): • Authentication • Mapping • Authorization.

The source identity is set by the SecurityPEP or input node only if a security profile is associated with the node. The information to complete these fields is typically found in the headers of a message but can also be located in the body (provided that the node has been configured with an ESQL Path or XPath reference for the various properties). If multiple identities are available (for example, if you are using message aggregation), the first identity is used. The token extraction is transport specific and can be performed only using transports that support the flow of identities. These transports are: Websphere MQ, HTTP(S), and SOAP. See node and node for more information.

You can modify the values in the properties (for example, from ESQL), but do not write to the *IdentitySource** values. For example, you can create a custom identity mapping routine in ESQL or Java by using the *IdentitySource** values to create custom *IdentityMapped** values.

SAML and Universal WSSE tokens are stored in the Properties tree IdentitySourceToken or IdentityMappedToken field as a character bit stream. To access this data as a message tree, parse it into a suitable parser, such as XMLNSC:

```
-- Parse the mapped SAML2.0 token in the properties folder and set it in the message body
   CREATE LASTCHILD OF OutputRoot DOMAIN('XMLNSC')
 PARSE(InputRoot.Properties.IdentityMappedToken,
   InputProperties.Encoding, InputProperties.CodedCharSetId);
```

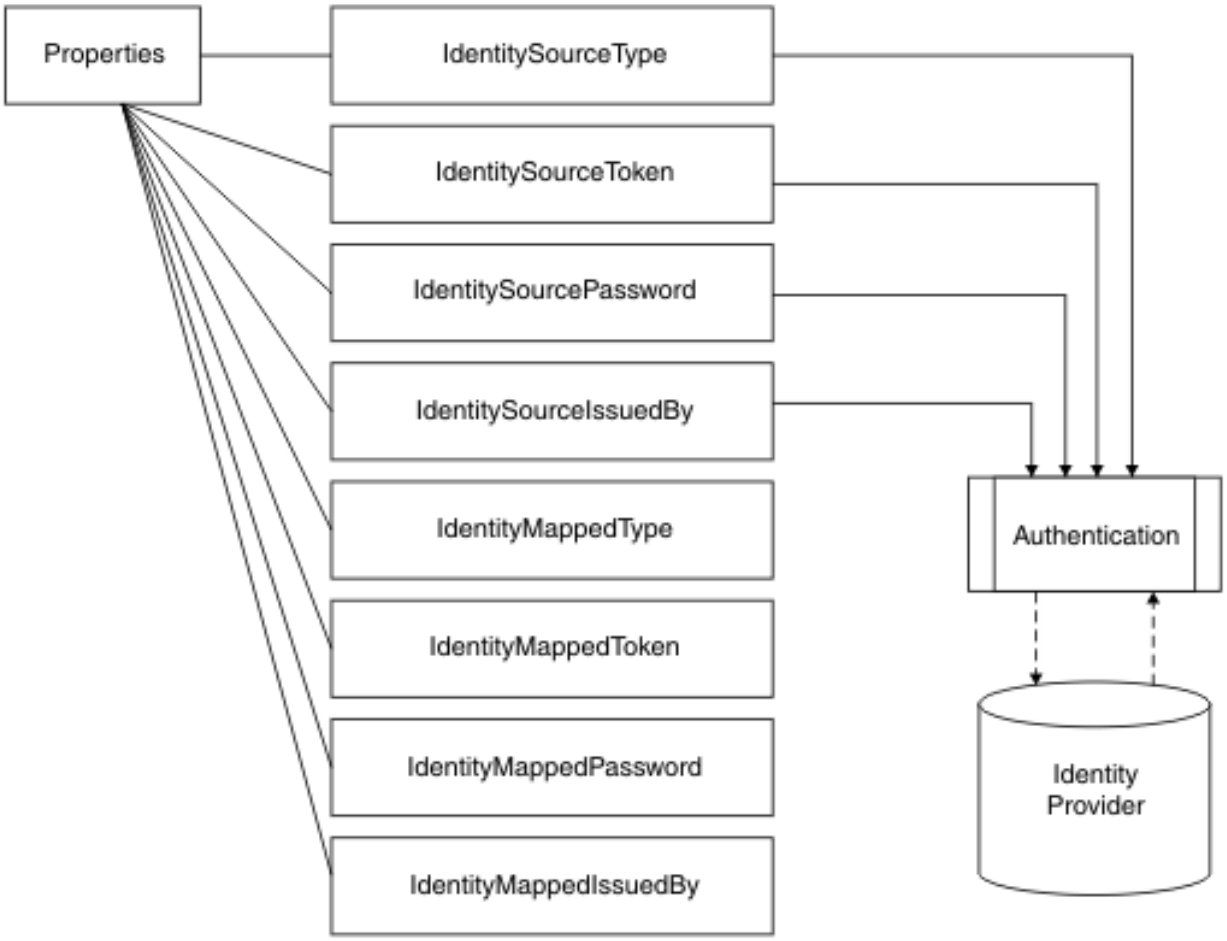
To set either SAML or Universal WSSE tokens into the properties fields, you must obtain the bit stream of a tree; for example, by using the ESQL ASBITSTREAM function.

Authentication and validation

Authentication is the process of establishing the identity of a user or system and verifying that the identity is valid. Applying authentication to a SAML security token involves validating the assertions that it carries and confirming that it is being processed within its validity period.

In IBM App Connect Enterprise message flow security, authentication involves the security manager either passing the identity type and token to an external security provider or checking the identity by using credentials stored locally in the integration server's vault. For more information about security tokens, see “Identity” on page 2554.

Authentication by an external security provider:



The following external security providers (also known as Policy Decision Points) are supported for authentication:

- Lightweight Directory Access Protocol (LDAP)
- Tivoli Federated Identity Manager (TFIM) V6.1
- WS-Trust V1.3 Security Token Service (STS), including TFIM V6.2
- Windows domain controller and Kerberos Key Distribution Center

The external security provider checks the identities and returns a value to confirm whether the identity is authentic. If the identity is not authentic, a security exception is raised.

Consider setting the **`Reject Empty Password`** property to TRUE to specify that you want the security manager to reject a user name during authentication if the user name has an empty password token, without authenticating the user name with the configured provider.

Some identity providers support only a single type of authentication token. If a token of another type is passed into the message flow, an exception is raised. For example, LDAP supports only a *Username and password* token.

You can use an LDAP provider for the authentication of an incoming identity token. The LDAP server must be LDAP Version 3 compliant.

Alternatively, you can use a WS-Trust v1.3 STS provider (for example, TFIM Version 6.2) for the authentication of an incoming identity or security token. The security manager invokes the WS-Trust v1.3 provider once, even if it is set for additional security operations (such as mapping or authorization). As a result, when you are using TFIM, you must configure a single module chain to perform all the required authentication, mapping, and authorization operations.

For more information about using TFIM V6.2 for authentication, see “Authentication, mapping, and authorization with TFIM V6.2 and TAM” on page 2574.

TFIM V6.1 is also supported, for compatibility with previous versions of IBM App Connect Enterprise. For more information about using TFIM V6.1 for authentication, see “Authentication, mapping, and authorization with TFIM V6.1 and TAM” on page 2572.

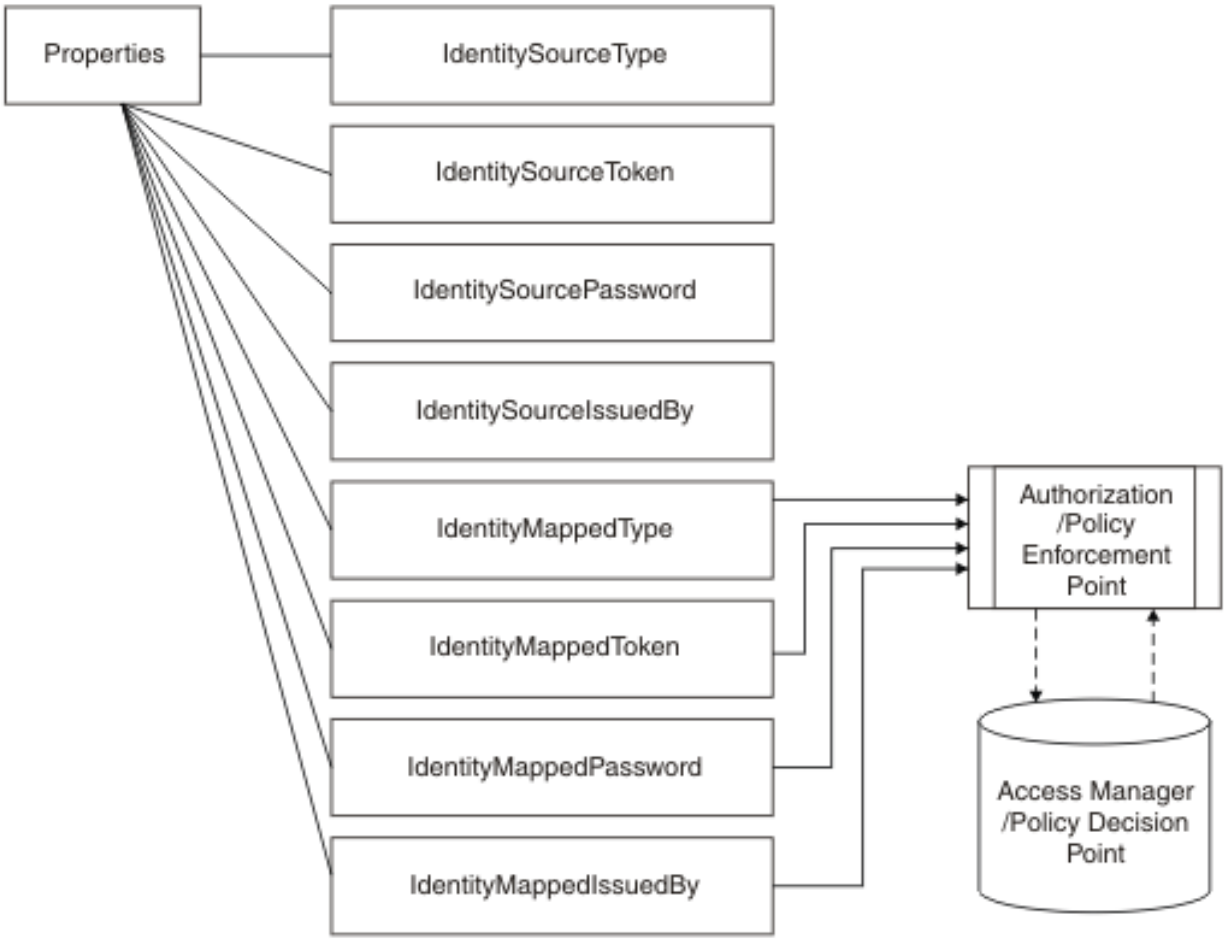
Authentication using locally stored credentials:

As an alternative to using an external security provider, you can implement basic authentication on incoming requests by using credentials stored locally in an independent integration server's vault. For information about using locally stored credentials, see “Authenticating incoming requests by using credentials stored in the vault” on page 2597.

Authorization

Authorization is the process of verifying that an identity token has permission to access a message flow.

If authentication and mapping are configured, they are used to verify the identity before it is authorized.



If a mapped identity exists, authorization is applied to the mapped identity. If a mapped identity does not exist, the source identity is used.

If you specify LDAP as the provider for authorization, the security manager queries the configured LDAP server (which must be LDAP Version 3 compliant), to validate that the identity is a member of the LDAP group that is configured in the security profile.

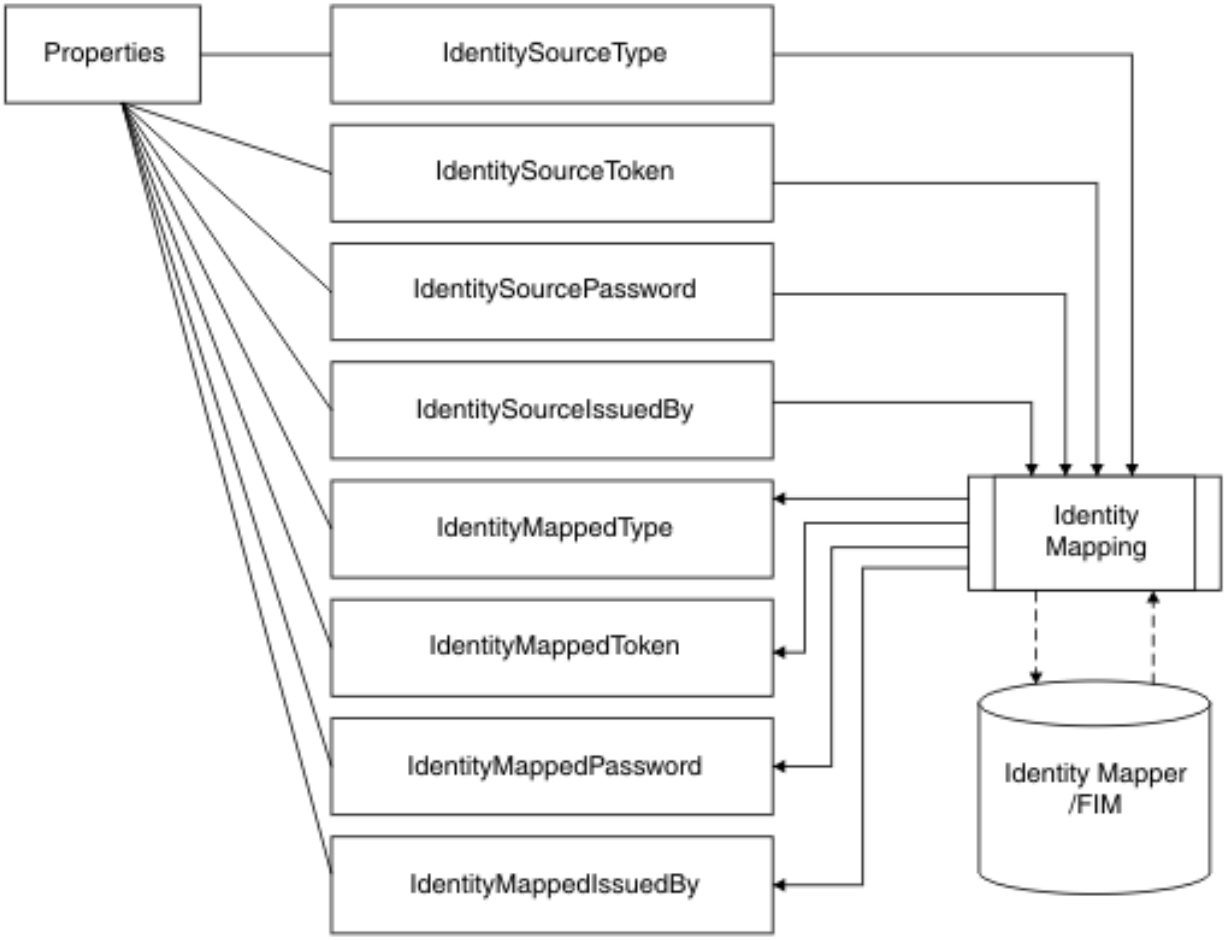
If you specify *WS-Trust v1.3 STS* as the provider for authorization, the security manager invokes the Security Token Service (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2, to validate that the identity token provided has permission to access the message flow. If you are using TFIM V6.1 rather than TFIM V6.2, you can specify *TFIM* as the provider for authorization.

For more information about using TFIM V6.2 for authorization, see “Authentication, mapping, and authorization with TFIM V6.2 and TAM” on page 2574.

For information about using TFIM V6.1 for authorization, see “Authentication, mapping, and authorization with TFIM V6.1 and TAM” on page 2572.

Identity mapping

Identity mapping is the transformation of a security token from one format to another format, or the federation of an identity from one realm to an equivalent identity in another realm.



IBM App Connect Enterprise provides support for identity mapping (also known as identity federation) and token issuance and exchange. Identity mapping is the process of mapping an identity in one realm to another identity in a different realm. For example, you might map *User001* from the eSellers realm to *eSellerUser01* in the eShipping realm. Token issuance and exchange involves the mapping of a token of one type to a token of a different type. For example, an incoming Username and Password token from a client over MQ might be mapped into an equivalent SAML assertion, to be propagated to a web services call. Alternatively, you might exchange a SAML 1.1 assertion from a client application for an equivalent SAML 2.0 assertion for an updated backend server.

Mapping using a WS-Trust provider

The IBM App Connect Enterprise security manager supports mapping operations through a WS-Trust V1.3 compliant Security Token Service (STS), such as IBM Tivoli Federated Identity Manager (TFIM) V6.2. Mapping is performed for SecurityPEP nodes and input nodes that have an associated security profile that includes a mapping operation configured with a WS-Trust V1.3 STS.

WS-Trust V1.3 (TFIM V6.2) can also be selected for authentication and authorization in the profile. However, if more than one security operation is associated with the security profile, only one WS-Trust request is issued to the STS. As a result, the STS must be configured to perform all the required operations. For example, if a TFIM V 6.2 server is specified, the TFIM module chain that is invoked must include the appropriate validate, authorize, and issue modules. If you require each operation to be performed through a separate WS-Trust call, you must use a series of SecurityPEP nodes, each associated

with a different security profile that is configured for only one security operation (authentication, authorization, or mapping).

If the security profile specifies only mapping with WS-Trust v1.3 STS, the request is sent with a request type of *Issue*, whereas a mixed set of security operations sends a request type of *Validate*. When mapping is included, the STS must return a token in its response, even if it is the original token; otherwise, an error occurs.

To provide compatibility with previous versions of IBM App Connect Enterprise, support is also provided for TFIM V6.1.

In the integration node, identity mapping is performed at the input node or SecurityPEP node, after authentication but before authorization. The source identity is passed to an identity mapper for processing. If both mapping and authorization are configured, the authorization operation uses the mapped output token rather than the source token, which means that the authorization is performed on the federated identity.

Mapping is not performed in output nodes, even if the output node has been configured with a security profile.

IBM App Connect Enterprise supports mapping between any type of security token that is supported by the configured security provider. For more information about the support provided, see "Identity" on page 2554.

When mapping from an X.509 certificate, TFIM can validate the certificate but cannot verify the identity of the original sender. However, if it is required, this verification integrity check can be performed by the SOAPInput node.

For more information about using TFIM V6.2 for mapping, see "Authentication, mapping, and authorization with TFIM V6.2 and TAM" on page 2574.

For information about using TFIM V6.1, see "Authentication, mapping, and authorization with TFIM V6.1 and TAM" on page 2572.

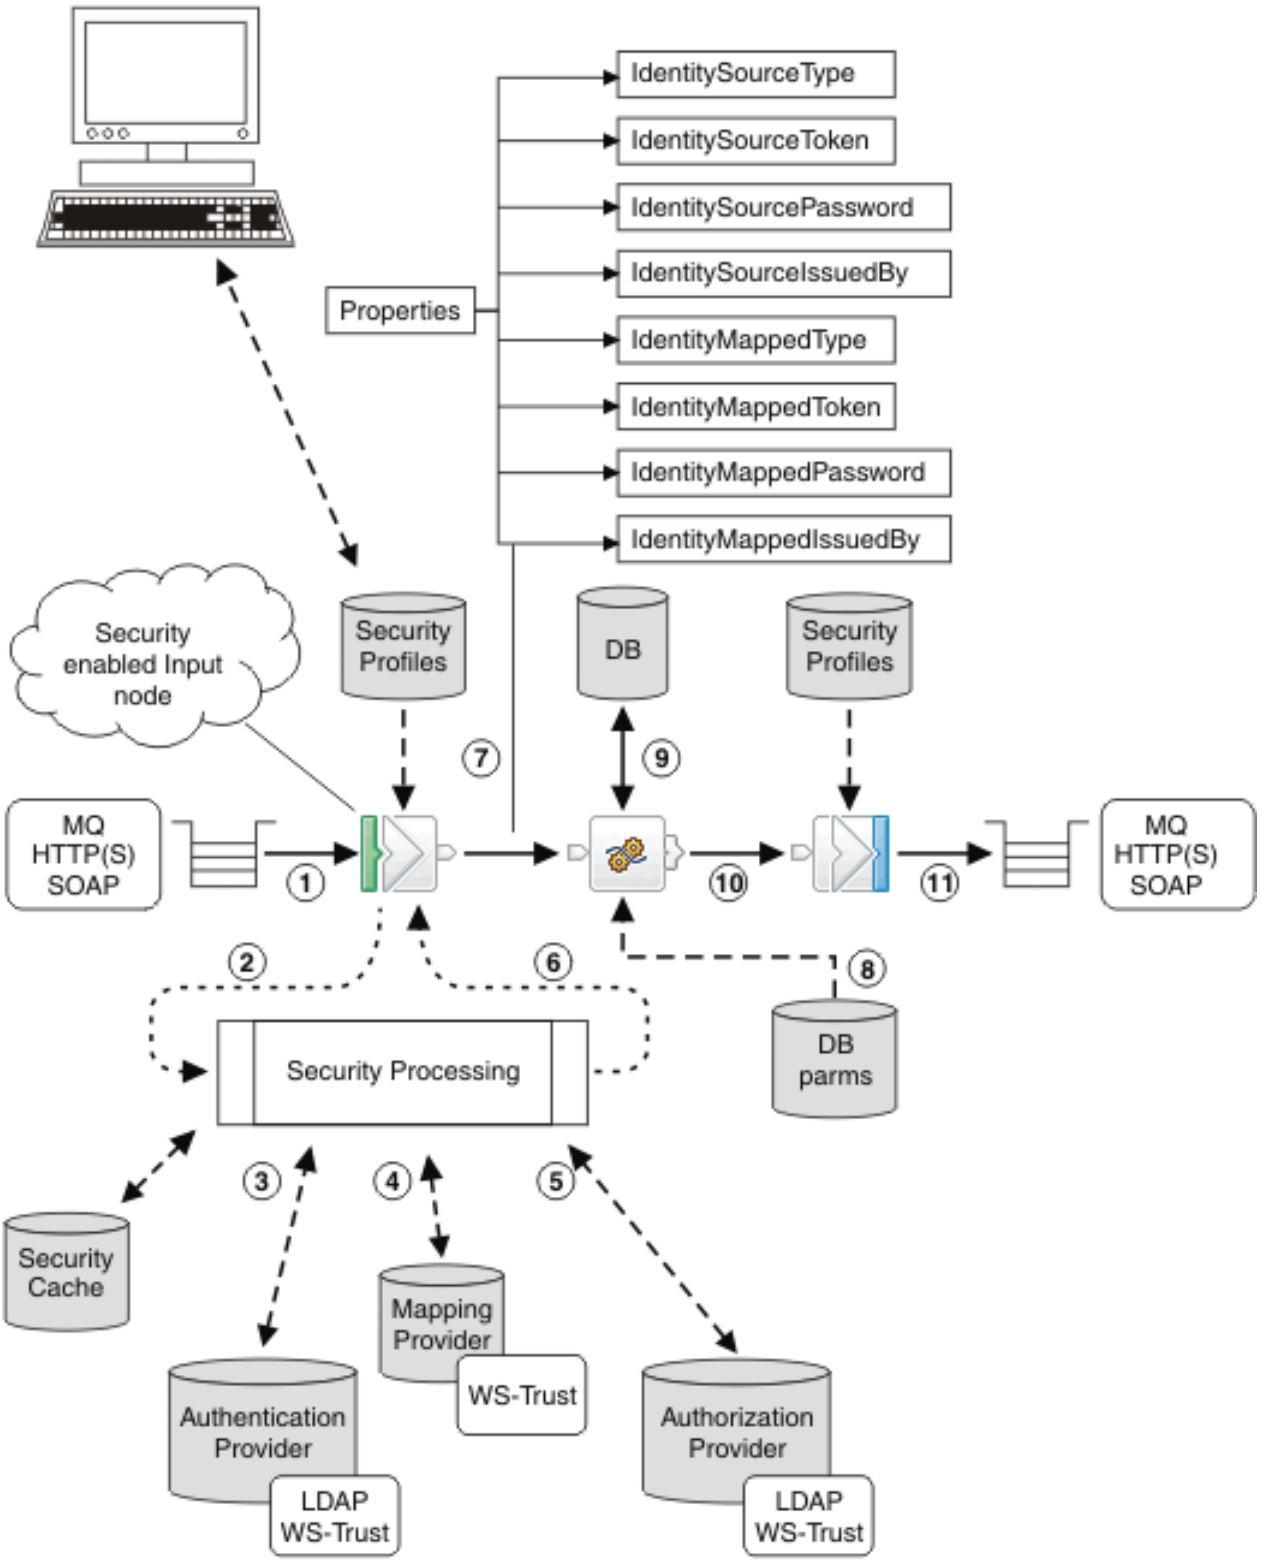
User-defined mapping

When you develop a message flow, you can implement a custom token mapping to be used for identity propagation. For example, you can implement a custom token mapping using a compute node (which can be a Compute or JavaCompute node) following the input node. In the compute node, you can read the source identity values from the Properties folder, process them, then write the new identity values to the mapped identity fields. If there is no identity provided in the message, you can still use a compute node to insert some identity credentials into the mapped identity fields. The mapped identity fields are then used in place of the source identity fields by subsequent nodes. Any security operations that are configured on the input node are performed using the source identity, before you can create a new identity in the mapped identity fields (by using the compute node). However, you can include a SecurityPEP node after your compute node has created a new mapped identity.

Invoking message flow security using a security enabled input node

You can invoke the message flow security manager by configuring a security enabled input node.

The following diagram shows an example message flow and gives an overview of the sequence of events that occur when an input message is received by a security enabled input node in the message flow:



For information about the security-enabled message flow nodes, see "Message flow security overview" on page 2550.

The following steps explain the sequence of events that occur when a message arrives at a security enabled input node in the message flow. The numbers correspond to those in the preceding diagram:

1. When a message arrives at a security enabled input node (MQ, HTTP, or SOAP), the presence of a security profile associated with the node indicates whether message flow security is configured.

SOAP nodes can implement some WS-Security capabilities without using the integration node's security manager; for more information, see “Implementing WS-Security” on page 2652. The integration server's security manager is called to read the profile, which specifies the combination of propagation, authentication, authorization, and mapping to be performed with the identity of the message. If an external security provider (Policy Decision Point or PDP) is to be used for one or more of these functions, the security profile specifies details of the provider to be used. If locally-stored credentials are to be used for authentication, the profile sets `Local` authentication and specifies the local credentials alias for the credentials in the independent integration server's vault. For more information, see “Authenticating incoming requests by using credentials stored in the vault” on page 2597.

You can create security profiles by using the Policy editor, as described in “Creating policies with the IBM App Connect Enterprise Toolkit” on page 327. You then deploy the policy to the integration server where your associated message flows are deployed.

2. If a security profile is associated with the node or message flow, the security enabled input node extracts the identity information from the input message (based on the configuration on the node's **Security** properties page) and sets the Source Identity elements in the Properties folder. If the security tokens cannot be successfully extracted, a security exception is raised.

   If you require a SOAPInput node to use the identity in the WS-Security header (rather than an underlying transport identity), you must also define and specify an appropriate policy set and bindings for the relevant token profile. For more information, see “Policy sets” on page 2662.

   For HTTP and MQ input nodes, the **Security** properties page is used to configure the extraction of the identity. This defaults to *Transport Default*. For example, an HTTPInput node extracts a username and password from the HTTP BasicAuth header. The **Security** properties page allows the Identity token type and its location to be explicitly configured to control the extraction. This source identity information can be in a message header, the message body, or both.

   For information about the tokens that are supported by each node, see “Identity” on page 2554.

3. If authentication is specified in the security profile, the security manager either calls the configured security provider to authenticate the identity, or, if `Local` authentication has been configured, it authenticates the identity against the credentials that are held in the integration server's vault. A failure results in a security exception being returned to the node. The security providers that are supported by IBM Integration for authentication are LDAP, a WS-Trust v1.3 compliant Security Token Service (such as TFIM V6.2) and TFIM V6.1.

   A security cache is provided for the authentication result, which enables subsequent messages (with the same credentials) arriving at the message flow to be completed with the cached result, provided that it has not expired.

   For information about configuring an independent integration server to enforce authentication on all HTTP and SOAP input nodes, see “Configuring authentication for all HTTP and SOAP input nodes in an independent integration server” on page 2598.

4. If identity mapping is specified in the security profile, the security manager calls the configured security provider to map the identity to an alternative identity. A failure results in a security exception being returned to the node. Otherwise, the mapped identity information is set in the Mapped Identity elements in the Properties folder.

   The security providers that are supported by IBM Integration for identity mapping are a WS-Trust V1.3 compliant Security Token Service (such as TFIM V6.2) and TFIM V6.1.

   A security cache is provided for the result of the identity mapping.

   Alternatively, you can use a SecurityPEP node at any point in the message flow to map the identity that was authenticated at the security enabled input node. For more information, see “Invoking message flow security using a SecurityPEP node” on page 2569.

5. If authorization is specified in the security profile, the security manager calls the configured security provider to authorize that the identity (either mapped or source) has access to this message flow. A failure results in a security exception being returned to the node.

   The security providers that are supported by IBM Integration for authorization are LDAP, a WS-Trust V1.3 compliant Security Token Service (such as TFIM V6.2) and TFIM V6.1.

   A security cache is provided for the authorization result.

   Alternatively, you can use a SecurityPEP node at any point in the message flow to authorize the identity that was authenticated at the security enabled input node. For more information, see "Invoking message flow security using a SecurityPEP node" on page 2569.
6. When all security processing is complete, or when a security exception is raised by the message flow security manager, control returns to the input node.

   When a security exception is returned to the security enabled input node, it performs the appropriate transport handling and ends the message flow transaction. For example, an HTTPInput node returns an HTTP header with a 401 HTTP response code, without propagating to an output terminal. A SOAPInput node returns a SOAP Fault, reporting the security exception. Alternatively, if the `Treat security exceptions as normal` property is set on the security enabled input node, a security exception is propagated to the node's Failure terminal. The security enabled input node propagates to its Out terminal only if all the configured operations in the associated security profile complete successfully.
7. The message, including the Properties folder and its source and mapped identity information, is propagated down the message flow.
8. At subsequent nodes in the message flow an identity might be required to access a resource such as a database. The identity used to access such a resource is a proxy identity, an identity configured for the specific resource by using the **mqsisetdbparms** command.
9. When you are developing a message flow you can use the identity fields in the Properties folder for application processing (for example, identity-based routing or content building based on identity). Also, as an alternative to invoking mapping through a WS-Trust V1.3 enabled STS (such as TFIM V6.2) or TFIM V6.1, you can set the mapped identity fields in a compute node, such as a Compute, JavaCompute, or Mapping node.
10. When the message reaches a security enabled output or request node (MQOutput, HTTPRequest, SOAPRequest, or SOAPAsyncRequest), a security profile (with propagation enabled) associated with the node indicates that the current identity token is to be propagated when the message is sent.

    If the security profile indicates that propagation is required, the mapped identity is used. If the mapped identity is not set, or if it has a token type that is not supported by the node, the source identity is used. If no identity is set, or if neither the mapped nor source identity has a token type that is supported by the node, a security exception is returned to the node.

    SOAP nodes also require the appropriate policy set and bindings for the token profile to be associated with the node.

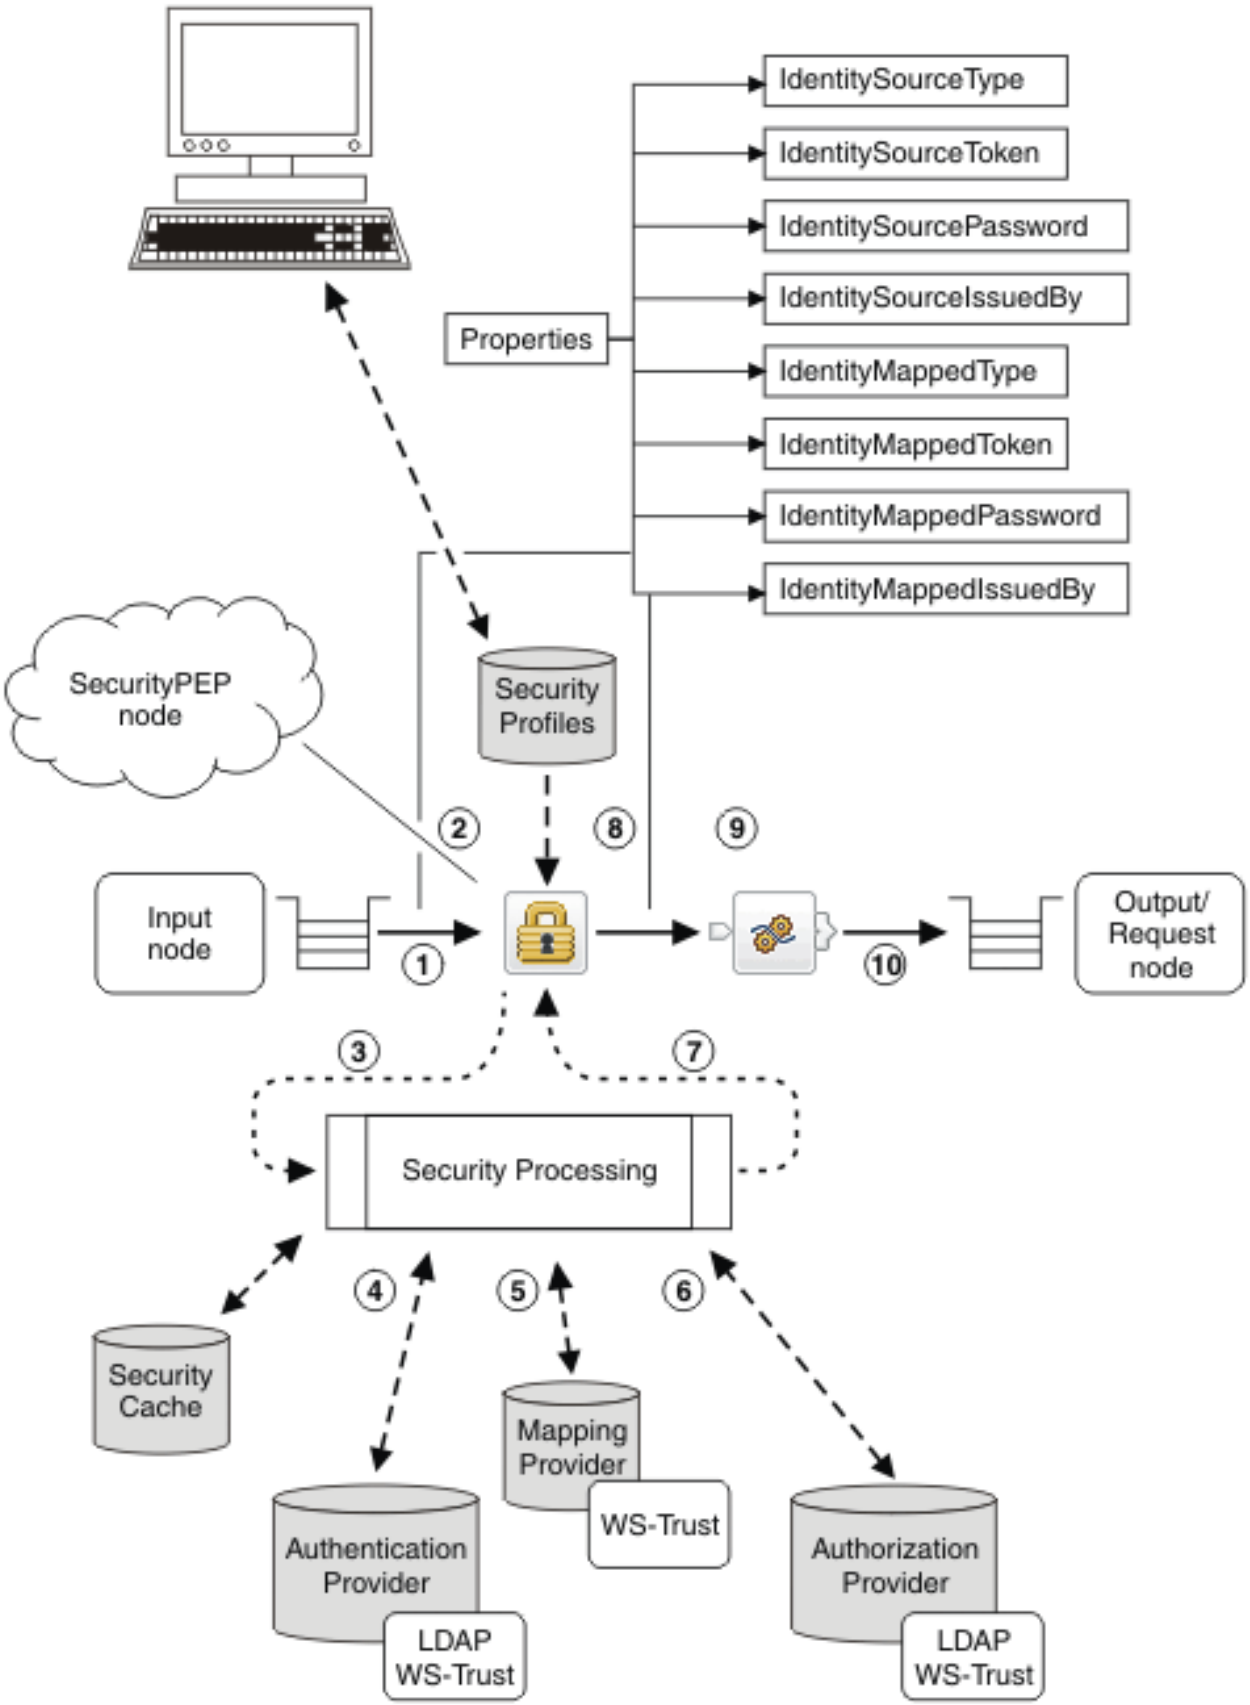
    If you want to include a security token in the message that is issued at an output node, and if the output node is not able to propagate that type of token, you can use a compute node (before the output node) to put the token from the properties tree into the relevant message location.

    For information about the tokens that are supported by each node, see "Identity and security token propagation" on page 2580.
11. The propagated identity is included in the appropriate message header when it is sent.

Invoking message flow security using a SecurityPEP node

You can invoke the message flow security manager at any point in a message flow, between an input node and an output or request node, by using a SecurityPEP node.

The following diagram shows an example message flow and gives an overview of the sequence of events that occur when an input message is received by an input node that is not security enabled (or that has no associated security profile) and is later processed by a SecurityPEP node in the message flow:



IdentitySourceType

6
Security Cache
Mapping Provider
WS-Trust
Authentication Provider
LDAP WS-Trust
Authorization Provider
LDAP WS-Trust

The following steps explain the sequence of events that occur when a message arrives at an input node that is not security enabled (or that has no associated security profile). The numbers correspond to those in the preceding diagram:

1. You can use a SecurityPEP node at any point in a message flow between an input and an output or request node. The SecurityPEP node enables security to be applied in a message flow in the following situations:

   - When the message flow input node is not security enabled (for example, FileInput, TCPIPClientInput, SAPInput, and JMSInput nodes).
   - When the message flow input node is security enabled and might be configured to perform authentication operations, but the message flow is required to perform some routing or filtering before the business function being invoked is known; as a result, authorization needs to be performed later in the message flow logic.
   - When the message flow includes multiple output or request nodes, which require a specific identity mapping to be performed before each node, to obtain the appropriate security tokens for propagation.

   The message tree that is propagated into the SecurityPEP node includes the properties tree identity fields. These fields are empty, unless a security enabled input node (or a prior SecurityPEP node) has already extracted identity tokens, and possibly performed some security operations.

2. When a message arrives at a SecurityPEP node, the presence of a security profile associated with the node indicates whether message flow security is configured. The integration server's security manager is called to read the profile, which specifies the combination of propagation, authentication, authorization, and mapping to be performed with the identity of the message. If an external security provider (Policy Decision Point or PDP) is to be used for one or more of these functions, the security profile specifies details of the provider to be used. If locally-stored credentials are to be used for authentication, the profile sets `Local` authentication and specifies the local credentials alias for the credentials in the independent integration server's vault. For more information, see “Authenticating incoming requests by using credentials stored in the vault” on page 2597.

   You can create security profiles by using the Policy editor, as described in “Creating policies with the IBM App Connect Enterprise Toolkit” on page 327. You then deploy the policy to the integration server where your associated message flows are running.

3. If a security profile is associated with the SecurityPEP node or message flow, the node extracts the identity information from the message tree based on the node configuration and sets the Source Identity elements in the Properties folder. If the node sets a token type of *Current token*, the existing identity tokens in the Mapped Identity properties fields are used (if they exist); if there are no identity tokens in the Mapped Identity properties fields, the tokens in the Source Identity properties fields are used. If the security tokens cannot be successfully extracted, a security exception is raised and propagated to the failure terminal (if wired).

4. If authentication is specified in the security profile, the security manager either calls the configured security provider to authenticate the identity, or, if `Local` authentication has been configured, it authenticates the identity against the credentials that are held in the integration server's vault. A failure results in a security exception being returned to the node. The external security providers that are supported by IBM App Connect Enterprise for authentication are a LDAP, WS-Trust v1.3 compliant Security Token Service (such as TFIM V6.2), and TFIM V6.1.

   A security cache is provided for the authentication result, which enables subsequent messages (with the same credentials) arriving at the message flow to be completed with the cached result, provided that it has not expired.

5. If identity mapping is specified in the security profile, the security manager calls the configured security provider to map the identity to an alternative identity. A failure results in a security exception

being returned to the node. Otherwise, the mapped identity information is set in the Mapped Identity elements in the Properties folder.

The security providers that are supported by IBM App Connect Enterprise for identity mapping are a WS-Trust V1.3 compliant Security Token Service (such as TFIM V6.2) and TFIM V6.1.

A security cache is provided for the result of the identity mapping.

6. If authorization is specified in the security profile, the security manager calls the configured security provider to authorize that the identity (either mapped or source) has access to this message flow. A failure results in a security exception being returned to the node.

   The security providers that are supported by IBM App Connect Enterprise for authorization are LDAP, a WS-Trust V1.3 compliant Security Token Service (such as TFIM V6.2) and TFIM V6.1.

   A security cache is provided for the authorization result.

7. When all security processing is complete, or when a security exception is raised by the message flow security manager, control returns to the SecurityPEP node.

   When a security exception is returned to the SecurityPEP node, the exception is either propagated to the failure terminal if it is connected, or returned to the preceding node as a recoverable exception. The SecurityPEP node propagates to its Out terminal only if all the configured operations in the associated security profile complete successfully.

8. The message, including the populated Properties folder and its source and mapped identity information, is propagated down the message flow.

9. When you are developing a message flow, you can use the identity fields in the Properties folder for application processing (for example, identity-based routing or content building based on identity). If the identity is to be propagated in an outbound message from an output or request node that does not support propagation of the token, you can use a compute node (including a Compute, JavaCompute, or Mapping node), to move the identity token into the required transport header or message body location.

10. When the message reaches an output node, a security profile associated with the node can indicate whether an identity is to be taken from the Properties folder and propagated when the message is sent. Only specific transport nodes can propagate tokens that are the default for the transport; any other token type must be handled by a compute node, as described above.

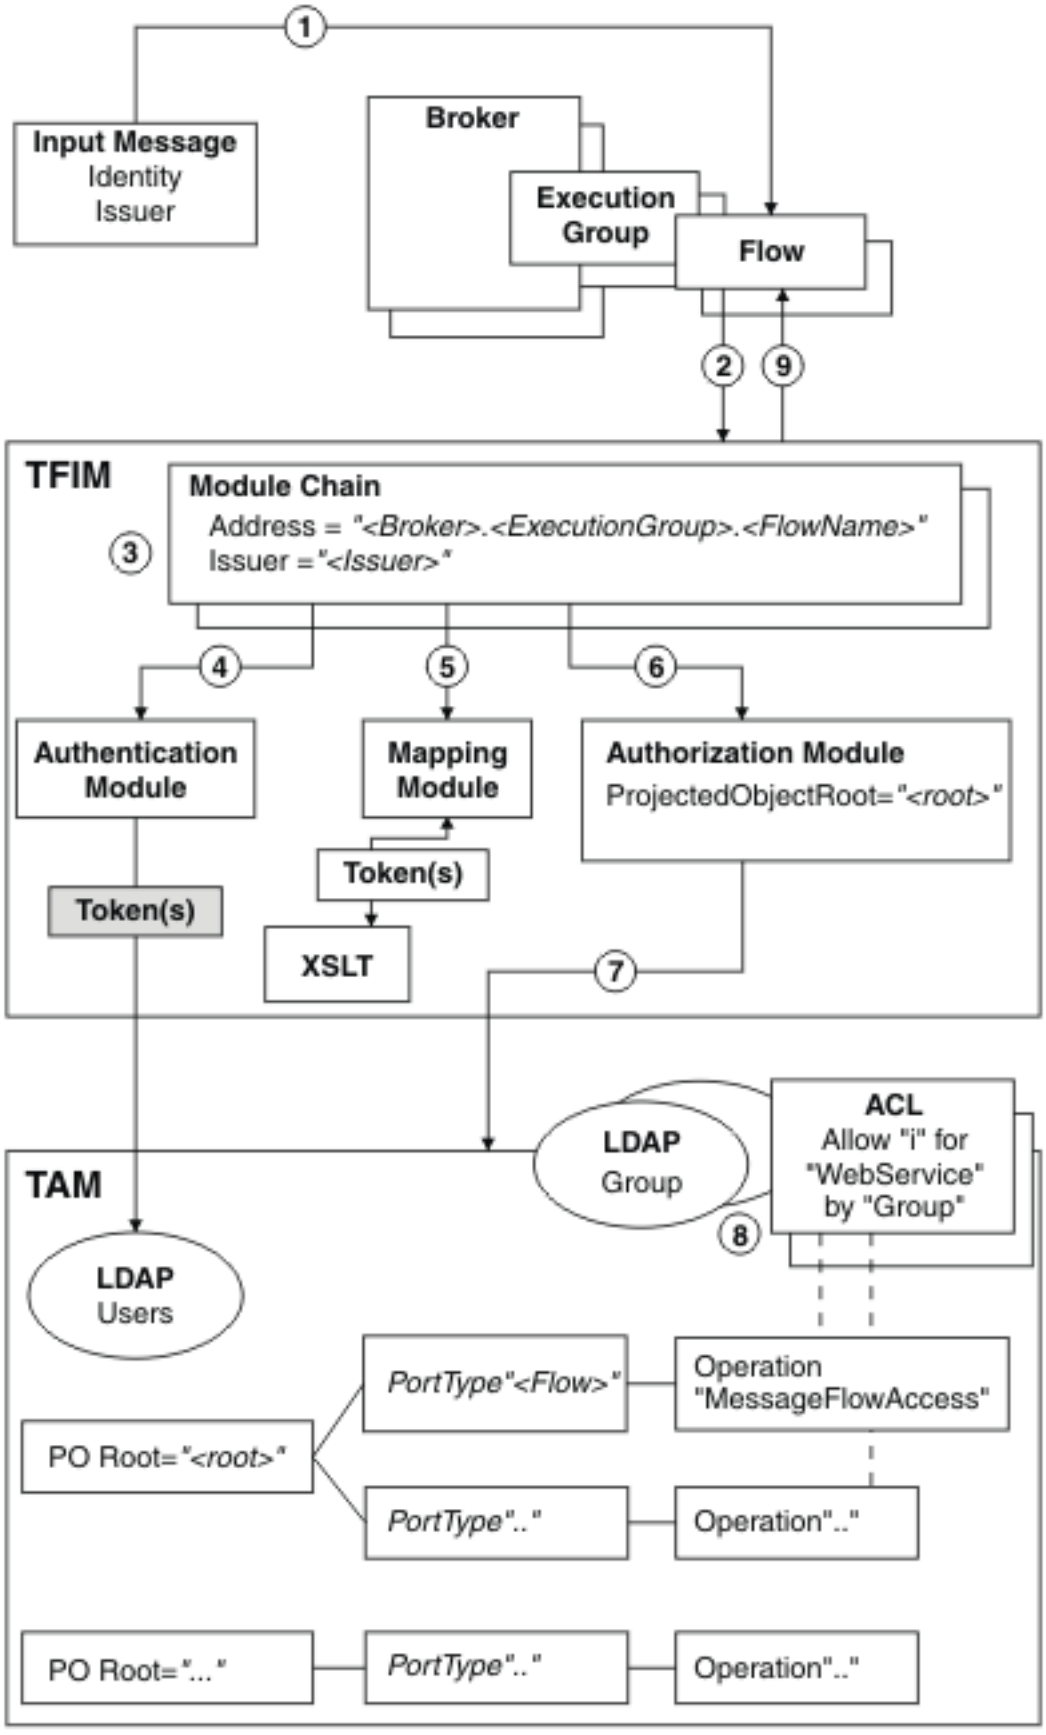
Authentication, mapping, and authorization with TFIM V6.1 and TAM

Use IBM App Connect Enterprise, Tivoli Federated Identity Manager (TFIM) V6.1, and Tivoli Access Manager (TAM) to control authentication, mapping, and authorization.

Note: Support for TFIM V6.1 is included for compatibility with previous versions of IBM App Connect Enterprise. If possible, upgrade to TFIM V6.2 and refer to the information in "Authentication, mapping, and authorization with TFIM V6.2 and TAM" on page 2574.

IBM App Connect Enterprise makes a single TFIM WS-Trust call for an input node that is configured with a TFIM security profile, which means that a single module chain must be configured to perform all the required authentication, mapping, and authorization operations.

The following diagram shows the configuration of IBM App Connect Enterprise, TFIM, and TAM to enable authentication, mapping, and authorization of an identity in a message flow:



The numbers in the preceding diagram correspond to the following sequence of events:

1. A message enters a message flow.
2. A WS-Trust request is issued by the integration node, with these properties:
   - RequestType = Validate
   - Identity = Token(s) from input message
   - Issuer = Issuer from input message
   - AppliesTo Address = *"Broker.IntegrationServer.FlowName"*
   - PortType = *"FlowName"*
   - Operation = "MessageFlowAccess"
3. TFIM selects a module chain to process the WS-Trust request, based on the AppliesTo Address and Issuer properties of the request.
4. A module chain can perform authentication if it includes a module (such as a UsernameTokenSTSModule or X509STSModule) in `validate` mode.
5. A module chain can perform mapping by using an XSLTransformationModule in `mapping` mode to manipulate the identity information.
6. A module chain can perform authorization by using an AuthorizationSTSModule in `other` mode. The module chain must be configured with a *Protected Object Root* value.
7. The AuthorizationSTSModule performs the authorization check by making a request to TAM with these properties:
   - Action = "i" (invoke)
   - Action Group = "WebService"
   - Protected Object = "*ProtectedObjectRoot.FlowName.MessageFlowAccess"*

     where *"i"* and *"WebService"* are default values used by an AuthorizationSTSModule; and *FlowName* and *MessageFlowAccess* are the WS-Trust request PortType and Operation values.
8. TAM processes the authorization request by:
   a. Finding the Access Control Lists (ACLs) associated with protected object *"<ProtectedObjectRoot>.<FlowName>.MessageFlowAccess"*.
   b. Checking whether or not the ACLs grant action "i" on action group "WebService" to the user (with the user either named directly, or by membership of a named group).
9. The WS-Trust reply is returned to the integration node. If this action is the result of a mapping request, the WS-Trust reply contains the mapped identity token.

Authentication, mapping, and authorization with TFIM V6.2 and TAM

You can use IBM App Connect Enterprise, Tivoli Federated Identity Manager (TFIM) V6.2, and Tivoli Access Manager (TAM) to control authentication, mapping, and authorization.

IBM App Connect Enterprise makes a single TFIM WS-Trust call for an input node or SecurityPEP node that is configured with a WS-Trust V1.3 STS security profile. As a result, a single module chain must be configured to perform all the required authentication, mapping, and authorization operations.

When you use a WS-Trust v1.3 STS for authentication, authorization, or mapping, a request is made to the trust service with the following parameters, which control the STS processing. If you are using TFIM V6.2, these parameters are used in the selection of the TFIM module chain:

Parameter	Value
RequestType	The type of request issued to the trust service. Valid values are: **`Issue`** This value can be specified when mapping is the only operation that is set to `WS-Trust V1.3 STS` in the security profile. It is not valid if `WS-Trust V1.3 STS` is specified for authentication or authorization. The namespace qualified value is `http://docs.oasis-open.org/ws-sx/ws-trust/200512/Issue`, which shows in TFIM V6.2 as *Issue Oasis URI*. **`Validate`** This value must be set when the security profile also includes authentication or authorization (in addition to mapping) for the same `WS-Trust V1.3 STS` provider. The namespace qualified value is `http://docs.oasis-open.org/ws-sx/ws-trust/200512/Validate`, which shows in TFIM V6.2 as *Validate Oasis URI*.
Issuer	This value is determined by the effective setting of the `IssuedBy` property on the **Basic** tab of the SecurityPEP node or the **Security** tab of the input node.

Parameter	Value

AppliesTo	This value is determined by the type of node:
	MQInput node with MQ binding:
	The IBM MQ IRI of the node's input queue; for example:
	`wmq://msg/queue/queue_name@queue_manager_name`
	HTTPInput, SOAPInput, or SOAPAsyncResponse node with HTTP binding:
	The endpoint URL; for example:
	`http://myflow/myInputNodePath`
	SecurityPEP node with a default (blank) WS-Trust AppliesTo address:
	The URN for the message flow that contains the node; for example:
	`urn:/integrationNodeName.integrationServerName.flowName`
	SecurityPEP node with WS-Trust AppliesTo address set on the Advanced tab of the node:
	The URI value configured in the property. This value is typically the URL of the target service that is used when you invoke a mapping operation to obtain the required token for the following request node; for example:
	`http://remotehost.ibm.com:9080/targetservice`
	You can also set the `AppliesTo service name` and `AppliesTo port type` properties on the **Advanced** tab of the node. The WS-Trust request includes these optional elements only when they are configured. These values are typically valid QNames; for example:
	`http://myservice.mycom.com:myservicename`
	When you set these properties in the SecurityPEP node, you must configure them in the TFIM module chain:
	• In the service name and port type TFIM properties, the information to the left of the colon must match the namespace URI of the WS-Addressing namespace that is used for the PortType and ServiceName elements in the WS-Trust request set by the integration node, which is:
	`http://www.w3.org/2005/08/addressing`
	• The information to the right of the colon in the service name and port type TFIM properties must match the value configured on the SecurityPEP node. You can also configure a regular expression in TFIM to specify a match.

This section describes an authorization configuration that you can use to perform the authorization operation with TFIM V6.2 and TAM.

In the security profile, set the TFIM V6.2 endpoint for the authorization operation. When you create a module chain to be used by a security enabled input node or SecurityPEP node, and resolved by *AppliesTo* information, you must include the TFIM TAMAuthorizationSTModule to invoke TAM authorization.

The TAMAuthorizationSTSModule requires the following TFIM STS universal user context attributes:

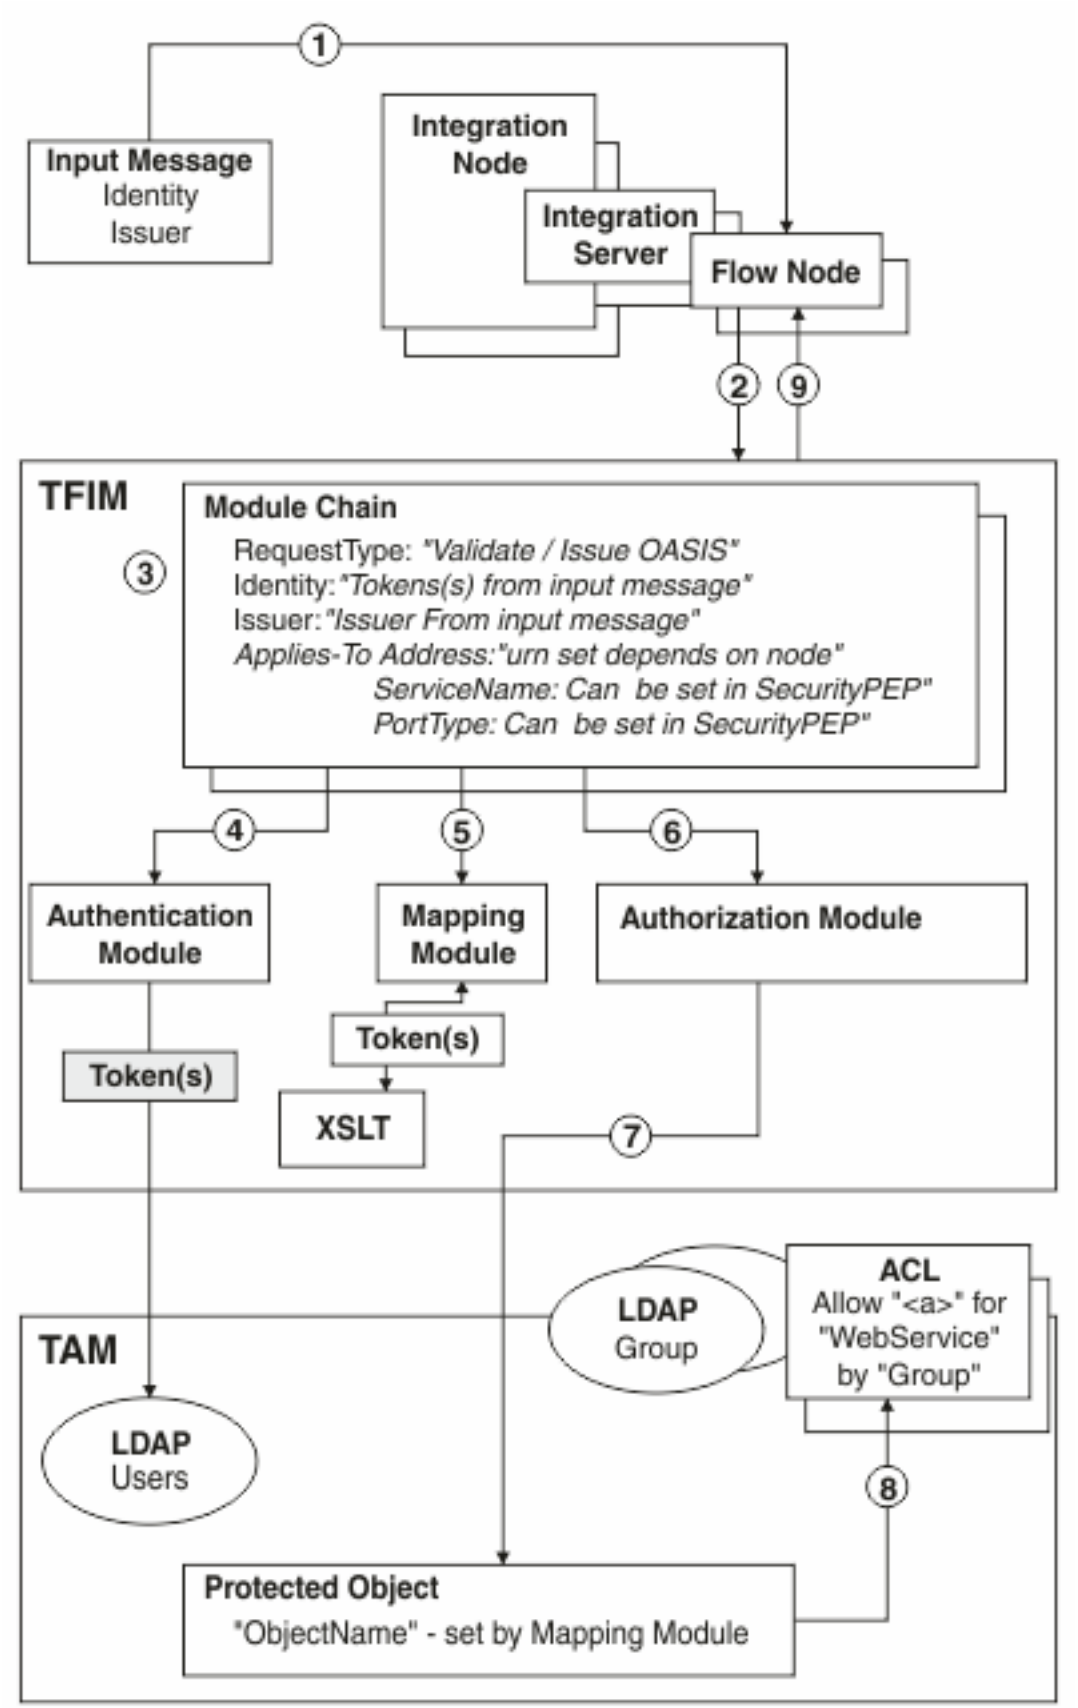
PrincipalName
The username to be authorized. This username must exist in your TAM user repository.

ObjectName
The TAM object name of the resource on which an authorization check is to be made. Typically this is derived from the *AppliesTo* information that is passed by the message flow security manager from the security enabled input node or SecurityPEP node.

Action
The TAM action to be authorized; for example, *x* (eXecute).

The TAM Access Control List (ACL), which determines the authorization decision, is located in the TAM protected object space using the path that is set on the *ObjectName* attribute of the TFIM STS universal user context input to the TAMAuthorizationSTSModule module.

The following diagram shows the configuration of IBM App Connect Enterprise, TFIM V6.2, and TAM to enable authentication, mapping, and authorization of an identity in a message flow:



The numbers in the preceding diagram correspond to the following sequence of events:

1. A message enters a message flow.

2. A WS-Trust request is issued by the integration node, with the *RequestType*, *Issuer*, and *AppliesTo* properties set.
3. TFIM selects a module chain to process the WS-Trust request, based on the *RequestType*, *Issuer*, and *AppliesTo* properties of the request.
4. A module chain can perform authentication if it includes a module in *Validate* mode that is appropriate to the token type that is being passed in the request from the message flow input message. For example, a Username and Password token can be authenticated using a UsernameTokenSTSModule .
5. The module chain must perform some mapping by using an XSLTransformationModule in mapping mode to manipulate the identity information and to provide the required context attributes in the TFIM stsuser object for use by subsequent modules.
6. A module chain can perform authorization in TAM by using the TAMAuthorizationSTSModule.
7. The TAMAuthorizationSTSModule performs the authorization check by making a request to TAM with these properties:
   - Action = *a* (where *a* is the stsuser context action attribute). For example, *x* for eXecute could be set using the following code:

     ```
     <stsuuser:ContextAttributes>
         <!-- Action -->
         <stsuuser:Attribute name="Action" type="urn:ibm:names:ITFIM:stsmodule:tamazn">
           <stsuuser:Value>x</stsuuser:Value>
         </stsuuser:Attribute>
       </stsuuser:ContextAttributes>
     ```

   - Action Group = *WebService*
   - Protected Object = *ProtectedObjectName* (where *ProtectedObjectName* is the stsuser context action attribute). For example, *x* for eXecute could be set using the following code:

     ```
     <stsuuser:ContextAttributes>
         <!-- ObjectName -->
         <stsuuser:Attribute name="ObjectName" type="urn:ibm:names:ITFIM:stsmodule:tamazn">
           <stsuuser:Value>ProtectedObjectName</stsuuser:Value>
         </stsuuser:Attribute>
       </stsuuser:ContextAttributes>
     ```

     Typically, *ProtectedObjectName* is set conditionally from the *AppliesTo* information in the request.
8. TAM processes the authorization request by:
   a. Finding the Access Control Lists (ACLs) associated with protected object *ProtectedObjectName*
   b. Checking whether the ACLs grant action *a* on action group *WebService* to the user (the user is named either directly or indirectly, through membership of a named group).
9. The WS-Trust reply is returned to the integration node. If this action is the result of a mapping request, the WS-Trust reply contains the mapped identity token.

Configuring the security cache

You can configure the security cache by specifying a value for the **cacheTimeout** property for an independent integration server by updating the `server.conf.yaml` configuration file or, for on an integration node, by using the **mqsichangeproperties** command.

About this task

To improve performance, the security manager uses a security cache. Entries are created in the security cache when a message flow with a security profile performs authentication, mapping, or authorization. The entries are valid for the length of time that is specified by the `cacheTimeout` property of the `SecurityCache` component after which the entries are marked as expired.

Procedure

- For an independent integration server:
  a) Open the configuration file for your integration server (`server.conf.yaml`) by using a YAML editor.

     If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, which are invalid characters in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file. For more information about configuring an integration server, see "Configuring an integration server by modifying the server.conf.yaml file" on page 172.
  b) Set the security cache timeout property, **cacheTimeout**, in the **SecurityCache** section of the `server.conf.yaml` configuration file.

     The default value is 60 seconds.
  c) When you have modified and saved the `server.conf.yaml` file, restart the integration server for the changes to take effect.

     For information about how to start an integration server, see "Starting an integration server" on page 250.
- For an integration node:
  a) Use the **mqsichangeproperties** command.

     For example, to change the value of the security cache timeout parameter, **cacheTimeout**, to 200 seconds, use the following command:

     ```
     mqsichangeproperties INODE -b SecurityCache -n cacheTimeout -v 200
     ```
  b) Restart the integration node for the change to take effect.

Identity and security token propagation

Identity and security token propagation enables the identity and security tokens (associated with each message) to be propagated throughout a message flow, and on to target applications through output or request nodes.

In an enterprise system, you can use different physical identities or security tokens (such as user names, certificates, and SAML assertions) to represent a single logical identity through different parts of the enterprise. The propagation of an identity or security token ensures that the logical identity is kept throughout the system by mapping between the various physical forms as necessary. For example, a message might enter the system using a certificate, but a user name token might be required for server processing of the message. Identity mapping is used to convert from the certificate to the `Username` token, and identity propagation ensures that the mapped identity is placed in the correct place for the outbound transport.

When an output or request node propagates an identity, the mapped identity is used. If the mapped identity is not set, or if it has a token type that is not supported by the node, the source identity is used. You can also configure a fixed identity by using the **mqsisetdbparms** command; see "Configuring a message flow for identity propagation" on page 2613. If no identity is set, or if neither the mapped nor source identity has a token type that is supported by the node, a security exception is thrown by the node.

The following output nodes support identity propagation:

- CICSRequest
- HTTPRequest
- IMSRequest
- MQOutput
- SAPRequest
- SOAPAsyncRequest

- SOAPRequest
- SiebelRequest
- RESTRequest
- RESTAsyncRequest

The following table shows the support that is provided by the message flow security manager for the propagation of the different types of security token. For more information about these security tokens, see “Identity” on page 2554.

Table 91. Support for security token types - token propagation

Token type (format)	**Integration node security manager support**	**Token propagated in**
Username	Username tokens are supported for propagation by the following nodes: • CICSRequest • HTTPRequest • IMSRequest • MQOutput • RESTAsyncRequest • RESTRequest • SOAPRequest	**CICS** The request security credentials **HTTP** BasicAuth header **IMS** The request security credentials **IWA** The request security credentials **MQ** MQMD.UserIdentifier transport header
Username and password	Username and password tokens are supported for propagation by the following nodes: • CICSRequest • HTTPRequest • IMSRequest • MQOutput • RESTAsyncRequest • RESTRequest • SAPRequest • SOAPAsyncRequest • SOAPRequest • SiebelRequest	**CICS** The request security credentials **HTTP** BasicAuth header **IMS** The request security credentials **IWA** The request security credentials **MQ** MQMD.UserIdentifier transport header **SAP** The request security credentials **SOAP** • BasicAuth header, if there is no policy set and binding • SOAP header, if a policy set and binding sets the Username token profile • Kerberos client credentials, if a policy set and binding sets the Kerberos token profile **SIEBEL** The request security credentials

Table 91. Support for security token types - token propagation (continued)		
Token type (format)	**Integration node security manager support**	**Token propagated in**
SAML assertion	SAML tokens are supported for propagation by the following nodes: • SOAPRequest • SOAPAsyncRequest	SOAP header when a policy set and binding sets the SAML token profile
X.509 certificate	X.509 tokens are supported for propagation by the following nodes: • SOAPRequest • SOAPAsyncRequest	SOAP header when a policy set and binding sets the X.509 binary token profile
LTPA v2 token	LTPA v2 tokens are supported for propagation by the following nodes: • SOAPRequest • SOAPAsyncRequest	SOAP header when a policy set and binding sets the LTPA token profile
Universal WSSE token	Universal WSSE tokens are not supported for propagation by any node.	

For information about how to configure a message flow to propagate a message identity, see “Configuring a message flow for identity propagation” on page 2613. For more information about how one physical identity is converted to another, see “Identity mapping” on page 2564.

Security identities for the integration server connecting to external systems

You can access external systems from the message flows that you deploy to your integration server, and you must therefore consider the steps that you might want to take to secure that access.

You can set a user ID and password that you want the integration server to use for access to an external system or database by using the **mqsisetdbparms** command on a policy .

After you have defined user IDs, you must authorize those IDs so that the integration server can access your databases from deployed message flows. See the documentation for your database provider to authorize your integration node user ID.

To see how to set security authorization for a message flow node, refer to the table of properties for that specific node.

IBM App Connect Enterprise does not provide special commands to administer databases. Discuss your database security requirements with the database administrator for the database manager that you are using, or refer to the documentation provided by your database supplier.

Security exception processing

A security exception is raised when a message flow security failure occurs during security processing in an input node or SecurityPEP node.

Security exceptions are processed in a different way from other errors on the input node. An error is typically caught on the input node and routed down the Failure terminal for error processing, but security exceptions are not processed in the same way. By default, the integration node does not allow security exceptions to be caught within the message flow, but backs the message out or returns an error (as in the case of HTTP). Security exceptions in input nodes are managed in this way to prevent a security denial of service attack filling the logs and destabilizing the system.

However, security exceptions in SecurityPEP nodes are managed in a different way. If a security operation fails in a SecurityPEP node, a security exception is raised, wrapped in a normal recoverable exception, which invokes the error handling that is provided by the message flow.

If you have designed the message flow to be in a secure area and you want to explicitly perform processing of security exceptions, you can select the **Treat Security Exceptions as normal exceptions** property on the MQInput or HTTPInput nodes. This property causes security exceptions to be processed in the same way as other exceptions in the message flow.

If you associate the Default Propagation security profile with an output or request node, the token type of the mapped or source security token must be the same as the transport default for that node; otherwise, a security exception occurs. For example, for an MQOutput node, the token type must be *Username*, for an HTTPRequest node, the token type must be *Username + Password*, and for a SOAPRequest node, the token type must be the type that is defined in either the policy set and binding or the transport binding.

For information on how to diagnose the causes of security exceptions, see "Diagnosing security problems" on page 2630.

Setting up message flow security

Set up security on a message flow to control access based on the identity of a message passing through the message flow.

About this task

You can configure the integration server to perform end-to-end processing of an identity carried in a message through a message flow. Administrators can configure security at message flow level, controlling access based on the identity flowed in a message. This security mechanism is independent of both the transport and the message format.

To set up security for a message flow, perform the tasks described in the following topics:

Procedure

1. "Creating a security profile" on page 2584
2. "Configuring the extraction of an identity or security token" on page 2590
3. "Configuring identity authentication and security token validation" on page 2593
4. "Configuring identity mapping" on page 2603
5. "Configuring authorization" on page 2605
6. "Configuring a message flow for identity propagation" on page 2613
7. Securing access to external systems
8. "Diagnosing security problems" on page 2630

What to do next

If the message flow is a web service implemented by using the "SOAP nodes" on page 811, and the identity is to be taken from the "WS-Security" on page 2650 header tokens, you must also create appropriate "Policy sets" on page 2662 and bindings, then configure them on the relevant SOAP nodes (in addition to the security profile). See "Associating policy sets and bindings with message flows and nodes" on page 2672.

To work with an identity, you must configure the policy sets and bindings for the relevant capabilities:

- To work with a Username and Password identity, configure the policy sets and bindings for "Username token capabilities" on page 2675.

- To work with an X.509 Certificate identity, configure the policy sets and bindings for "X.509 certificate token capabilities" on page 2677.

  In the policy set binding, the `Certificates` mode of the X.509 certificate authentication token must be set as `Trust Any` (rather than `Trust Store`), so that the certificate is passed to the security provider defined by the security profile. Setting *Trust Store* causes the certificate to be validated in the local trust store.
- To work with a SAML assertion, configure the policy sets and bindings for "SAML token capabilities" on page 2680.
- To work with an LTPA token, configure the policy sets and bindings for "LTPA token capabilities" on page 2684.
- To work with a Kerberos ticket, configure the policy sets and bindings for "Kerberos token capabilities" on page 2682.

For more information, see Policy Sets and Policy Set Bindings editor: Authentication and Protection Tokens panel.

Creating a security profile

You can create a security profile for use with an external security provider such as Lightweight Directory Access Protocol (LDAP) or a WS-Trust V1.3 compliant Security Token Service (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2. Support is also provided for TFIM V6.1, for compatibility with previous versions of IBM App Connect Enterprise. You can also create a security profile for authenticating against credentials that are held locally in the integration server's vault.

About this task

Before you can enable security on a node or a message flow, you need to create a security profile that defines the security operations that you want to perform.

You can create a security profile for use with external security providers to provide the required security enforcement and mapping. You can configure the security profile to use different security providers for different security functions; for example, you might use LDAP for authentication and WS-Trust V1.3 STS for mapping and authorization. You can also create a security profile for authenticating against credentials that are held locally in the integration server's vault, as described in "Authenticating incoming requests by using credentials stored in the vault" on page 2597.

You can create the security profile by using the Policy editor (see Security Profiles policy (SecurityProfiles)).

If you want to extract and propagate an identity without security enforcement or mapping, you can use the supplied security profile called Default Propagation. The Default Propagation profile is a predefined profile that requests only identity propagation.

To create a security profile, see:

- "Creating a security profile for LDAP" on page 2584
- "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 2588
- "Creating a security profile for TFIM V6.1" on page 2589
- "Creating a security profile for using locally-stored credentials" on page 2590

Creating a security profile for LDAP

Create a security profile for use with Lightweight Directory Access Protocol (LDAP) or Secure LDAP (LDAPS), by using the Policy editor.

Before you begin

Ensure that you have an LDAP server that is LDAP Version 3 compliant, for example:

- IBM Tivoli Directory Server

- Microsoft Active Directory
- OpenLDAP.

About this task

If your LDAP directory does not permit login by unrecognized user IDs, and does not grant search access rights on the subtree, you must also set up a separate authorized login ID that the integration node can use for the search. For information on how to do this, see “Configuring authorization with LDAP” on page 2606 or “Authenticating incoming requests with LDAP” on page 2593.

Creating a security profile

About this task

You can create a Security Profiles policy that uses LDAP for authentication, authorization, or both. The security profile ensures that each message has an authenticated ID and is authorized for the message flow.

Procedure

1. Create a policy and choose the Security Profiles type (see “Creating policies with the IBM App Connect Enterprise Toolkit” on page 327).
2. Set appropriate values for the properties (see Security Profiles policy (SecurityProfiles)).

   You must enclose the LDAP URL (which contains commas) with escaped double quotation marks (\" and \") so that the URL commas are not confused with the comma separator of the value parameter.

   If the LDAP URL includes an element name with a space, in this case `cn=All Sales`, the set of values after the -v flag must be enclosed by double quotation marks, (")

   You can define the security-specific parts of the command in the following way:

   a) Set the **`authentication`** to *LDAP*.
   This ensures that the incoming identity is validated.

   b) Set the **`authenticationConfig`** using the following syntax:

   ```
   ldap[s]://server[:port]/baseDN[?[uid_attr][?[base|sub]]]
   ```

   For example:

   ```
   ldap://ldap.acme.com:389/ou=sales,o=acme.com
   ```

```
ldaps://localhost:636/ou=sales,o=acme?cn?base
```

ldap:
(Required) Fixed protocol string.

s:
(Optional) Specifies whether SSL should be used. Default is not to use SSL.

server:
(Required) The name or IP address of the LDAP server to contact.

port:
(Optional) The port to connect to. Default is 389 (non-SSL). For LDAP servers with SSL enabled, the port is typically 636.

baseDN
(Required) String defining the base distinguished name (DN) of all users in the directory. If users exist in different subtrees, specify a common subtree under which a search on the username uniquely resolves to the required user entry, and set the *sub* attribute.

uid_attr:
(Optional) String defining the attribute to which the incoming username maps, typically uid, CN, or email address. Default is *uid*.

base|sub:
(Optional) Defines whether to perform a base or subtree search. If `base` is defined, the authentication is faster because the DN of the user can be constructed from the *uid_att*, *username*, and *baseDN* values. If *sub* is selected, a search must be performed before the DN can be resolved. Default is *sub*.

c) (Optional) To specify that you want the security manager to reject a user name during authentication if the user name has an empty password token, set **rejectBlankpassword** to TRUE.

The default is FALSE, which means that a user name is authenticated against the LDAP server even if it has an empty password token.

d) (Optional) To specify the way that the password is displayed in the properties folder, set **passwordValue** to one of the following values:

PLAIN
The password is displayed in the Properties folder as plain text.

OBFUSCATE
The password is displayed in the Properties folder as base64 encoding.

MASK
The password is displayed in the Properties folder as four asterisks (****).

e) Set **authorization** to *LDAP*.

This ensures that the incoming identity is checked for group membership in LDAP.

f) Set **authorizationConfig** using the following syntax:

```
ldap[s]://server[:port]/groupDN[?[member_attr]
[?[base|sub][?[x-userBaseDN=baseDN,
x-uid_attr=uid_attr]]]]
```

For example:

```
ldap://ldap.acme.com:389/cn=All Sales,ou=acmegroups,
o=acme.com?uniquemember?sub?x-userBaseDN=ou=sales%2co=ibm.com,
```

```
x-uid_attr=emailaddress
```

ldap:
(Required) Fixed protocol string

s:
(Optional) Specifies whether SSL is used. Default is not to use SSL.

server:
(Required) The name or IP address of the LDAP server to contact.

port:
(Optional) The port to connect to. Default is 389 (non-SSL). For LDAP servers with SSL enabled, the port is typically 636.

groupDN
(Required) Fully defined distinguished name (DN) of the group in which users must be members to be granted access.

You can specify multiple group DNs by using the following formats:

- ```
  |(groupDN1)(groupDN2)(groupDN3)...(groupDNn)
  ```

  Authorization succeeds if the user is a member of any of the groups that are specified. For example:

  ```
  ldap://ldap.acme.com:389/|(cn=UK Sales,ou=acmegroups,o=acme.com)(cn=US
   Sales,ou=acmegroups,o=acme.com)?uniquemember?sub?x-userBaseDN=ou=sales
  %2co=ibm.com,x-uid_attr=emailaddress
  ```

- ```
  &(groupDN1)(groupDN2)(groupDN3)...(groupDNn)
  ```

  Authorization succeeds if the user is a member of all the groups that are specified. For example:

  ```
  ldap://ldap.acme.com:389/&(cn=UK Sales,ou=acmegroups,o=acme.com)(cn=US
   Sales,ou=acmegroups,o=acme.com)?uniquemember?sub?x-userBaseDN=ou=sales
  %2co=ibm.com,x-uid_attr=emailaddress
  ```

- UNIX The UNIX command line interprets the | and & characters as special characters. You must enclose multiple group DNs in double quotation marks, as shown in the following example:

  ```
  ldap://ldap.acme.com:389/"|(cn=UK Sales,ou=acmegroups,o=acme.com)(cn=US
   Sales,ou=acmegroups,o=acme.com)"?uniquemember?sub?x-userBaseDN=ou=sales
  %2co=ibm.com,x-uid_attr=emailaddress
  ```

member_attr:
(Optional) The attribute of the group used to filter the search. Default is to look for both **`member`** and **`uniquemember`** attributes.

The following options are required only if authentication has not preceded the authorization, and if the authentication configuration string has not been specified. If the authentication configuration

string has been specified, the following parameters are ignored and those provided by the **baseDN**, **uid_attr**, and **[base|sub]** for authentication are used instead:

base|sub:
Defines whether to perform a base or subtree search. If `base` is defined, the authentication is faster because the DN of the user can be constructed from uid_att + username + baseDN. If `sub` is selected, a search must be performed before the DN can be resolved. Default is `sub`.

baseDN
String defining the base distinguished name of all users in the directory. Must be preceded by the string `x-userBaseDN`. Any commas in the BaseDN must be rendered as `%2c`.

x-uid_attr:
String defining the attribute to which the incoming username should map, typically uid, CN, or email address. Default is uid. Must be preceded by the string `x-uid_attr`.

When you submit the command from a batch (.bat) file or command (.cmd) file, if the LDAP URL includes an extension with LDAP URL "percent hex hex" escaped characters (for example, a comma replaced by `%2c`, or a space replaced by `%20`), the percent signs must be escaped from the batch interpreter with an extra percent sign (`%%`).

The selected group must be defined on the LDAP server, and all of the required users must be members of the group.

Creating a security profile for WS-Trust V1.3 (TFIM V6.2)

You can create a security profile for a WS-Trust V1.3 compliant Security Token Service (STS), for example, Tivoli Federated Identity Manager (TFIM) V6.2, for any combination of the following security operations: authentication, authorization, and mapping.

Creating a profile

About this task

To create a security profile that uses a WS-Trust V1.3 compliant STS, set the configuration parameter of a Security Profiles policy to the full URL of the STS. The URL must consist of the transport scheme, host name, port, and path. For TFIM V6.2 WS-Trust V1.3 endpoint, the path is `/TrustServerWST13/services/RequestSecurityToken`. For example:

```
http://stsserver.mycompany.com:9080/TrustServerWST13/services/RequestSecurityToken
```

Procedure

1. Create a policy and choose the Security Profiles policy type (see “Creating policies with the IBM App Connect Enterprise Toolkit” on page 327).
2. Set the `Mapping` property to `WS-Trust v1.3 STS`.
3. Set the Mapping configuration property to the full URL of the STS.

   To specify that you want the security manager to reject a user name during authentication if the user name has an empty password token, set **`rejectBlankpassword`** to TRUE. The default is FALSE,

which means that a user name is authenticated against the WS-Trust server even if it has an empty password token.

To specify the way that the password is displayed in the properties folder, set **passwordValue** to one of the following values:

PLAIN
The password is displayed in the Properties folder as plain text.

OBFUSCATE
The password is displayed in the Properties folder as base64 encoding.

MASK
The password is displayed in the Properties folder as four asterisks (****).

If the URL specifies an address beginning with `https://`, an SSL secured connection is used for requests to the WS-Trust v1.3 server.

In addition to specifying the security profile URL as an address beginning with `https://`, you can configure the following advanced parameters, by setting integration node environment variables:

MQSI_STS_SSL_PROTOCOL
The version of the SSL protocol to be used. Valid values are:

- SSL
- SSLv3

  Note: SSLv3 is disabled by default in IBM App Connect Enterprise 12.0, because SSLv3 is no longer considered secure.
- TLS

The initial value is TLS.

MQSI_STS_SSL_ALLOWED_CIPHERS
A space-separated list of the encryption ciphers that can be used. For a list of all the cipher suites that are supported by IBM App Connect Enterprise, see the Java product information for your operating system. For operating systems that use IBM Java, see Appendix A of the IBM JSSE2 Guide: http://www.ibm.com/developerworks/java/jdk/security/60/secguides/jsse2Docs/JSSE2RefGuide.html

MQSI_STS_REQUEST_TIMEOUT
The STS request timeout, specified in seconds. The initial value is `100`. For information about providing environment variables to the integration node, see "Setting up a command environment" on page 64.

MQSI_STS_REQUEST_ONBEHALFOF
If you set this environment variable to `enabled`, the WS-trust requests include the optional field `wst:OnBehalfOf`. This field is required when the STS server is secured and needs credentials/authentication tokens before it process the request.

If WS-Trust v1.3 STS is selected for more than one operation (for example, for authentication and mapping), the WS-Trust v1.3 server URL must be identical for all the operations, and is therefore specified only once.

Creating a security profile for TFIM V6.1

You can create a security profile for Tivoli Federated Identity Manager (TFIM) V6.1 for any combination of the following functions: authentication, authorization, and mapping.

About this task

Note: Support for TFIM V6.1 is included for compatibility with previous versions of IBM App Connect Enterprise. If possible, upgrade to TFIM V6.2 and follow the instructions in "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 2588.

About this task

Create a Security Profiles policy that uses TFIM V6.1, and set the configuration parameter to the URL of the TFIM server. For example: `http://tfimserver.mycompany.com:9080`

Procedure

1. Create a policy and choose the Security Profiles type (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).
2. Set the `Mapping` property to `TFIM`.
3. Set the `Mapping configuration` property to the URL of the provider, for example `http://tfimserver.mycompany.com:9080`.

   If the URL specifies an address beginning with `https://`, an SSL secured connection is used for requests to the TFIM server.

   If TFIM is selected for more than one operation (for example, for authentication and mapping), the TFIM server URL must be identical for all the operations, and is therefore specified only once.

Creating a security profile for using locally-stored credentials

You can create a security profile for authentication against credentials stored locally in the integration server's vault.

About this task

Create a Security Profiles policy that uses locally-stored credentials for authentication, by completing the following steps:

Procedure

1. Create a Security Profiles policy in a policy project (for example, `SecPolicy/BasicAuthLocal.policyxml`), as described in "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327.
2. Set the **`Authentication`** property to `Local`.
3. Set the **`AuthenticationConfiguration`** property to the local credential alias of the credential that is stored in the integration server's vault. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<policies>
  <policy policyType="SecurityProfiles" policyName="LocalAuth"
 policyTemplate="SecurityProfiles">
    <authentication>Local</authentication>
    <authenticationConfig>LocalCredentialsAlias</authenticationConfig>
  </policy>
</policies>
```

Configuring the extraction of an identity or security token

You can configure the SecurityPEP node or security enabled input nodes to extract the identity or security token from a message and store it in the properties tree identity fields, enabling it to be processed throughout the message flow and propagated at output or request nodes.

Before you begin

Check that an appropriate security profile exists or create a new security profile. See "Creating a security profile" on page 2584.

About this task

If an input node or SecurityPEP node is associated with a profile that specifies a security operation (authentication, mapping, or authorization), or specifies propagation as enabled, the node can retrieve an identity or security token from the message bit stream.

- An MQInput node, with the `Identity token type` security property set to `Transport default`, retrieves the UserIdentifier element from the message descriptor (MQMD) and puts it into the Identity Source Token element of the Properties folder. At the same time, it sets the Identity Source Type element to `username` and the Identity Source Issued By element to `MQMD.PutApplName` (the put application name).
- An HTTPInput node, with the `Identity token type` security property set to `Transport default`, retrieves the BasicAuth header from the HTTP request, decodes it, and puts it into the Identity Source Token and Password elements in the Properties folder. At the same time, it sets the Identity Source Type element to `username + Password` and the Identity Source Issued By element to the HTTP header `UserAgent` property.
- A SOAPInput node retrieves the appropriate tokens as defined by the configured WS-Security policy sets and bindings, or (if they are not set), the transport binding determines the token type; for example, HTTP transport is BasicAuth. The SOAPInput node then populates the identity source fields in the Properties folder with the retrieved tokens. With a Kerberos policy set and bindings, the token type is a Username containing the Service Principal Name (SPN) from the Kerberos ticket.
- A SecurityPEP node, with the `Identity token type` property set to `Current token`, can use the token that has been extracted by an upstream input or SecurityPEP node and stored in the Properties folder.

In some cases, the information extracted from the transport headers is not set or is insufficient to perform authentication or authorization. For example, for authentication to occur, a Username + Password type token is required; however, with WebSphere MQ, only a username is available, which means that the incoming identity has to be trusted. However, you can increase security by applying transport-level security using WebSphere MQ Extended Security Edition.

If the transport header cannot provide the required identity credentials, the information must be provided as part of the body of the incoming message. To enable the identity information to be taken from the body of the message, you must specify the location of the information by using either the **Security** tab on the HTTP, MQ, and SCA input nodes or the **Basic** tab on the SecurityPEP node, or by configuring the required policy set and bindings WS-Security profile on the SOAP node. A SOAP node with a Kerberos policy set and bindings extracts a Username token containing the Service Principal Name (SPN) of the Kerberos ticket.

Procedure

1. In **Identity Token Type**, specify the type of identity token that is in the message.

   The type can have one of the following values:

   - `Transport Default` (on the security enabled input nodes)
   - `Current token` (on the SecurityPEP node)
   - `Username`
   - `Username and password`
   - `X.509 Certificate`
   - `SAML assertion`
   - `Kerberos GSS v5 AP_REQ` (on the SecurityPEP node)
   - `LTPA v2 token` (on the SecurityPEP node)
   - `Universal WSSE token` (on the SecurityPEP node)

   On the security enabled input nodes, the default value is *Transport Default*. On the SecurityPEP node, the default value is *Current token*, which means that the token type that exists in the identity mapped or source field in the Properties folder is used.
2. In **Identity Token Location**, specify the location in the message where the identity is specified.

   This string is in the form of an ESQL field reference, XPath expression, or string literal, and must resolve to a token with the type `Username`, `Username and password`, `SAML assertion`, `Kerberos GSS v5 AP_REQ`, `LTPA v2 token`, or `X.509 Certificate`. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.).
3. In **Identity Password Location**, enter the location in the message where the password is specified.

   This string is in the form of an ESQL field reference, XPath expression, or string literal, and must resolve to a string containing a password. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.). This option can be set only if the **Identity Token Type** is set to `Username and password`.
4. In **Identity IssuedBy Location**, specify a string or path expression to show where (in the message) information about the issuer of the identity is held.

   This string is in the form of an ESQL field reference, XPath expression, or string literal, defining where the identity was defined. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.).

   If you leave this property blank on the security enabled input nodes, the transport header value is used (if there is one). For example, for MQ the MQMD.PutApplName value is used. If you leave this property blank on the SecurityPEP node, the WS-Trust request is sent to the STS without the optional Issuer element in the WS-Trust message.
5. (Optional) Ensure that all input nodes share the same information by promoting the properties to the message flow.

What to do next

To enable the extraction of an identity in a security enabled input node or SecurityPEP node, select a security profile that has at least one security operation configured (authentication, mapping, or authorization) or propagation enabled:

1. In the IBM App Connect Enterprise Toolkit, right-click the BAR file, then click **Open with** > **BAR Editor**.
2. Click the **Manage and Configure** tab.
3. Click the flow or node on which you want to set the security profile. The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.
4. In the **Security Profile Name** field, select a security profile.
5. Save the BAR file.

Alternatively, you can set a security profile on the flow or the input node by using the **mqsiapplybaroverride** command. For example:

```
mqsiapplybaroverride -b barFileName -k applicationName -m
flowName#nodeName.securityProfileName=securityProfileName
```

For more information, see command.

Configuring identity authentication and security token validation

You can configure a message flow to perform identity authentication or security token validation by using Lightweight Directory Access Protocol (LDAP), a WS-Trust V1.3 compliant Security Token Service (STS) such as Tivoli Federated Identity Manager (TFIM) Version 6.2, or HTTP requests. Support for TFIM V6.1 is also provided, for compatibility with previous versions of IBM App Connect Enterprise. Alternatively, you can configure a message flow or integration server to authenticate requests against credentials that are stored locally in the integration server's vault.

Before you begin

Check that an appropriate security profile exists, or create a new security profile. See “Creating a security profile” on page 2584.

About this task

For information about configuring authentication, see:

- “Authenticating incoming requests with LDAP” on page 2593
- “Authenticating incoming requests with WS-Trust v1.3 STS (TFIM V6.2)” on page 2595
- “Authenticating incoming requests with TFIM V6.1” on page 2596
- “Authenticating incoming requests by using credentials stored in the vault” on page 2597
- “Configuring authentication for all HTTP and SOAP input nodes in an independent integration server” on page 2598
- “Providing credentials in HTTP requests” on page 2599

Authenticating incoming requests with LDAP

Configure a message flow to perform identity authentication using Lightweight Directory Access Protocol (LDAP).

Before you begin

Before you can configure a message flow to perform identity authentication using LDAP, you need to check that an appropriate security profile exists, or create a new security profile. See “Creating a security profile for LDAP” on page 2584.

About this task

To authenticate the identity of a user or system, the integration server attempts to connect to the LDAP server using the username and password associated with the identity. To do this, the integration server needs the following information:

- To resolve the username to an LDAP entry, the integration server needs to know the base distinguished name (base DN) of the accepted login IDs. This is required to enable the integration server to differentiate between different entries with the same name.
- If the identities do not all have a common base DN, but can be uniquely resolved from a subtree, the DN can be specified in the integration server configuration. When a subtree search has been specified, the integration server must first connect to the LDAP server and search for the given username in order to obtain the full username distinguished name (DN) to be used for authentication. If your LDAP directory does not permit login of unrecognized IDs, and does not grant search access rights on the subtree, you

must set up a separate authorized login ID that the integration server can use for the search. Use the **mqsisetdbparms** command to specify a username and password. For example:

```
mqsisetdbparms -w workDir-n ldap::LDAP -u username -p password
```

or

```
mqsisetdbparms -w workDir -n ldap::<servername> -u username -p password
```

where *<servername>* is your base LDAP server name, for example, `ldap.mydomain.com`.

If you specify `ldap::LDAP`, it creates a default setting for the integration server, which the integration server attempts to use if you have not explicitly used the **mqsisetdbparms** command to create a login ID for a specific *<servername>*. All servers that do not have an explicit `ldap::servername` entry then start using the credentials in the `ldap::LDAP` entry. This means that any servers that were previously using anonymous bind by default will start using the details in `ldap::LDAP`.

The username that you specify in the **-u** parameter must be recognized by the LDAP server as a complete user name. In most cases this means that you need to specify the full DN of the user. Alternatively, by specifying a username to be anonymous, you can force the integration server to bind anonymously to this LDAP server. This might be useful if you have specified a non-anonymous bind as your default (ldap::LDAP). For example:

```
mqsisetdbparms -w workDir -n ldap::<servername> -u anonymous -p password
```

In this case, the value specified for *password* is ignored.

Steps for enabling LDAP authentication:

Procedure

To enable an existing message flow to perform identity authentication, use the BAR editor to select a security profile that uses LDAP for authentication.

You can set a security profile on a message flow or on individual input nodes. If no security profile is set for the input nodes, the setting is inherited from the setting on the message flow.

a) Switch to the Integration Development perspective.

b) In the Application Development view, right-click the BAR file and then click **Open with** > **BAR Editor**.

c) Click the **Manage and Configure** tab.

d) Click the flow or node on which you want to set the security profile.

The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.

e) In the **Security Profile Name** field, select a security profile that uses LDAP for authentication.

f) Save the BAR file.

What to do next

For a SOAPInput node to use the identity in the WS-Security header (rather than an underlying transport identity) an appropriate policy set and bindings must also be defined and specified. For more information, see “Policy sets” on page 2662.

If the message identity does not contain enough information for authentication, the information must be taken from the message body. For example, if a password is required for authentication but the message came from IBM MQ with only a username, the password information must be taken from the message body. For more information, see “Configuring the extraction of an identity or security token” on page 2590.

Authenticating incoming requests with WS-Trust v1.3 STS (TFIM V6.2)

You can configure supported message flow input nodes or SecurityPEP nodes to perform identity authentication or security token validation using a WS-Trust v1.3 compliant Security Token Service (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2.

Before you begin

Before you can configure identity authentication or token validation, you need to check that an appropriate security profile exists, or create a new security profile. See "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 2588.

About this task

When you use a WS-Trust v1.3 STS for authentication, a request is made to the trust service with the following parameters, which control the STS processing. If you are using TFIM V6.2, the following parameters are used in the selection of the TFIM module chain:

- RequestType
- Issuer
- AppliesTo

For more information about these parameters, see:"Authentication, mapping, and authorization with TFIM V6.2 and TAM" on page 2574 .

The WS-Trust v1.3 specification, published by OASIS, is available at:

```
http://docs.oasis-open.org/ws-sx/ws-trust/200512/ws-trust-1.3-os.html
```

.

Steps for enabling WS-Trust v1.3 authentication:

Procedure

To enable an existing message flow to perform authentication or token validation, use the BAR file editor to select a security profile that uses a WS-Trust v1.3 STS for authentication and to associate it with the node or message flow.

If a security profile is specified on either a message flow or a node, the profile must be available when the message flow is deployed; otherwise, a deployment error occurs.

a) In the IBM App Connect Enterprise Toolkit, right-click the BAR file, then click **Open with** > **BAR Editor**.

b) Click the **Manage and Configure** tab.

c) Click the flow or node on which you want to set the security profile.

The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.

d) In the **Security Profile Name** field, select a security profile that configures WS-Trust v1.3 STS for authentication.

e) Save the BAR file.

What to do next

For a SOAPInput node to use the identity in the WS-Security header (rather than an underlying transport identity) an appropriate policy set and bindings must also be defined and specified.

If the message identity (or security token) does not contain enough information for authentication, the information must be taken from the message body. For example, if a password is required for authentication but the message came from IBM MQ with only a username, the password information must be taken from the message body. For more information, see "Configuring the extraction of an identity or security token" on page 2590.

Authenticating incoming requests with TFIM V6.1

You can configure a message flow to perform identity authentication by using Tivoli Federated Identity Manager (TFIM) V6.1.

Before you begin

Before you can configure a message flow to perform identity authentication, you need to check that an appropriate security profile exists, or create a new security profile. See "Creating a security profile for TFIM V6.1" on page 2589.

About this task

Note: Support for TFIM V6.1 is included for compatibility with previous versions of IBM App Connect Enterprise. If possible, upgrade to TFIM V6.2 and follow the instructions in "Authenticating incoming requests with WS-Trust v1.3 STS (TFIM V6.2)" on page 2595.

When you use TFIM V6.1 for authentication, a request is made to the TFIM trust service with the following three parameters, which select the module chain:

- Issuer = Properties.IdentitySourceIssuedBy
- Applies To = The Fully Qualified Name of the Flow: <*integrationNodeName*>.<*Integration Server Name*>.<*Message Flow Name*>
- Token = Properties.IdentitySourceToken

For more information about these parameters, see "Authentication, mapping, and authorization with TFIM V6.1 and TAM" on page 2572.

For further information about how to configure TFIM, see the IBM Tivoli Federated Identity Manager product documentation online.

Steps for enabling TFIM authentication:

Procedure

To enable an existing message flow to perform identity authentication, use the BAR editor to select a security profile that uses TFIM for authentication.

You can set a security profile on a message flow or on individual input nodes. If no security profile is set for the input nodes, the setting is inherited from the setting on the message flow.

a) Switch to the Integration Development perspective.

b) In the Application Development view, right-click the BAR file, then click **Open with** > **BAR Editor**.

c) Click the **Manage and Configure** tab.

d) Click the flow or node on which you want to set the security profile.

The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.

e) In the **Security Profile Name** field, select a security profile that uses TFIM for authentication.

f) Save the BAR file.

What to do next

If the message identity does not contain enough information for authentication, the information must be taken from the message body. For example, if a password is required for authentication but the message came from IBM MQ with only a username, the password information must be taken from the message body. For more information, see "Configuring the extraction of an identity or security token" on page 2590.

Authenticating incoming requests by using credentials stored in the vault

Implement basic authentication on incoming requests by using credentials stored locally in an independent integration server's vault.

About this task

You can secure your integrations by implementing basic authentication on deployed integrations, so that incoming HTTP requests must supply a username and password, which are then authenticated against credentials that are stored in an independent integration server's vault.

Procedure

To configure the authentication of incoming requests by using credentials stored in the vault, complete the following steps:

1. Create a Security Profiles policy in a Policy project (for example, `SecPolicy/BasicAuthLocal.policyxml`) and configure authentication against locally stored credentials, by setting the **Authentication** property to `Local` and the **AuthenticationConfiguration** property to the name of a local credential alias. For example:

```
<policies>
  <policy policyType="SecurityProfiles" policyName="BasicAuthLocal"
 policyTemplate="SecurityProfiles">
    <authentication>Local</authentication>
    <authenticationConfig>LocalCredentialsAlias</authenticationConfig>
    <mapping>NONE</mapping>
    <mappingConfig></mappingConfig>
    <authorization>NONE</authorization>
    <authorizationConfig></authorizationConfig>
    <propagation>false</propagation>
    <idToPropagateToTransport>Message ID</idToPropagateToTransport>
    <transportPropagationConfig></transportPropagationConfig>
    <keyStore>Reserved for future use</keyStore>
    <trustStore>Reserved for future use</trustStore>
    <passwordValue>PLAIN</passwordValue>
    <rejectBlankpassword>false</rejectBlankpassword>
  </policy>
</policies>
```

   For information about how to create a policy, see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327.

2. Deploy the policy project that contains the new security profile, by using one of the following methods:
   - Add the policy project to a BAR file and deploy it
   - Copy the policy project to the integration server's overrides directory (*work_directory*`/overrides`)
3. Create the vault for the integration server, by using the command; for example:

```
mqsivault --work-dir c:\mywrk\myaceworkdir --create --vault-key abcd1234
```

   For more information about creating a vault, see "Creating a vault by using the mqsivault command" on page 177.

4. Create the local credentials with the configured alias name in the integration server's vault, by using the command; for example:

```
mqsicredentials --work-dir c:\mywrk\myaceworkdir --create --vault-key abcd1234 --credential-
type local
--credential-name LocalCredentialsAlias --username SecUserName --password SecPwd
```

   For more information about creating security credentials, see "Configuring encrypted credentials by using the mqsicredentials command" on page 177.

5. Set the security profile to apply to the whole message flow, to a specific message flow node, or to the whole independent integration server, by completing one of the following steps:
   - Set the security profile to apply to the whole message flow by creating a BAR override, setting the security profile to *{policy_project_name}:security_profile_name* as a property on the message flow
   - Set the security profile to apply to a specific message flow node in either of the following ways:
     - Create a BAR override, setting the security profile to *{policy_project_name}:security_profile_name* as a property on the message flow node
     - Set the **Security profile** property in the **Security** tab of the appropriate message flow node. The **Security profile** property can be set on the following nodes:
       - CICSRequest
       - HTTPInput, HTTPRequest, HTTPAsyncRequest
       - IMSRequest
       - MQInput, MQOutput, MQReply
       - RESTRequest, RESTAsyncRequest
       - SAPRequest
       - SecurityPEP
       - SiebelRequest
       - SOAPInput, SOAPReply, SOAPRequest, SOAPAsyncRequest
   - Set the security profile to apply to the whole integration server, by setting the **forceServerHTTPSecurityProfile** property in the integration server's `server.conf.yaml` configuration file to the name of the policy, in the form *{policy_project_name}:security_profile_name*; for example:

     ```
     forceServerHTTPSecurityProfile: '{SecPolicy}:BasicAuthLocal'
     ```

     The setting specified in the **forceServerHTTPSecurityProfile** property in the `server.conf.yaml` file overrides any specific settings made at the level of the message flow or message flow node.
6. Restart the integration server for the changes to take effect, ensuring that you specify the vault key; for example:

   ```
   IntegrationServer --work-dir c:\mywrk\myaceworkdir --vault-key abcd1234
   ```

What to do next

When the deployed message flows are invoked with security applied, any request to the flow must provide the required credentials. Failure to do so will result in an authentication error and the request will fail.

Configuring authentication for all HTTP and SOAP input nodes in an independent integration server

Enforce authentication on all HTTP and SOAP input nodes deployed to an independent integration server.

About this task

You can configure an independent integration server to enforce basic authentication on all HTTP and SOAP input nodes by setting **forceServer** properties in the `server.conf.yaml` configuration file:

```
#forceServerHTTP:               false  # Set true to override and force unsecured HTTP on all
 HTTP/SOAP input nodes deployed in this server. Defaults to false.
```

```
#forceServerHTTPS:              false  # Set true to override and force secured HTTPS on all
 HTTP/SOAP input nodes deployed in this server. Defaults to false.
#forceServerHTTPSecurityProfile: ''    # Set a security profile, {<policy project
 name>}:<security profile basename>, to override and force all HTTP/SOAP transport
                                       # input nodes deployed in this server to apply the
 security set in the profile. Default is unset, so flow or node setting applies
```

Procedure

To configure the independent integration server to enforce basic authentication on HTTP and SOAP input nodes, complete the following steps:

1. Open the `server.conf.yaml` configuration file for the integration server, by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, which are not valid in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
2. Enforce secured HTTPS on all HTTP and SOAP input nodes deployed to the integration server, by uncommenting the **`forceServerHTTPS`** property and setting it to `true`.

   This setting overrides any existing authentication settings specified on the HTTP and SOAP input nodes and on the message flow.
3. Specify a security profile to apply to all HTTP and SOAP input nodes deployed to the integration server, by setting the **`forceServerHTTPSecurityProfile`** property to the name of the policy, in the form *{policy_project_name}:security_profile_name*; for example:

   ```
   forceServerHTTPSecurityProfile: '{SecPolicy}:BasicAuthLocal'
   ```

   The security settings in the security profile will override any security settings specified on the HTTP and SOAP input nodes and on the message flow. If this property is not set, the settings specified on the input nodes or message flow apply.
4. Restart the integration server for the changes to take effect.

Providing credentials in HTTP requests

Use a security profile to configure HTTPRequest and SOAPRequest nodes to authenticate with a remote server.

About this task

Basic authentication is a common extension in the HTTP protocol that allows a client to provide identity information to a remote web server in the form of a username and password sent in the HTTP header data. Security profiles in IBM App Connect Enterprise provide a way for message flow designers to provide these credentials without building the HTTP headers in a Compute node.

The identity that is to be propagated in the HTTP request can be provided in any of the following ways:

- If identity propagation is enabled for the selected security profile, the HTTPRequest and SOAPRequest nodes automatically pick up username and password credentials, if present, from the Properties tree. This setting is enabled for the predefined Default Propagation security profile. For more information, see “Configuring a message flow for identity propagation” on page 2613.
- You can configure a static username and password identity to be used, by specifying credentials with the command and the command. For information about using these commands to configure credentials, see “Configuring encrypted security credentials” on page 177. Alternatively, you can use the **`mqsisetdbparms`** command. For more information, see “Configuring a message flow for identity propagation” on page 2613.

Note: By default, the credentials are placed in the HTTP request only in response to a 401 challenge response from the server. The response includes a list of authentication mechanisms that are supported by the remote server that is providing the requested service. The integration server selects the highest level authentication protocol from this list of authentication mechanisms based on the set of protocols

that it supports. Nodes then use this protocol for the connection. You can configure the supported protocol by using the **allowedAuthTypes** property of the ComIbmSocketConnectionManager object. You can configure the nodes to send pre-emptively by setting the **preemptiveAuthType** property. For examples of how to set these properties, see "Providing credentials for outbound requests by using IWA" on page 2600.

To enable basic authentication, select an appropriate security profile for the output node or the message flow in the BAR file editor. The credentials are picked up from the following Properties tree locations if set:

```
Properties.IdentityMappedType
Properties.IdentityMappedToken
Properties.IdentityMappedPassword
```

If the mapped identity fields are not set, the credentials are picked up from the following Properties tree locations:

```
Properties.IdentitySourceType
Properties.IdentitySourceToken
Properties.IdentitySourcePassword
```

For basic authentication both a username and password are required, therefore the appropriate Type field must be set to the string `usernameAndPassword`. For example:

```
SET OutputRoot.Properties.IdentitySourceType='usernameAndPassword';
SET OutputRoot.Properties.IdentitySourceToken = 'myUser';
SET OutputRoot.Properties.IdentitySourcePassword = 'myPassw0rd';
SET OutputRoot.Properties.IdentitySourceIssuedBy = 'myDomain';
```

These fields are interpreted by a subsequent HTTPRequest or SOAPRequest node and converted into a basic authentication HTTP header.

You can also propagate credentials from an input message by setting a security profile which includes propagation on an input node, and then using the input node properties `Identity token type`, `Identity Token location` and `Identity password location`. These three properties take an XPath expression that specifies the location in the input message to retrieve the appropriate token or password from. When configured correctly, these properties place the identity information in the `Properties.IdentitySourceType`, `Properties.IdentitySourceToken` and `Properties.IdentitySourcePassword` fields. HTTPRequest or SOAPRequest nodes then use these values directly, with an appropriate security policy.

You can override the configuration of the security profile by selecting the build option **Override configurable property values** in the BAR file editor.

Providing credentials for outbound requests by using IWA
Set up IBM App Connect Enterprise to consume a remote service that is secured with Integrated Windows Authentication (IWA). Only IBM App Connect Enterprise running on Windows can consume an IWA-secured service.

Before you begin

Your IBM App Connect Enterprise must be running on the Windows operating system. If it is running on a different operating system, an IWA-secured remote service cannot be consumed.

Your message flow must include one or more of the following nodes:

- HTTPRequest
- SOAPRequest
- RESTRequest

You cannot use the HTTPAsyncRequest, SOAPAsyncRequest, or RESTAsyncRequest nodes to consume a remote service that is secured with Integrated Windows Authentication (IWA). If your message flow includes an HTTPRequest node, you must set the **HTTP version** property to *1.1* and select *Enable HTTP/1.1 keep-alive* on the **HTTP Settings** tab in the **Properties** view of the node.

A security identity is required for outbound authentication. By default, the identity credentials of the integration node user ID (the **serviceUserId** parameter that is specified by the **mqsicreatebroker** command) is sent to the remote service to use for authentication. If you require a specific security identity to be propagated, you must set the appropriate identity credentials in the Properties tree. For more information, see "Providing credentials in HTTP requests" on page 2599.

About this task

Use the following commands to set up and manage outbound support for the NTLM, Kerberos, SPNEGO, and SPNEGO-2 protocols, which together are referred to as Integrated Windows Authentication (IWA). By default IWA is enabled.

To consume a remote service that is secured with IWA, stop the integration node and run the following command:

```
mqsichangeproperties integrationNodeName -e integrationServerName -o
 ComIbmSocketConnectionManager
 -n allowedAuthTypes -v "PropertyValue" -f
```

Where:

- *integrationNodeName* is the name of the integration node you want to modify.
- *integrationServerName* is the name of the integration server on that integration node.
- *PropertyValue* is one of the following values:

  IWA
  Allow the integration node to authenticate by using any IWA protocol.

  NTLM
  Allow the integration node to authenticate by using the NTLM protocol.

  Negotiate
  Allow the integration node to authenticate by using the SPNEGO process to negotiate the use of the NTLM or Kerberos protocols.

  Nego2
  Allow the integration node to authenticate by using the SPNEGO-2 process to negotiate the use of the NTLM or Kerberos protocols.

  Basic
  Allow authentication with Basic Authentication.

  All
  Allow authentication with any supported protocol from this list.

  None
  Do not authenticate.

  Multiple values can be given, separated by a semicolon or a space, and these values are not case-sensitive. IBM App Connect Enterprise selects one value from the list of supported IWA protocols by the server, in the following order: Nego2, Negotiate, NTLM.

When security is enabled, the HTTPRequest and SOAPRequest nodes wait for a 401 response from the server that indicates which authentication mechanisms the server supports. The nodes then use the highest supported protocol for the connection, which is selected in the order that is listed previously. When connected, this protocol is used to authenticate pre-emptively until the flow is stopped or the allowedAuthTypes property is changed. To configure any of the protocols to be used pre-emptively, stop the integration node and run the following command:

```
mqsichangeproperties integrationNodeName -e integrationServerName -o
 ComIbmSocketConnectionManager
 -n preemptiveAuthType -v "PropertyValue" -f
```

Where:

- *integrationNodeName* is the name of the integration node you want to modify.

- *integrationServerName* is the name of the integration server on that integration node.
- *PropertyValue* is one of the following values:

  Basic
  Pre-emptively authenticate by using Basic Authentication.

  NTLM
  Pre-emptively authenticate by using the NTLM protocol.

  Negotiate
  Pre-emptively authenticate by using the SPNEGO process to negotiate the use of the NTLM or Kerberos protocols.

  Nego2
  Pre-emptively authenticate by using the SPNEGO-2 process to negotiate the use of the NTLM or Kerberos protocols.

For more advanced scenarios, the following optional configuration properties can also be used with the ComIbmSocketConnectionManager object:

allowNtlmNegotiation='*TRUE*'
Set to '*FALSE*' to prevent NTLM from being negotiated with the SPNEGO and SPNEGO-2 protocols. The default value is '*TRUE*'.

negotiateMutualAuth='*FALSE*'
Set to '*TRUE*' if you require mutual authentication when the Kerberos protocol is negotiated. The default value is '*FALSE*'.

Note: When IBM App Connect Enterprise is authenticating by using Kerberos, the integration node automatically generates a service principal name (SPN) for the service that is based on the host name for the request. For example, if the URL for the service is http://iib.iibservice/testservice/service1.svc the SPN is assumed to be HTTP/`iib.iibservice`. If the service exists at a different SPN, use the following local environment overrides to provide an explicit SPN for the service:

HTTP
```
SET OutputLocalEnvironment.Destination.HTTP.ServicePrincipalName = 'HTTP/
iib.iibservice2.com:7800';
```

REST
```
SET OutputLocalEnvironment.Destination.REST.Request.ServicePrincipalName =
'HTTP/iib.iibservice2.com:7800';
```

SOAP
```
SET
OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.ServicePrincipalName
= 'HTTP/iib.iibservice2.com:7800';
```

To check the current outbound authentication setting, start the integration node and run the following command:

```
mqsireportproperties integrationNodeName -e integrationServerName
 -o ComIbmSocketConnectionManager -r
```

The following output is displayed within the connector properties:

- allowedAuthTypes='*PropertyValue*'

Where *PropertyValue* is *NTLM*, *Negotiate*, *Nego2*, *None*, or *Basic*. If multiple values are set, they are separated by a semicolon.

Examples

To enable all IWA protocols, stop the integration node and run the following command:

```
mqsichangeproperties INODE -e default -o ComIbmSocketConnectionManager
 -n allowedAuthTypes -v "IWA" -f
```

To enable NTLM and Negotiate (SPNEGO) protocols, stop the integration node and run the following command:

```
mqsichangeproperties INODE -e default -o ComIbmSocketConnectionManager
 -n allowedAuthTypes -v "NTLM;Negotiate" -f
```

To disable all outbound security protocols, stop the integration node and run the following command:

```
mqsichangeproperties INODE -e default -o ComIbmSocketConnectionManager
 -n allowedAuthTypes -v "None" -f
```

Configuring identity mapping

Configure a Security Token Service (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2, to map the incoming security token and, if required, to authenticate and authorize it.

Before you begin

Before you can configure a message flow to perform identity mapping, you need to check that an appropriate security profile exists, or create a new security profile. For information about security profiles, see “Creating a security profile” on page 2584.

About this task

IBM App Connect Enterprise provides support for identity mapping (also known as identity federation) and token issuance and exchange. Identity mapping is the process of mapping an identity in one realm to another identity in a different realm. For example, you might map *User001* from the eSellers realm to *eSellerUser01* in the eShipping realm. Token issuance and exchange involves the mapping of a token of one type to a token of a different type. For example, an incoming Username and Password token from a client over MQ might be mapped into an equivalent SAML assertion, to be propagated to a web services call. Alternatively, you might exchange a SAML 1.1 assertion from a client application for an equivalent SAML 2.0 assertion for an updated backend server.

For information about configuring identity mapping with either a WS-Trust V1.3 STS (for example, TFIM V6.2) or with TFIM V6.1, see:

- “Configuring identity mapping with a WS-Trust V1.3 STS (TFIM V6.2)” on page 2603
- “Configuring identity mapping with TFIM V6.1” on page 2604

Configuring identity mapping with a WS-Trust V1.3 STS (TFIM V6.2)

Configure a WS-Trust V1.3 compliant Security Token Service (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2, to map the incoming security token and, if required, to authenticate and authorize it.

Before you begin

Before you can configure a message flow to perform identity mapping, you need to check that an appropriate security profile exists, or create a new security profile. For information about security profiles, see “Creating a security profile” on page 2584.

About this task

To configure TFIM V6.2 to map an incoming security token, you must create a custom module chain in TFIM, which performs the security operations. The TFIM configuration controls the token type that is returned from the mapping.

When you use a WS-Trust V1.3 STS for identity mapping, a request is made to the security token server with the following parameters, which control the STS processing:

- RequestType

- Issuer
- AppliesTo

If you are using TFIM V6.2, these parameters are used in the selection of the module chain.

The security manager invokes the WS-Trust v1.3 provider only once, even if it is set for additional security operations (such as authentication or authorization). As a result, when you are using TFIM V6.2, you must configure a single module chain to perform all the required authentication, mapping, and authorization operations.

When the security profile includes a mapping operation, the STS (for example, TFIM V6.2) must return a security token in its response. The STS can return the original unmodified token if no token exchange is required.

For more information about these parameters, see:"Authentication, mapping, and authorization with TFIM V6.2 and TAM" on page 2574 .

The WS-Trust v1.3 specification, published by OASIS, is available at:

```
http://docs.oasis-open.org/ws-sx/ws-trust/200512/ws-trust-1.3-os.html
```

For information on how to configure TFIM, see the IBM Tivoli Federated Identity Manager product documentation online.

Follow these steps to enable an existing message flow to perform identity mapping.

Procedure

Using the BAR editor, select a security profile that has mapping enabled.

You can set a security profile on a message flow or on individual input nodes. If no security profile is set for the input nodes, the setting is inherited from the setting on the message flow.

a) In the IBM App Connect Enterprise Toolkit, right-click the BAR file, then click **Open with** > **BAR Editor**.

b) Click the **Manage and Configure** tab.

c) Click the message flow or node on which you want to set the security profile.

The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.

d) In the **Security Profile Name** field, enter the name of a security profile that has mapping enabled.

e) Save the BAR file.

Configuring identity mapping with TFIM V6.1

Configure Tivoli Federated Identity Manager (TFIM) V6.1 to map the incoming security token and, if required, to authenticate and authorize it.

Before you begin

Before you can configure a message flow to perform identity mapping, you need to check that an appropriate security profile exists, or create a new security profile. For information about security profiles, see "Creating a security profile" on page 2584.

About this task

Note: Support for TFIM V6.1 is included for compatibility with previous versions of IBM App Connect Enterprise. If possible, upgrade to TFIM V6.2 and follow the instructions in "Configuring identity mapping with a WS-Trust V1.3 STS (TFIM V6.2)" on page 2603.

To configure TFIM V6.1 to map the incoming security token, you need to create a custom module chain in TFIM, which performs the security operations. The TFIM configuration controls the token type that is returned from the mapping.

When you use TFIM for mapping, a request is made to the TFIM trust service with the following three parameters, which select the module chain:

- Issuer = Properties.IdentitySourceIssuedBy
- AppliesTo = The fully qualified name of the flow: *integrationNodeName.Integration Server Name.Message Flow Name*
- Token = Properties.IdentitySourceToken

The security manager invokes the security provider only once, even if it is set for additional security operations (such as authentication or authorization). As a result, when you are using TFIM V6.1, you must configure a single module chain to perform all the required authentication, mapping, and authorization operations.

For information on how to configure TFIM, see the IBM Tivoli Federated Identity Manager product documentation online.

Follow these steps to enable an existing message flow to perform identity mapping.

Procedure

Using the BAR editor, select a security profile that has mapping enabled.

You can set a security profile on a message flow or on individual input nodes. If no security profile is set for the input nodes, the setting is inherited from the setting on the message flow.

a) In the IBM App Connect Enterprise Toolkit, right-click the BAR file, then click **Open with** > **BAR Editor**.

b) Click the **Manage and Configure** tab.

c) Click the flow or node on which you want to set the security profile.

The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.

d) In the **Security Profile Name** field, enter the name of a security profile that has mapping enabled.

e) Save the BAR file.

Configuring authorization

Configure the integration node to use an external security provider to authorize an identity in a message flow. You can use either Lightweight Directory Access Protocol (LDAP) or a WS-Trust V1.3 compliant Security Token Service (STS) such as Tivoli Federated Identity Manager (TFIM) V6.2. Support for TFIM V6.1 is also provided for compatibility with previous versions.

Before you begin

Check that an appropriate security profile exists, or create a new security profile. See “Creating a security profile” on page 2584.

About this task

For information about configuring authorization for LDAP, WS-Trust V1.3 (TFIM V6.2), or TFIM V6.1, see:

- “Configuring authorization with LDAP” on page 2606
- “Configuring authorization with a WS-Trust v1.3 STS (TFIM V6.2)” on page 2607
- “Configuring authorization with TFIM V6.1” on page 2610

What to do next

Configuring authorization with LDAP

This topic describes how to configure a message flow to perform authorization on an identity using Lightweight Directory Access Protocol (LDAP).

Before you begin

Before you can configure a message flow to perform authorization, you need to check that an appropriate security profile exists, or create a new security profile. See "Creating a security profile for LDAP" on page 2584.

About this task

When LDAP is used for authorization, the integration server needs to determine whether the incoming username is a member of the given group. To do this, the integration server requires the following information:

- To resolve the username to an LDAP entry, the integration server needs to know the base distinguished name (Base DN) of the accepted login IDs. This is required to enable the integration server to differentiate between different entries with the same name.
- To get an entry list from a group name, the group name must be the distinguished name of the group, not just a common name. An LDAP search is made for the group, and the username is checked by finding an entry matching the distinguished name of the user.
- If your LDAP directory does not permit login by unrecognized IDs, and does not grant search access rights on the subtree, you must set up a separate authorized login ID that the integration server can use for the search. Use the **mqsisetdbparms** command to specify a username and password:

  ```
  mqsisetdbparms -w workDir -n ldap::LDAP -u username -p password
  ```

  or

  ```
  mqsisetdbparms -w workDir -n ldap::<servername> -u username -p password
  ```

  where *<servername>* is your base LDAP server name. For example: `ldap.mydomain.com`.

  If you specify `ldap::LDAP`, it creates a default setting for the integration server, which the integration server attempts to use if you have not explicitly used the **mqsisetdbparms** command to create a login ID for a specific *<servername>*. All servers that do not have an explicit `ldap::servername` entry then start using the credentials in the `ldap::LDAP` entry. This means that any servers that were previously using anonymous bind by default will start using the details in `ldap::LDAP`.

  The username that you specify in the **-u** parameter must be recognized by the LDAP server as a complete user name. In most cases this means that you need to specify the full DN of the user. Alternatively, by specifying a username to be anonymous, you can force the integration server to bind anonymously to this LDAP server. This might be useful if you have specified a non-anonymous bind as your default (ldap::LDAP). For example:

  ```
  mqsisetdbparms -w workDir -n ldap::<servername> -u anonymous -p password
  ```

  In this case, the value specified for *password* is ignored.

Steps for enabling LDAP authorization:

Procedure

To enable an existing message flow to perform authorization using LDAP, use the BAR editor to select a security profile that has authorization enabled.

You can set a security profile on a message flow or on individual input nodes. If no security profile is set for the input nodes, the setting is inherited from the setting on the message flow.

a) Switch to the Integration Development perspective.

b) In the Application Development view, right-click the BAR file and then click **Open with** > **BAR Editor**.

c) Click the **Manage and Configure** tab.

d) Click the flow or node on which you want to set the security profile.

The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.

e) In the **Security Profile Name** field, select a security profile that uses LDAP for authorization.

f) Save the BAR file.

What to do next

For a SOAPInput node to use the identity in the WS-Security header (rather than an underlying transport identity) an appropriate policy set and bindings must also be defined and specified. For more information, see "Policy sets" on page 2662.

Configuring authorization with a WS-Trust v1.3 STS (TFIM V6.2)

You can configure supported message flow input nodes or SecurityPEP nodes to perform authorization of an identity or security token by using a WS-Trust v1.3 compliant Security Token Service (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2.

Before you begin

Before you configure a message flow to perform authorization with a WS-Trust v1.3 STS:

- Check that an appropriate security profile exists, or create a new security profile. See "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 2588.

About this task

The message flow security manager issues an authorization request to the WS-Trust service with the following parameters, which select the TFIM module chain to be used:

- RequestType
- Issuer
- AppliesTo

For more information about these parameters, see:"Authentication, mapping, and authorization with TFIM V6.2 and TAM" on page 2574 .

In addition to configuring IBM App Connect Enterprise to perform authorization with a WS-Trust compliant STS, you must configure TAM. For information about how to do this, see the following topics:

- "Creating a module chain in TFIM V6.2" on page 2608
- "Configuring TAM for authorization using TFIM V6.2" on page 2608

Steps for enabling authorization using a WS-Trust v1.3 STS provider:

Procedure

To enable an existing message flow to enforce authorization using a WS-Trust v1.3 STS provider, use the BAR editor to select a security profile that has authorization set for that provider.

You can set a security profile on a message flow or on individual input nodes or SecurityPEP nodes. If you leave the **`Security Profile`** property blank, the node inherits the **`Security Profile`** property that is set at the message flow level. If you leave the property blank at both levels, security is turned off for the node.

a) In the IBM App Connect Enterprise Toolkit, right-click the BAR file, then click **Open with** > **BAR Editor**.

b) Click the **Manage and Configure** tab.

c) Click the flow or node on which you want to set the security profile.

The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.

d) In the **Security Profile Name** field, select a security profile that has authorization set for *WS-Trust V1.3 STS*.

e) Save the BAR file.

What to do next

For a SOAPInput node to use the token in the WS-Security header (rather than an underlying transport identity) an appropriate policy set and bindings must also be defined and specified.

The WS-Trust v1.3 specification is available at: `http://docs.oasis-open.org/ws-sx/ws-trust/200512/ws-trust-1.3-os.html`.

Creating a module chain in TFIM V6.2
This topic describes how to create a module chain in Tivoli Federated Identity Manager (TFIM) V6.2.

About this task

When you use a WS-Trust v1.3 Security Token Service (STS) for authentication, authorization, or mapping (or any combination of those operations), a single WS-Trust request is made to the trust service with the required parameters, which control the STS processing.

To enable IBM App Connect Enterprise to use TFIM V6.2 for authorization, you need to configure TFIM to process the single WS-Trust request from the integration node security manager. To configure TFIM, you must create a module chain to handle the request:

Procedure

1. Create a *Custom* module chain, and ensure that the chain performs all the actions that are specified in the integration node security profile (Authenticate, Map, Authorize).
2. Set the *RequestType*, *Issuer* and *AppliesTo* properties of the module chain, so that it is invoked for the requests from the security enabled input node or SecurityPEP node.

   The parameters that are passed by the integration node to TFIM are shown in the table in “Authentication, mapping, and authorization with TFIM V6.2 and TAM” on page 2574.

What to do next

If your module chain includes an authorization module, and if the module specifies TAM, you must configure TAM to process the authorization requests from TFIM. For more information about how to do this, see “Configuring TAM for authorization using TFIM V6.2” on page 2608.

Configuring TAM for authorization using TFIM V6.2
Configure Tivoli Access Manager (TAM) to enable authorization using Tivoli Federated Identity Manager (TFIM) V6.2.

About this task

To configure TAM for a TFIM V6.2 TAMAuthorizationSTSModule, complete the following steps using the pdadmin utility.

Procedure

1. Check that the **`action group`** used by the TFIM authorization module is available.

   The action group used is *WebService*:

```
action group list
```

If *WebService* is not listed, create it:

```
action group create WebService
```

2. Display the **action** in the action group used by the TFIM authorization module.
   The action used is *"i"*:

```
action list WebService
```

   If action *"i" <label> 0* is not listed, create it. The value of *<label>* can vary:

```
action create i <label> 0 WebService
```

3. Create the Access Control List (ACL) that will be used to grant access to one or more message flows.
   First, create the ACL and give the administrators access to it. In this example, `iv-admin` is the administration group and `sec_master` is the main administrator:

```
acl create <AclName>
acl modify <AclName> set Group iv-admin TcmdbsvaBRxl[WebService]i
acl modify <AclName> set User sec_master TcmdbsvaBRxl[WebService]i
```

4. Grant access to all authenticated users, or specific groups, by adding them to the ACL. Grant any authenticated identity access:

```
acl modify <AclName> set Any-other Trx[WebService]i
```

   To add a specific group:

```
acl modify <AclName> set group <GroupName> Trx[WebService]i
```

   In these strings, each occurrence of `Trx[ ]` is an action, and corresponds to the value of the stsuser Action context attribute that is passed into the TAMAuthorizationSTSModule. For more information, see “Authentication, mapping, and authorization with TFIM V6.2 and TAM” on page 2574.

5. Create a protected object space path in TAM to correspond to the value of the stsuser ObjectName context attribute that is passed into the TAMAuthorizationSTSModule using the following command syntax:

```
objectspace create /<ObjectName>
```

   For more information, see “Authentication, mapping, and authorization with TFIM V6.2 and TAM” on page 2574.

6. Attach the ACL to the protected object space path that you have created.
   Each node in the object space inherits ACLs from its parent, and a lower level ACL can override a higher level one. Use the following command syntax to attach an ACL to a node in the object space path:

```
acl attach /<ObjectSpacePath> <AclName>
```

Configuring authorization with TFIM V6.1

You can configure a message flow to perform authorization on an identity by using Tivoli Federated Identity Manager (TFIM) V6.1.

Before you begin

Before you configure a message flow to perform authorization with TFIM V6.1:

- Check that an appropriate security profile exists, or create a new security profile. See "Creating a security profile for TFIM V6.1" on page 2589.
- Define the required users and groups in TFIM.

About this task

Note: Support for TFIM V6.1 is included for compatibility with previous versions of IBM App Connect Enterprise. If possible, upgrade to TFIM V6.2 and follow the instructions in "Configuring authorization with a WS-Trust v1.3 STS (TFIM V6.2)" on page 2607.

The integration node security manager issues an authorization request to the TFIM trust service with the following three parameters, which select the TFIM module chain to be used:

- Issuer = Properties.IdentitySourceIssuedBy
- Applies To = The Fully Qualified Name of the Flow: <*integrationNodeName*>.<*Integration Server Name*>.<*Message Flow Name*>
- Token = Properties.IdentitySourceToken

Authorization is performed with TFIM using an instance of the TFIM AuthorizationSTSModule in the selected module chain. The TFIM AuthorizationSTSModule must be set with `Mode = Other`. This AuthorizationSTSModule authorizes a user by checking an Access Control List (ACL) from Tivoli Access Manager (TAM). TFIM performs the authorization check by verifying that the action "i" (invoke) has been granted in an ACL for the `WebService` action group.

The ACL is found starting from the root of the TAM object space using a path formed from the Authorization module **`Web service protected object name`** parameter, followed by the **`Port Type`** and **`Operation Name`** from the authorization request. When the integration node makes an authorization request to TFIM, the **`Port Type`** and **`Operation Name`** parameters have the following values:

- PortType:<*Message flow name*>
- Operation "MessageFlowAccess"

Therefore, the ACL is found at this location in the TAM object space:

```
/<WSProtectedObjectName>.<MessageFlowName>."MessageFlowAccess"
```

For more information about this process and the parameters, see "Authentication, mapping, and authorization with TFIM V6.1 and TAM" on page 2572.

Steps for enabling TFIM authorization:

Procedure

To enable an existing message flow to perform authorization with TFIM, use the BAR editor to select a security profile that has authorization enabled.

You can set a security profile on a message flow or on individual input nodes. If no security profile is set for the input nodes, the setting is inherited from the setting on the message flow.

a) Switch to the Integration Development perspective.

b) In the Application Development view, right-click the BAR file, then click **Open with** > **BAR Editor**.

c) Click the **Manage and Configure** tab.

d) Click the flow or node on which you want to set the security profile.

The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.

e) In the **Security Profile Name** field, select a security profile that has authorization enabled.

f) Save the BAR file.

What to do next

For a SOAPInput node to use the identity in the WS-Security header (rather than an underlying transport identity) an appropriate policy set and bindings must also be defined and specified. For more information, see "Policy sets" on page 2662.

In addition to configuring IBM App Connect Enterprise to perform authorization with TFIM, you must configure TFIM and TAM. For information about how to do this, see the following topics:

- "Creating a module chain in TFIM V6.1" on page 2611
- "Configuring TAM for authorization using TFIM V6.1" on page 2612.

For further information on how to configure TFIM, see the IBM Tivoli Federated Identity Manager product documentation online.

Creating a module chain in TFIM V6.1

This topic describes how to create a module chain in Tivoli Federated Identity Manager (TFIM) V6.1.

About this task

To enable IBM App Connect Enterprise to use TFIM V6.1 for authorization, you need to configure TFIM to process the security request from the message flow. To do this you need to create a module chain in TFIM to handle the request:

Procedure

1. Create a *Custom* module chain, and ensure that the chain performs all the actions required (Authenticate, Map, Authorize).
2. Set the *Issuer* and *AppliesTo* properties of the module chain, so that it is invoked for the requests from the message flow.

   When the integration node makes a request to TFIM, the **`Port Type`** and **`Operation Name`** parameters have the following values:

   - PortType:*<Message flow name>*
   - Operation "MessageFlowAccess"

   The *RequestType* is always set to *Validate*.
3. To perform authorization in a module chain, add an instance of the Authorization module in *other* mode, which allows the module parameter **`Web Service protected object name`** to be set for the Tivoli Access Manager (TAM) configuration.

What to do next

When you have created the module chain in TFIM, see "Configuring TAM for authorization using TFIM V6.1" on page 2612 for information on how to configure TAM to process authorization requests from TFIM.

Configuring TAM for authorization using TFIM V6.1
This topic describes how to configure Tivoli Access Manager (TAM) to enable authorization using Tivoli Federated Identity Manager (TFIM) V6.1.

About this task

To configure TAM to process an authorization request from TFIM, complete the following steps. The examples relate to the TAM Version 6.01 pdadmin utility:

Procedure

1. Check that the **action group** used by the TFIM authorization module is available.
   The action group used is *WebService*:

   ```
   action group list
   ```

   If *WebService* is not listed, create it:

   ```
   action group create WebService
   ```

2. Display the **action** in the action group used by the TFIM authorization module.
   The action used is *"i"*:

   ```
   action list WebService
   ```

   If action *"i" <label> 0* is not listed, create it. The value of *<label>* can vary:

   ```
   action create i <label> 0 WebService
   ```

3. Create the Access Control List (ACL) that will be used to grant access to one or more message flows.
   First, create the ACL and give the administrators access to it. In this example, `iv-admin` is the administration group and `sec_master` is the main administrator:

   ```
   acl create <AclName>
   acl modify <AclName> set Group iv-admin TcmdbsvaBRxl[WebService]i
   acl modify <AclName> set User sec_master TcmdbsvaBRxl[WebService]i
   ```

4. Grant access to all authenticated users, or specific groups, by adding them to the ACL. Grant any authenticated identity access:

   ```
   acl modify <AclName> set Any-other Trx[WebService]i
   ```

   To add a specific group:

   ```
   acl modify <AclName> set group <GroupName> Trx[WebService]i
   ```

5. Define protected object spaces in TAM for authorization of message flows:
   a) Create the *application container object* as the root of the protected object space.
      This is the name that is used to link an instance of a TFIM AuthorizationSTSModule (within a module chain) into the TAM object space. The container object name is specified to match the **Web Service protected object name** parameter on a TFIM Authorization module.

```
objectspace create /<ContainerObjectName> <Description> 14
```

b) Create the container objects in the tree for each integration node message flow that is being authorized.

The message flow name is used by TFIM to locate a point in the TAM Object Space tree for Authorization, through the attached ACL. The message flow name is passed as the **PortType** in the WS-Trust request to TFIM. Use the following command to create the object tree node representing each flow to be authorized:

```
object create /<ContainerObjectName>/<FlowName> <Description> 11 ispolicyattachable yes
```

The **ispolicyattachable** parameter applies to all levels, so you can attach an ACL at any level.

c) Create the leaf object that represents the authorized object to grant access to the message flow.

This is the fixed string *MessageFlowAccess*, which the integration node sends to TFIM through the TFIM **OperationName** extension to the WS-Trust request. A fixed name (MessageFlowAccess) is used instead of a true operation name, because the integration node does not necessarily know at the input node which operation a flow is going to perform. The command syntax is:

```
object create /<ContainerObjectName>/<FlowName>/MessageFlowAccess <Description> 12 ispolicyattachable
 yes
```

where *<FlowName>* has been created in a previous step.

6. Attach the ACL to the relevant node in the protected object space tree.

Each node in the object space inherits ACLs from its parent, and a lower level ACL can override a higher level one. Use the following command syntax to attach an ACL to a node in the object space:

```
acl attach /<ObjectSpacePath> <AclName>
```

To attach an ACL to the leaf node:

```
acl attach /<ContainerObjectName>/<FlowName>/MessageFlowAccess <AclName>
```

Configuring a message flow for identity propagation

To enable a message flow to perform identity propagation, the input nodes must extract the identity from the message flow and the output node must propagate it. If the message identity does not contain enough information for identity propagation, you can provide the identity to propagate.

Before you begin

Before you can configure a message flow to perform identity propagation, you must check that an appropriate security profile exists, or create a new security profile. See “Creating a security profile” on page 2584.

About this task

To configure a message flow to perform identity propagation, complete the following tasks:

1. “Enabling identity propagation” on page 2614
2. “Providing the identity to propagate” on page 2614

Enabling identity propagation

About this task

An input node extracts security tokens if it is configured with a security profile at deployment time. An output node propagates an identity if it is configured with a security profile that enables propagation at deployment time.

To enable a message flow to perform identity propagation, complete the following steps.

Procedure

By using the BAR editor, select a security profile that has identity propagation enabled.

You can use the `Default Propagation` profile, which is a predefined profile that requests only identity propagation. You can set a security profile on a message flow or on individual input and output nodes. If no security profile is set for the input and output nodes, the setting is inherited from the setting on the message flow.

a) In the Application Development view, right-click the BAR file, then click **Open with** > **BAR Editor**.

b) Click the **Manage and Configure** tab.

c) Click the flow or node on which you want to set the security profile.

The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.

d) In the **Security Profile Name** field, select a security profile that has identity propagation enabled.

e) Save the BAR file.

Alternatively, you can set a security profile on the flow or the input node by using the **mqsiapplybaroverride** command. For example:

```
mqsiapplybaroverride -b barFileName -k applicationName -m
flowName#nodeName.securityProfileName=securityProfileName
```

For more information, see command.

Providing the identity to propagate

About this task

For information about the identity tokens that you can propagate with each node type, see “Identity and security token propagation” on page 2580.

If the message identity does not contain enough information for identity propagation, you can use any of the following methods to acquire the necessary information:

- Use information that is in the message body. For example, if the message comes from IBM MQ with only a `Username` token, and the output is an HTTPRequest node that requires a `Username and password` token, the password might be present in the body of the incoming message. For more information, see “Configuring the extraction of an identity or security token” on page 2590.
- Configure an identity mapper by using IBM Tivoli Federated Identity Manager. For more information, see the IBM Tivoli Federated Identity Manager product documentation online.
- Use ESQL or Java to set the Mapped Identity fields in the Properties tree.

- Configure a static user name and password identity by completing the following steps:
  1. Run the **mqsisetdbparms** command:

     ```
     mqsisetdbparms -w workDir -n securityIDName -u username -p password
     ```

     Where *securityIDName* is a name to associate with the static user name and password identity, and *username* and *password* are the identity credentials that you want to use. For more information, see command.
  2. Create a Security Profiles policy that sets the property values listed in the following table:

Properties	Values
Propagation	True
Identifier to propagate	Static ID
Transport propagation configuration	*securityIDName*

     Where *securityIDName* is the name that you associated with the static user name and password identity in the **mqsisetdbparms** command.

Securing message flows by using SSL

You can secure message flows by enabling nodes within message flows to use SSL and certificates.

After you establish a public key infrastructure (PKI) configuration for your integrations servers or integration nodes, you can use the PKI configuration within your message flows. For information on establishing a public key infrastructure, see “Setting up a public key infrastructure” on page 2635.

When you configure message flow nodes that make or accept TCP connections, you can set SSL encryption and certificates on those connections.

For more information about using SSL and certificates to secure your message flows, see:

- “Configuring JMS nodes to use to use SSL” on page 2615
- Configuring SOAPRequest and SOAPAsyncRequest nodes to use SSL (HTTPS)
- Configuring HTTPInput and HTTPReply nodes to use SSL (HTTPS)
- Securing the connection to CICS Transaction Server for z/OS by using SSL
- SSL and the TCP/IP nodes

Configuring JMS nodes to use to use SSL

Configure your JMS nodes to work with a JMS provider that supports JMS clients that can connect by using the Secure Sockets Layer (SSL) protocol.

About this task

The JMS 1.1 Specification states that JMS does not provide features for controlling or configuring message integrity or message privacy. JMS providers typically support these additional features, and provide their own administration tools to configure these services. Clients can get the appropriate security configuration as part of the administered objects that they use.

If you want to apply SSL security to the JMS connections created by the three built-in nodes JMSInput, JMSOutput, and JMSReply, check the documentation supplied by your chosen JMS provider. The configuration of the JNDI administered objects that are used by the JMS nodes is specific to each JMS provider.

The three built-in nodes JMSInput, JMSOutput, and JMSReply are referred to in this topic by the generic term JMS nodes; apply the information and instructions here to the specific type of node that you are using.

One example of a JMS provider that provides SSL support for connecting JMS clients is TIBCO Enterprise Message Service (EMS). The following sections describe the authentication model used for JMS nodes, with specific reference to TIBCO EMS, and provide information about how to connect JMS nodes to a TIBCO EMS JMS Server securely by using SSL:

1. "SSL authentication model for the JMS nodes" on page 2616
2. "Configuring your JMS nodes to use SSL-enabled JNDI administered objects" on page 2616

SSL authentication model for the JMS nodes

About this task

The JMS provider TIBCO EMS supports Java clients that can use either the Java Secure Sockets Extension (JSSE) Java package, or an SSL implementation supplied by Entrust. For details about the services provided, see the documentation provided with your chosen package.

TIBCO EMS supports a number of different authentication scenarios, but JMS nodes can use only client authentication to the server. In this scenario, the TIBCO EMS server requests the client's digital certificate during an SSL handshake, and checks its issuer against the server's list of trusted Certificate Authorities. If the authority is not in the server's list, further communications are prevented with the JMS node.

Therefore, you must configure the EMS server to explicitly enable client authentication of the SSL certificates in its configuration file; configure the JNDI administered SSL JMS connection factories for the same level of support.

Configuring your JMS nodes to use SSL-enabled JNDI administered objects

About this task

The JMS nodes use JNDI to look up a connection factory object that is used to create JMS connections to a TIBCO EMS server.

Procedure

1. Configure the JMS node property Connection factory name to specify a pre-configured connection factory that is enabled for SSL connectivity.

   Make sure that you have set the appropriate parameters in the corresponding SSL JMS connection factory definition:

   - Enable client authentication
   - Specify the SSL protocol in the server URL
   - Set other parameters to define the support your require.

   See the provider's documentation for information about how to generate this JNDI administered object:
2. Configure the JMS node property Location JNDI Bindings with the URL that points to the JNDI bindings containing the JNDI administered objects for SSL connectivity.

   For TIBCO EMS , this URL takes the following format:

   ```
   tibjmsnaming://server_name:ssl_port
   ```

   - *server_name* is the host name of the computer where the server is installed.
   - *ssl_port* is the server port for SSL connectivity; typically, this is port 7243 for a TIBCO EMS server.

3. Make the TIBCO EMS client JAR files available to the integration server to which you deploy the message flow that includes your JMS nodes.

   Set the JMS Providers policy property `Type 4 driver class JARs URL` to point to the directory that contains the JMS provider's client JAR files and the SSL vendor's JAR files.

   Some JMS providers use JSSE to implement SSL support; ensure that the following JAR files are in the `jarsURL` directory:

   - `jsse.jar`
   - `net.jar`
   - `jcert.jar`
   - `tibcrypt.jar`

   You can find standard non-SSL client JAR files in the same location.

   Refer to your JMS provider's documentation for more details on the specific JAR files that are required.

Configuring SOAPInput and SOAPReply nodes to use SSL (HTTPS)

Configure the SOAP nodes to communicate with other applications that use HTTPS by creating a keystore file, and configuring the integration server or integration node to use SSL.

Before you begin

Set up a public key infrastructure (PKI) at integration server level: "Setting up a public key infrastructure" on page 2635.

About this task

Follow these steps to configure the SOAPInput and SOAPReply nodes to communicate with other applications using HTTP over SSL:

1. If you are using the integration node listener: Configure the integration node to use SSL
2. If you are using the integration server (embedded) listener: Configure an integration server to use SSL

If you configured your integration node and integration servers such that the integration node listener is used for some integration servers, and the integration server listener for other integration servers, you must complete step 1 for the first set of integration servers and step 2 for each integration server in the second set.

For information about which listener to use for HTTP messages, see "HTTP listeners" on page 795.

Configuring an integration node to use SSL

If you want to use the integration node listener for HTTPS, configure values for the node's HTTP listener properties.

About this task

Complete the following steps:

Procedure

1. Optional: If you do not want to use the default port 7083 for HTTPS messages, specify the **port** on which the integration node listens:

```
mqsichangeproperties integrationNodeName
  -b httplistener -o HTTPSConnector
```

```
  -n port -v Port_to_listen_on_for_https
```

On UNIX systems, only processes that run under a privileged user account (in most cases, root) can bind to ports lower than 1024.

For the integration node to listen on these ports, the user ID under which the integration node is started must be root.

2. Optional: Enable Client Authentication (mutual authentication):

```
mqsichangeproperties integrationNodeName -b httplistener -o HTTPSConnector
  -n ReqClientAuth -v true
```

3. Restart the integration node after you change one or more of the HTTP listener properties.
4. Optional: Use the following commands to display HTTP listener properties:

```
mqsireportproperties integrationNodeName -b httplistener -o AllReportableEntityNames -a
mqsireportproperties integrationNodeName -b httplistener -o HTTPListener -a
mqsireportproperties integrationNodeName -b httplistener -o HTTPSConnector  -a
```

Configuring an integration server to use SSL
If you want to use the integration server listener for HTTPS, configure values for the server's HTTP listener properties.

About this task

Complete the following steps:

Procedure

1. Optional: Specify a specific port on which the integration server listens for HTTPS requests, or leave the value unset to use the next available port number.

```
mqsichangeproperties integrationNodeName
  -e integration_server_name -o HTTPSConnector
  -n explicitlySetPortNumber -v port_number
```

On UNIX systems, only processes that run under a privileged user account (in most cases, root) can bind to ports lower than 1024. For the integration server to listen on these ports, the user ID under which the integration node is started must be root.

If you do not complete this step, the first available port in the default range (7843 - 7884) is used.

2. Optional: Enable Client Authentication (mutual authentication):

```
mqsichangeproperties integrationNodeName
  -e integration_server_name -o HTTPSConnector
  -n ReqClientAuth -v true
```

3. Optional: Change the SSL protocol.

The default protocol for the HTTPInput node is TLS. Run the following command to change it to SSL. The only supported versions of **TLSProtocols** are *TLSv1.2* and *TLSv1.3*. The values are not case-sensitive. If **TLSProtocols** is set to *all*, both versions are enabled. For more information, see Integration server HTTP listener parameters (SOAP and HTTP nodes). :

```
mqsichangeproperties integrationNodeName
  -e integration_server_name -o HTTPSConnector
  -n TLSProtocols -v TLSv1.2
```

4. Restart the integration node after you change one or more of the listener properties.
5. Optional: Use the following command to display HTTPS properties:

```
mqsireportproperties integrationNodeName
  -e integration_server_name -o HTTPSConnector  -r
```

Configuring SOAPRequest and SOAPAsyncRequest nodes to use SSL (HTTPS)

Configure the SOAPRequest and SOAPAsyncRequest nodes to communicate with other applications that use HTTP over SSL.

Configuring the nodes

Procedure

On the **HTTP Transport** page of the properties for the node, set the following properties:

1. In the `Web Service URL` property, type the URL of the web service you want to call.
2. Optional: Select the `Enable certificate revocation list checking` property.
3. Set other SSL properties as appropriate.

What to do next

Test your configuration.

Configuring HTTPInput and HTTPReply nodes to use SSL (HTTPS)

Enable a message flow that uses HTTPInput and HTTPReply nodes to communicate with other applications that use HTTPS.

Before you begin

- Create the integration server to which you want to deploy the message flow. Follow the instructions in "Creating an integration server" on page 168.
- Decide which HTTP Listener you want to use for HTTPS messages. For more information about which listener to use for HTTPS messages, see "HTTP listeners" on page 795.
- Set up a public key infrastructure (PKI) to configure the keystores, truststores, passwords, and certificates to enable SSL communication. Follow the instructions in "Setting up a public key infrastructure" on page 2635. Following these instructions results in the integration server or integration node being configured for the PKI.

About this task

Complete these steps to enable a message flow that uses HTTPInput and HTTPReply nodes to communicate with other applications by using HTTP over SSL (HTTPS).

Procedure

1. Configure the integration server or integration node to use SSL.

   Complete one of the following substeps, depending on which HTTP listener you chose to use for HTTPS messages:

   - If you are using the integration node listener: Configure the integration node to use SSL
   - If you are using the integration server listener: Configure the integration server to use SSL

   Note: If you configure your integration node and integration servers such that the integration node listener is used for some integration servers, and the integration server listener for other integration servers, you must complete the first substep for the first set of integration servers and second substep for each integration server in the second set.
2. Create a message flow to use HTTPS
3. Test your configuration

Configuring an integration node to use SSL
If you want to use the integration node listener for HTTPS, configure values for the node's HTTP listener properties.

About this task

Complete the following steps:

Procedure

1. Optional: If you do not want to use the default port 7083 for HTTPS messages, specify the **port** on which the integration node listens:

   ```
   mqsichangeproperties integrationNodeName
     -b httplistener -o HTTPSConnector
     -n port -v Port_to_listen_on_for_https
   ```

   On UNIX systems, only processes that run under a privileged user account (in most cases, root) can bind to ports lower than 1024.

   For the integration node to listen on these ports, the user ID under which the integration node is started must be root.
2. Optional: Enable Client Authentication (mutual authentication):

   ```
   mqsichangeproperties integrationNodeName -b httplistener -o HTTPSConnector
     -n ReqClientAuth -v true
   ```
3. Restart the integration node after you change one or more of the HTTP listener properties.
4. Optional: Use the following commands to display HTTP listener properties:

   ```
   mqsireportproperties integrationNodeName -b httplistener -o AllReportableEntityNames -a
   mqsireportproperties integrationNodeName -b httplistener -o HTTPListener -a
   mqsireportproperties integrationNodeName -b httplistener -o HTTPSConnector  -a
   ```

Configuring an integration server to use SSL
If you want to use the integration server listener for HTTPS, configure values for the server's HTTP listener properties.

About this task

Complete the following steps:

Procedure

1. Optional: Specify a specific port on which the integration server listens for HTTPS requests, or leave the value unset to use the next available port number.

   ```
   mqsichangeproperties integrationNodeName
     -e integration_server_name -o HTTPSConnector
     -n explicitlySetPortNumber -v port_number
   ```

   On UNIX systems, only processes that run under a privileged user account (in most cases, root) can bind to ports lower than 1024. For the integration server to listen on these ports, the user ID under which the integration node is started must be root.

   If you do not complete this step, the first available port in the default range (7843 - 7884) is used.
2. Optional: Enable Client Authentication (mutual authentication):

   ```
   mqsichangeproperties integrationNodeName
     -e integration_server_name -o HTTPSConnector
     -n ReqClientAuth -v true
   ```

3. Optional: Change the SSL protocol.

   The default protocol for the HTTPInput node is TLS. Run the following command to change it to SSL. The only supported versions of **TLSProtocols** are *TLSv1.2* and *TLSv1.3*. The values are not case-sensitive. If **TLSProtocols** is set to *all*, both versions are enabled. For more information, see Integration server HTTP listener parameters (SOAP and HTTP nodes). :

   ```
   mqsichangeproperties integrationNodeName
     -e integration_server_name -o HTTPSConnector
     -n TLSProtocols -v TLSv1.2
   ```

4. Restart the integration node after you change one or more of the listener properties.
5. Optional: Use the following command to display HTTPS properties:

   ```
   mqsireportproperties integrationNodeName
     -e integration_server_name -o HTTPSConnector  -r
   ```

Creating a message flow to process HTTPS requests

About this task

You can create a simple message flow to use HTTPS by connecting an HTTPInput node to an HTTPReply node. The two most important properties to set on the HTTPInput node are:

- Path suffix for URL; for example, /* or /testHTTPS.
- Use HTTPS.

/* means that the HTTPInput node matches against any request that is sent to the HTTP listener on a designated port. This option is useful for testing purposes, but is not suitable for production systems.

You can now deploy the message flow to the broker. If you completed all the documented steps, message BIP3132 is written to the local system log (on Windows, the event log), stating that the HTTPS listener is started.

You can now test the system.

Testing your configuration

About this task

The simplest method of confirming the correct configuration of HTTPS, is to use a Web browser to make a request to the integration node over HTTPS.

Start a Web browser and enter the following URL:

```
https://localhost:7083/testHTTPS
```

Change values in the URL to reflect the changes that you made in your broker configuration; for example, the port number. When a window is displayed and you are asked to accept the certificate, select **Yes**. The browser refreshes the window and displays an empty HTML page:

- In Mozilla browsers, the empty HTML page looks like the following example:

  ```
  <html>
    <body/>
  </html>
  ```

- In Internet Explorer, the following information is displayed:

  ```
  XML document must have a top level element. Error processing resource
  'https://localhost:7083/testHTTPS'
  ```

These responses mean that a blank page was returned, indicating that the setup worked correctly. To add content to the empty page, you can add a Compute node to the flow.

You can use another HTTPS client to process HTTPS requests. Read the documentation for the client to find out how to configure it to make client connections over SSL.

You can also use another HTTPS client, such as a Java or .NET client, instead of the Web browser. Depending on the type of client, you might need to export the certificate (which was created with keytool) from the keystore file that is associated with the HTTP listener. Then, import it into the keystore for the client. Read the client documentation to find out how to configure the client to make client connections over SSL.

Configuring the HTTPRequest and HTTPAsyncRequest nodes to use SSL (HTTPS)

Configure the HTTPRequest or HTTPAsyncRequest nodes to communicate with other applications that use HTTP over SSL.

Before you begin

Set up a public key infrastructure (PKI) at integration node level: "Setting up a public key infrastructure" on page 2635

About this task

This topic describes the steps that you need to follow when configuring an HTTPRequest node on a Windows system. The steps that you must follow on other operating systems are almost identical.

To enable an HTTPRequest node to communicate using HTTP over SSL, an HTTPS server application is required. The information provided in this topic shows how to use the HTTPInput node for SSL as the server application, but the same details also apply when you are using any other server application. You specify the appropriate SSL client Authentication key alias field (Key Alias) on the HTTPRequest node or HTTPAsyncRequest node when the server key store contains multiple certificates for the server.

Complete the following sub-tasks:

1. "Creating a message flow to make HTTPS requests" on page 2622
2. "Testing your example" on page 2623.

Creating a message flow to make HTTPS requests

About this task

The following message flow creates a generic message flow for converting an IBM MQ message into an HTTP Request:

Procedure

1. Create a message flow with the nodes MQInput->HTTPRequest->Compute->MQOutput.
2. On the MQInput node, set the queue name to HTTPS.IN1 and create the IBM MQ queue.
3. On the MQOutput node, set the queue name to HTTPS.OUT1 and create the IBM MQ queue.
4. On the HTTPRequest node, set the web service URL to point to the HTTP server to call. To call the HTTPInput node, use `https://localhost:7083/testHTTPS`.
5. Optional: On the SSL settings properties tab, select `Enable certificate revocation list checking`.

   For more information on Certificate Revocation List (CRL) checking see, Working with certificate revocation lists.
6. On the Advanced properties tab of the HTTPRequest node, set the **`Response message location in tree`** property to *OutputRoot.BLOB*.
7. On the Compute node, add the following ESQL code:

```
CREATE COMPUTE MODULE test_https_Compute
    CREATE FUNCTION Main() RETURNS BOOLEAN
    BEGIN
        -- CALL CopyMessageHeaders();
```

```
        CALL CopyEntireMessage();
        set OutputRoot.HTTPResponseHeader = null;
        RETURN TRUE;
    END;

    CREATE PROCEDURE CopyMessageHeaders() BEGIN
        DECLARE I INTEGER;
        DECLARE J INTEGER;
        SET I = 1;
        SET J = CARDINALITY(InputRoot.*[]);
        WHILE I < J DO
            SET OutputRoot.*[I] = InputRoot.*[I];
            SET I = I + 1;
        END WHILE;
    END;

    CREATE PROCEDURE CopyEntireMessage() BEGIN
        SET OutputRoot = InputRoot;
    END;
END MODULE;
```

What to do next

The message flow is now ready to be deployed to the integration node and tested.

Testing your example

About this task

To test that the example works, complete the following steps:

Procedure

1. Follow the instructions in "Configuring HTTPInput and HTTPReply nodes to use SSL (HTTPS)" on page 2619, including testing the example.
2. Deploy the HTTPRequest message flow.
3. Put a message to the IBM MQ queue HTTPS.IN1.

   If successful, a message appears on the output queue. If the process fails, an error appears in the local error log (which is the event log on Windows).

Securing the connection to CICS Transaction Server for z/OS by using SSL

Configure the CICSRequest node to communicate with CICS Transaction Server for z/OS over the Secure Sockets Layer (SSL) protocol by updating a CICS Connection policy or the CICSRequest node to use SSL.

Before you begin

Ensure that you have completed the following tasks:

1. The CICSRequest node does not support a separate truststore, so the keystore file must provide both personal and signer certificates. If client-authentication (CLIENTAUTH) is enabled in the TCPIPSERVICE in CICS, the IBM App Connect Enterprise keystore file must also contain a personal certificate that is trusted by CICS.
2. Define the COMMAREA data structure as a message set, as described in "Defining a CICS Transaction Server for z/OS data structure" on page 1186.
3. Configure IP InterCommunications (IPIC) protocol on CICS, as described in "Preparing the environment for the CICSRequest node" on page 1187.

About this task

To configure the CICSRequest node to use SSL, complete the following steps:

Procedure

1. For client-authenticated (CLIENTAUTH) SSL connections, CICS expects the SSL client certificate to be mapped to a RACF user ID. Therefore the SSL client certificate must be mapped to a RACF user ID before attempting to establish the SSL connection to CICS. If the client certificate is not mapped to a RACF user ID, IBM App Connect Enterprise might display a `ECI_ERR_NO_CICS` response. You can map a client certificate to a RACF user ID by using the RACF command **RACDCERT**, which stores the client certificate in the RACF database and associates a user ID with it, or by using RACF certificate name filtering. Client certificates can be mapped one-to-one with a user ID, or a mapping from one to the other can be provided to allow a many-to-one mapping. You can achieve this mapping by using one of the following methods:

   - **Associating a client certificate with a RACF user ID**

     a. Copy the certificate that you want to process into an MVS sequential file. The file must have variable length, blocked records (RECFM=VB), and be accessible from TSO.

     b. Run the **RACDCERT** command in TSO by using the following syntax:

     ```
     RACDCERT ADD('datasetname') TRUST [ ID(userid) ]
     ```

     Where:

     – *datasetname* is the name of the data set containing the client certificate.

     – *userid* is the user ID to be associated with the certificate. This parameter is optional. If omitted, the certificate is associated with the user issuing the **RACDCERT** command.

     When you issue the **RACDCERT** command, RACF creates a profile in the DIGTCERT class. This profile associates the certificate with the user ID. You can then use the profile to translate a certificate to a user ID without giving a password. For full details of RACF commands, see z/OS Security Server RACF Command Language Reference.

   - **RACF certificate name filtering**

     With certificate name filtering, client certificates are not stored in the RACF database. The association between one or more certificates and a RACF user ID is achieved by defining a filter rule that matches the distinguished name of the certificate owner or issuer (CA). A sample filter rule might look like the following example:

     ```
     RACDCERT ID(DEPT3USR) MAP SDNFILTER
     (OU=DEPT1.OU=DEPT2.O=IBM.L=LOC.SP=NY.C=US)
     ```

     This sample filter rule would associate user ID DEPT3USR with all certificates when the distinguished name of the certificate owner contains the organizational unit DEPT1 and DEPT2, the organization IBM, the locality LOC, the state/province NY, and the country US.

2. Turn on SSL support in the integration server by setting the `CICS Server` property on the CICS Connection policy.

   Alternatively you can configure the `CICS server` property directly on the CICSRequest node.

What to do next

When you have configured the integration server or the CICSRequest node to use SSL, develop a message flow that contains a CICSRequest node by following the steps in “Developing a message flow with a CICSRequest node” on page 1188.

SSL and the TCP/IP nodes

Configure a TCP/IP configuration to use SSL to secure connectivity to and from the TCPIP nodes.

Configuring TCP/IP client nodes to use SSL
Configure a TCP/IP configuration to use SSL to secure connectivity to and from the TCPIP client nodes.

You can create or modify TCP/IP client connections that use SSL, by creating or modifying a policy. You can specify the type of protocol, and the allowed cipher suites. By default, SSL is not enabled for any policies.

Before you begin
Set up a public key infrastructure (PKI) at integration server level.

About this task

Follow these steps to configure the TCPIP nodes to use SSL:

1. "Changing a TCP/IP client configuration to use SSL" on page 2625
2. "Creating a TCP/IP client configuration that uses SSL" on page 2625

Changing a TCP/IP client configuration to use SSL

About this task

Use the Policy editor to change an existing TCPIP Client policy.

Procedure

1. Set the `SSL protocol` property to `TLS`.
2. Leave the `Cipher suites` property blank so that all available cipher suites can be used.
3. Deploy the policy project that contains your TCPIP Client policy to the integration server where you will deploy your associated message flow.

Creating a TCP/IP client configuration that uses SSL

About this task

Use the Policy editor to create a TCPIP Client policy (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).

Procedure

1. Set appropriate values for the `Port number` and `Host name` properties.
2. Set the `SSL protocol` property to `TLS`.
3. Set the Cipher suites property to a list of allowed cipher suites.
   For example, `SSL_RSA_WITH_RC4_128_MD5`.
4. Deploy the policy project that contains your TCPIP Client policy to the integration server where you will deploy your associated message flow.

Testing your configuration

About this task
Use either a TCPIPClientInput node, or a TCPIPClientOutput node to open a connection to a remote SSL server application that is listening on a TCP/IP port.

Configuring TCP/IP server nodes to use SSL
Configure a TCP/IP configuration to use SSL to secure connectivity to and from the TCPIP server nodes.

You can create or modify TCP/IP server connections that use SSL, by creating or modifying a policy. You can specify:

The type of protocol.
The allowed cipher suites.
A key alias.
Whether a connecting client should provide authentication information.

By default, SSL is not enabled for any policies.

About this task

Follow these steps to configure the TCPIP nodes to use SSL:

1. "Changing a TCP/IP server configuration to use SSL" on page 2626
2. "Creating a TCP/IP server configuration that uses SSL" on page 2626

Changing a TCP/IP server configuration to use SSL

About this task

Use the Policy editor to change an existing TCPIP Server policy.

Procedure

1. Set the `SSL protocol` property to TLS.
2. Leave the `Cipher suites` property blank so that all available cipher suites can be used.
3. Deploy the policy project that contains your TCPIP Server policy to the integration server where you will deploy your associated message flow.

Creating a TCP/IP server configuration that uses SSL

About this task

Use the Policy editor to create a TCPIP Server policy (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).

Procedure

1. Set the `Port number` property to an appropriate value.
2. Set the `SSL protocol` property to TLS.
3. Set the `Cipher suites` property to a list of allowed cipher suites, such as `SSL_RSA_WITH_RC4_128_MD5;SSL_RSA_WITH_3DES_EDE_CBC_SHA`.
4. Set the `SSL client authentication` property to `require` to indicate that connecting clients must authenticate.
5. Deploy the policy project that contains your TCPIP Server policy to the integration server where you will deploy your associated message flow.

Using an SSL key alias

About this task

A key alias identifies the key that is to be used for the SSL connection, if the keystore for your integration server contains more than one key. Specify the `SSL key alias` property on the TCPIP Server policy. The default value " " or `none`, means that an SSL key alias is not used. Any other string identifies the alias.

Note: If the keystore contains more than one key, and no key alias is defined, the Java virtual machine arbitrarily chooses a key at run time.

Procedure

1. Create a TCPIP Server policy (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).
2. Set the `Port number` property to the port number to use to make connections.
3. Set the `SSL protocol` property to TLS.
4. Specify a list of cipher suites to use (such as `SSL_RSA_WITH_RC4_128_MD5;SSL_RSA_WITH_3DES_EDE_CBC_SHA`).
5. Set the `SSL client authentication` property to require to indicate that connecting clients must authenticate.
6. Set the `SSL key alias` property to identify the key to be used.
7. Deploy the policy project that contains your TCPIP Server policy to the integration server where you will deploy your associated message flow.

Testing your configuration

About this task

To test your configuration, connect an SSL-enabled client, such as another program, or a web browser, to the server port. Connection error messages, such as handshake failures, or untrusted keys, indicate that you must change the configuration.

Client identity

About this task

If SSL client authentication is requested or required, and the client successfully authenticates, the distinguished name is present as an identity source token in the properties parser, in the tree propagated from the Open terminal at connection time. This applies only to the TCPIPServerInput node.

The `IdentitySourceToken` field is set to the distinguished name from the client certificate.
The `IdentitySourceType` field is set to the string `username`.
The `IdentitySourceIssuedBy` field is set to the issuer of the certificate presented by the client.

If SSL client authentication is requested, and the client does not provide the required credentials, the fields are set to blank.

Securing integration services by using SSL

You can secure integration services by configuring the SOAP/HTTP binding or JavaScript client API to use SSL and certificates.

Before you begin

- Create the integration server to which you want to deploy the integration service. Follow the instructions in "Creating an integration server" on page 168.
- Decide which HTTP Listener you want to use for HTTPS messages. For information about which listener to use for HTTPS messages, see "HTTP listeners" on page 795.
- Set up a public key infrastructure (PKI) to configure the keystores, truststores, passwords, and certificates to enable SSL communication. Follow the instructions in "Setting up a public key infrastructure" on page 2635. This results in the integration server or integration node being configured for the PKI.

About this task

Secure your integration services by configuring the integration node or integration server to use the PKI and SSL, and configuring the integration service bindings to use SSL.

Procedure

To secure your integration services by using SSL, complete the following steps:

1. Configure the integration server or integration node to use SSL.

   Complete one of the following substeps, depending on which HTTP listener you have chosen to use for HTTPS messages:

   - If you are using the integration node listener: Configure the integration node to use SSL
   - If you are using the integration server (embedded) listener: Configure the integration server to use SSL
2. Configure the integration service bindings to use SSL

Configuring an integration node to use SSL

If you want to use the integration node listener for HTTPS, configure values for the node's HTTP listener properties.

About this task

Complete the following steps:

Procedure

1. Optional: If you do not want to use the default port 7083 for HTTPS messages, specify the **port** on which the integration node listens:

   ```
   mqsichangeproperties integrationNodeName
     -b httplistener -o HTTPSConnector
     -n port -v Port_to_listen_on_for_https
   ```

   On UNIX systems, only processes that run under a privileged user account (in most cases, root) can bind to ports lower than 1024.

   For the integration node to listen on these ports, the user ID under which the integration node is started must be root.
2. Optional: Enable Client Authentication (mutual authentication):

   ```
   mqsichangeproperties integrationNodeName -b httplistener -o HTTPSConnector
     -n ReqClientAuth -v true
   ```
3. Restart the integration node after you change one or more of the HTTP listener properties.
4. Optional: Use the following commands to display HTTP listener properties:

   ```
   mqsireportproperties integrationNodeName -b httplistener -o AllReportableEntityNames -a
   mqsireportproperties integrationNodeName -b httplistener -o HTTPListener -a
   mqsireportproperties integrationNodeName -b httplistener -o HTTPSConnector  -a
   ```

Configuring an integration server to use SSL

If you want to use the integration server listener for HTTPS, configure values for the server's HTTP listener properties.

About this task

Complete the following steps:

Procedure

1. Optional: Specify a specific port on which the integration server listens for HTTPS requests, or leave the value unset to use the next available port number.

   ```
   mqsichangeproperties integrationNodeName
   ```

```
  -e integration_server_name -o HTTPSConnector
  -n explicitlySetPortNumber -v port_number
```

On UNIX systems, only processes that run under a privileged user account (in most cases, root) can bind to ports lower than 1024. For the integration server to listen on these ports, the user ID under which the integration node is started must be root.

If you do not complete this step, the first available port in the default range (7843 - 7884) is used.

2. Optional: Enable Client Authentication (mutual authentication):

```
mqsichangeproperties integrationNodeName
  -e integration_server_name -o HTTPSConnector
  -n ReqClientAuth -v true
```

3. Optional: Change the SSL protocol.

The default protocol for the HTTPInput node is TLS. Run the following command to change it to SSL. The only supported versions of **TLSProtocols** are *TLSv1.2* and *TLSv1.3*. The values are not case-sensitive. If **TLSProtocols** is set to *all*, both versions are enabled. For more information, see Integration server HTTP listener parameters (SOAP and HTTP nodes). :

```
mqsichangeproperties integrationNodeName
  -e integration_server_name -o HTTPSConnector
  -n TLSProtocols -v TLSv1.2
```

4. Restart the integration node after you change one or more of the listener properties.
5. Optional: Use the following command to display HTTPS properties:

```
mqsireportproperties integrationNodeName
  -e integration_server_name -o HTTPSConnector  -r
```

Configuring the integration service bindings to use SSL

About this task

Configure the integration service bindings to use SSL by completing the following steps:

Procedure

1. In the IBM App Connect Enterprise Toolkit, open your integration service in the integration service editor by double-clicking **Integration Service Description** in the Application Development view.
2. Click the **Service** tab.

   The integration service description is displayed, which includes the integration service bindings.
3. If you are using the SOAP/HTTP binding, then click **SOAP/HTTP Binding** and select **Use HTTPS** from the HTTP Transport properties panel.
4. If you are using the JavaScript client API, then click **JavaScript client API** and then select **Use HTTPS** from the Basic properties panel.

   Note: If you are using a web browser-based JavaScript application to call the integration service, then you must select **Use HTTPS** on both the SOAP/HTTP binding and the JavaScript client API. The HTTP proxy servlet routes requests only to endpoints that use the same protocol as the web browser. The HTTP proxy servlet routes requests to both the SOAP and JavaScript client API endpoints, and so both endpoints must match the web browser protocol.
5. Save and redeploy the integration service.

Results

You have configured the integration service to use SSL.

Checking the password for a resource that is used by an integration server

To check what security credentials are set on an integration server that is connected to a remote system or database, use the **mqsireportdbparms** command.

About this task

If you have an integration server that accesses external resources, you can check what security credentials are set if a security identity was created for the integration server. For more information, see “Security identities for the integration server connecting to external systems” on page 2582.

You can check whether a password is valid for a set of security credentials. You might want to check a password if you recently updated the password while the integration server was running, to see whether the new password is in effect.

To review the security credentials that are set for a resource that is connected to an integration serverintegration server, complete the following steps.

Procedure

Run the **mqsireportdbparms** command with the work directory of the integration server that you want to check in the following format:

- If you are connecting to an SFTP data source:
- If you are connecting to a non-SFTP data source:

```
mqsireportdbparms -w workDir  userdb -u user_id -p password
```

Where the names represent:

- *workDir* is the work directory of the integration server
- *server* as the details of your SFTP connection
- *SSH_identity* as the SSH connection name
- *userdb* as the data source name
- *user_id* as the user ID that you want to check
- *password* as the password that you want to check is valid for the integration server

Results

A result is returned that confirms whether the password that was provided is correct, or if it was incorrect. If there are no security credentials set for that integration node, then an information message is displayed.

Additionally, the command returns if the integration server was restarted after a password change, so that you know what password is valid for the integration server while it is running.

Diagnosing security problems

This topic explains how to find out why access to a secured flow has been denied.

About this task

By default, security exceptions occurring in an input node are not processed in the same way as other errors (see “Security exception processing” on page 2582). Security exceptions are not logged to the system event log, to prevent a security denial of service attack filling the logs and destabilizing the system.

This means that, by default, you cannot diagnose input node security exceptions in the same way as other errors. However, in a SecurityPEP node, a failing security operation causes a security exception to be

raised, wrapped in a normal recoverable exception, which invokes the error handling that is provided by the message flow.

To see what might be causing the security exceptions, you can do either of the following things:

- Select the **Treat Security Exceptions as normal exceptions** property on the input nodes.
- Use the user trace.

The following steps show you how to use the user trace to find out why access to a secured message flow has been denied:

Procedure

1. Use the **mqsireloadsecurity** command to clear the security cache, so that the traced request goes to the security provider rather than using a result held in the cache. This ensures that the reason codes returned from the security provider are displayed in the traced exception.
2. Enable user trace (see "User trace example" on page 3030 for more information).
3. Resend the request that has been rejected by the security provider.
4. Stop the user trace.
5. Examine the trace information that was recorded by the user trace. This trace information contains the error codes provided by the integration server and the security provider.

Permitting web browsers to access deployed HTTP services by enabling Cross-Origin Resource Sharing

You can configure IBM App Connect Enterprise to permit cross-origin requests from a web browser by enabling Cross-Origin Resource Sharing (CORS).

About this task

IBM App Connect Enterprise includes full support for CORS according to the specification that is available online at Cross-Origin Resource Sharing. You can configure the HTTP listeners for an integration server and the HTTP listeners for an integration node so that they respond to and permit cross-origin requests from a web browser.

Procedure

If you want to permit a web page that is running in a web browser to make HTTP requests to HTTP services that are deployed to IBM App Connect Enterprise, where those HTTP services are being hosted on an HTTP listener for an integration server or an HTTP listener for the integration node, complete the following steps:

1. Enable CORS on the HTTP listeners. The connectorName for the HTTP listener is HTTPConnector, and for the HTTPS listener is HTTPSConnector. If both HTTP and HTTPS are in use, you must configure the HTTP listeners for HTTP and HTTPS independently.

   The following example shows how to configure the integration server HTTP listener:

   ```
   mqsichangeproperties integrationNodeName -e integrationServerName -o connectorName -n
    corsEnabled -v true
   ```

   The following example shows how to configure the integration node HTTP listener:

   ```
   mqsichangeproperties integrationNodeName -b httplistener -o connectorName -n corsEnabled -v
    true
   ```

2. Optional: The default values for the CORS properties for the HTTP listener are permissive. All origins and HTTP methods are permitted by default. You can restrict the permitted origins and HTTP methods for cross-origin requests by configuring other CORS properties.

3. Optional: To display the currently configured CORS properties on the HTTP listener, run the following command:

   For the integration server HTTP listener:

   ```
   mqsireportproperties integrationNodeName -e integrationServerName -o connectorName -r
   ```

   For the integration node HTTP listener:

   ```
   mqsireportproperties integrationNodeName -b httplistener -o connectorName -r
   ```

Results

Cross-Origin Resource Sharing is now enabled. The web page that is running in a web browser is now permitted to make HTTP requests to HTTP services that are deployed to IBM App Connect Enterprise, where those HTTP services are being hosted on an HTTP listener for an integration server or an HTTP listener for the integration node.

What to do next

When CORS properties are modified on an HTTP listener for the integration server or an HTTP listener for the integration node, the changes take effect immediately. You are not required to restart any of the deployed HTTP services, the integration server, or the integration node.

Complete the following checks:

- Test the configuration by making HTTP requests from a web page that is running in a web browser to the deployed HTTP services that are being hosted on the HTTP listener that you configured.
- Check that the HTTPInput node in the message flow is called when the request is made, and that the message flow processes the request as expected.
- Check that the response that is sent through the HTTPReply node in the message flow is returned to the web page that made the request, and that the response is not dropped by the web browser.
- Check that this processing works for all the HTTP methods that the web page makes requests for.

Security for runtime components

You must consider several security aspects when you are configuring integration nodes or integration servers running on Windows or Linux platforms.

Before you begin

- Read “Security overview” on page 2491 for an introduction to various aspects of security.
- Refer to “Planning for security” on page 17, which contains links to security information that you need before, during, and after installation of IBM App Connect Enterprise.

About this task

Use the following list of tasks as a security checklist:

- “Creating user IDs” on page 2633
- “Controlling access to IBM App Connect Enterprise” on page 2633
- “Implementing SSL authentication” on page 2635

Creating user IDs

When you plan the administration of your integration node configuration, you might have to define one or more user IDs for the tasks associated with particular roles.

About this task

Some operating systems, and other products, impose restrictions on user IDs:

- On Windows systems, user IDs can be up to 12 characters long, but on Linux, UNIX, and z/OS systems, they are restricted to eight characters.
- Database products might also restrict user IDs to eight characters; for example DB2 has this restriction. If you have a mixed environment, ensure that the user IDs that you use are limited to a maximum of eight characters.
- Ensure that the case (upper, lower, or mixed) of user IDs is consistent. In some environments, uppercase and lowercase user IDs are considered the same, but in other environments, user IDs of different case are considered unique.

  For example, on Windows systems, the user IDs 'tester' and 'TESTER' are identical; on Linux and UNIX systems, they are recognized as different user IDs.
- Check the validity of spaces and special characters in user IDs to ensure that, if used, these characters are accepted by all relevant systems and products that you install.

Consider the following roles:

Procedure

- Administrator user IDs that can issue **mqsi*** commands.

  Ensure that all these user IDs are members of the mqbrkrs group.

  If you enable integration node administration security, you must set up additional authorization for user IDs for the commands listed in Commands and authorizations for administration security. For more information about integration node administration security, see “Administration security overview” on page 2497.
- On Windows only, service user IDs under which integration nodes run.

  For further information, see “Deciding which user account to use for the integration node service ID ” on page 2634.
- IBM App Connect Enterprise Toolkit users.

  See “Security for the IBM App Connect Enterprise Toolkit ” on page 2648 for information about checking and securing connections from the IBM App Connect Enterprise Toolkit.

Controlling access to IBM App Connect Enterprise

There are several factors to consider when you are deciding which users can execute App Connect Enterprise commands, and which users can control security for your resources.

About this task

Although most security for App Connect Enterprise and its resources is optional, you might find it appropriate to restrict the tasks that some user IDs can perform. You can then apply greater control to monitor changes.

You can control all IBM App Connect Enterprise administration tasks by enabling administration security. You can enable administration security and specify the authorization mode, either by setting the **authorizationEnabled** and **authorizationMode** properties in the `node.conf.yaml` or `server.conf.yaml` configuration files, or by using the **mqsichangeauthmode** command. This task is described in “Enabling administration security” on page 2504, and is independent of the tasks described in this section.

When you are deciding which users are to perform the different tasks, consider the following steps:

Procedure

1. “Deciding which user account to use for the integration node service ID ” on page 2634
2. “Setting security on the integration node” on page 2635
3. “Securing the integration node registry” on page 2635

Deciding which user account to use for the integration node service ID

About this task

On a Linux or UNIX operating system, when you run the **mqsistart** command with a user ID that is a member of the mqm and mqbrkrs groups, the user ID under which you run the **mqsistart** command becomes the user ID under which the integration node process runs.

On the Windows platform, the integration node runs under a service user account. To decide which user ID to use for the service ID, answer the following questions:

Procedure

1. Do you want the integration node to run under a Windows local account?
   a) No: Go to the next question.
   b) Yes: Ensure that your user ID has the following characteristics:
      - It is defined in your local domain.
      - It is a member of the mqbrkrs group.

      Go to “Setting security on the integration node” on page 2635.
2. Do you want the integration node to run under a Windows domain account?
   a) No: Go to the next question.
   b) Yes: Assume that your computer named, for example, WKSTN1, is a member of a domain named DOMAIN1. When you run an integration node using, for example, DOMAIN1\user1, ensure that:
      - Your user ID has been granted the `Logon as a service` privilege (from the Local Security Policy).
      - DOMAIN1\user1 is a member of DOMAIN1\MyDomainGroup group, where MyDomainGroup is a domain group which you have defined on your domain controller.
      - DOMAIN1\MyDomainGroup is a member of WKSTN1\mqbrkrs.

      Go to “Setting security on the integration node” on page 2635.
3. Do you want the integration node to run under theWindows built-in `LocalSystem` account?
   a) Yes: Specify `LocalSystem` for the *-i* parameter on the **mqsicreatebroker** command.

      In either case you must enter the *-a* (password) parameter on the command line, but the value entered is ignored.

Results

Note that for cases one and two above, the user ID chosen must be granted the `Logon as a service` privilege.

This is normally done automatically by the **mqsichangeproperties** command when a service user ID is specified that does not have this privilege.

However, if you want to do this manually before running these commands, you can do this by using the Local Security Policy tool in Windows, which you can access by selecting **Control Panel** > **Performance and maintenance** > **Administrative Tools** > **Local Security Policy**.

Setting security on the integration node

About this task

If you are using the queue-based authorization mode for the integration node (*mq* mode), the local mqbrkrs group is granted access to internal queues whose names begin with the characters SYSTEM.BROKER. If you are using the file-based authorization mode, the local mqbrkrs group is granted read, write, and execute permissions on the integration node for running local mqsi commands. Ensure that user IDs requiring these permissions are members of the mqbrkrs group.

Securing the integration node registry

About this task

Integration node operation depends on the information in the integration node registry, which you must secure to guard against accidental corruption. The integration node registry is stored on the file system under the work path directory, which is specified by the MQSI_WORKPATH environment variable. Set your operating system security options so that only user IDs that are members of the group mqbrkrs can read from or write to *integrationNodeName*/`CurrentVersion` and all subkeys.

Implementing SSL authentication

Use SSL authentication to enhance security in your integration node environment.

About this task

The following topics contain instructions for implementing SSL authentication:

- "Setting up a public key infrastructure" on page 2635
- "Authorization by using SSL Client Certificates" on page 2643
- "Securing a REST API by using HTTPS" on page 2041
- "Securing message flows by using SSL" on page 2615
- "Securing integration services by using SSL" on page 2627

Setting up a public key infrastructure

Configure keystores, truststores, passwords, and certificates to enable SSL communication, and web services security.

Before you begin

- For an overview of encryption and public key infrastructure (PKI), see "Public key cryptography" on page 2492.
- Make sure you understand the purpose of certificates, keystores, and truststores; see "Digital certificates" on page 2493.
- Decide how you want to use the PKI. You can configure keystores and truststores at the following levels:
  - Integration node level (one keystore, and one truststore for each integration node).
  - Integration node listener level (one keystore and one truststore for each listener in an integration node). Integration node listeners that do not have a PKI configured use the integration node level PKI configuration.
  - Integration server level (one keystore and one truststore for each integration server). For integration servers under an integration node, if a PKI is not configured at the integration server level, the integration node level PKI configuration is used.
  - Integration server listener level (one keystore and one truststore for each listener in an integration server). Integration server listeners that do not have a PKI configured use the integration server level

PKI configuration. For integration servers under an integration node, if a PKI is not configured at either the integration server listener level or the integration server level, the integration node level PKI configuration is used.

Encryption strength

The IBM App Connect Enterprise Java runtime environment (JRE) is provided with strong but limited strength encryption. If you cannot import keys into keystores, limited strength encryption might be the cause. Either start ikeyman by using the **strmqikm** command, or download unrestricted jurisdiction policy files from IBM developer kits: Security information.

Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before you download or use the unrestricted policy files, you must check the laws of your country. Check its regulations and its policies on the import, possession, use, and re-export of encryption software, to determine whether it is permitted. Note that when you apply a fix pack to an existing IBM App Connect Enterprise installation, the JVM is overwritten, including any updated policy set files. These policy set files must be restored before you restart the integration node.

IBM App Connect Enterprise currently supports up to 4096 bit keys. Larger keys require more CPU resources for encryption and decryption.

About this task

This topic uses the command line tool **gsk8capicmd_64** to create and populate keystores and truststores. The **gsk8capicmd_64** tool is a part of the Global Secure Toolkit, supplied with IBM MQ and located in the `gskit8\bin` subdirectory of the IBM MQ installation directory. For example, on Windows the **gsk8capicmd_64** tool is in the `C:\Program Files\IBM\MQ\gskit8\bin` directory.

The IBM App Connect Enterprise JVM also supplies other options, for example:

- A command-line tool, **keytool**.
- A graphical tool, **iKeyman**.

To create the infrastructure, complete the following tasks:

1. "Creating a keystore file or a truststore" on page 2636
2. Either "Creating a self-signed certificate for test use" on page 2637 or "Importing a certificate for production use" on page 2637
3. "Viewing details of a certificate" on page 2638
4. "Extracting a certificate" on page 2638
5. "Adding a signer certificate to the truststore" on page 2639
6. "Listing all certificates in a keystore" on page 2640
7. "Configuring PKI at integration node level" on page 2640
8. "Configuring PKI for the integration node HTTP listener" on page 2641
9. "Configuring PKI at an integration server level" on page 2642

Creating a keystore file or a truststore

The keystore file contains the personal certificate for the integration node or for the integration server. You can have only one personal certificate in the keystore. You can store signer certificates in the same file, or create a separate file, which is known as a truststore.

Procedure

1. Set the PATH environment variable to point to the GSKit library directory.
   For example,

```
set PATH=C:\Program Files\IBM\MQ\gskit8\bin;C:\Program Files\IBM\MQ\gskit8\lib;%PATH%
```

2. Issue the following command:

```
gsk8capicmd_64 -keydb -create
  -db keystore_name
  [-pw password]
  -type jks
```

The *password* argument is optional. If you omit it, you are prompted to enter a password.

For example:

```
gsk8capicmd_64 -keydb -create
  -db myBrokerKeystore.jks
  -type jks
A password is required to access this key database.
Please enter a password:
```

Creating a self-signed certificate for test use

Use self-signed certificates only for testing SSL, not in production.

Procedure

Enter the following command:

```
gsk8capicmd_64 -cert -create
  -db keystore_name
  [-pw password]
  -label cert_label
  -dn "distinguished_name"
```

For example:

```
gsk8capicmd_64 -cert -create
  -db myBrokerKeystore.jks
  -label MyCert
  -dn "CN=MyBroker.Server,O=IBM,OU=ISSW,L=Hursley,C=GB"
A password is required to access this key database.
Please enter a password:
```

Importing a certificate for production use

Import a personal certificate from a certificate authority for production use.

Procedure

Issue the following command:

```
gsk8capicmd_64 -cert -import
  -db pkcs12_file_name
  [-pw pkcs12_password]
  -label label
  -type pkcs12
  -target keystore_name
  [-target_pw keystore_password]
```

If you are going to use the keystore for inbound https connections, then ensure that you always specify a **target_pw**, and that it matches the password required to access the key database (keystore).

For example:

```
gsk8capicmd_64 -cert -import
  -db SOAPListenerCertificate.p12
  -label soaplistener
  -type pkcs12
  -target myBrokerKeystore.jks
  -target_pw  myBrokerKpass
A password is required to access this key database.
Please enter a password:
```

Viewing details of a certificate

View details of a certificate to verify that they are correct and appropriate for your needs.

Procedure

Issue the following command:

```
gsk8capicmd_64 -cert -details
  -db keystore_name
  [-pw password]
  -label label
```

For example:

```
gsk8capicmd_64 -cert -details
  -db myKeyStore.jks
  -label MyCert
A password is required to access this key database.
Please enter a password:

Label: MyCert
Key Size: 1024
Version: X509 V3
Serial Number: 4A D7 39 1F
Issued By: MyBroker.Server
ISSW
IBM
Hursley, GB
Subject: MyBroker.Server
ISSW
IBM
Hursley, GB
Valid From: 15 October 2018 16:00:47 o'clock BST To: 15 October 2020 16:00:47 o'
clock BST
Fingerprint: 98:5D:C4:70:A0:28:84:72:FB:F6:3A:D2:D2:F5:EE:8D:30:33:87:82
Signature Algorithm: 1.2.840.113549.1.1.4
Trust Status: enabled
```

Extracting a certificate

Generate a copy of a self-signed certificate that you can import as a trusted (or signer certificate) into a truststore file. Use this procedure only for testing, not production.

About this task

Certificates can be extracted in two formats:

- Base64-encoded ASCII data (`.arm`). This format is convenient for inclusion in XML messages, and transmission over the Internet.
- Binary DER data (`.der`).

Procedure

Issue the following command:

```
gsk8capicmd_64 -cert -extract
  -db keystore_name
  -pw keystore_passwd
  -label label
  -target file_name
  [-format ascii | binary]
```

For example:

```
gsk8capicmd_64 -cert -extract
  -db myBrokerKeystore.jks
  -pw myKeyPass
  -label MyCert
  -target MyCert.arm
  -format ascii
```

You can then view the certificate in a text editor, such as Notepad:

```
notepad MyCert.arm
-----BEGIN CERTIFICATE-----

-----END CERTIFICATE-----
```

Adding a signer certificate to the truststore

Add a signer certificate to the truststore of an integration node or integration server.

About this task

The following steps show how to add an extracted certificate as signer certificate to the truststore file. Adding the integration node self-signed certificate to an integration node or integration server truststore enables request nodes (HTTP or SOAP) to send test messages to input nodes (HTTP or SOAP) when the flows are running on the integration node or integration server.

Procedure

Issue the following command:

```
gsk8capicmd_64 -cert -add
  -db truststore_name
  [-pw password]
  -label label
  -file file_name
  -format [ascii | binary]
```

For example:

```
gsk8capicmd_64 -cert -add
  -db myBrokerTruststore.jks
  -label CACert
  -file TRUSTEDPublicCerticate.arm
  -format ascii
```

You can view details of the certificate:

```
gsk8capicmd_64 -cert -details -db myBrokerTruststore.jks -label CACert
A password is required to access this key database.
Please enter a password:

Label: CACert
Key Size: 1024
Version: X509 V3
Serial Number: 49 49 23 1B
Issued By: VSR1BK
ISSW
IBM
GB
Subject: VSR1BK
ISSW
IBM
GB
Valid From: 17 December 2008 16:04:43 o'clock GMT To: 17 December 2009 16:04:43
o'clock GMT
Fingerprint: CB:39:E7:D8:1D:C0:00:A1:3D:B1:97:69:7A:A7:77:19:6D:09:C2:A7
Signature Algorithm: 1.2.840.113549.1.1.4
Trust Status: enabled
```

Listing all certificates in a keystore

Procedure

Issue the following command:

```
gsk8capicmd_64 -cert -list
  -db keystore_name
```

For example:

```
gsk8capicmd_64 -cert -list
  -db myBrokerKeystore.jks
A password is required to access this key database.
Please enter a password:

Certificates in database: myBrokerKeystore.jks

Configuring PKI at integration node level

Define the integration node registry properties that identify the location, name, and password of the keystore and truststore files.

About this task

These settings are used as the default settings for the integration node HTTP listener and all embedded HTTP listeners in integration servers on the integration node. These settings can be overridden for the integration node HTTP listener (see “Configuring PKI for the integration node HTTP listener” on page 2641) and for individual embedded HTTP listeners (see “Configuring PKI at an integration server level” on page 2642).

1. Start the integration node:

   ```
   mqsistart integrationNodeName
   ```

2. Display the current settings of the integration node registry properties:

   ```
   mqsireportproperties integrationNodeName
     -o BrokerRegistry
     -r
   ```

3. Set the keystore property:

   ```
   mqsichangeproperties integrationNodeName
     -o BrokerRegistry
   ```

```
  -n brokerKeystoreFile
  -v install_dir\MyBrokerKeystore.jks
```

4. Set the truststore property:

```
mqsichangeproperties integrationNodeName
  -o BrokerRegistry
  -n brokerTruststoreFile
  -v install_dir\MyBrokerTruststore.jks
```

5. Stop the integration node:

```
mqsistop integrationNodeName
```

6. Set the password for the keystore:

```
mqsisetdbparms integrationNodeName
  -n brokerKeystore::password
  -u ignore
  -p keystore_pass
```

7. Set the password for the truststore:

```
mqsisetdbparms integrationNodeName
  -n brokerTruststore::password
  -u ignore
  -p truststore_pass
```

8. Start the integration node:

```
mqsistart integrationNodeName
```

9. Display and verify the integration node registry properties:

```
mqsireportproperties integrationNodeName
  -o BrokerRegistry
  -r
```

Configuring PKI for the integration node HTTP listener

Define the properties for the integration node HTTP listener to identify the location, name, and password of the keystore and truststore files.

About this task

These settings override any PKI configuration that is set at the integration node level. If you enable SSL on the integration node HTTP listener but do not set the following properties, then the integration node-level settings are applied, see “Configuring PKI at integration node level” on page 2640.

1. Start the integration node.

```
mqsistart integrationNodeName
```

2. Display the current settings of the integration node listener properties.

```
mqsireportproperties integrationNodeName
  -b NodeHttpListener
  -o HTTPSConnector
  -a
```

3. Set the keystore property.

```
mqsichangeproperties integrationNodeName
  -b NodeHttpListener
  -o HTTPSConnector
  -n keystoreFile
  -v install_dir\MyBrokerKeystore.jks
```

4. Set the truststore property.

```
mqsichangeproperties integrationNodeName
  -b NodeHttpListener
  -o HTTPSConnector
  -n truststoreFile
  -v install_dir\MyBrokerTruststore.jks
```

5. Set the password for the keystore.

```
mqsichangeproperties integrationNodeName
  -b NodeHttpListener
  -o HTTPSConnector
  -n keystorePass
  -v keystore_pass
```

6. Set the password for the truststore.

```
mqsichangeproperties integrationNodeName
  -b NodeHttpListener
  -o HTTPSConnector
  -n TruststorePassword
  -v truststore_pass
```

7. Display and verify the integration node listener properties.

```
mqsireportproperties integrationNodeName
  -b NodeHttpListener
  -o HTTPSConnector
  -a
```

Configuring PKI at an integration server level

Define the properties for the integration server HTTP listener to identify the location, name, and password of the keystore and truststore files.

About this task

These settings override any PKI configuration that is set at the integration node level.

If you enable SSL for the integration server HTTP listener but do not set the following properties, then the integration node-level settings are applied, see “Configuring PKI at integration node level” on page 2640.

1. Start the integration node.

```
mqsistart integrationNodeName
```

2. Display the current settings of the ComIbmJVMManager properties.

```
mqsireportproperties integrationNodeName
  -e exec_grp_name
  -o ComIbmJVMManager
  -r
```

3. Set the keystore property.

```
mqsichangeproperties integrationNodeName
  -e exec_grp_name
  -o ComIbmJVMManager
  -n keystoreFile
  -v install_dir\MyExecGrpKeystore.jks
```

4. Set the keystore password key property. The value for this property is in the format *any_prefix_name*`::password`. This value is used to correlate the password that is defined in the **mqsisetdbparms** command.

```
mqsichangeproperties integrationNodeName
  -e exec_grp_name
  -o ComIbmJVMManager
  -n keystorePass
  -v brokerKeystore::password
```

5. Set the truststore property.

```
mqsichangeproperties integrationNodeName
  -e exec_grp_name
  -o ComIbmJVMManager
  -n truststoreFile
  -v install_dir\MyExecGrpTruststore.jks
```

6. Set the truststore password key property. The value for this property is in the format *any_prefix_name*::password. This value is used to correlate the password that is defined in the **mqsisetdbparms** command.

```
mqsichangeproperties integrationNodeName
  -e exec_grp_name
  -o ComIbmJVMManager
  -n truststorePass
  -v brokerTruststore::password
```

7. Stop the integration node.

```
mqsistop integrationNodeName
```

8. Set the password for the keystore.

```
mqsisetdbparms integrationNodeName
  -n brokerKeystore::password
  -u ignore
  -p keystore_pass
```

9. Set the password for the truststore.

```
mqsisetdbparms integrationNodeName
  -n brokerTruststore::password
  -u ignore
  -p truststore_pass
```

10. Start the integration node.

```
mqsistart integrationNodeName
```

11. Display and verify the ComIbmJVMManager properties.

```
mqsireportproperties integrationNodeName
  -e exec_grp_name
  -o ComIbmJVMManager
  -r
```

For information about cipher-suite requirements (such as the cryptographic algorithm and corresponding key lengths), see the Java Secure Socket Extension (JSSE) IBMJSSE2 Provider reference guide.

Authorization by using SSL Client Certificates

Client authentication data for SSL X509 certificates can be propagated into the local environment and used for authorization.

When you implement a message flow to use SSL authentication, you can check authenticated client certificates for authorization. When a security profile is configured for authorization and set on the input node, the data is passed to a security manager. An integration node security manager receives relevant parts of the certificate for authorization and sends it to the properties parser. During authentication, data from the identity or security token that is provided replaces the values in the properties tree identity fields. This data can be from a Basic-Auth transport header or a WS-Security token, for example. Parameter data in the certificate replaces fields in the properties tree. The following fields are reset with new data:

- The **IdentitySourceType** is set to the user name.
- The **IdentitySourceToken** is set to the subject name of the client certificate.
- The **IdentitySourceIssuedBy** is set to the issuer name of the client certificate.

When you use the SOAPInput, HTTPInput, SCAInput, or TCPIPServerInput nodes, properties tree fields contain the information from the client certificate. Propagation is not automatically enabled but when it is enabled, a certificate is processed throughout the message flow and propagated for output or request nodes. By populating the local environment, the certificate data becomes available to the rest of the message flow.

A higher level of authentication (such as Basic-Auth or WS-Security) can overwrite the properties tree. Because of missing properties tree data, you are unable to authorize the client at the input node. However, you can use a SecurityPEP node to locate authentication (or other certificate) fields in the local environment to do the authorization. You can locate client certificates by using the local variable `LocalEnvironment.`*`input_node_name`*`.Input.TransportSecurity.ClientAuth.Certificate`, where *input_node_name* is one of SOAP, HTTP, or TCPIP.

Different nodes access the client certificate in different ways:

- Use a SecurityPEP node for authorization of the **`subject`** field in a client certificate that is received by a SOAPInput node. Specify the following XPath in the `identity token location` property on a SecurityPEP node:

  ```
  $LocalEnvironment/SOAP/Input/TransportSecurity/ClientAuth/Certificate/Subject
  ```

  For more information about the SecurityPEP node, see node.
- Use a JavaCompute node to retrieve the **`issuer`** field in a client certificate that is received by an HTTPInput node.

  ```
  String clientCertSubject = localEnv.getFirstElementByPath("HTTP/Input/TransportSecurity/
  ClientAuth/Certificate/Issuer").getValueAsString();
  ```

  For more information about the JavaCompute node, see node.
- Use a Compute node to set the **`subject`** field of a certificate that is received by a TCPIPServerInput node.

  ```
  SET LocalEnvironment.TCPIP.Input.TransportSecurity.ClientAuth.Certificate.Subject =
   'BROKERUSER';
  ```

  For more information about the Compute node, see node.

SSL cipher suites

A cipher suite is a collection of algorithms that are used to encrypt data.

During SSL authentication, the client and server compare cipher suites and select the first one that they have in common. If no suitable cipher suites exist, the server returns a handshake failure alert and closes the connection.

To use SSL encryption, you need a Java Secure Socket Extension (JSSE) provider. IBM App Connect Enterprise supports the ciphers that are provided by the JSSE provider. For more information about Java security, see IBM Java security web page.

For a list of all the cipher suites that are supported by IBM App Connect Enterprise, see Appendix A of the IBM JSSE2 Guide.

SSL and Kerberos support for SQL server for Linux and UNIX clients

Connecting Microsoft SQL Server with SSL protection and Kerberos authentication to propagate user ID without the need to reenter the password multiple times.

Secure Sockets Layers (SSL) is a standard that provides confidentiality and integrity to a TCP/IP transport, such as the one that the ODBC driver uses to communicate with an SQL Server instance.

Kerberos is a protocol that is devised by MIT to allow resources to be secured through a trusted third party (The Kerberos KDC). When the protocol is implemented by Microsoft, it can be used only to secure access within a complete active directory domain.

The tasks in the following topics configure the product so that at runtime IBM App Connect Enterprise completes the following actions:

1. Connects to the directory server
2. Retrieves the TGT (Ticket-Granting Ticket)
3. Store the TGT in the credential cache
4. Update the environment to point to the credential cache
5. Pass control to the DataDirect driver

These tasks require the following things:

- A Linux or UNIX client machine
- An Active Directory server
- An SQL server

Configuring IBM App Connect Enterprise to connect to SQL server: Part 1

The following task demonstrates the initial setup of the `odbc.ini` and `krb5.conf` files.

About this task

These tasks are required to connect your IBM App Connect Enterprise machine to SQL server without using SSL. There are some initial tasks to configure the `odbc.ini` and `krb5.conf` files before you begin:

Procedure

1. Configure the Linux or UNIX client machine to connect to the SQL server by adding the following entry to your `odbc.ini` file:

```
[TESTDB]
Driver=/opt/IBM/mqsi/11.0.0.n/server/ODBC/drivers/lib/UKsqls95.so
Description=DataDirect SQL Server Wire Protocol
Database=TESTDB
HostName=sqlserver.domain.company.com
PortNumber=1433
AnsiNPW=1
LoginTimeout=0
QueryTimeout=0
;# To specify a named instance of SQLServer replace the HostName and PortNumber lines with
;#HostName=sqlserver.domain.company.com\named_instance
;# To use Integrated Windows Authentication uncomment the following lines.
;#AuthenticationMethod=9
;#Domain=domain.company.com
```

   In this example:

   - *TESTDB* is the name of a database.
   - *sqlserver.domain.company.com* is the address of your SQL server.
   - *1433* is the port number of your SQL server.

     To use a named instance instead of a port number, comment out the `PortNumber` property and change `HostName` to `HostName=sqlserver.domain.company.com\named_instance`

   If your SQL server host uses Integrated Windows Authentication, uncomment and configure the final 2 lines in the example.
2. If you have not already done so, join the SQL server host machine to the Windows Active Directory domain.
3. Create a sample message flow that connects to the database and set up the **mqsisetdbparms** parameters and associated permissions in the SQL server as you would a normal ODBC connection. Now test that this initial setup works correctly.

What to do next

Now that these initial steps are complete, you must re-edit the odbc.ini as described in the next task.

Configuring IBM App Connect Enterprise to connect to SQL server with Kerberos: Part 2

The following task demonstrates the next steps in enabling Kerberos support for SQL server.

Before you begin

You must complete the steps in the previous task: "Configuring IBM App Connect Enterprise to connect to SQL server: Part 1" on page 2645

About this task

Now that the initial steps are complete, you must re-edit the odbc.ini file, and begin that next set of steps:

Procedure

1. Update the previous entry that you made to the odbc.ini file with the following changes:

```
[TESTDB]
Driver=/opt/IBM/mqsi/11.0.0.n/server/ODBC/drivers/lib/UKsqls95.so
Description=DataDirect SQL Server Wire Protocol
Database=TESTDB
HostName=sqlserver.ad.domain.company.com
PortNumber=1433
AnsiNPW=1
LoginTimeout=0
QueryTimeout=0
AuthenticationMethod=4
GSSClient=libgssapi_krb5.so
```

   In this example:

   - *TESTDB* is the name of a database.
   - *sqlserver.ad.domain.company.com* is the address of your SQL server in the Active Directory domain.
   - *1433* is the port number of your SQL server.
   - *libgssapi_krb5.so* is an existing Kerberos implementation on the system that is present and available through the library path. On AIX, use the following format: *GSSClient=libgssapi_krb5.a(libgssapi_krb5.a.so)*

2. Update the Kerberos configuration file, krb5.conf, on the Linux or UNIX machine.

   You can typically find the file in /etc or /etc/krb5. Add the following entries to the configuration file:

```
[libdefaults]
  default_realm = AD.DOMAIN.COMPANY.COM
  default_tkt_enctypes = rc4-hmac
  default_tgs_enctypes = rc4-hmac

[realms]
  AD.DOMAIN.COMPANY.COM = {
    kdc = adserver.ad.domain.company.com:88
    default_domain = ad.domain.company.com
  }

[domain_realm]
  .domain.company.com = AD.DOMAIN.COMPANY.COM
```

   where the Kerberos realm is your Active Directory domain name, which you must specify in upper case. kdc=adserver.ad.domain.company.com is the name of your host that you are running the Key Distribution Center for the Kerberos realm.

3. Use the **kinit** *username* command, where *username* is the user name that will be used to connect to the SQL server, to test that the krb5.conf file is set up to acquire a Ticket Granting Ticket for the user name.

4. Ensure that a Service Principal Name (SPN) for the SQL Server service is registered in the Active Directory.

   On starting, the SQL Service database engine normally attempts to register an SPN but if the SPN has not already been registered, issue the **setspn** command on the Active Directory, as in the following example:

   ```
   setspn -S MSSQLSvc/sqlserver.ad.domain.company.com:1433 windowsDomain\accountName
   ```

   where `sqlserver.ad.domain.company.com:1433` is the address and port number of your SQL server.
5. Open SQL Server Management Studio, and grant SQL Server login permission to the domain user on the server and on the database that you specified in the `odbc.ini` file in a previous step.
6. Run the following commands in a broker console on the Linux or UNIX client machine:

   ```
   mqsisetdbparms ACENODE -n odbc::TESTDB -u kerberos::username@AD.DOMAIN.COMPANY.COM -p
    N0chang3
   mqsichangeproperties ACENODE -e integration_server -o ComIbmJVMMangaer -n kerberosConfigFile
    -v /location_of_krb_config_file/krb.conf
   ```

   where *username* is the domain user, and *AD.DOMAIN.COMPANY.COM* is the address of your Kerberos realm.
7. Run the flow from "Configuring IBM App Connect Enterprise to connect to SQL server: Part 1" on page 2645 again. The broker now connects to SQL Server using the Kerberos ticket.

What to do next

Now that these steps are complete, you must continue to the next task as an administrator on your SQL Server machine.

Configuring IBM App Connect Enterprise to connect to SQL Server with Kerberos and SSL support: Part 3

The following task demonstrates the next steps in enabling SSL support for SQL server.

Before you begin

You must complete the steps in the previous tasks: "Configuring IBM App Connect Enterprise to connect to SQL server: Part 1" on page 2645 and "Configuring IBM App Connect Enterprise to connect to SQL server with Kerberos: Part 2" on page 2646. You must have administrator privileges on your SQL server machine.

About this task

Now that the initial steps are complete, you must log in as an administrator on your SQL Server machine to complete that next set of steps.

The following set of certificates are needed:

1. A certificate for the SQL Server.
2. A certificate for IBM App Connect Enterprise

Note: These certificates cannot be self-signed certificates, they must be issued by a trusted authority. Create a temporary certificate authority for development purposes if necessary, using openssl or lightweight CA software. You must ensure that the certificates match the machine names.

Complete the following steps.

Procedure

1. Open the Microsoft Management Console as an administrator on your SQL server machine.
2. Go to **File** > **Add/Remove snap in** and select **Certificates** > **Computer Account** > **Local Computer**.

3. Optional: (Complete this step only if you are using a local certificate authority). Expand the **Trusted Root Certification Authorities** folder.
4. Optional: (Complete this step only if you are using a local certificate authority). Right-click the open folder and select **All Tasks** > **import**. Browse and select your certificate authority root certificate `cacert.pem`, and import it to `Trusted Root Certification Authorities`.
5. Expand the **Personal** folder.
6. Right-click the open folder and select **All Tasks** > **import**. Browse and select the private key and certificate for the server as provided by the certificate authority , and import it to `Personal`.
7. Right-click on the newly imported *`sqlserver.domain.company.com`* certificate, and select **All Tasks** > **Manage Private Keys**
8. Open the SQL Server Configuration Manager, and select **SQL Server Services**.
9. Double-click the **SQL Server** entry and copy the **`Account Name`**.
10. Switch back to the Microsoft Management Console **Certificates** dialog and complete the following steps:and add the **`Account Name`** that you copied in the previous step, and search on the local machine.
    a) Click **Add**.
    b) Paste the **`Account Name`** that you copied in step "9" on page 2648
    c) Click **Check Names**.
    d) Click **OK**.
    e) Enable the account **Full Control** on the private keys.
    f) Click **OK**.
11. Switch back to the SQL Server Configuration Manager, and expand **SQL Server and Network Configuration.**
12. Right-click **Protocols for *SQLServer*** where *SQLServer* is the name you have used throughout these tasks, and select **Properties**.
    Open the **Certificate** tab.
13. Select the imported certificate from the drop-down box.
14. Select the **Flags** tab, and set **Force Encryption** to `Yes`.
15. Restart the SQL Server from the **SQL Services** window.
16. Update the odbc `.ini` file again to add the following configuration:

```
EncryptionMethod=1
TrustStore=/path/to/certificates/cacert.pem
```

17. Rerun the test application.

Security for the IBM App Connect Enterprise Toolkit

What to consider when you set up security for the IBM App Connect Enterprise Toolkit.

If administration security is enabled for a local integration node, the user ID that is used to run the IBM App Connect Enterprise Toolkit is passed to the integration node and used for authorization. For a remote integration node, the connection must be made using a web user ID, which is assigned to a role. For more information, see "Managing web user accounts" on page 2510.

If a user ID is a member of the group mqbrkrs, it has full permissions to act on all resources; for more information, see "Permissions for administrators" on page 2522. For information about authorizations for administration applications, see Tasks and authorizations for administration security.

Routing requests through an HTTP proxy server that has authentication enabled

You can send requests through an HTTP proxy server that requires authentication, by using the **mqsisetdbparms** command to specify credentials on the `httpproxy::` resource name.

About this task

You can configure the following message flow nodes to route requests through an HTTP proxy server, by setting the **HTTP(S) proxy location** parameter:

- HTTPAsyncRequest
- HTTPRequest
- RESTAsyncRequest
- RESTRequest
- SalesforceRequest
- SOAPAsyncRequest
- SOAPRequest

If the HTTP proxy server requires authentication, you can provide the user name and password by specifying the `httpproxy::` resource name through the **mqsisetdbparms** command.

Note: A message flow can provide the proxy authentication user name and password through the `ProxyConnectHeaders` property in the local environment for HTTPS requests, or the `Proxy-Authorization` header for HTTP requests. If these are present in the flow, they take precedence over values set by the **mqsisetdbparms** command; this applies to the HTTP, REST, and SOAP nodes listed above, but not to the SalesforceRequest node.

Procedure

Follow these steps to enable a message flow node to route requests through an HTTP proxy server:

1. Specify the URL of the proxy server in the **HTTP(S) proxy location** parameter of the node.
2. If the HTTP proxy server requires authentication through a user name and password, use the **mqsisetdbparms** command to provide these credentials on the `httpproxy::` resource name.

   You can set the resource name to apply to either an HTTP proxy with a specified host name, in the form `httpproxy::`*`proxy_hostname`*, or to any HTTP proxy, by specifying `httpproxy::HTTPPROXY`. If you set the resource name to apply to specific HTTP proxy server, the *proxy_hostname* must match the hostname of the configured proxy, without the port.

   For example, use the following command to associate a user name and password with a connection to a specified HTTP proxy server (in this example, *myProxyHostname*):

   ```
   mqsisetdbparms -w c:\workdir\ACEServ1 -n httpproxy::myProxyHostname -u myUserID -p myPassword
   ```

   Alternatively, use the following command to specify the credentials to be used as a default, for connecting to any HTTP proxy server that does not have a matching host name:

   ```
   mqsisetdbparms -w c:\workdir\ACEServ1 -n httpproxy::HTTPPROXY -u myProxyUsername -p
    myProxyPassword
   ```

3. If you add or modify the credentials by using the **mqsisetdbparms** command, you must restart the integration server for the changes to take effect.

   For more information, see command.

WS-Security

Web Services Security (WS-Security) describes enhancements to SOAP messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. WS-Security mechanisms can be used to accommodate a wide variety of security models and encryption technologies.

WS-Security is a message-level standard that is based on securing SOAP messages through XML digital signature, confidentiality through XML encryption, and credential propagation through security tokens. The web services security specification defines the facilities for protecting the integrity and confidentiality of a message and provides mechanisms for associating security-related claims with the message.

WS-Security provides a general-purpose mechanism for associating security tokens with messages. No specific type of security token is required by WS-Security. It is designed to be extensible, for example, to support multiple security token formats.

WS-Security also describes how to encode binary security tokens and attach them to SOAP messages. Specifically, the WS-Security profile specifications describe how to encode the following tokens:

- Username tokens
- X.509 certificates
- SAML assertions
- Kerberos tickets
- LTPA binary tokens

With WS-Security, the domain of these mechanisms can be extended by carrying authentication information in web services requests. WS-Security also includes extensibility mechanisms that can be used to further describe the credentials that are included with a message. WS-Security is a building block that can be used in conjunction with other web service protocols to address a wide variety of application security requirements.

There are numerous advantages to using WS-Security.

- Different parts of a message can be secured in a variety of ways. For example, you can use integrity on the security token (user ID and password) and confidentiality on the SOAP message body.
- Intermediaries can be used and end-to-end message-level security can be provided through any number of intermediaries.
- WS-Security works across multiple transports and is independent of the underlying transport protocol.
- Authentication of both individual users and multiple party identities is possible.

Traditional Web security mechanisms, such as HTTPS, might be insufficient to manage the security requirements of all web service scenarios. For example, when an application sends a SOAP message using HTTPS, the message is secured only for the HTTPS connection, meaning during the transport of the message between the service requester (the client) and the service. However, the application might require that the message data be secured beyond the HTTPS connection, or even beyond the transport layer. By securing web services at the message level, message-level security is capable of meeting these expanded requirements.

Message-level security, or securing web services at the message level, addresses the same security requirements as for traditional Web security. These security requirements include: identity, authentication, authorization, integrity, confidentiality, nonrepudiation, and basic message exchange. Both traditional Web and message-level security share many of the same mechanisms for handling security, including digital certificates, encryption, and digital signatures.

With message-level security, the SOAP message itself either contains the information needed to secure the message or it contains information about where to get that information to handle security needs. The SOAP message also contains information relevant to the protocols and procedures for processing the specified message-level security. However, message-level security is not tied to any particular transport mechanism. Because the security information is part of the message, it is independent of a transport protocol, such as HTTPS.

The client adds to the SOAP message header security information that applies to that particular message. When the message is received, the web service endpoint, using the security information in the header, verifies the secured message and validates it against the policy. For example, the service endpoint might verify the message signature and check that the message has not been tampered with. It is possible to add signature and encryption information to the SOAP message headers, as well as other information such as security tokens for identity (for example, an X.509 certificate) that are bound to the SOAP message content.

Without message-level security, the SOAP message is sent in clear text, and personal information such as a user ID or an account number is not protected. Without applying message-level security, there is only a SOAP body under the SOAP envelope in the SOAP message. By applying features from the WS-Security specification, the SOAP security header is inserted under the SOAP envelope in the SOAP message when the SOAP body is signed and encrypted.

To keep the integrity or confidentiality of the message, digital signatures and encryption are typically applied.

- Confidentiality specifies the confidentiality constraints that are applied to generated messages. This includes specifying which message parts within the generated message must be encrypted, and the message parts to attach encrypted Nonce and time stamp elements to.
- Integrity is provided by applying a digital signature to a SOAP message. Confidentiality is applied by SOAP message encryption.

You can add an authentication mechanism by inserting various types of security tokens, such as the Username token (element). When the Username token is received by the web service server, the user name and password are extracted and verified. Only when the user name and password combination is valid, will the message be accepted and processed at the server. Using the Username token is just one of the ways of implementing authentication. This mechanism is also known as basic authentication.

The OASIS Web Services Security Specification provides a set of mechanisms to help developers of web services secure SOAP message exchanges. For details of the OASIS Web Services Security Specification, see OASIS Standard for WS-Security Specification.

WS-Security mechanisms

The WS-Security specification provides three mechanisms for securing web services at the message level: authentication, integrity, and confidentiality.

Authentication

This mechanism uses a security token to validate the user and determine whether a client is valid in a particular context. A client can be a user, computer, or application. Without authentication, an attacker can use spoofing techniques to send a modified SOAP message to the service provider.

In authentication, a security token is inserted in the request message. Depending on the type of security token that is being used, the security token can also be inserted in the response message. The following types of security token are supported for authentication:

- Username tokens
- X.509 certificates
- SAML assertions
- Kerberos tickets
- LTPA binary tokens

Username tokens are used to validate user names and passwords. When a web service server receives a username token, the user name and password are extracted and passed to a user registry for verification. If the user name and password combination is valid, the result is returned to the server and the message is accepted and processed. When used in authentication, username tokens are typically passed only in the request message, not the response message.

X.509 tokens are validated by using a certificate path.

The integration node support for SAML assertions is restricted to passing the token to a WS-Trust Security Token Service (STS) for validation.

Kerberos tickets are validated against the host's Kerberos `keytab` file.

The integration node support for LTPA binary tokens is restricted to passing the token to a WS-Trust STS for validation.

All types of token must be protected. For this reason, if you send them over an untrusted network, take one of the following precautions:

- Use HTTPS
- Configure the policy set to protect the appropriate elements in the SOAP header

Integrity

This mechanism uses message signing to ensure that information is not changed, altered, or lost accidentally. When integrity is implemented, an XML digital signature is generated on the contents of a SOAP message. If unauthorized changes are made to the message data, the signature is not validated. Without integrity, an attacker can use tampering techniques to intercept a SOAP message between the web service client and server, and modify it.

Confidentiality

This mechanism uses message encryption to ensure that no party or process can access or disclose the information in the message. When a SOAP message is encrypted, only a service that knows the appropriate key can decrypt and read the message.

Implementing WS-Security

Configure authentication, XML encryption, XML signature, and message expiration by using the WS Policy Sets and Bindings editor.

About this task

You use the WS Policy Sets and Bindings editor in the IBM App Connect Enterprise Toolkit to configure the following aspects of WS-Security:

"Authentication" on page 2652
"Confidentiality" on page 2654
"Integrity" on page 2655
"Expiration" on page 2655

Authentication

About this task

The following tokens are supported:

- Username
- X.509
- SAML assertions
- Kerberos tickets
- LTPA binary tokens

Configuring authentication with username tokens:

1. In the IBM App Connect Enterprise Toolkit, create a policy project by clicking **File** > **New** > **Policy Project**.

2. In the Application Development view, right-click the policy project, then click **New** > **WS Policy Sets and Bindings**. The WS Policy Sets and Bindings editor opens.
3. Click **Add** to create a policy set.
4. Select the new policy in the tree view, then click **Add WS-Security** to add the policy type to the policy set.
5. Expand the WS-Security policy type in the tree view, click **Authentication Tokens**, then click **Add** to add UserName authentication tokens to the policy (see Policy Sets and Policy Set Bindings editor: Authentication tokens panel).
6. Repeat the previous step to configure X.509 authentication tokens (see Policy Sets and Policy Set Bindings editor: Authentication and Protection Tokens panel).
7. Configure a security profile (see “Message flow security and security profiles” on page 2673).
8. Associate the policy set with a message flow or node (see “Associating policy sets and bindings with message flows and nodes” on page 2672).

Configuring authentication with X.509 tokens:

1. If you are using the integration node's truststore to hold the trusted certificate, you must configure it. See “Viewing and setting keystore and truststore runtime properties at integration node level” on page 2667 or “Viewing and setting keystore and truststore runtime properties at integration server level ” on page 2669, depending on where you want to set keystore and truststore runtime properties.
2. Create a policy set (as described in the previous section), then add UserName and X.509 authentication tokens to it.
3. Configure the certificate mode for either integration node truststore or an external security provider (see Policy Sets and Policy Set Bindings editor: Authentication and Protection Tokens panel).
4. If you are using an external security provider, configure a security profile (see “Message flow security and security profiles” on page 2673).
5. Associate the policy set with a message flow or node (see “Associating policy sets and bindings with message flows and nodes” on page 2672).

Configuring authentication with SAML assertions:

1. Create a policy set and add SAML pass-through 1.1 or SAML pass-through 2.0 tokens to it (see Policy Sets and Policy Set Bindings editor: Authentication tokens panel). SAML pass-though does not enforce subject confirmation, but the assertion is simply provided as a token to be processed in the external Security Token Server specified in the security profile that is associated with the node.
2. Configure a security profile. The security profile must be configured to use a WS-Trust v1.3 STS (see “Message flow security and security profiles” on page 2673).
3. Associate the policy set with a message flow or node (see “Associating policy sets and bindings with message flows and nodes” on page 2672).

Configuring authentication with Kerberos tickets:

1. Create a policy set and add your Kerberos token type as symmetric tokens (see Policy Sets and Policy Set Bindings editor: Message Level Protection panel).
2. Associate the policy set with a message flow or node (see “Associating policy sets and bindings with message flows and nodes” on page 2672).
3. Configure the host's Kerberos `keytab` file. For more information about Kerberos configuration, see the documentation for your integration node's host system. For example, for Windows, see the "Step-by-Step Guide to Kerberos 5 (krb5 1.0) Interoperability", which you can access at `http://technet.microsoft.com/en-us/library/`.

Configuring authentication with LTPA binary tokens:

1. Create a policy set and add LTPA tokens to it (see Policy Sets and Policy Set Bindings editor: Authentication tokens panel). The LTPA binary token is passed through to the external Security Token Service (STS) specified in the security profile that is associated with the node.
2. Configure a security profile. The security profile must be configured to use a WS-Trust v1.3 STS (see "Message flow security and security profiles" on page 2673).
3. Associate the policy set with a message flow or node (see "Associating policy sets and bindings with message flows and nodes" on page 2672).

Confidentiality

About this task

Confidentiality is provided by XML encryption, and requires either X.509 tokens or Kerberos tickets.

Configuring XML encryption with X.509 tokens:

1. If you are using the integration node's truststore to hold the trusted certificate, you must configure it. See "Viewing and setting keystore and truststore runtime properties at integration node level" on page 2667 or "Viewing and setting keystore and truststore runtime properties at integration server level " on page 2669, depending on where you want to set keystore and truststore runtime properties.
2. Create a policy set, enable XML encryption, create encryption tokens, and select the encryption algorithms that you will use (see Policy Sets and Policy Set Bindings editor: Message Level Protection panel).
3. Define which parts of a message are to be encrypted (see Policy Sets and Policy Set Bindings editor: Message Part Protection panel).
4. Further configure message part encryption (see Policy Sets and Policy Set Bindings editor: Message Part Policies panel).
5. Further configure the keystore and truststore (see Policy Sets and Policy Set Bindings editor: Key Information panel).
6. Associate the policy set with a message flow or node (see "Associating policy sets and bindings with message flows and nodes" on page 2672).

Configuring XML encryption with Kerberos tickets:

1. Configure your host for Kerberos, providing a `krb.conf` configuration file. This step is required on all operating systems, including Windows.
2. Provide the integration node with the Kerberos client credentials for accessing the Kerberos Key Distribution Center (KDC). These credentials (which are required for SOAPRequest nodes) can be provided in the Integration node properties tree, or by using the **mqsisetdbparms** command. The credentials are taken in order of priority:
   - The node has a security profile with the `Propagation` property set to *True* and the Properties tree UserName and password token is present. If no UserName and password token exists, an exception in thrown.
   - ```
     mqsisetdbparms kerberos::<realm>::<integrationServerName>
     ```
   - ```
     mqsisetdbparms kerberos::<realm>
     ```
   - ```
     mqsisetdbparms kerberos::kerberos
     ```
3. Create a policy set and add the required Kerberos token type as Symmetric Tokens (see Policy Sets and Policy Set Bindings editor: Message Level Protection panel).
     ```

Integrity

About this task

Integrity is provided by XML signature, and requires either X.509 tokens or Kerberos tickets.

Configuring XML signature with X.509 tokens:

1. If you are using the integration node's truststore to hold the trusted certificate, you must configure it. See “Viewing and setting keystore and truststore runtime properties at integration node level” on page 2667 or “Viewing and setting keystore and truststore runtime properties at integration server level ” on page 2669, depending on where you want to set keystore and truststore runtime properties.
2. Create a policy set, enable XML signature, and create signature tokens (see Policy Sets and Policy Set Bindings editor: Message Level Protection panel).
3. Define which parts of a message are to be signed (see Policy Sets and Policy Set Bindings editor: Message Part Protection panel).
4. Further configure message part signature (see Policy Sets and Policy Set Bindings editor: Message Part Policies panel).
5. Further configure the keystore and truststore (see Policy Sets and Policy Set Bindings editor: Key Information panel).
6. Associate the policy set with a message flow or node (see “Associating policy sets and bindings with message flows and nodes” on page 2672).

Configuring XML signature with Kerberos tickets:

1. Configure your host for Kerberos, providing a `krb.conf` configuration file. This step is required on all operating systems, including Windows.
2. Provide the integration node with the Kerberos client credentials for accessing the Kerberos Key Distribution Center (KDC). These credentials (which are required for SOAPRequest nodes) can be provided in the Integration node properties tree, or by using the **mqsisetdbparms** command. The credentials are taken in the following order of priority:
   - The node has a security profile with the `Propagation` property set to *True* and the Properties tree UserName and password token is present. If no UserName and password token exists, an exception in thrown.
   - ```
     mqsisetdbparms kerberos::<realm>::<integrationServerName>
     ```
   - ```
     mqsisetdbparms kerberos::<realm>
     ```
   - ```
     mqsisetdbparms kerberos::kerberos
     ```
3. Create a policy set and add the required Kerberos token type as Symmetric Tokens (see Policy Sets and Policy Set Bindings editor: Message Level Protection panel).

Expiration

Procedure

To configure message expiration, see Policy Sets and Policy Set Bindings editor: Message Expiration panel.

Kerberos-based WS-Security

You can use Kerberos authentication with WS-Security either as a service or as a client.

Kerberos is a network authentication protocol that enables mutual authentication with symmetric keys. Users and services on a network authenticate with each other through a Key Distribution Center (KDC), as
     ```

a trusted third party. IBM App Connect Enterprise provides support for Kerberos either as a service or as a client.

You can use message flows to call web services that are secured with Kerberos by using a SOAP Request node. You can also provide web services that are secured with Kerberos by using SOAP Input Nodes. The WS-Security header passes Kerberos tokens. You can sign and encrypt either parts or all of a SOAP message by using Kerberos tokens. Signing and encrypting messages provides message integrity, confidentiality, and authenticity.

For information about Kerberos terminology and concepts, see Concepts for Kerberos security.

You can configure IBM App Connect Enterprise to act as a Kerberos secured service or as a client to a Kerberos secured service. Install a Kerberos KDC and configure it to contain all the principals that are required by the environment, then configure for a service or client. For more information about configuring Kerberos, see your host Kerberos documentation.

- For the steps needed to embed IBM App Connect Enterprise as a client, see Configuring IBM App Connect Enterprise as a client to a Kerberos secured Service.
- For the steps needed to configure IBM App Connect Enterprise as a secured service, see Configuring IBM App Connect Enterprise as a Kerberos secured Service.
- For the steps needed to configure separate Kerberos configuration files for each integration server, see “Configuring separate Kerberos configuration files for each integration server” on page 2660.

Kerberos security concepts

Learn about Kerberos authentication and WS-Security concepts.

Concepts

Kerberos configuration file
The configuration file contains information that is important for authentication and access. The configuration file contains the key distribution center (KDC) realm and location, supported encryption types, and keytab file location. Clients use the configuration file to authenticate with the KDC and request access to networked services. Kerberos secured services also use the configuration file to locate the keytab file that contains the private key that is associated with it.

Kerberos keytab file
The keytab file contains the principal and encrypted private key that is associated with the principal. The keytab file is created by exporting a principal from the KDC. Using the keytab file, a service can check the authenticity of a client and provide authentication without contacting the KDC.

Key Distribution Center (KDC)
The Key Distribution Center stores user and service principals with their associated key. A combination of either a user name and a password or a service name and a password provide the key. The KDC also provides an authentication server and a server that grants tickets.

Principals
Networked users and Services are known as principals. They authenticate with a Key Distribution Center (KDC).

Realm
The unique range of control that is provided by the KDC. By convention the realm is the DNS domain name that is converted to uppercase.

Service Principal Name (SPN)
The service principal name represents a unique, networked service. For a client to use a Kerberos secured service, the client must authenticate with a KDC and provide the SPN for the service. The ticketing server provides a ticket to the client that allows it to authenticate itself to the service.

Configuring IBM App Connect Enterprise as a client to a Kerberos secured service

You can configure IBM App Connect Enterprise to operate as a client to a Kerberos secured service for message integrity, confidentiality, and authenticity.

Before you begin

You must have access to a Key Distribution Center (KDC) and a server that is hosting the service. For more information about configuring Kerberos, see your host Kerberos documentation.

Procedure

1. Set the user credentials that are used to authenticate with the KDC.

   - You can configure the credentials at the integration node level by issuing a **mqsisetdbparms**. For example,

     ```
     mqsisetdbparms integrationNodeName -n SPN::realm -u username -p password
     ```

   - You can also set the user credentials at the integration server level. For example, you can set a specific realm in any integration server with

     ```
     mqsisetdbparms integrationNodeName -n kerberos::realm1::integrationServerName -u clientId -
     p password
     ```

   - You can also use the Properties tree to set the credentials by using the following ESQL in a compute node:

     ```
     SET OutputRoot.Properties.IdentitySourceType = 'usernameAndPassword';
     SET OutputRoot.Properties.IdentitySourceToken = Username;
     SET OutputRoot.Properties.IdentitySourcePassword = Password;
     ```

2. Create a Kerberos configuration file. The client can authenticate with the KDC, using the configuration file.

   For more information about Kerberos-based WS-Security that is supported in SOAP nodes, see Message flow security and security profiles.

   When you use Kerberos for security, the default Kerberos configuration file is the one on your workstation. The location for the configuration file differs depending on the system. The usual locations are:

   - For Windows - `C:\Windows\krb5.ini` and `C:\WINNT\krb5.ini`
   - For Linux - `/etc/krb5.conf` , UNIX (AIX) `/etc/krb5/krb5.conf`
   - For z/OS - `/krb5/krb5.conf`

   You can configure Kerberos configuration files for use by an integration node or integration server.

   The following sample Kerberos configuration file shows typical values for the variables. The variables *default_realm*, *default_keytab_name*, and the names in the *realms* are among the values you change in the configuration file, depending on your network and location of the configuration file.

   ```
   [libdefaults]
   default_realm = MYREALM.EXAMPLE.COM
   default_keytab_name = FILE:c:\Windows\krb5.keytab
   default_tkt_enctypes = rc4-hmac
   default_tgs_enctypes = rc4-hmac
   dns_lookup_realm = false
   dns_lookup_kdc = false
   ticket_lifetime = 24h
   renew_lifetime = 7d
   forwardable = true
   [realms]
   MYREALM.EXAMPLE.COM = {
   kdc = kdc.myrealm.example.com
   admin_server = kdc.myrealm.example.com
   ```

```
}
```

For example, you can set the variables for an IBM App Connect Enterprise level Kerberos configuration with

```
mqsichangeproperties integrationNodeName -o BrokerRegistry -n brokerKerberosConfigFile -
v kerberosConfigLocation
```

For example, you can set the variables for an integration server level Kerberos configuration with

```
mqsichangeproperties integrationNodeName -e integrationServerName -o ComIbmJVMManager -n
 brokerKerberosConfigFile -v kerberosConfigLocation
```

3. Configure a policy set and binding that is associated with the SOAPRequest node for the BAR containing the message flow.
   - To configure the Kerberos token with a policy set, see Policy Sets and Policy Set Bindings editor: Message Level Protection panel.
   - To configure a consumer message part policy, see Policy Sets and Policy Set Bindings editor: Message Part Protection panel.
   - To optionally sign or encrypt message parts using the policy set, see Policy Sets and Policy Set Bindings editor: Message Part Policies panel.
   - To configure Kerberos specific settings such as target service name and target service realm, see Policy Sets and Policy Set Bindings editor: Message Part Policies panel.

Results

You have configured IBM App Connect Enterprise to operate as a client to a Kerberos secured service.

Configuring IBM App Connect Enterprise as a Kerberos secured service

You can configure IBM App Connect Enterprise to operate as a Kerberos secured service for message integrity, confidentiality, and authenticity.

Before you begin

You must have access to a Key Distribution Center (KDC) and a server that is hosting the Kerberos secured service. For more information about configuring Kerberos, see your host Kerberos documentation.

About this task

Use this task to configure Kerberos as a secured service for IBM App Connect Enterprise.

Procedure

1. Export a keytab that contains the private key of the service principal from the KDC.
   For example:

```
ktpass -out c:\Windows\krb5.keytab -princ SomePrincipal@YourDomain
```

```
  -crypto RC4-HMAC-NT mapUser Username -pass Password -mapOp set
```

where

out *filename*
Specifies the name and path of the keytab file to be generated.

princ *principal_name*
Specifies the principal name.

crypto *encryption_type*
Specifies the encryption type.

mapUser *username*
Maps the name of a Kerberos principal to a local account.

pass *password*
Specifies the password to use for this principal name.

mapOp *attribute*
Defines how the mapping attribute is set. The attribute alternatives are either `add` or `set`.

2. Copy the keytab file to the server that hosts the service. You can copy the file to the server by exporting the keytab file and transferring it to the server, for instance by using FTP. The Kerberos configuration file contains a reference to the keytab file in the form of a file URL (such as: `/home/user/my.keytab`).

   Because the reference is in the configuration file on the server, the server service can take on the Kerberos principal that is defined in the keytab.

3. Create a Kerberos configuration file that specifies the location of the keytab file on the local workstation.

   You can use more than one service principal name per integration node per Kerberos realm. Use your workstation default Kerberos configuration file when you are using Kerberos for security. The location for the configuration file differs depending on the system. The usual locations are:

   - Windows: `C:\Windows\krb5.ini` and `C:\WINNT\krb5.ini`
   - Linux : `/etc/krb5.conf`
   - UNIX (AIX): `/etc/krb5/krb5.conf`
   - z/OS: `/krb5/krb5.conf`

   Different Kerberos configuration files can be configured for use by the integration node and integration servers.

   The following sample Kerberos configuration file shows typical values for the variables. The variables *default_realm*, *default_keytab_name*, and the names in the *realms* are among the values you change in the configuration file, depending on your network and location of the configuration file.

```
[libdefaults]
default_realm = MYREALM.EXAMPLE.COM
default_keytab_name = FILE:c:\Windows\krb5.keytab
default_tkt_enctypes = rc4-hmac
default_tgs_enctypes = rc4-hmac
dns_lookup_realm = false
dns_lookup_kdc = false
ticket_lifetime = 24h
renew_lifetime = 7d
forwardable = true
[realms]
MYREALM.EXAMPLE.COM = {
kdc = kdc.myrealm.example.com
admin_server = kdc.myrealm.example.com
}
```

4. Create a new Kerberos configuration file to use unique Kerberos Service Principals per integration node or per integration server. You do so by specifying the keytab file that contains the required service principal.

5. Use one of these **mqsichangeproperties** commands to specify the location of your new configuration file.
   - For an integration node level Kerberos configuration:

     ```
     mqsichangeproperties integrationNodeName -o BrokerRegistry
     -n brokerKerberosConfigFile -v kerberosConfigLocation
     ```

   - For an integration server level Kerberos configuration:

     ```
     mqsichangeproperties integrationNodeName -e integrationServerName
     -o ComIbmJVMManager -n brokerKerberosConfigFile -v kerberosConfigLocation
     ```

6. Configure a policy set and binding that is associated with the SOAPInput node for the BAR containing the message flow.
   - To configure the Kerberos token with a policy set, see Policy Sets and Policy Set Bindings editor: Message Level Protection panel.
   - To configure a provider message part policy, see Policy Sets and Policy Set Bindings editor: Message Part Protection panel.
   - To sign or encrypt message parts optionally by using a policy set, see Policy Sets and Policy Set Bindings editor: Message Part Policies panel.
   - To configure Kerberos specific settings (such as, target service name and target service realm), see Policy Sets and Policy Set Bindings editor: Message Part Policies panel.

Results

You configured IBM App Connect Enterprise to be a Kerberos secured service.

Configuring separate Kerberos configuration files for each integration server

You can create multiple Kerberos configuration files and then use a separate Kerberos configuration file with each integration server.

Before you begin

You must have access to a Key Distribution Center (KDC) and a server that is hosting the Kerberos-secured service, or you must have an existing Kerberos configuration file. For more information about configuring Kerberos, see your host Kerberos documentation.

About this task

Each integration server in an integration node has a separate JVM, and each JVM has a configuration setting for a Kerberos configuration file. Complete the following steps to configure a separate Kerberos configuration file for each integration server:

Procedure

1. Create a Kerberos configuration file or identify an existing Kerberos configuration file.

   When you use Kerberos for security, the default Kerberos configuration file is the one on your workstation. The location for the configuration file differs depending on the system. The usual locations are as follows:

   - For Windows: `C:\Windows\krb5.ini` or `C:\WINNT\krb5.ini`
   - For Linux: `/etc/krb5.conf`
   - For UNIX (AIX): `/etc/krb5/krb5.conf`
   - For z/OS: `/krb5/krb5.conf`

2. Create a new directory for each integration server.
   For example, on Windows, you might create the following directories:
   - *work_path*/krb5/server1 (to hold the copy of the Kerberos configuration file for integration server "server1")
   - *work_path*/krb5/server2 (to hold the copy of the Kerberos configuration file for integration server "server2")

   where *work_path* is the machine-wide IBM App Connect Enterprise working directory. By using this directory, you can manage the configuration of both the active and the standby integration nodes in a high availability deployment.

   Note: To verify the machine-wide IBM App Connect Enterprise working directory, enter the following command in a command console:

   ```
   echo %MQSI_WORKPATH%
   ```
3. Add a copy of the default Kerberos configuration file to each of the new directories.
4. If you have an integration server that exposes one or more services, generate a keytab file for each service and place it in the directory for that integration server. For information about creating keytab files, see " Configuring IBM App Connect Enterprise as a Kerberos secured service" on page 2658.
5. Edit each of the Kerberos configuration files and add the path to the keytab file (if required) and the realm information.
   For example, on Windows, you might add the following entries:

   ```
   default_keytab_name=work_path/krb5/server1/krb.keytab
   default_realm=server1Realm
   ```

   where *server1Realm* is the realm name for the integration server "server1". If you have to support multiple realms, you can also add entries for each realm into the [realms] section. The following code shows an example of the configuration for multiple realms:

   ```
   [libdefaults]
     default_keytab_name = FILE:/krb/test.keytab
     default_realm = REALM2.MYCO.COM
   #  default_realm = REALM1.MYCO.COM
     default_tkt_enctypes = rc4-hmac
     default_tgs_enctypes = rc4-hmac

   [realms]
     REALM1.MYCO.COM = {
       kdc = kdc1.myco.com:88
       admin_server = kdc.myco.ibm.com:749
       default_domain = myco.com
     }
     REALM2.MYCO.COM = {
       kdc = kdc2.myco.com:88
       default_domain = realm2.myco.com
     }

   [domain_realm]
   # defines how to map from internet domain names to Kerberos realms
     REALM2.MYCO.COM.MYCO.COM = REALM2.MYCO.COM
     .myco.com = REALM1.MYCO.COM
     .test.myco.com = REALM1.MYCO.COM
   ```
6. For each integration server, run the following command on your integration node:

   ```
   mqsichangeproperties node -e server -n jvmSystemProperty -v "-Djava.security.krb5.conf=path"
   ```

   where *node* is the name of your integration node, *server* is the name of your integration server, and *path* is the path to your Kerberos configuration file.
7. Remove the java.security.krb5.conf setting from **IBM_JAVA_OPTIONS** environment variable and restart your integration node.

Results

You configured a separate Kerberos configuration file (and optional keytab files) for each integration server.

Policy sets

Policy sets and bindings define and configure your WS-Security and WS-RM requirements, supported by IBM App Connect Enterprise, for the SOAPInput, SOAPReply, SOAPRequest, SOAPAsyncRequest, and SOAPAsyncResponse nodes.

A *policy set* is a container for the WS-Security and WS-RM policy types.

A policy set *binding* is associated with a policy set and contains information that is specific to the environment and platform, such as information about keys.

Use policy sets and bindings to define the following items for both request and response SOAP messages:

- Authentication for the following tokens:
  - Username tokens (requires a security profile to specify the external security provider)
  - X.509 certificates (requires the integration node keystore and truststore, or a security profile to specify the external security provider)
  - SAML assertions, using SAML 1.1 or 2.0 pass-through (requires a security profile to specify the external security provider)
  - LTPA tokens, using LTPA pass-through (requires a security profile to specify the external security provider)
- Asymmetric encryption (confidentiality) using X.509 certificates (requires the integration node keystore and truststore)
- Symmetric encryption (confidentiality) using Kerberos tokens (requires the host to be configured for Kerberos)
- Asymmetric signature (integrity) (requires the integration node keystore and truststore)

Either the whole SOAP message body, or specific parts of the SOAP message header and body can be encrypted and signed.

You can administer policy sets and bindings from the IBM App Connect Enterprise Toolkit, where you can add, delete, display and edit them. However, policy sets and bindings are non-dynamic, which means that they cannot be changed or redeployed while applications and message flows are using them. Before you can change and redeploy them, you must restart all applications on the integration server. You can do this by specifying the **`--restart-all-applications`** parameter on the mqsideploy or ibmint deploy command. Alternatively, if you try to redeploy policy sets and bindings by using the Toolkit, the initial attempt fails and you are then offered the option of restarting all applications and redeploying.

You can also export policy sets and bindings from an integration node (see "Exporting a policy set and policy set binding" on page 2673).

Policy sets are associated with a message flow, a message node, or both, in the BAR file editor. For convenience, you can specify settings for *provider* and *consumer* at the message flow level. The provider setting applies to all SOAPInput and SOAPReply nodes in the message flow. The consumer setting applies to all SOAPRequest, SOAPAsyncRequest, and SOAPAsyncResponse nodes. Individual policy set and binding assignments can be applied at the node level in the BAR editor, and these take precedence over the flow-level provider and consumer settings. The default setting is *none*, meaning that no policy set and bindings are to be used. For more information, see "Associating policy sets and bindings with message flows and nodes" on page 2672.

Several nodes in the same message flow can refer to the same policy set and bindings. It is the responsibility of the administrator to ensure that the required policy sets are available to the integration node at run time. An error is reported if the integration node cannot find the associated policy set or bindings.

The rest of this topic describes some of the terms that you will meet when configuring policy sets and bindings.

Default policy set and bindings

When an integration node is created, default policy set and bindings are created called `WSS10Default`. This default policy set contains a limited security policy, which specifies that a Username token is present in request messages (inbound) to SOAPInput nodes in the associated message flow. A default WS-RM policy set called `WSRMDefault` is also created.

The default policy set binding refers to the default `WSS10Default` policy set, but not to `WSRMDefault`. They are not editable.

Consumer and provider nodes

Nodes are either consumers or providers.

Consumer nodes

SOAPRequest
SOAPAsyncRequest
SOAPAsyncResponse

Provider nodes

SOAPInput
SOAPReply

Request and response

Request and response is a message exchange pattern (MEP). It describes a client that sends a SOAP Request message to a web services server, which in turn sends a Response SOAP message back to the client. The Request message is always the SOAP message from the client to the server, and the Response message is always the SOAP message reply from server to the client. The following table describes this pattern in relation to the IBM App Connect Enterprise SOAP nodes:

Node	Integration node viewpoint	Request	Response
SOAPInput	SOAP message inbound	Inbound message	Not applicable
SOAPReply	SOAP message outbound	Not applicable	Outbound message
SOAPRequest	SOAP message outbound followed by a SOAP message inbound	Outbound message	Inbound message
SOAPAsyncRequest	SOAP message outbound	Outbound message	Not applicable
SOAPAsyncResponse	SOAP message inbound	Not applicable	Inbound message

Initiator and recipient

Initiator and recipient are roles defined in the exchange of SOAP messages.

Initiator
The role that sends the initial message in a message exchange.

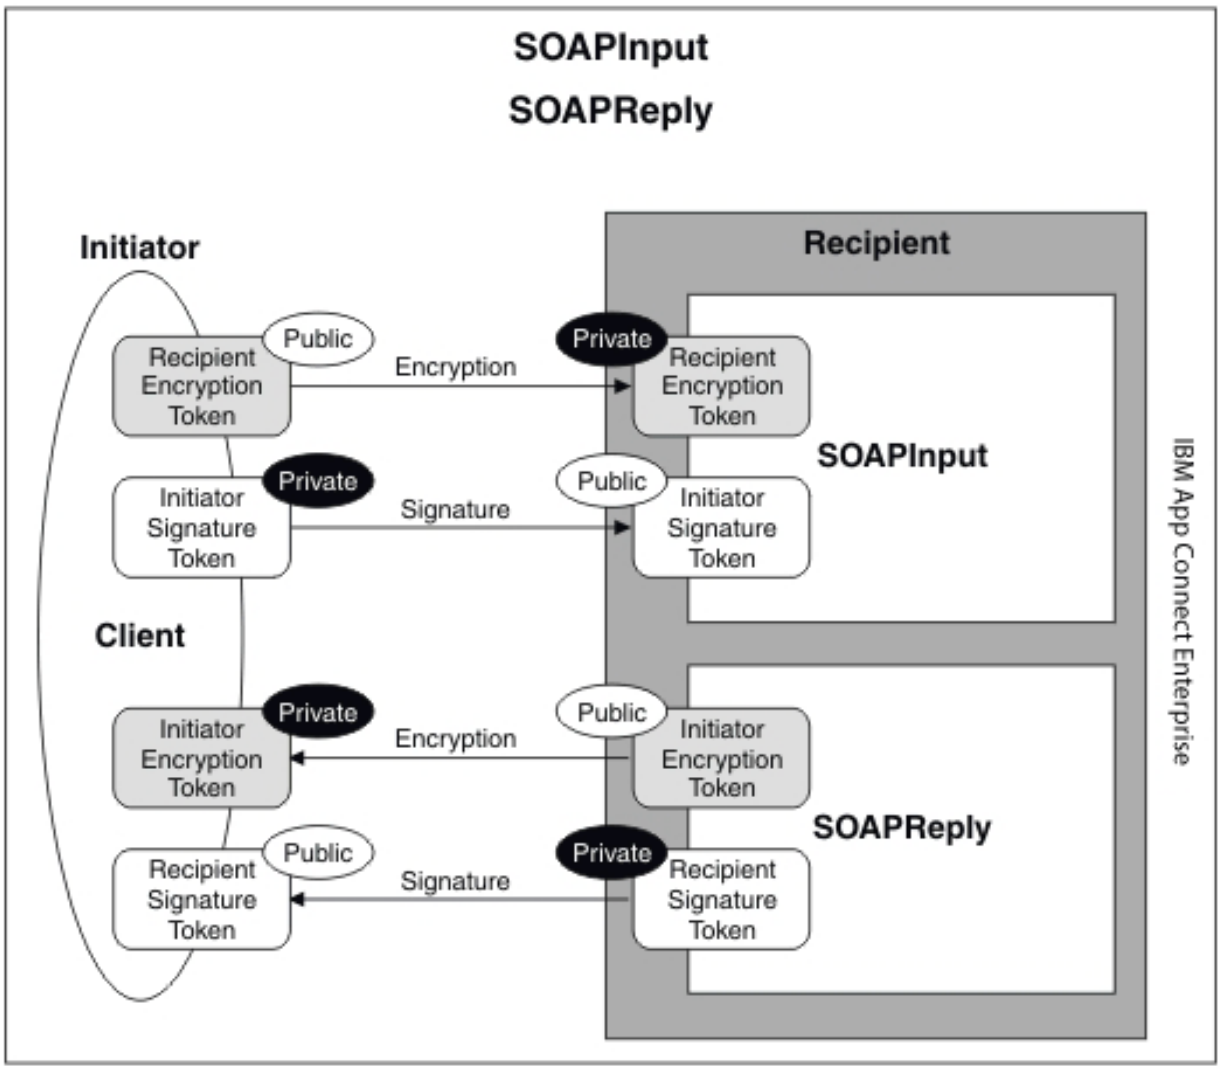
Recipient
The targeted role to process the initial message in a message exchange.

The following table describes these roles in relation to the SOAP nodes:

Node	Integration node viewpoint	Initiator	Recipient
SOAPInput	SOAP message inbound	External client sending SOAP message to the integration node.	SOAPInput node
SOAPReply	SOAP message outbound	External client that sent the original SOAP message to the integration node.	SOAPReply node
SOAPRequest (outbound)	SOAP message outbound followed by a SOAP message inbound	SOAPRequest node	External provider receiving the SOAP message
SOAPRequest (inbound)	SOAP message outbound followed by a SOAP message inbound	SOAPRequest node	External provider receiving the SOAP message
SOAPAsyncRequest	SOAP message outbound	SOAPAsyncRequest node	External provider receiving the SOAP message
SOAPAsyncResponse	SOAP message inbound	SOAPAsyncRequest node	External provider receiving the SOAP message

SOAPInput and SOAPReply nodes

In this diagram, the integration node acts as recipient. A SOAPInput node receives a message from a client (initiator). A SOAPReply node replies. Inbound and outbound messages are signed and encrypted.



In the request:

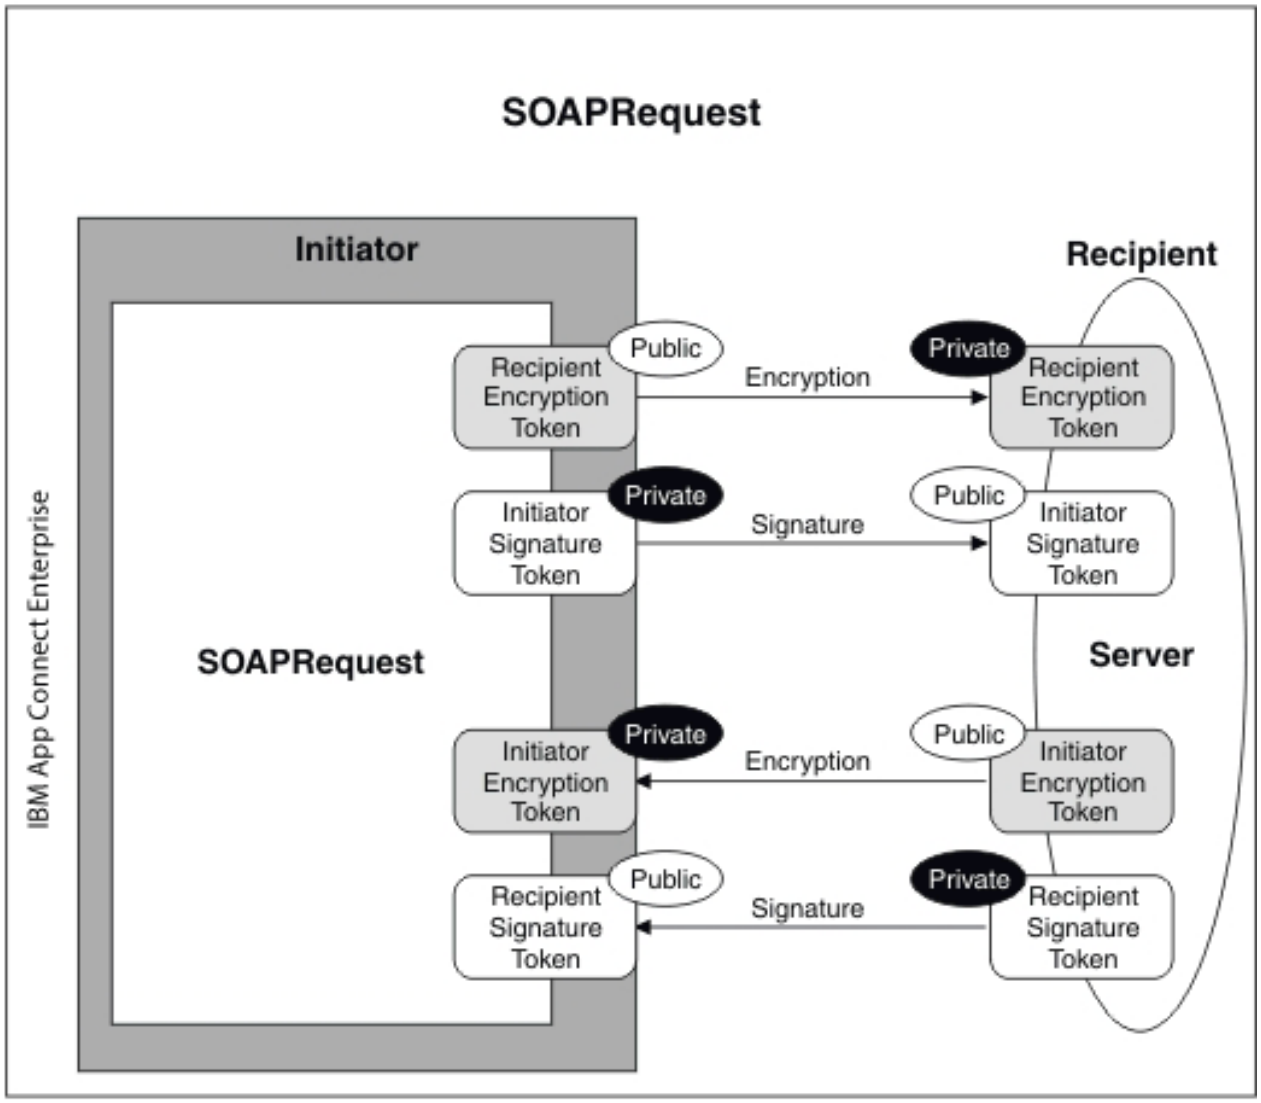
- The initiator uses the public encryption token of the integration node to encrypt the message, and its own private signature token to sign it.
- The integration node uses its own private encryption token to decrypt the message, and the initiator's public signature token to verify the signature.

In the response:

- The integration node uses the initiator's public encryption token to encrypt the message, and its own private signature token to sign the message.
- The initiator uses its own private encryption token to decrypt the message, and the public signature token of the integration node to verify the signature.

SOAPRequest node

This diagram shows the integration node acting as an initiator. It uses the SOAPRequest node to make a synchronous request to an external provider (the recipient). Inbound and outbound messages are signed and encrypted. Use of tokens is similar to the example of the asynchronous SOAP nodes, shown earlier.



In the request:

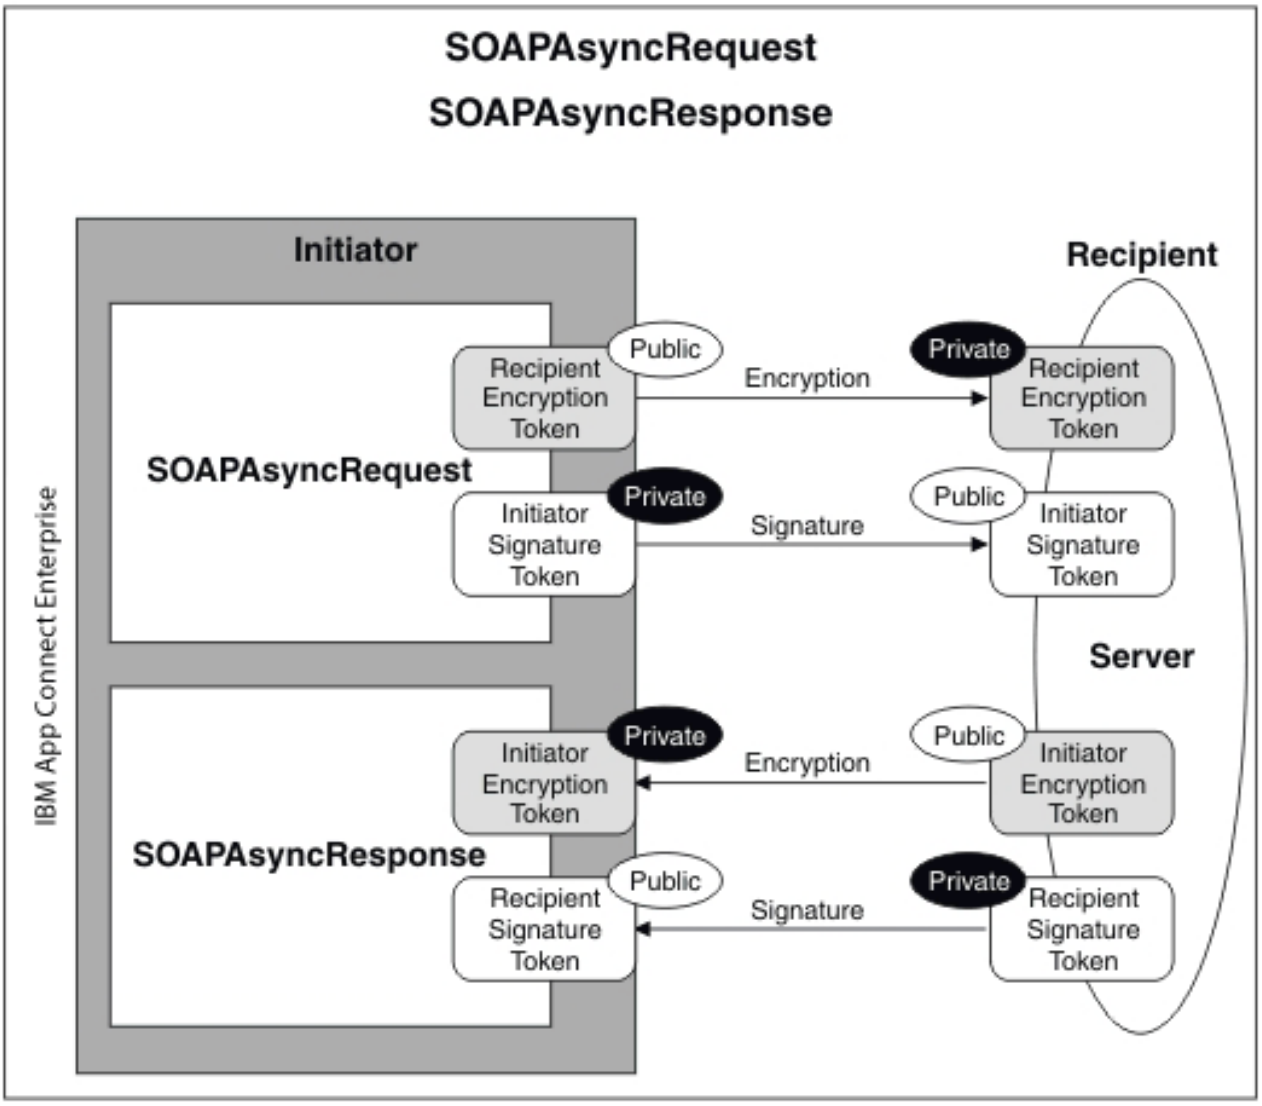
- The integration node uses the recipient's public encryption token to encrypt the message, and its own private signature token to sign the message.
- The recipient uses its own private encryption token to decrypt the message, and the public signature token of the integration node to verify the signature.

In the response:

- The recipient uses the public encryption token of the integration node to encrypt the message, and its own private signature token to sign the message.
- The integration node uses its own private encryption token to decrypt the message, and the initiator's public signature token to verify the signature.

Asynchronous SOAP nodes

This diagram shows the integration node acting as an initiator. It uses the asynchronous SOAP nodes to make a request to an external provider (the recipient). Inbound and outbound messages are signed and encrypted.



In the request:

- The integration node uses the recipient's public encryption token to encrypt the message, and its own private signature token to sign the message.
- The recipient uses its own private encryption token to decrypt the message, and the public signature token of the integration node to verify the signature.

In the response:

- The recipient uses the public encryption token of the integration node to encrypt the message, and its own private signature token to sign the message.
- The integration node uses its own private encryption token to decrypt the message, and the initiator's public signature token to verify the signature.

Viewing and setting keystore and truststore runtime properties at integration node level

Configure the integration node to refer to a keystore, a truststore, or both, before deploying any message flows that require policy set or bindings for signature, encryption, or X.509 Authentication.

About this task

Keystores and truststores are both keystores. They differ only in the way in which they are used.

- Put all private keys and public key certificates (PKC) in the keystore.
- Put all trusted root certificate authority (CA) certificates in the truststore. These certificates are used to establish the trust of any inbound public key certificates.

The only supported type of store is Java keystore (JKS).

Each instance of an integration node can be configured to refer to one keystore and one truststore.

The following properties of the integration node registry component must be defined correctly for policy sets and bindings:

brokerKeystoreFile
The directory and file location of the keystore.

brokerTruststoreFile
The directory and file location of the truststore.

To check what security properties you have set for an integration node, use the **mqsireportdbparms** command.

Listing existing integration node registry entries

About this task

To display all integration node registry values, run the following command:

```
mqsireportproperties integrationNodeName -o BrokerRegistry -a
```

This command returns entries like these:

```
BrokerRegistry=''
  uuid='BrokerRegistry'
  brokerKeystoreType='JKS'
  brokerKeystoreFile=''
  brokerKeystorePass='brokerKeystore::password'
  brokerTruststoreType='JKS'
  brokerTruststoreFile=''
  brokerTruststorePass='brokerTruststore::password'
  httpConnectorPortRange=''
  httpsConnectorPortRange=''
```

Updating the integration node reference to a keystore

About this task

To update the integration node reference to a keystore, use the following command:

```
mqsichangeproperties integrationNodeName -o BrokerRegistry
  -n  brokerKeystoreFile
  -v c:\keystore\server.keystore
```

Where `c:\keystore\server.keystore` is the keystore to be referenced.

Updating the integration node reference to a truststore

About this task

To update the integration node reference to a truststore, use the following command:

```
mqsichangeproperties integrationNodeName -o BrokerRegistry
  -n  brokerTruststoreFile
  -v c:\truststore\server.truststore
```

Where `c:\truststore\server.truststore` is the truststore to be referenced.

Updating the integration node with the keystore password

About this task

Keystores and truststores normally require passwords for access. Use the **mqsisetdbparms** command to add these passwords to the IBM App Connect Enterprise runtime component. To check a password that you have set, use the **mqsireportdbparms** command.

```
mqsireportdbparms integrationNodeName
  -n brokerKeystore::password
  -u temp -p pa55word
```

The user ID, which can be any value, is not required to access the keystore.

Updating the integration node with the truststore password

About this task

To update the integration node with the truststore password, use the following command:

```
mqsisetdbparms integrationNodeName
  -n brokerTruststore::password
  -u temp -p pa55word
```

The user ID, which can be any value, is not required to access the keystore.

Updating the integration node with a private key password

About this task

Private keys in the keystore might have their own individual passwords. These can be configured based on the alias name that is specified for the key in the Policy sets and bindings editor. If a key password that is based on the alias is not found, the keystore password is used. The following command updates the integration node with the private key password for the key whose alias is *encKey*.

```
mqsisetdbparms integrationNodeName
  -n brokerTruststore::KeyPassword::encKey
  -u temp -p pa55word
```

The user ID, which can be any value, is not required to access the keystore.

Viewing and setting keystore and truststore runtime properties at integration server level

Configure an integration server to refer to a keystore, a truststore, or both. You must do this configuration before you deploy any message flows that require SSL connections, policy set or bindings for signature, encryption, or X.509 authentication. You must also do this configuration before you enable services that use SSL connections, such as IBM Cloud reporting services.

About this task

An integration server is a named grouping of message flows. You can configure integration servers to be associated with an *integration node* that looks after them, or to run independently of an integration node. For more information about integration servers, see Integration servers and integration nodes.

For integration servers that are managed by an *integration node*, the integration server keystore and truststore runtime property values override equivalent property values on the *integration node*, if any are set.

Keystores can contain two kinds of entries: key entries and trusted certificate entries. If a keystore is used to contain trusted certificates, it is typically referred to as a truststore. IBM App Connect Enterprise can

refer to a keystore and a truststore per integration server. When the integration node or integration server is encrypting or decrypting, it uses entries in its keystore. If the integration node or integration server is verifying a signature or performing X.509 authentication, it uses entries in its truststore.

Displaying integration server level properties

About this task

Integration servers that are managed by integration nodes:

To display the properties of an integration server that is managed by an integration node, run the command:

```
mqsireportproperties integrationNodeName -o ComIbmJVMManager -a -e integration_server
```

Independent integration servers:

To display the properties of an independent integration server, view the <work directory>/server.conf.yaml configuration file.

Updating the integration server reference to a keystore

About this task

Integration servers that are managed by integration nodes:
To update the reference to a keystore for an integration server that is managed by an integration node, use the following command:

```
mqsichangeproperties integrationNodeName -e integration_server -o ComIbmJVMManager
  -n  keystoreFile -v c:\keystore\server.keystore
```

where c:\keystore\server.keystore is the fully qualified path to the Java keystore (JKS), containing the private certificates that is used by the integration server.
Independent integration servers:

To update the reference to a keystore for an independent integration server, edit the <work directory>/server.conf.yaml configuration file.

```
ResourceManagers:
  JVM:
    keystoreFile: 'c:\keystore\server.keystore' # JVM location of the key store
```

where c:\keystore\server.keystore is the fully qualified path to the Java keystore (JKS), containing the private certificates that is used by the integration server.

Updating the integration server reference to a truststore

About this task

Integration servers that are managed by integration nodes:
To update the reference to a truststore for an integration server that is managed by an integration node, use the following command.

```
mqsichangeproperties integrationNodeName -e integration_server -o ComIbmJVMManager
  -n  truststoreFile -v c:\truststore\server.truststore
```

The path, c:\truststore\server.truststore is the fully qualified path to the Java truststore. The Java truststore contains the public certificates that are required by the integration server to establish trust with the services that it connects to.
Independent integration servers:

To update the reference to a truststore for an independent integration server, edit the <work directory>/server.conf.yaml configuration file.

```
ResourceManagers:
  JVM:
    truststoreFile: 'c:\truststore\server.truststore'             # JVM location of the trust
 store
```

where c:\truststore\server.truststore is the fully qualified path to the Java truststore. The Java truststore contains the public certificates that are required by the integration server to establish trust with the services that it connects to.

Updating the keystore and truststore passwords

About this task

Integration servers that are managed by integration nodes:

To update the keystore and truststore passwords for an integration server that is managed by an integration node, use the same commands that are used for setting keystore and truststore runtime properties at integration node level.

- To update the integration node with the keystore password; see "Updating the integration node with the keystore password" on page 2669.
- To update the integration node with the truststore password; see "Updating the integration node with the truststore password" on page 2669.
- To update the integration node with a private key password; see "Updating the integration node with a private key password" on page 2669.

To use the default integration node password for the keystore, the **keystorePass** parameter must be blank, or it must be set to brokerKeystore::password. To use a password other than the default integration node password, use the following commands:

```
mqsichangeproperties integrationNodeName -e integration_server -o ComIbmJVMManager -n
 keystorePass
-v integration_server::keystorePass

mqsisetdbparms integrationNodeName -n integration_server::keystorePass -u na -p password
```

To use the default integration node password for the truststore, the **truststorePass** parameter must be blank, or it must be set to brokerTruststore::password. To use a password other than the default integration node password, use the following commands:

```
mqsichangeproperties integrationNodeName -e integration_server -o ComIbmJVMManager -n
 truststorePass
-v integration_server::truststorePass

mqsisetdbparms integrationNodeName -n integration_server::truststorePass -u na -p password
```

Independent integration servers:

To update the keystore password for an independent integration server, edit the <work directory>/server.conf.yaml configuration file.

```
ResourceManagers:
  JVM:

    #keystorePass: 'keyStorePassword'               # JVM resource alias containing the key
 store password
```

To update the truststore password for an independent integration server, edit the <work directory>/server.conf.yaml configuration file.

```
ResourceManagers:
  JVM:
```

```
    #truststorePass: 'TrustStorePassword'                # JVM resource alias containing the
trust store password
```

Adding new certificates to a keystore or truststore

About this task

If you add new certificates to a keystore or truststore, to ensure that the new certificates are picked up, you must reload the Java virtual machine (JVM). You can reload the JVM by restarting the integration server.

Associating policy sets and bindings with message flows and nodes

Use the BAR file editor to associate policy sets and bindings with message flows and nodes, so that they are available to the integration node at run time.

Before you begin

Use the WS Policy Sets and Bindings editor to create and configure policy sets and bindings (see "Implementing WS-Security" on page 2652).

These instructions also assume that you have packaged your message flow in a BAR file.

About this task

You can associate a policy set with a message flow or with specific message flow nodes. Associations that are made with a flow apply to all message flow nodes described in the Policy Set and Bindings file. Associations at the flow level are defined as being either for consumer or provider nodes.

An association at the message flow node level overrides any association made at the message flow level. You do not enter information about consumer or provider for an association at message flow node level.

Procedure

1. In the IBM App Connect Enterprise Toolkit, open the BAR file that contains the message flow that you want to associate with a policy set and binding.
2. Click the **Manage** tab.
3. Click the message flow or node that you want to associate with a policy set and binding.

   The properties that you can configure for the message flow or for the message flow node are displayed in the **Properties** view.
4. If you are configuring a message flow, enter values in the following fields in the **Properties** view, in the form *{policy_project_name}:policy_set_name* or *{policy_project_name}:policy_set_bindings_name*
   - **Consumer Policy Set**
   - **Consumer Policy Set Bindings**
   - **Provider Policy Set**
   - **Provider Policy Set Bindings**
5. If you are configuring a message flow node, enter values in the following fields in the **Properties** view, in the form *{policy_project_name}:policy_set_name* or *{policy_project_name}:policy_set_bindings_name*
   - **Policy Set**
   - **Policy Set Bindings**

What to do next

For new associations to take effect, deploy the BAR file, then stop and restart the associated message flow.

Exporting a policy set and policy set binding

Use the **mqsireportproperties** command to export a policy set and associated policy set binding to a file.

About this task

This topic shows how to export policy set *myPolicySet* from integration node *myBroker* to a file called *myPolicySet.xml*. The associated binding is *myPolicySetBinding*, which you export to *myPolicySetBinding.xml*.

Procedure

1. Export the policy set to a file:

```
mqsireportproperties myBroker -c PolicySets -o myPolicySet -n ws-security -p myPolicySet.xml
```

2. Export the policy set binding to a file:

```
mqsireportproperties myBroker -c PolicySetBindings -o myPolicySetBinding
   -n ws-security -p myPolicySetBinding.xml
```

What to do next

Make a note of the policy set that is associated to the binding; you will need this information when you import the policy set and binding. This command displays the policy set associated with a binding:

```
mqsireportproperties myBroker -c PolicySetBindings -o myPolicySetBinding -n associatedPolicySet
```

This displays:

```
PolicySetBindings   myPolicySetBinding     associatedPolicySet='myPolicySet'
BIP8071I: Successful command completion.
```

Note: To export a policy set with more than one policy, you must run the **mqsireportproperties** command once for each policy. For example, a policy set might contain a WS-Security policy and a WS-RM policy.

Message flow security and security profiles

IBM App Connect Enterprise provides a security manager for implementing message flow security, so that end-to-end processing of a message through a message flow is secured based on an identity carried in that message instance.

For details of the supported external providers and the operation of the message flow security manager, see “Message flow security overview” on page 2550. For information about the token types that are supported by the SOAP nodes and by external security providers, see “Identity” on page 2554.

When the message flow is a web service implemented by using “SOAP nodes” on page 811 and the identity is to be taken from the “WS-Security” on page 2650 SOAP headers, the SOAP nodes are the Policy Enforcement Point (PEP) and the external provider defined by the “Security profiles” on page 2552 is the Policy Decision Point (PDP).

The following configuration is required to implement message flow security based on an identity carried in `WS_Security` tokens.

- "Policy sets" on page 2662 define the type of tokens used for the identity.
  - To work with a Username and Password identity, configure the policy and binding for Username token "Authentication" on page 2652.
  - To work with a X.509 Certificate identity, configure the policy and binding for X.509 certificate token "Authentication" on page 2652.

    In the Policy Set Binding, set the X.509 certificate Authentication Token `certificates` mode to `Trust Any`. You set it this way (and not to `Trust Store`) so that the certificate is passed to the security provider defined by the Security Profile. Setting it to `Trust Store` will cause the certificate to be validated in the local Integration node Trust Store. For more details, see Policy Sets and Policy Set Bindings editor: Authentication and Protection Tokens panel.
  - To work with a SAML assertion token, configure the policy and binding for SAML token "Authentication" on page 2652.
- The message flow security operation and external provider are defined by the "Security profiles" on page 2552

As an alternative to message flow security and an external PDP, the integration node's truststore can be used as a local PDP for X.509 certificate authentication. For WS-Security signing and encryption using only the local integration node capability, you must configure the integration node's truststore. For details, see "Viewing and setting keystore and truststore runtime properties at integration node level" on page 2667, or "Viewing and setting keystore and truststore runtime properties at integration server level " on page 2669.

Kerberos based WS-Security is supported in the SOAP nodes. When you use Kerberos for security, the SOAP node's WS-Security processing links directly with the host's Kerberos infrastructure. The integration node host must be configured for Kerberos, providing a `krb.conf` file to define the Kerberos Key Distribution Center (KDC) and default realm. A Kerberos `keytab` file must also be configured. For more information about configuring Kerberos, see your host's Kerberos documentation.

To work with Kerberos WS-Security in SOAP nodes, create a policy set and bindings specifying Kerberos symmetric encryption tokens on the Message Level Protection panel; see Policy Sets and Policy Set Bindings editor: Message Level Protection panel. Also configure the required settings on the Kerberos settings panel, as described in Policy Sets and Policy Set Bindings editor: Kerberos settings panel, and then associate this policy set and bindings with the SOAP node. You can also associate SOAP nodes with a security profile that sets only propagation, so that Kerberos can be used to:

- Extract the service principal as a Username token from SOAP input nodes
- Propagate the Kerberos Key Distribution Center (KDC) credentials as a Username and password to SOAP request nodes.

WS-Security capabilities

Web service security capabilities are supported by the integration node.

Web service security mechanisms are defined by OASIS standards. See OASIS Standard for WS-Security Specification

For information about the token profile standards, see:

- OASIS Web Services Security Username Token Profile
- OASIS Web Services Security X.509 Certificate Token Profile
- OASIS Web Services Security Kerberos Token Profile

SAML pass-through support is provided, which enables interoperability with WS-Security SAML profiles, without performing subject confirmation processing. This means that it does not provide validation of the trust relationship between the SAML subject and message content signatures. For information about the SAML token profile standards, see:

- OASIS Web Services Security SAML Token Profile 1.1
- SAML V2 Specification

LTPA pass-through support is also provided, which enables LTPA binary tokens to be passed to an external Security Token Service (STS) for processing.

For more information about using the token profiles, see the following topics:

- "Username token capabilities" on page 2675
- "X.509 certificate token capabilities" on page 2677
- "SAML token capabilities" on page 2680
- "Kerberos token capabilities" on page 2682
- "LTPA token capabilities" on page 2684

Username token capabilities

This topic describes WS-Security username token capabilities of the integration node.

For details of using WS-Security username token, see the following capabilities:

- "Username token capabilities for encryption, decryption, signing, and verifying" on page 2675
- "Username token capabilities for authentication and authorization" on page 2675
- "Username token capabilities for identity mapping" on page 2676
- "Username token capabilities for extraction and propagation" on page 2676

Username token capabilities for encryption, decryption, signing, and verifying

For web services, you cannot complete encryption, decryption, signing, and verification by using username tokens.

The username token is not applicable, or supported, for the following in any configuration or direction:

- Encryption
- Decryption
- Signing
- Verification

Username token capabilities for authentication and authorization

For web services, you can complete authentication and authorization by using a Web Services Security username token.

For authentication, the Web Services Security username token must include both the username and the optional password.

The Web Services Security username token "Authentication" on page 2651 and "Authorization" on page 2562 is supported only in the following configuration:

Capability

- Authenticate
- Authorize

Policy Enforcement Point (PEP) and direction

- In (provider)

  node

  Configured with a security policy and binding that defines that a Web Services Security username token is present for authentication; see "Authentication" on page 2652. You can use the default policy and binding WSS10Default; see "Default policy set and bindings" on page 2663.

  Configured with a security profile defining the Policy Decision Point (PDP); see the PDP section that follows.

Trust Store or PDP

- LDAP

  Configured by using an LDAP security profile specifying authentication, authorization, or both; see "Creating a security profile for LDAP" on page 2584. For authentication, both a username and password are required.

- WS-Trust v1.3 STS

  Configured by using a WS-Trust v1.3 STS security profile specifying authentication, authorization or both; see "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 2588. For authentication, both a username and password are required.

- TFIM V6.1

  Configured by using a TFIM security profile specifying authentication, authorization or both; see "Creating a security profile for TFIM V6.1" on page 2589. For authentication, both a username and password are required.

Username token capabilities for identity mapping

For web services, you can map an identity by using a username token.

"Identity mapping" on page 2564 from a username identity token to a mapped username identity token is supported only in the following configurations:

Capability

- Identity mapping

Policy Enforcement Point (PEP) and direction

- In (provider)

  node

  Configured with a security policy and binding that defines that a username taken is present. You can use the default policy and binding WSS10Default; see "Default policy set and bindings" on page 2663.

  Configured with a security profile defining the external Policy Decision Point (PDP); see the PDP section that follows.

Trust store or PDP

- WS-Trust v1.3 STS

  Configured by using a WS-Trust v1.3 STS security profile that specifies identity mapping; see "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 2588.

- TFIM V6.1

  Configured by using a TFIM security profile that specifies identity mapping; see "Creating a security profile for TFIM V6.1" on page 2589.

Username token capabilities for extraction and propagation

This topic describes integration node capability for extraction, propagation, or both using a username token in web services.

The extraction of username into the Properties folder source "Identity" on page 2554 fields, is supported in the following configurations:

Capability

- Extraction

Policy Enforcement Point (PEP) and direction

- In (provider)

  node

  Configured with a security policy and binding which defines that a username taken is present. You can use the default policy and binding WSS10Default; see “Default policy set and bindings” on page 2663.

  Configured with a security profile that defines propagation; see “Creating a security profile” on page 2584

The propagation of a username token into the SOAP WS-Security header, from the token present in either the mapped or the source identity fields in the properties folder, is supported in the following configuration. See “Identity” on page 2554.

Capability

- Propagate

Policy Enforcement Point (PEP) and direction

- Out (consumer)

  node
  node

  Configured with a security profile that defines propagation; for example, Default Propagation. See “Security profiles” on page 2552

X.509 certificate token capabilities

Various WS-Services Security X.509 certificate token profile standards are supported by IBM App Connect Enterprise.

For details of using the X.509 certificates, see the following capabilities:

- “X.509 certificate token capabilities for encryption” on page 2677
- “X.509 certificate token capabilities for decryption” on page 2678
- “X.509 certificate token capabilities for signing” on page 2678
- “X.509 certificate token capabilities for verifying” on page 2679
- “X.509 certificate token capabilities for authentication” on page 2679
- “X.509 certificate token capabilities for authorization” on page 2679
- “X.509 certificate token capabilities for identity mapping” on page 2680
- “X.509 certificate token capabilities for extraction and propagation” on page 2680

X.509 certificate token capabilities for encryption

For web services, you can complete encryption by using an X.509 certificate token.

X.509 certificate token encryption for providing message “Confidentiality” on page 2652 on outgoing SOAP messages from the integration node is supported in the following configurations:

Capability

- Encrypt (by using a partner public key)

Policy Enforcement Point (PEP) and direction

- Out (consumer)

  node
  node

- Out (provider)

  node

  Configured with a policy set and binding defining the message “Confidentiality” on page 2654.

Trust Store or Policy Decision Point (PDP)

- Integration node Truststore; for more details, see "Viewing and setting keystore and truststore runtime properties at integration node level" on page 2667.

Encryption is not supported with external PDPs such as TFIM or LDAP.

X.509 certificate token capabilities for decryption

For web services, you can complete decryption by using an X.509 certificate token.

X.509 certificate token decryption for incoming SOAP message "Confidentiality" on page 2652 is supported in the following configurations:

Capability

- Decrypt (by using an integration node private key)

Policy Enforcement Point (PEP) and direction.

- In (provider)

  node
- In (consumer)

  node
  node

  Configured with a policy set and binding defining the message "Confidentiality" on page 2654.

Trust Store or Policy Decision Point (PDP).

- Integration node Truststore; for details, see "Viewing and setting keystore and truststore runtime properties at integration node level" on page 2667.

Decryption is not supported with external PDPs such as TFIM or LDAP.

X.509 certificate token capabilities for signing

For web services, you can use an X.509 certificate token for signing.

X.509 certificate token signing for outgoing SOAP message "Integrity" on page 2652 is supported in the following configurations:

Capability

- Sign (by using an integration node private key)

Policy Enforcement Point (PEP) and direction

- Out (consumer)

  node
  node
- Out (provider)

  node

  Configured with a policy set and binding defining the message "Integrity" on page 2655.

Trust Store or Policy Decision Point (PDP)

- Integration node Truststore; for details, see "Viewing and setting keystore and truststore runtime properties at integration node level" on page 2667.

Signing is not supported with an external PDP such as TFIM or LDAP.

X.509 certificate token capabilities for verifying

For web services, you can verify a signing by using an X.509 certificate token profile.

X.509 certificate token verification of the "Integrity" on page 2652 of a signed incoming SOAP message is supported in the following configurations:

Capability

- Verify signature (by using a partner public key)

Policy Enforcement Point (PEP) and direction

- In (provider)

  node
- In (consumer)

  node
  node

  Configured with a policy set and binding defining the message "Integrity" on page 2655

Trust Store or Policy Decision Point (PDP)

- Integration node Trust store; for details, see "Viewing and setting keystore and truststore runtime properties at integration node level" on page 2667.

  Signature verification is not supported with an external PDP, such as TFIM or LDAP.

X.509 certificate token capabilities for authentication

For web services, you can complete authentication by using an X.509 certificate token.

The X.509 certificate token "Authentication" on page 2651 of an incoming SOAP message is supported in the following configurations:

Capability

- Authenticate

Policy Enforcement Point (PEP) and direction

- In (provider)

  node

  Configured with a policy set and binding defining the certificate "Authentication" on page 2652.

  Optionally configured with a security profile defining an external Policy Decision Point (PDP); see the PDP section that follows.

Trust Store or PDP

- Integration node Trust store; for details, see "Viewing and setting keystore and truststore runtime properties at integration node level" on page 2667.
- WS-Trust v1.3 STS

  Configured by using a WS-Trust v1.3 STS security profile specifying authentication; see "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 2588.
- TFIM V6.1

  Configured by using a TFIM security profile specifying authentication; for details, see "Creating a security profile for TFIM V6.1" on page 2589.

Certificate authentication with an external LDAP PDP is not supported.

X.509 certificate token capabilities for authorization

The X.509 certificate token is not supported for authorization in any configuration or direction.

X.509 certificate token capabilities for identity mapping

For web services, you can map an identity by using an X.509 certificate token.

The integration node supports "Identity mapping" on page 2564 from an X.509 certificate token in an incoming SOAP message header to username tokens in the following configurations:

Capability

- Identity mapping

Policy Enforcement Point (PEP) and direction

- In (provider)

  node

  Configured with a policy set and binding defining the certificate "Authentication" on page 2652.

  Configured with a security profile defining an external Policy Decision Point (PDP); see the PDP section that follows.

Trust Store or PDP

- TFIM V6.1

  Configured by using a TFIM security profile specifying identity mapping; for details, see "Creating a security profile for TFIM V6.1" on page 2589.

- WS-Trust v1.3 STS (TFIM V6.2)

  Configured by using a WS-Trust v1.3 STS security profile specifying identity mapping; for details, see "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 2588.

Identity mapping is not supported with LDAP, or at outbound nodes.

Username tokens only can be propagated.

X.509 certificate token capabilities for extraction and propagation

This topic describes integration node web services capability for extraction and propagation X.509 certificate token.

The integration node does not support propagation of an X.509 certificate.

The X.509 certificate token extraction is supported in the following configurations:

Capability

- Extraction

Policy Enforcement Point (PEP) and direction

- In (provider)

  node

  Configured with a policy set and binding defining the X.509 certificate is present; see "Implementing WS-Security" on page 2652.

  Configured with a security profile defining propagation; see the "Security profiles" on page 2552.

SAML token capabilities

This topic describes WS-Security SAML token capabilities of the integration node.

The integration node provides SAML pass-through support, which means that the mechanisms for subject confirmation are not enforced. The SAML token is extracted and passed to an external Security Token Service (STS) for validation. The STS to be used is specified on a security profile.

For information about using WS-Security SAML tokens, see the following topics:

- "SAML token capabilities for encryption, decryption, signing, and verifying" on page 2681

- "SAML token capabilities for authentication and authorization" on page 2681
- "SAML token capabilities for identity mapping" on page 2681
- "SAML token capabilities for extraction and propagation" on page 2682

SAML token capabilities for encryption, decryption, signing, and verifying

The integration node provides SAML pass-through support, which means that the encryption, decryption, signing, and verifying mechanisms for achieving SAML subject confirmation are not enforced by the broker.

SAML token capabilities for authentication and authorization

For web services, you can complete authentication and authorization using a SAML token.

The SAML token "Authentication" on page 2651 and "Authorization" on page 2562 are supported only in the following configuration:

Capability

- Authenticate
- Authorize

Policy Enforcement Point (PEP) and direction

- In (provider)

  node

  Configured with a security policy set and binding that defines that a SAML pass-through 1.1 or SAML pass-through 2.0 token is present for authentication; see "Authentication" on page 2652. The integration node provides only SAML pass-through support, which means that the SAML token is extracted and passed to an external Security Token Service (STS) for validation. The STS to be used is specified in a security profile. The STS processing can be used to implement authentication based on the SAML principal, and authorization based on SAML attributes.

  Configured with a security profile defining the Policy Decision Point (PDP); see the PDP section that follows.

Trust Store or PDP

- WS-Trust v1.3 STS

  Configured by using a WS-Trust v1.3 STS security profile specifying authentication, authorization or both; see "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 2588.

SAML token capabilities for identity mapping

This topic describes the integration node web services capability for identity mapping using a SAML token.

"Identity mapping" on page 2564 from a SAML identity token to a mapped SAML identity token is supported only in the following configurations:

Capability

- Identity mapping

Policy Enforcement Point (PEP) and direction

- In (provider)

  node

  Configured with a security policy set and bindings that specifies a SAML pass-though 1.1 or SAML pass-through 2.0 authentication token.

  Configured with a security profile defining the external Policy Decision Point (PDP); see the PDP section that follows.

Trust store or PDP

- WS-Trust v1.3 STS

  Configured by using a WS-Trust v1.3 STS security profile that specifies identity mapping; see “Creating a security profile for WS-Trust V1.3 (TFIM V6.2)” on page 2588.

SAML token capabilities for extraction and propagation

This topic describes integration node capability for extraction, propagation, or both using a SAML token in web services.

The extraction of a SAML token into the Properties folder source “Identity” on page 2554 fields, is supported in the following configurations:

Capability

- Extraction

Policy Enforcement Point (PEP) and direction

- In (provider)

  node

  Configured with a security policy set and bindings that specifies a SAML pass-though 1.1 or SAML pass-through 2.0 authentication token.

  Configured with a security profile that defines propagation; see “Creating a security profile” on page 2584

The propagation of a SAML token into the SOAP WS-Security header, from the token present in either the mapped or the source identity fields in the properties folder, is supported in the following configuration. For more information, see “Identity” on page 2554.

Capability

- Propagate

Policy Enforcement Point (PEP) and direction

- Out (consumer)

  node
  node

  Configured with a security profile that defines propagation. For more information, see “Security profiles” on page 2552.

  Configured with a security policy set and bindings that specifies SAML pass-though 1.1 or SAML pass-through 2.0 authentication token.

Kerberos token capabilities

This topic describes WS-Security Kerberos token capabilities of the integration node.

For details of using WS-Security Kerberos tokens, see the following topics:

- “Kerberos token capabilities for encryption, decryption, signing, and verifying” on page 2682
- “Kerberos token capabilities for authentication and authorization” on page 2683
- “Kerberos token capabilities for identity mapping” on page 2683
- “Kerberos token capabilities for extraction and propagation” on page 2684

Kerberos token capabilities for encryption, decryption, signing, and verifying

You can use Kerberos tokens for encryption, decryption, signing, and verifying.

Kerberos token encryption for providing message “Confidentiality” on page 2652 and “Integrity” on page 2652 on outgoing SOAP messages from the integration node is supported in the following configurations:

Capability

- Encrypt, by using a Kerberos Key Distribution Center (KDC)
- Decrypt, by using the Kerberos `keytab` file

Policy Enforcement Point (PEP) and direction

- In (provider)

  node
- In (consumer)

  node
  node

  Configured with a policy set and binding defining the message "Integrity" on page 2655
- Out (consumer)

  node
  node
- Out (provider)

  node

  Configured with a Kerberos policy set and binding.

Trust Store or Policy Decision Point (PDP)

- Kerberos KDC.

Kerberos token capabilities for authentication and authorization

This topic describes the integration node web services capability for authentication, authorization, or both using a Kerberos token.

Kerberos is not applicable to authorization. Kerberos token encryption for providing message "Authentication" on page 2652 on outgoing SOAP messages from the integration node is supported in the following configurations:

Capability

- Authenticate using a Kerberos `keytab` file.

Policy Enforcement Point (PEP) and direction

- In (provider)

  node
- In (consumer)

  node
  node

  Configured with a policy set and binding defining the message "Integrity" on page 2655

Trust Store or Policy Decision Point (PDP)

- Kerberos `keytab` file.

Kerberos token capabilities for identity mapping

This topic describes integration node web services capability for identity mapping using a Kerberos token.

Kerberos tickets from SOAP nodes are not supported for token mapping with an external Security Token Service (STS) configured in the security profile.

On the Inbound route, with SOAPInput and SOAPAsyncResponse nodes, the presence of a security profile with propagation enabled causes the Kerberos Service Principal Name (SPN) to be placed in the properties tree as a Username token.

On the Outbound route, with SOAPRequest and SOAPAsyncRequest nodes, identity propagation can be used to provide the Kerberos Key Distribution Center (KDC) credentials. Arrange for the KDC credentials to be set as a Username and password token in the properties tree and associate the SOAP node with a security profile that specifies propagation; otherwise the KDC credentials are obtained using the Kerberos resource credentials that are created using the **mqsisetdbparms** command.

Kerberos token capabilities for extraction and propagation

This topic describes integration node capability for extraction, propagation, or both using a Kerberos token in web services.

Kerberos tickets from SOAP nodes are not supported for token extraction and propagation with an external Security Token Service (STS) configured in the security profile.

On the Inbound route, with SOAPInput and SOAPAsyncResponse nodes, the presence of a security profile with propagation enabled causes the Kerberos Service Principal Name (SPN) to be placed in the properties tree as a Username token.

On the Outbound route, with SOAPRequest and SOAPAsyncRequest nodes, identity propagation can be used to provide the Kerberos Key Distribution Center (KDC) credentials. Arrange for the KDC credentials to be set as a Username and password token in the properties tree and associate the SOAP node with a security profile that specifies propagation; otherwise the KDC credentials are obtained using the Kerberos resource credentials that are created using the **mqsisetdbparms** command.

LTPA token capabilities

This topic describes WS-Security LTPA token capabilities of the integration node.

The integration node provides LTPA pass-through support, which means that the LTPA token is extracted and passed to an external Security Token Service (STS) for validation. The STS to be used is specified on a security profile.

For information about using WS-Security LTPA tokens, see the following topics:

- "LTPA token capabilities for encryption, decryption, signing, and verifying" on page 2684
- "LTPA token capabilities for authentication and authorization" on page 2684
- "LTPA token capabilities for identity mapping" on page 2685
- "LTPA token capabilities for extraction and propagation" on page 2685

LTPA token capabilities for encryption, decryption, signing, and verifying

This topic describes integration node web services capability for encryption, decryption, signing, and verifying using LTPA tokens.

The LTPA token is not applicable, or supported, for the following in any configuration or direction:

- Encryption
- Decryption
- Signing
- Verifying

LTPA token capabilities for authentication and authorization

For web services, you can complete authentication and authorization using an LTPA token.

The LTPA token "Authentication" on page 2651 and "Authorization" on page 2562 are supported only in the following configuration:

Capability

- Authenticate
- Authorize

Policy Enforcement Point (PEP) and direction

- In (provider)

  node

  Configured with a security policy set and binding that defines that an LTPA token is present for authentication; see “Authentication” on page 2652. The integration node provides only LTPA pass-through support, which means that the LTPA token is extracted and passed to an external Security Token Service (STS) for validation. The STS to be used is specified in a security profile. The STS processing can be used to implement authentication and authorization based on the LTPA principal and realm.

  Configured with a security profile defining the Policy Decision Point (PDP); see the PDP section that follows.

Trust Store or PDP

- WS-Trust v1.3 STS

  Configured by using a WS-Trust v1.3 STS security profile specifying authentication, authorization or both; see “Creating a security profile for WS-Trust V1.3 (TFIM V6.2)” on page 2588.

LTPA token capabilities for identity mapping

This topic describes the integration node web services capability for identity mapping using an LTPA token.

“Identity mapping” on page 2564 from or to an LTPA identity token is supported only in the following configurations:

Capability

- Identity mapping

Policy Enforcement Point (PEP) and direction

- In (provider)

  node

  Configured with a security policy set and bindings that specifies an LTPA pass-through authentication token.

  Configured with a security profile defining the external Policy Decision Point (PDP); see the PDP section that follows.

Trust store or PDP

- WS-Trust v1.3 STS

  Configured by using a WS-Trust v1.3 STS security profile that specifies identity mapping; see “Creating a security profile for WS-Trust V1.3 (TFIM V6.2)” on page 2588.

LTPA token capabilities for extraction and propagation

This topic describes integration node capability for extraction, propagation, or both using an LTPA token in web services.

The extraction of an LTPA token into the Properties folder source “Identity” on page 2554 fields, is supported in the following configurations:

Capability

- Extraction

Policy Enforcement Point (PEP) and direction

- In (provider)

  node

  Configured with a security policy set and bindings that specifies an LTPA pass-though authentication token.

  Configured with a security profile that defines propagation; see “Creating a security profile” on page 2584

The propagation of an LTPA token into the SOAP WS-Security header, from the token present in either the mapped or the source identity fields in the properties folder, is supported in the following configuration. For more information, see “Identity” on page 2554.

Capability

- Propagate

Policy Enforcement Point (PEP) and direction

- Out (consumer)

  node
  node

  Configured with a security profile that defines propagation. For more information, see “Security profiles” on page 2552.

  Configured with a security policy set and bindings that specifies an LTPA pass-through authentication token.

Chapter 9. Performance, monitoring, and workload management

You can change various aspects of your configuration to tune integration servers and message flows, and to monitor message flows and publish/subscribe applications. You can also send logging information to an Elasticsearch, Logstash, and Kibana (ELK) server, and view the data in a Kibana dashboard.

About this task

Performance

How you configure your IBM App Connect Enterprise environment can affect the performance of your applications. For more information about these options, see “Performance” on page 2688.

Monitoring

You can configure your integration nodes or message flows to generate data and statistics that you can use to assess behavior and performance. For more information about these options, see “Message flow monitoring” on page 2771.

Statistics and accounting

You can collect message flow statistics and accounting data to record performance and operating details of one or more message flows. For more information, see “Message flow statistics and accounting data” on page 2699.

Recording and viewing messages

You can configure a message flow to capture some of the data that it processes. You can then view this data from the web user interface or programmatically. For more information, see “Recording, viewing, and replaying data” on page 2834.

Activity logging

Activity logs help you understand what your message flows are doing by providing a high-level overview of how IBM App Connect Enterprise interacts with external resources. For more information about activity logs, see “Activity Logs” on page 2854.

Reporting logs and events to a Logstash input in an ELK stack

You can configure integration servers to send the following information to a Logstash input in an Elasticsearch, Logstash, and Kibana (ELK) stack, so that you can view the data in a Kibana dashboard:

- Logging information (BIP messages)
- Message flow monitoring events
- Activity logging events

For more information, see “Reporting logs and monitoring events to a Logstash input in an ELK stack” on page 2869 and “Configuring integration servers to send logs and events to Logstash in an ELK stack” on page 2870.

Workload management

System administrators can monitor and control the speed that messages are processed within message flows. For more information, see “Workload management” on page 2873.

Performance

You can use message flow design and coding techniques to optimize the performance of your message flows. You can then analyze statistical information for your message flows and modify aspects of your integration server configuration to tune the performance of your integration servers and message flows.

About this task

The way in which you configure your integration server environment can affect the performance of your applications. Review the information in "Performance planning" on page 16, and decide which actions you can take to improve performance.

The following topics describe some design tips and techniques for optimizing performance, and explain how you can collect message flow and resource statistics and then use the data to help you tune performance:

- "Message flow design and performance" on page 2689
- "Code design and performance" on page 2690
- "Analyzing message flow performance" on page 2699
- "Analyzing resource performance" on page 2739

Activity Logs also provide information that you might find helpful when analyzing and tuning the performance of your integration servers. For more information, see "Activity Logs structure and types" on page 2858.

The following IBM Support pages provide results of a competitive performance evaluation of IBM App Connect Enterprise Version 11.0.0 against IBM Integration Bus Version 10.0.0:

- IBM App Connect Enterprise V11 performance reports

  Results of a competitive performance evaluation of IBM App Connect Enterprise Version 11.0.0.6 against IBM Integration Bus Version 10.0.0.18 in traditional non-virtualized environments on Linux, Windows, and AIX.
- IBM App Connect Enterprise V11 container performance reports

  Results of a competitive performance evaluation of IBM App Connect Enterprise Version 11.0.0.4 against IBM Integration Bus Version 10.0.0.16 in Docker container environments on Linux and Windows.

Performance planning

When you design your IBM App Connect Enterprise environment and the associated resources, the decisions that you make can affect the performance of your applications.

About this task

If you are planning to create and maintain a small, stand-alone system with limited requirements for availability and performance, it is possible to achieve this relatively quickly. However, if you are planning a large or complex system, or if you have specific requirements for high availability or performance, it is worth taking time to understand the factors that can influence your design and the techniques that you can use to optimize it. As a starting point, consider the following aspects of your system and understand how these factors can influence performance:

Message flows
: A message flow includes an input node that receives a message from an application over a particular protocol; for example, IBM MQ. The message must be parsed by the input node, and the performance impact of this parsing varies according to the parser that is used and the number of parses required. You can reduce the impact of parsing by using some optimization techniques such as parsing avoidance or partial parsing. For more information about parsing, see "Parsing and message flow performance" on page 2697.

The number and length of message flows have implications for performance, and it is important to keep the number of nodes to a minimum. See “Message flow design and performance” on page 2689 for more information about optimizing message flow performance. Other aspects of processing in a message flow that might affect performance are the amount, efficiency, and complexity of ESQL, access to databases, and how many message tree copies are made. For more guidance about these factors, see “Code design and performance” on page 2690.

It is also important to consider how you split your business logic; how much work should the application do, and how much should the message flow do? Every interaction between an application and a message flow involves I/O and message parsing, and therefore adds to processing time. Design your message flows, and design or restructure you applications, to minimize these interactions.

Messages and message models

The type, format, and size of the messages that are processed can have a significant effect on the performance of a message flow. For example, if you process persistent messages, they must be stored for safekeeping.

If you do not plan to interrogate the structure, you can use the BLOB domain.

If you are working with general text or binary messages, then you need to create a DFDL (or MRM) model to describe the message. The organization of the model can have a significant effect on performance. For fields that are choices, are optional, or are in arrays, the model must identify the field as efficiently as possible. Use tags (named initiators in DFDL) if they are available. To resolve a choice, DFDL provides a direct dispatch mechanism, which avoids parsing each branch in turn if there is a field that indicates which branch to take. If you are using a DFDL discriminator, ensure that the discriminator is placed so that it is evaluated as early as possible. While regular expressions can be used to identify and extract fields, they are generally slower than other techniques.

If you are working in XML, be aware that it can be verbose, and therefore produce large messages. However, XML message content is easier to understand than other formats, such as binary fixed-length format.

For more information about these factors, see Performance considerations for regular expressions in TDS messages.

Integration node configuration

You can create and configure one or more integration nodes, on one or more computers, and for each integration node you can create multiple integration servers, and multiple message flows. Your configuration decisions can influence message flow performance, and how efficiently messages can be processed.

For more information about these factors, see “Tuning the integration node” on page 2762, and “Optimizing message flow throughput” on page 2763.

Message flow design and performance

Consider the performance implications arising from the design of your message flow.

Before you begin

Read the following topics:

- “Performance” on page 2688
- “Performance planning” on page 16

About this task

To achieve the best performance from your message flows, consider the following points:

- Ensure that message flows are an appropriate length. Long message flows take longer to execute than short ones, but the use of many short message flows reduces performance more than the use of a few longer message flows.

- Use the minimum number of nodes required, and ensure that any subflows or loops are used appropriately.
- Avoid having consecutive ESQL Compute nodes in a message flow with no other nodes between them. Combine the logic into a single Compute node instead. Also avoid having consecutive JavaCompute nodes in the message flow.
- Minimize the volume of message parsing and adopt the most efficient parsing strategy; for more information, see “Parsing and message flow performance” on page 2697.
- Custom canonical data formats provide a point of standardization, but they also involve additional CPU processing. The use of such formats typically results in two additional conversions per invocation of a message flow: from the external format into the canonical format and then from the canonical format to the final external format.
- If a message flow makes a synchronous call to an external application or service that can be slow or unpredictable in its response, it is more efficient to write the message flow using an asynchronous model.
- Ensure that your processing logic implements the coding tips provided in “Code design and performance” on page 2690.

Code design and performance

Consider the performance implications arising from the design of your code.

Before you begin

Read the following topics:

- “Performance” on page 2688
- “Performance planning” on page 16

About this task

The following topics describe some of the design decisions that can influence the performance of your code:

- “ESQL code tips” on page 2690
- “Java code tips” on page 2694
- “XPath and XSLT code tips” on page 2696
- “Parsing and message flow performance” on page 2697
- “Message tree navigation and copying” on page 2698

ESQL code tips

You can improve message flow performance with ESQL by using some optimization techniques.

Before you begin

Read the following topics:

- “Performance” on page 2688
- “Performance planning” on page 16

About this task

When you write your ESQL code, you can use several techniques to improve the performance of your message flows. The following sections contain guidance about how to improve the performance of your ESQL code:

- “ESQL array processing” on page 2691

ESQL array processing

About this task

Array subscripts [ ] are expensive in terms of performance because of the way in which subscript is evaluated dynamically at run time. By avoiding the use of array subscripts wherever possible, you can improve the performance of your ESQL code. You can use reference variables instead, which maintain a pointer into the array and which can then be reused; for example:

```
DECLARE myref REFERENCE TO InputRoot.XML.Invoice.Purchases.Item[1];
-- Continue processing for each item in the array
WHILE LASTMOVE(myref)=TRUE DO
   -- Add 1 to each item in the array
   SET myref = myref + 1;
   -- Do some processing
   -- Move the dynamic reference to the next item in the array
   MOVE myref NEXTSIBLING;
END WHILE;
```

ESQL array processing example:

The following example shows ESQL being used to process records read from a database. The repeated use of array subscripts such as `Environment.Variables.DBData[A]` increases the processing time significantly:

```
SET Environment.Variables.DBDATA[] =
(
SELECT T.*
FROM Database.{'ABC'}.{'XYZ'} as T
);

DECLARE A INTEGER 1;
DECLARE B INTEGER CARDINALITY(Environment.Variables.*[]);
SET JPcntFODS = B;
WHILE A <= B DO
            CALL CopyMessageHeaders();
            CREATE FIELD OutputRoot.XML.FODS;
            DECLARE outRootRef REFERENCE TO OutputRoot.XML.Data;

            SET outRootRef.Field1 = Trim(Environment.Variables.DBDATA[A].Field1);
            SET outRootRef.Field2 = Trim(Environment.Variables.DBDATA[A].Field2);
            SET outRootRef.Field3 = Trim(Environment.Variables.DBDATA[A].Field3);
            SET outRootRef.Field4 = Trim(Environment.Variables.DBDATA[A].Field4);
            SET outRootRef.Field5 = Trim(Environment.Variables.DBDATA[A].Field5);
            . . .
            . . .
            SET outRootRef.Field37 = CAST(Environment.Variables.DBDATA[A].Field37)

            SET A = A + 1;
            PROPAGATE;
END WHILE;
```

You can reduce the processing time significantly by using reference variables

ESQL CARDINALITY function

About this task

Avoid the use of CARDINALITY in a loop; for example:

```
WHILE ( I < CARDINALITY (InputRoot.MRM.A.B.C[]
```

The CARDINALITY function must be evaluated each time the loop is traversed, which is costly in performance terms. This is particularly true with large arrays because the loop is repeated more frequently. It is more efficient to determine the size of the array before the WHILE loop (unless it changes in the loop) so that it is evaluated only once; for example:

```
SET ARRAY_SIZE = CARDINALITY (InputRoot.MRM.A.B.C[]
WHILE ( I < ARRAY_SIZE )
```

ESQL DECLARE and EVAL statements

About this task

Reduce the number of DECLARE statements (and therefore the performance cost) by declaring a variable and setting its initial value within a single statement. Alternatively, you can declare multiple variables of the same data type within a single ESQL statement rather than in multiple statements. This technique also helps to reduce memory usage.

The EVAL statement is sometimes used when there is a requirement to dynamically determine correlation names. However, it is expensive in terms of CPU use, because it involves the statement being run twice. The first time it runs, the component parts are determined, in order to construct the statement that will be run; then the statement that has been constructed is run.

ESQL PASSTHRU statement

About this task

The following techniques can significantly improve performance when you are using PASSTHRU statements:

- Avoid the use of the PASSTHRU statement with a CALL statement to invoke a stored procedure. As an alternative, you can use the `CREATE PROCEDURE ... EXTERNAL ...` and `CALL ...` commands.
- When you are working with SQL statements that require literal or data values, use host variables, which map a column value to a variable. This enables dynamic SQL statements to be reused within the database. An SQL PREPARE on a dynamic statement is an expensive operation in performance terms, so it is more efficient to run this only once and then EXECUTE the statement repeatedly, rather than to PREPARE and EXECUTE every time.

For example, the following statement has two data and literal values, `100` and `IBM`:

```
PASSTHRU('UPDATE SHAREPRICES AS SP SET Price = 100 WHERE SP.COMPANY = ‘IBM'');
```

This statement is effective when the price is `100` and the company is `IBM`. When either the *Price* or *Company* changes, another statement is required, with another SQL PREPARE statement, which impacts performance.

However, by using the following statement, *Price* and *Company* can change without requiring another statement or another PREPARE:

```
PASSTHRU('UPDATE SHAREPRICES AS SP SET Price = ? WHERE SP.COMPANY = ?',
InputRoot.XML.Message.Price,InputRoot.XML.Message.Company);
```

You can check that dynamic SQL is achieving maximum statement reuse, by using the following commands to display the contents of the SQL statement cache in DB2:

```
db2 connect to <database name>
db2 get snapshot for database on <database name>
```

Use the following commands to see the contents of the dynamic statement cache:

```
db2 connect to <database name>
db2 get snapshot for dynamic SQL on <database name>
```

ESQL reference variables

About this task

You can use reference variables to refer to long correlation names such as `InputRoot.XMLNSC.A.B.C.D.E`. Declare a reference pointer as shown in the following example:

```
DECLARE refPtr REFERENCE to InputRoot.XMLNSC.A.B.C.D;
```

To access element E of the message tree, use the correlation name `refPtr.E`.

You can use REFERENCE and MOVE statements to help reduce the amount of navigation within the message tree, which improves performance. This technique can be useful when you are constructing a large number of SET or CREATE statements; rather than navigating to the same branch in the tree, you can use a REFERENCE variable to establish a pointer to the branch and then use the MOVE statement to process one field at a time.

ESQL string functions

About this task

String manipulation functions used within ESQL can be CPU intensive; functions such as LENGTH, SUBSTRING, and RTRIM must access individual bytes in the message tree. These functions are expensive in performance terms, so minimizing their use can help to improve performance. Where possible, also avoid executing the same concatenations repeatedly, by storing intermediate results in variables.

Message trees with repeating records

About this task

Performance can be reduced under the following conditions:

- You are using ESQL processing to manipulate a large message tree
- The message tree consists of repeating records or many fields
- You have used explicit SET statements with field reference paths to access or create the fields
- You have observed a gradual slowing of message flow processing as the ESQL processes more fields or repetitions

This problem occurs when you use field references, rather than reference variables, to access or create consecutive fields or records.

The following example shows independent SET statements using field reference paths to manipulate the message tree. The SET statement takes a source and target parameter, where either or both parameters are field references:

```
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field = '1';
```

Performance is affected by the SET statement being used to create many more fields, as shown in the following example:

```
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field1 = '1';
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field2 = '2';
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field3 = '3';
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field4 = '4';
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field5 = '5';
```

In this example, the five fields that are created are all children of ParentA. Before the specified field can be created or modified, the integration node must navigate the named message tree to locate the point in the message tree that is to be altered. For example:

- To access field 1, the SET statement navigates to ParentA, then to the first field, involving two navigations.
- To access field 5, the SET statement navigates to ParentA, then traverses each of the previous fields until it reaches field 5, involving six navigations.

Navigating over all the fields that precede the specified field causes the loss in performance.

The following example shows repeating fields being accessed in an input message tree:

```
DECLARE myChar CHAR;
DECLARE thisRecord INT 0;
WHILE thisRecord < 10000 DO
 SET thisRecord = thisRecord + 1;
 SET myChar = InputRoot.MRM.myParent.myRepeatingRecord[thisRecord];
END WHILE;
```

When index notation is used, as the count increases, the processing must navigate over all the preceding fields to get the required field; it must count over the previous records to get to the one that is represented by the current indexed reference.

- When accessing InputRoot.MRM.myParent.myRepeatingRecord[1], one navigation takes place to get to the first record
- When accessing InputRoot.MRM.myParent.myRepeatingRecord[2], two navigations take place to get to the second record
- When accessing InputRoot.MRM.myParent.myRepeatingRecord[N], *N* navigations take place to get to the N-th record

Therefore, the total number of navigations for this WHILE loop is: 1 + 2 + 3 + ... + *N*, which is not linear.

If you are accessing or creating consecutive fields or records, you can solve this problem by using reference variables.

When you use reference variables, the statement navigates to the main parent, which maintains a pointer to the field in the message tree. The following example shows the ESQL that can be used to reduce the number of navigations when creating new output message tree fields:

```
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field1 = '1';
DECLARE outRef REFERENCE TO OutputRoot.XMLNS.TestCase.StructureA.ParentA;
SET outRef.field2 = '2';
SET outRef.field3 = '3';
SET outRef.field4 = '4';
SET outRef.field5 = '5';
```

When referencing repeating input message tree fields, you can use the following ESQL:

```
DECLARE myChar CHAR;
DECLARE inputRef REFERENCE TO InputRoot.MRM.myParent.myRepeatingRecord[1];
WHILE LASTMOVE(inputRef) DO
 SET myChar = inputRef;
 MOVE inputRef NEXTSIBLING NAME 'myRepeatingRecord';
END WHILE;
```

For further information, see “Creating dynamic field references” on page 1639.

Java code tips

You can improve message flow performance with Java by using some optimization techniques.

Before you begin

Read the following topics:

- “Performance” on page 2688
- “Performance planning” on page 16

About this task

A significant proportion of the performance problems relating to Java are caused by memory and garbage collection issues, by interaction with external resources, and by Java code that could benefit from optimization. Follow these steps to identify and solve such performance issues:

- Use the JVM resource statistics to review how much memory is in use by the JVM, and how often garbage collection is occurring in the integration server. For more information, see “Resource statistics data: Java Virtual Machine (JVM)” on page 2754.
- If you are calling external resources, review the elapsed time of the call.
- Review your Java code to identify any aspects that might benefit from optimization. There are several techniques that you can use to optimize the performance of your Java code in a message flow, including those described in the following sections:
  - “Tree references” on page 2695
  - “Java string concatenation” on page 2696
  - “Java BLOB processing” on page 2696
  - “Java manual garbage collection” on page 2696

The JavaCompute node enables you to include any valid Java processing, and it is common to reuse existing Java classes for specific functions. However, this code impacts the performance of the message flow, so ensure that any code used in this way is efficient.

Where possible, use the supplied nodes and functions of IBM App Connect Enterprise to perform processing on a message, rather than re-creating function that is already provided. For example, do not use a custom XML parser within the JavaCompute node. The XMLNSC parser that is provided with IBM App Connect Enterprise is a high-performing parser that also offers validation against a schema, and the message tree that it generates can be used throughout the message flow. This is not the case with a custom parser with its own data structures.

Avoid starting new processes in the JavaCompute node to perform a specific piece of work. This is expensive in performance terms and results in additional CPU costs and an increased load on the system, because many short-lived processes are started and terminated when the work is completed. One of the benefits of the IBM App Connect Enterprise runtime is that processes are long lived and initialization is minimized. This reduces total processing costs, because new processes are not started each time the message flow is invoked.

For information about tools that you can use to assess the current status of a running Java application, see developerWorks IBM Monitoring and Diagnostic Tools for Java - Health Center Version 2.1.

Tree references

About this task

Avoid building and navigating trees without storing intermediate references. For example, the following code repeatedly navigates from `root` to build the tree:

```
MbMessage newEnv = new MbMessage(inAssembly.getMessage());
newEnv.getRootElement().createElementAsFirstChild(MbElement.TYPE_NAME, "Destination", null);
newEnv.getRootElement().getFirstChild().createElementAsFirstChild(MbElement.TYPE_NAME,
 "MQDestinationList", null);
newEnv.getRootElement().getFirstChild().getFirstChild().createElementAsFirstChild(MbElement.TYPE_NAME,"Destin
 null);
```

However, it is more efficient to store references as shown in the following example:

```
MbMessage newEnv = new MbMessage(inAssembly.getMessage());
```

```
MbElement destination =
 newEnv.getRootElement().createElementAsFirstChild(MbElement.TYPE_NAME,"Destination", null);
MbElement mqDestinationList = destination.createElementAsFirstChild(MbElement.TYPE_NAME,
 "MQDestinationList",
    null);
mqDestinationList.createElementAsFirstChild(MbElement.TYPE_NAME,"DestinationData", null);
```

Java string concatenation

About this task

The + operator has a negative impact on performance because it involves creating a new String object for each concatenation; for example:

```
keyforCache = hostSystem + CommonFunctions.separator
+ sourceQueueValue + CommonFunctions.separator
+ smiKey + CommonFunctions.separator
+ newElement;
```

To improve performance, use the StringBuffer class and append method to concatenate java.lang.String objects, rather than the + operator, as shown in the following example:

```
StringBuffer keyforCacheBuf = new StringBuffer();
keyforCacheBuf.append(hostSystem);
keyforCacheBuf.append(CommonFunctions.separator);
keyforCacheBuf.append(sourceQueueValue);
keyforCacheBuf.append(CommonFunctions.separator);
keyforCacheBuf.append(smiKey);
keyforCacheBuf.append(CommonFunctions.separator);
keyforCacheBuf.append(newElement);
keyforCache = keyforCacheBuf.toString();
```

Java BLOB processing

About this task

If you want to process a BLOB (by cutting it into chunks or by inserting characters, for example), it is efficient to use a JavaCompute node with its strong processing capabilities. If you are using a JavaCompute node, use ByteArrays and ByteArrayOutputStream to process the BLOB.

Java manual garbage collection

About this task

Avoid manually invoking garbage collection, because it suspends the processing in the JVM, which significantly inhibits message throughput. In one example, a Java-based transformation message flow that was processing at the rate of 1300 messages per second without manual garbage collection was reduced to 100 messages per second when one manual garbage collection call was added to each message being processed.

XPath and XSLT code tips

You can improve message flow performance with XPath and XSLT by using some optimization techniques.

Before you begin

Read the following topics:

- “Performance” on page 2688
- “Performance planning” on page 16

About this task

You can improve the performance of XPath by explicitly specifying the number of instances that are required. For example:

- `/element[1]` finds the first occurrence of the element and then stops
- `/element[2]` finds the second occurrence of the element and then stops
- `/element` returns a node set of all instances in the message, which involves a full parse of the message

For more information about techniques that you can use to optimize your XML code, see Top 10 tips for using XPath.

XSLT has advantages in terms of its potential for code reuse, and caching is available for loaded stylesheets in IBM App Connect Enterprise. However, the stylesheet requires a BLOB as input and produces a BLOB as output, and it is less efficient than ESQL and Java in terms of interaction with the message tree. When it is used mid-stream with other IBM App Connect Enterprise technologies, it results in increased message parsing and serialization.

You can optimize the performance of your XSLT code by using a templates object (with different transformers for each transformation) to do multiple transformations with the same set of stylesheet instructions. You can also improve the efficiency of your stylesheets, by using the following techniques:

- Use `xsl:key` elements and the `key()` function as an efficient way to retrieve node sets
- Where possible, use pattern matching rather than `xsl:if` or `xsl:when` statements
- Avoid the use of `"//"` (descendant axes) patterns near the root of a large document

Also consider the following points:

- When you are creating variables, `<xsl:variable name="abcElem" select="abc"/>` is usually faster than `<xsl:variable name="abcElem"><xsl:value-of-select="abc"/></xsl:variable>`
- `xsl:for-each` is fast because it does not require pattern matching
- `xsl:sort` prevents incremental processing
- Use of index predicates within match patterns can be costly in terms of performance
- Decoding and encoding are costly in terms of performance
- If the XSLT is cached, the performance is improved because the XSLT is not parsed every time it is used; for more information, see node

Parsing and message flow performance

Understand the impact of parsing on message flow performance, and use techniques to limit the effect and improve performance.

Before you begin

Read the following topics:

- “Performance” on page 2688
- “Performance planning” on page 16

About this task

Parsing is the means of populating and serializing the message tree from the data, and it can occur whenever the message body is accessed. Multiple parsers are available, and the message complexity varies together with the cost in terms of performance. You can minimize the impact of parsing on message flow performance in the following ways:

Procedure

- Identify the message type as quickly as possible, and avoid using multiple parses to find it.
- Use the most efficient parser available, such as XMLNSC for XML parsing, and DFDL for non-XML parsing. For more information about parsing, see "Parsers" on page 520 and Available parsers.
- Use parser optimization techniques, such as parsing avoidance, partial parsing (parsing on demand), and opaque parsing:
  - If possible, avoid the use of parsing completely, or consider sending only changed data. If you promote or copy key data structures to MQMD, MQRFH2, or JMS properties, you might be able to avoid the need to parse the user data; this technique can be particularly useful for message routing.
  - Partial parsing (known as parsing on demand) involves parsing a message only when it is necessary to resolve the reference to a particular part of its content. For more information, see Parsing on demand.
  - Opaque parsing reduces the size of the message tree, which results in improved performance. You can configure opaque parsing on the **Parser Options** tab of input nodes. If you enable validation, you cannot use opaque parsing.

Message tree navigation and copying

Message tree navigation and message tree copying can reduce message flow performance, so it is important to use them appropriately and limit their usage where possible.

Before you begin

Read the following topics:

- "Performance" on page 2688
- "Performance planning" on page 16

About this task

Long paths are inefficient, so ensure that you minimize their usage, particularly in loops. Using reference variables and pointers in ESQL and Java can improve performance. Where possible, build a smaller message tree by using compact parsers such as DFDL, XMLNSC, MRM XML, RFH2C, and use opaque parsing.

Message tree copying is also costly in terms of resources, because it causes the logical tree to be duplicated in memory. You can improve performance by reducing the number of times that the message tree is copied, by using the following techniques:

- Reduce the number of Compute and JavaCompute nodes in a message flow
- If possible, set the `Compute Mode` property on the node to not include the message
- Copy at an appropriate level in the message tree; for example, copy once rather than for multiple branch nodes
- Copy data to the environment; however, remember that changes are not backed out

In addition to these techniques, the effect of copying the message tree is reduced if you also reduce the size of the message tree by using compact parsers and opaque parsing. For more information, see "Parsing and message flow performance" on page 2697.

Analyzing message flow performance

You can configure your integration servers to collect statistics about the operation and behavior of your message flows. Use this information to assess the performance of your message flows.

Before you begin

Read the concept topic "Message flow statistics and accounting data" on page 2699

About this task

Measures of performance typically include product speed in terms of processing rate and response times, and resource usage in terms of the CPU and memory consumed. In order to assess the performance of an application, metrics are used to compare the actual performance with the required or expected performance, using measures such as the number of messages per second, elapsed time, CPU utilization, or CPU cost per message. You can use the message flow statistics and accounting data to assess the performance of your message flows and applications using some of these metrics, and to identify the message flows and nodes that might benefit from tuning to improve performance.

Message flow statistics for subflows are accumulated in the metrics for the top-level parent flow. For example, if a subflow contains an Input node, the number of message flow threads and any node-level additional instances from the subflow will be reported in the **NumberOfThreadsInPool** property of the statistics for the parent flow.

You can configure and start or stop the collection of statistics data, either by modifying the `.yaml` configuration file for the integration node or server, or by running the command. For more information, see "Configuring the collection of message flow statistics by using a .yaml configuration file" on page 2729 and "Configuring the collection of message flow statistics by using the mqsichangeflowstats command" on page 2732.

You can view the collected statistics by using the web user interface, as described in "Viewing message flow statistics and accounting data" on page 2738.

For information about how to see the current settings for message flow statistics collection, see "Viewing message flow accounting and statistics data collection parameters by using the mqsireportflowstats command" on page 2736.

For troubleshooting information that includes guidance on dealing with performance issues, see "Troubleshooting performance problems" on page 2766.

Message flow statistics and accounting data

Message flow statistics and accounting data can be collected to record performance and operating details of one or more message flows.

You can use message flow statistics and accounting data to capture dynamic information about the runtime behavior of a message flow. For example, it indicates how many messages are processed and how large those messages are, processor usage and elapsed processing times. The statistical data is collected and recorded in a specified location when an event occurs. For example, when a snapshot interval expires or when the integration server that you are collecting information about stops. You can configure the data to be published in JSON or XML formats, or to be written in Comma Separated Values (CSV) format so that you can use it in a spreadsheet.

You can publish statistics and accounting data to one or more of the following destinations:

- The App Connect Enterprise web user interface (independent integration servers and integration servers that are managed by an integration node)
- Files
- User trace
- IBM MQ
- MQTT

You can use the statistics that are generated for the following purposes:

- You can use snapshot data to assess the execution of a message flow to determine why it, or a node within it, is not performing as you expect.
- You can determine the route that messages are taking through a message flow. For example, you might find that an error path is taken more frequently than you expect. You can use the statistics to understand when the messages are routed to this error path.

  Check the information provided by snapshot data for routing information. If this information is insufficient for your needs, use archive data.
- You can record the load that applications, business partners, or other users put on the integration server. You can use this information to calculate what to charge users based on their relative use of the integration server. For example, you might levy a nominal charge on every message that is processed by an integration server, or by a specific message flow. You can use archive data to make an assessment of this kind.

The integration server takes information about statistics and accounting from the operating system. On some operating systems, such as Windows and Linux, rounding can occur because the system calls that are used to determine the processor times are not sufficiently granular. This rounding might affect the accuracy of the data.

Data relating to the size of messages is not collected for WebSphere Adapters nodes. For example:

- The SAPInput node
- The FileInput node
- The JMSInput node
- Any user-defined input node that does not create a message tree from a bit stream.

You can start and stop data collection by modifying the statistics collection properties in the `node.conf.yaml` or `server.conf.yaml` configuration file for the integration node or server.

When an integration node or server is created, the publication of snapshot message flow statistics is enabled by default. The **`publicationOn`** property in the `node.conf.yaml` or `server.conf.yaml` file is explicitly set to `active` and the **`outputFormat`** property is set to `json`, which enables the publication of snapshot statistics to the web user interface. The publication of archive statistics is turned off by default.

For integration nodes and servers that were created prior to IBM App Connect Enterprise Version 11.0.0.8, the publication of all message flow statistics (snapshot and archive) was turned off by default. To enable the publication of statistics for integration nodes or servers that were created prior to V11.0.0.8, edit the relevant `.conf.yaml` file and activate the **`publicationOn`** and **`outputFormat`** properties.

For more information, see "Configuring the collection of message flow statistics by using a .yaml configuration file" on page 2729 and "Configuring an integration server by modifying the server.conf.yaml file" on page 172.

You can activate data collection on your production and test systems. If you collect the default level of statistics (message flow), the effect on performance is minimal. However, collecting more data than the default message flow statistics can generate high volumes of report data that might affect performance slightly.

The information in the following topics helps you when you are planning your data collection:

- "Message flow accounting and statistics collection options" on page 2702
- "Message flow accounting and statistics accounting origin" on page 2702
- "Output formats for message flow accounting and statistics data" on page 2704

The following topic contains reference information that you might find helpful when you analyze and tune the performance of your message flows: "Message flow accounting and statistics records" on page 2703.

Publishing data to IBM MQ and MQTT

If you want to publish data to IBM MQ or MQTT, ensure that the publication of events is enabled and that the pub/sub broker is configured before you start data collection. For more information, see "Configuring the publication of event messages" on page 2807 and "Configuring the built-in MQTT pub/sub broker" on page 2811.

The topic for each message has the following structure:

- For XML format:
  - For an IBM MQ pub/sub broker:

    ```
    $SYS/Broker/integrationNodeName/StatisticsAccounting/integration_server_name
    ```

  - For an MQTT pub/sub broker:

    ```
    IBM/IntegrationBus/integrationNodeName/StatisticsAccounting/integration_server_name
    ```

- For JSON format:
  - For an IBM MQ pub/sub broker:

    ```
    $SYS/Broker/integrationNodeName/Statistics/JSON/integration_server_name
    ```

  - For an MQTT pub/sub broker:

    ```
    IBM/IntegrationBus/integrationNodeName/Statistics/JSON/integration_server_name
    ```

You can set up subscriptions for a specific integration server on a specific integration node. For example:

- For XML format:
  - For an IBM MQ pub/sub broker:

    ```
    $SYS/Broker/INODE/StatisticsAccounting/default
    ```

  - For an MQTT pub/sub broker:

    ```
    IBM/IntegrationBus/INODE/StatisticsAccounting/default
    ```

- For JSON format:
  - For an IBM MQ pub/sub broker:

    ```
    $SYS/Broker/INODE/Statistics/JSON/default
    ```

  - For an MQTT pub/sub broker:

    ```
    IBM/IntegrationBus/INODE/Statistics/JSON/default
    ```

You can also use wildcards in the subscriptions to broaden the scope of what is returned. For example, to subscribe to reports for all integration servers on all integration nodes, use the following values:

- For XML format:
  - For an IBM MQ pub/sub broker:

    ```
    $SYS/Broker/+/StatisticsAccounting/#
    ```

  - For an MQTT pub/sub broker:

    ```
    IBM/IntegrationBus/+/StatisticsAccounting/#
    ```

- For JSON format:
  - For an IBM MQ pub/sub broker:

    ```
    $SYS/Broker/+/Statistics/JSON/#
    ```

  - For an MQTT pub/sub broker:

    ```
    IBM/IntegrationBus/+/Statistics/JSON/#
    ```

Message flow accounting and statistics collection options

The options that you specify for message flow accounting and statistics collection determine what information is collected. You can configure the collection of snapshot data, archive data, or both.

- Snapshot data is collected for an interval of approximately 20 seconds. The exact length of the interval depends on system loading and the level of current integration server activity. You cannot modify the length of time for which snapshot data is collected. At the end of this interval, the recorded statistics are written to the output destination and the interval is restarted.
- Archive data is collected for an interval that you have set for the integration node or integration server, by setting the **`Statistics.Archive.majorInterval`** property in the relevant `node.conf.yaml` or `server.conf.yaml` configuration file. You can specify an interval in the range 1 through 43200 minutes; the default value is 60 minutes. At the end of this interval, the recorded statistics are written to the output destination and the interval is restarted.

  An interval ends and restarts when any of the following events occur, to preserve the integrity of the data that has been collected prior to the event:

  - The message flow is redeployed
  - The set of statistics data to be collected is modified
  - The integration node is shut down

You can modify the statistics properties in the `node.conf.yaml` or `server.conf.yaml` files to specify snapshot data collection, archive data collection, or both. When you have updated the `.yaml` file, you must restart the integration node or server for the changes to take effect. The state of the statistics collection that is configured in the `.yaml` file is applied to all flows that are deployed when the integration server starts, and also to any additional flows that are deployed afterwards. For information about configuring an integration server or integration node by editing a `.yaml` file, see “Configuring an integration server by modifying the server.conf.yaml file” on page 172 and “Configuring an integration node by modifying the node.conf.yaml file” on page 118. Alternatively, by using the **`mqsichangeflowstats`** command, you can specify snapshot data collection, archive data collection, or both. You can activate snapshot data collection while archive data collection is active. The data recorded in both reports is the same, but is collected for different intervals. If you activate both snapshot and archive data collection, be careful not to combine information from the two different reports, because you might count information twice.

You can view statistics data as it is generated by selecting the **Statistics** tab in the web user interface.

For information about how to configure the collection of snapshot or archive statistics, see “Configuring the collection of message flow accounting and statistics data” on page 2728.

Message flow accounting and statistics accounting origin

Accounting and statistics data can be accumulated and reported with reference to an identifier associated with a message in a message flow. This identifier is the accounting origin, which provides a method of producing individual accounting and statistics data for multiple accounting origins that generate input to message flows. The accounting origin can be a fixed value, or it can be dynamically set according to your criteria.

For example, if your integration node hosts a set of message flows associated with a particular client in a single integration server, you can set a specific value for the accounting origin for all these flows. You can then analyze the output provided to assess the use that the client or department makes of the integration node, and charge them accordingly.

If you want to track the behavior of a particular message flow, you can set a unique accounting origin for this message flow, and analyze its activity over a specified period.

To make use of the accounting origin, you must perform the following tasks:

- Activate data collection, and request basic support by setting the **accountingOrigin** parameter in the `node.conf.yaml` or `server.conf.yaml` configuration file to `basic` (the default is none, or no support). For more information about configuring statistics collection, see "Configuring the collection of message flow accounting and statistics data" on page 2728.
- Configure each message flow for which you want a specific origin to include ESQL statements that set the unique value that is to be associated with the data collected. Data for message flows for which a specific value has not been set are identified with the value `Anonymous`.

  The ESQL statements can be coded in a Compute, Database, or Filter node.

  You can configure the message flow either to set a fixed value, or to determine a dynamic value, and can therefore create a very flexible method of recording sets of data that are specific to particular messages or circumstances. For more information, refer to "Setting message flow accounting and statistics accounting origin" on page 2735.

You can complete these tasks in either order; if you configure the message flow before starting data collection, the integration node ignores the setting. If you start data collection, specifying accounting origin support, before configuring the message flow, all data is collected with the Accounting Origin set to `Anonymous`. The integration node acknowledges the origin when you redeploy the message flow. You can also modify data collection that has already started to request accounting origin support from the time that you issue the command. In both cases, data that has already been collected is written out and collection is restarted.

When data has been collected, you can review information for one or more specific origins. For example, if you select XML publication messages as your output format, you can start an application that subscribes to the origin in which you are interested.

Message flow accounting and statistics records

You can collect message flow, thread, node, and terminal statistics for message flows.

Message flow statistics

One record is created for each message flow in an integration server. Each record contains the following details:

- Message flow name
- Integration server name
- Start and end times for data collection
- Type of data collected (snapshot or archive)
- Processor and elapsed time spent processing messages
- Processor and elapsed time spent waiting for input
- Number of messages processed
- Minimum, maximum, and average message sizes
- Number of threads available and maximum assigned at any time
- Number of messages committed and backed out
- Accounting origin

Thread statistics

One record is created for each thread assigned to the message flow. Each record contains the following details:

- Thread number (this has no significance and is for identification only)
- Processor and elapsed time spent processing messages
- Processor and elapsed time spent waiting for input

- Number of messages processed
- Minimum, maximum, and average message sizes

Node statistics
One record is created for each node in the message flow. Each record contains the following details:

- Node name
- Node type (for example MQInput)
- Processor time spent processing messages
- Elapsed time spent processing messages
- Number of times that the node is invoked
- Number of messages processed
- Minimum, maximum, and average message sizes. When the node type is FileInput, the message size is reported as 0 because the size is not known at the time that the message is propagated.

Terminal statistics
One record is created for each terminal on a node. Each record contains the following details:

- Terminal name
- Terminal type (input or output)
- Number of times that a message is propagated to this terminal

For further details about specific output formats, see the following topics:

- "User trace entries for message flow accounting and statistics data" on page 2708
- "XML publication for message flow accounting and statistics data" on page 2718

Output formats for message flow accounting and statistics data
When you collect message flow statistics, you can choose the output destination for the data.

You can select one or more of the following destinations, by setting the **outputFormat** property in the configuration file for your integration node (`node.conf.yaml`) or integration server (`server.conf.yaml`):

- User trace
- "JSON publication" on page 2706
- XML publication
- CSV records

If no format is specified, accounting and statistics data is sent to the user trace log by default.

You can change the output format and destination of statistics data (snapshot, archive, or both) by setting the **outputFormat** property in the configuration file for your integration node (`node.conf.yaml`) or integration server (`server.conf.yaml`. You can set the output format of **snapshot** statistics data to one or more of the following values (separated by commas):

- csv
- json
- xml
- usertrace

You can set the output format of **archive** statistics data to one or more of the following values (separated by commas):

- csv
- xml
- usertrace

For more information about configuring the collection and publishing of message flow accounting and statistics data, see “Configuring the collection of message flow accounting and statistics data” on page 2728.

Before message flow accounting and statistics can be collected, you must ensure that the publication of events has been enabled and a pub/sub broker has been configured. For more information, see “Configuring the publication of event messages” on page 2807 and “Configuring the built-in MQTT pub/sub broker” on page 2811.

If you start the collection of message flow statistics data by using the web user interface, the statistics are emitted in JSON format in addition to any other formats that are already being emitted. If the output format was previously not specified and therefore defaulted to the user trace, the newly specified format replaces the default, and the data is no longer emitted to the user trace. However, if user trace has been explicitly specified, any additional formats that are selected subsequently are emitted in addition to the user trace.

If you use the **mqsichangeflowstats** command to explicitly specify the required output formats, the formats specified by the command replace the formats that are currently being emitted for the message flow (they are not added to them).

If you stop statistics collection from the web user interface, all output formats are turned off. If statistics collection is subsequently restarted by using the **mqsichangeflowstats** command, the output format is reset to the default value of `user trace`, unless other formats are specified on the command. However, if statistics collection is restarted by using the web user interface, data is collected in JSON format.

Statistics data is written to the specified output location in the following circumstances:

- When the archive data interval expires.
- When the snapshot interval expires.
- When the integration node shuts down. Any data that has been collected by the integration node, but has not yet been written to the specified output destination, is written during shutdown. It might therefore represent data for an incomplete interval.
- When any part of the integration node configuration is redeployed. Redeployed configuration data might contain an updated configuration that is not consistent with the existing record structure (for example, a message flow might include an additional node, or an integration server might include a new message flow). Therefore the current data, which might represent an incomplete interval, is written to the output destination. Data collection continues for the redeployed configuration until you change data collection parameters or stop data collection.
- When data collection parameters are modified. If you update the parameters that you have set for data collection, all data that is collected for the message flow (or message flows) is written to the output destination to retain data integrity. Statistics collection is restarted according to the new parameters.
- When an error occurs that terminates data collection. You must restart data collection yourself in this case.

User trace entries

You can specify that the data that is collected is written to the user trace log. The data is written even when trace is switched off.

If no output destination is specified for accounting and statistics, the default is the user trace log. If one or more output formats are subsequently specified, the specified formats replace the default, and the data is no longer emitted to the user trace. However, if user trace has been explicitly specified, any additional formats that are selected subsequently are emitted in addition to the user trace.

The data is written to one of the following locations:

 **Windows**

If you set the work path by using the **-w** parameter of the **mqsicreatebroker** command, the location is `workpath\Common\log`.

If you have not specified the integration node work path, the location is:

- On Windows:`C:\ProgramData\IBM\MQSI\Common\log`.

Linux UNIX **Linux**

`/var/mqsi/common/log`

For information about the user trace entries, see "User trace entries for message flow accounting and statistics data" on page 2708.

JSON publication

You can specify that the data that is collected is published in JSON format, which is available for viewing in the web user interface. If statistics collection is started through the web user interface, statistics data is emitted in JSON format in addition to any other formats that are already being emitted.

The topic on which the data is published has the following structure:

- For publications on an MQ pub/sub broker:

```
$SYS/Broker/integrationNodeName/Statistics/JSON/SnapShot/integrationServerName/
applications/application_name
/libraries/library_name/messageflows/message_flow_name
```

- For publications on an MQTT pub/sub broker:

```
IBM/IntegrationBus/integrationNodeName/Statistics/JSON/SnapShot/integrationServerName/
applications/application_name
/libraries/library_name/messageflows/message_flow_name
```

The variables correspond to the following values:

integrationNodeName
The name of the integration node for which statistics are collected. For an integration server that is managed by an integration node, *integrationNodeName* is the name of the integration node that manages the integration server. For an independent integration server, specify the literal string `integration_server` in place of an integration node name.

integration_server_name
The name of the integration server for which statistics are collected

application_name
The name of the application for which statistics are collected

library_name
The name of the library for which statistics are collected

message_flow_name
The name of the message flow for which statistics are collected

For information about the JSON publication, see "JSON publication for message flow accounting and statistics data" on page 2713.

XML publication

You can specify that the data that is collected is published in XML format and is available to subscribers registered in the integration node network that subscribe to the correct topic.

The topic on which the data is published has the following structure:

- For publications on an MQ pub/sub broker:

```
$SYS/Broker/integrationNodeName/StatisticsAccounting/record_type/integrationServerName/message_flow_label
```

- For publications on an MQTT pub/sub broker:

```
IBM/IntegrationBus/integrationNodeName/
StatisticsAccounting/record_type/integrationServerName/message_flow_label
```

The variables correspond to the following values:

integrationNodeName
The name of the integration node for which statistics are collected. For an integration server that is managed by an integration node, *integrationNodeName* is the name of the integration node that manages the integration server. For an independent integration server, specify the literal string `integration_server` in place of an integration node name.

record_type
Set to `SnapShot` or `Archive`, depending on the type of data to which you are subscribing. Alternatively, use *+* to register for both snapshot and archive data if it is being produced. This value is case sensitive and must be entered as `SnapShot`.

integrationServerName
The name of the integration server for which statistics are collected.

message_flow_label
The label on the message flow for which statistics are collected.

Subscribers can include filter expressions to limit the publications that they receive. For example, they can choose to see only snapshot data, or to see data that is collected for a single integration node. Subscribers can specify wild cards (*+* and *#*) to receive publications that refer to multiple resources. Use *+* to receive resources on one topic level, and *#* to receive resources across multiple topic levels.

The following examples show the topic with which a subscriber registers to receive different sorts of data:

- Register the following topic for the subscriber to receive data for all message flows running on an integration node named INODE:

  ```
  $SYS/Broker/INODE/StatisticsAccounting/#
  ```

  or

  ```
  IBM/IntegrationBus/INODE/StatisticsAccounting/#
  ```

- Register the following topic for the subscriber to receive only archive statistics that relate to a message flow `Flow1` running on integration server `default` on integration node INODE:

  ```
  $SYS/Broker/INODE/StatisticsAccounting/Archive/default/Flow1
  ```

  or

  ```
  IBM/IntegrationBus/INODE/StatisticsAccounting/Archive/default/Flow1
  ```

- Register the following topic for the subscriber to receive both snapshot and archive data for message flow `Flow1` running on integration server `default` on integration node INODE:

  ```
  $SYS/Broker/INODE/StatisticsAccounting/+/default/Flow1
  ```

  or

  ```
  IBM/IntegrationBus/INODE/StatisticsAccounting/+/default/Flow1
  ```

For help with registering your subscriber, see Message display, test and performance utilities SupportPac (IH03).

For information about the XML publication, see “XML publication for message flow accounting and statistics data” on page 2718.

CSV records

You can specify that the data that is collected is published in comma-separated value (`.csv`) format. Snapshot and archive data records are written to output files, which include a header with the field name. The fields for averages are optional, and are written only if the `averages` property of the statistics file writer is set to `true`.

One line is written for each message flow that is producing data for the time period that you choose. For example, if `MessageFlowA` and `MessageFlowB` are both producing archive data over a period of 60 minutes, both message flows produce a line of statistics data every 60 minutes.

For more information about the CSV records, see "CSV file format for message flow accounting and statistics data" on page 2724.

User trace entries for message flow accounting and statistics data
Certain information is written to the user trace log for message flow accounting and statistics data.

The data records are identified by the following message numbers:

- BIP2380I
- BIP2381I
- BIP2382I
- BIP2383I

The inserts for each message are described in the following tables.

This table describes the inserts in message BIP2380I. One message is written for the message flow.

Field	Data type	Details
ProcessID	Numeric	Process ID
Key	Numeric	Key that is used to associate related accounting and statistics BIP messages
Type	Character	Type of output, one of: • Archive • Snapshot
Reason	Character	Reason for output, one of: • MajorInterval • Snapshot • Shutdown • ReDeploy • StatsSettingsModified
BrokerLabel	Character (maximum 32)	Integration node name
BrokerUUID	Character (maximum 32)	Integration node universal unique identifier
ExecutionGroupName	Character (maximum 32)	Integration server name
ExecutionGroupUUID	Character (maximum 32)	Integration server universal unique identifier

Field	Data type	Details
MessageFlowName	Character (maximum 32)	Message flow name
StartDate	Character	Interval start date (YYYY-MM-DD)
StartTime	Character	Interval start time (HH:MM:SS:NNNNNN)
GMTStartTime	Character	Interval start date and time (universal timestamp in ISO8601)
EndDate	Character	Interval end date (YYYY-MM-DD)
EndTime	Character	Interval end time (HH:MM:SS:NNNNNN)
GMTEndTime	Character	Interval end date and time (universal timestamp in ISO8601)
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
MaximumElapsedTime	Numeric	Maximum elapsed time that is spent processing an input message (microseconds)
MinimumElapsedTime	Numeric	Minimum elapsed time that is spent processing an input message (microseconds)
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)
MaximumCPUTime	Numeric	Maximum processor time that is spent processing an input message (microseconds)
MinimumCPUTime	Numeric	Minimum processor time that is spent processing an input message (microseconds)
CPUTimeWaitingForInputMessage	Numeric	Total processor time spent waiting for input messages (microseconds)
ElapsedTimeWaitingForInputMessage	Numeric	Total elapsed time that is spent waiting for input messages (microseconds)
TotalInputMessages	Numeric	Total number of messages processed TotalInputMessages records only those messages that are propagated from input node terminals.
TotalSizeOfInputMessages	Numeric	Total size of input messages (bytes)
MaximumSizeOfInputMessages	Numeric	Maximum input message size (bytes)
MinimumSizeOfInputMessages	Numeric	Minimum input message size (bytes)
NumberOfThreadsInPool	Numeric	Number of threads in pool
TimesMaximumNumberofThreadsReached	Numeric	Number of times the maximum number of threads is reached

Field	Data type	Details
TotalNumberOfMQErrors	Numeric	Number of MQGET errors (MQInput node) or web services errors (HTTPInput node) For example, a conversion error occurs when the message is got from the queue.
TotalNumberOfMessagesWithErrors	Numeric	Number of messages that contain errors These errors include exceptions that are thrown downstream of the input node, and errors that are detected by the input node after it successfully retrieves the message from the queue (for example, a format error). TotalNumberOfMessagesWithErrors can include messages that are not included in TotalInputMessages.
TotalNumberOfErrorsProcessingMessages	Numeric	Number of errors while processing a message
TotalNumberOfTimeOutsWaitingForRepliesToAggregateMessages	Numeric	Number of timeouts while processing a message (AggregateReply node only)
TotalNumberOfCommits	Numeric	Number of transaction commits
TotalNumberOfBackouts	Numeric	Number of transaction backouts
AccountingOrigin	Character (maximum 32)	Accounting origin

The following table describes the inserts in message BIP2381I. One message is written for each thread.

Field	Data type	Details
ProcessID	Numeric	Process ID
Key	Numeric	Key that is used to associate related accounting and statistics BIP messages
Number	Numeric	Relative thread number in pool
TotalNumberOfInputMessages	Numeric	Total number of messages that are processed by a thread
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
TotalCUPTime	Numeric	Total processor time spent processing input messages (microseconds)
CPUTimeWaitingForInputMessage	Numeric	Total processor time spent waiting for input messages (microseconds)
ElapsedTimeWaitingForInputMessage	Numeric	Total elapsed time that is spent waiting for input messages (microseconds)
TotalSizeOfInputMessages	Numeric	Total size of input messages (bytes)

Field	Data type	Details
MaximumSizeOfInputMessages	Numeric	Maximum size of input messages (bytes)
MinimumSizeOfInputMessages	Numeric	Minimum size of input messages (bytes)

The following table describes the inserts in message BIP2382I. One message is written for each node.

Field	Data type	Details
ProcessID	Numeric	Process ID
Key	Numeric	Key that is used to associate related accounting and statistics BIP messages
Label	Character	Name of node (Label)
Type	Character	Type of node
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
MaximumElapsedTime	Numeric	Maximum elapsed time spent processing input messages (microseconds)
MinimumElapsedTime	Numeric	Minimum elapsed time spent processing input messages (microseconds)
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)
MaximumCPUTime	Numeric	Maximum processor time spent processing input messages (microseconds)
MinimumCPUTime	Numeric	Minimum processor time spent processing input messages (microseconds)
CountOfInvocations	Numeric	Total number of messages that are processed by this node
NumberOfInputTerminals	Numeric	Number of input terminals
NumberOfOutputTerminals	Numeric	Number of output terminals

The following table describes the inserts in message BIP2383I. One message is written for each terminal on each node.

Field	Data type	Details
ProcessID	Numeric	Process ID
Key	Numeric	Key that is used to associate related accounting and statistics BIP messages
Label	Character	Name of terminal
Type	Character	Type of terminal, one of: • Input • Output
CountOfInvocations	Numeric	Total number of invocations

For an example of user trace entries, see “Example of user trace entries for message flow accounting and statistics” on page 2712.

Example of user trace entries for message flow accounting and statistics
This example shows a user trace that contains message flow accounting and statistics data.

The following example shows what is generated for a snapshot report. The messages that are written to the trace show that the message flow is called *myExampleFlow*, and that it is running in an integration server named *default* on integration node TESTNODE_*user_name* . The message flow contains the following message flow nodes:

- An MQInput node called *inNode*
- A Compute node called *First1*
- An MQOutput node called *outNode*

The nodes are connected together (Out terminal to In terminal for each connection).

During the interval for which statistics have been collected, this message flow processed 150 input messages.

The records show that two threads are assigned to this message flow. One thread is assigned when the message flow is deployed (the default number); an additional thread (thread 0) listens on the input queue. The listening thread starts additional threads to process input messages that are dependent on the number of instances that you have configured for the message flow, and on the rate of arrival of the input messages on the input queue.

The following command has been issued to achieve these results:

```
mqsichangeflowstats TESTNODE_user_name -s -c active -e default -f myExampleFlow -n advanced -t basic -b
 basic
```

The integration node takes information about statistics and accounting from the operating system. On some operating systems, such as Windows, UNIX, and Linux, rounding can occur because the system calls that are used to determine the processor times are not sufficiently granular. This rounding might affect the accuracy of the data.

```
BIP2380I: IIB message flow statistics. ProcessID='328467', Key='6', Type='SnapShot', Reason='Snapshot',

JSON publication for message flow accounting and statistics data
Information is written to the JSON publication for message flow accounting and statistics data.

The data is created in the folder `WMQIStatisticsAccounting`, which contains subfolders that provide more detailed information. All folders are present in the publication even if you set current data collection parameters to specify that the relevant data is not collected. The data is published to the following topics:

Snapshot data

- For publications on an MQ pub/sub broker:

  ```
  $SYS/Broker/integrationNodeName/Statistics/JSON/SnapShot/
  ```

- For publications on an MQTT pub/sub broker:

```
IBM/IntegrationBus/integrationNodeName/Statistics/JSON/SnapShot/
```

Archive data

- For publications on an MQ pub/sub broker:

```
$SYS/Broker/integrationNodeName/Statistics/JSON/Archive/
```

- For publications on an MQTT pub/sub broker:

```
IBM/IntegrationBus/integrationNodeName/Statistics/JSON/Archive/
```

For an integration server that is managed by an integration node, *integrationNodeName* is the name of the integration node that manages the integration server. For an independent integration server, specify the literal string `integration_server` in place of an integration node name.

Snapshot data is used for performance analysis, and is published as retained and not persistent. Snapshot data is produced every 20 seconds, and you can view it in the web user interface to help you analyze the performance of your message flows. If statistics collection is started through the web user interface, statistics data is emitted in JSON format in addition to any other formats that are already being emitted.

Archive data is used for accounting where an audit trail might be required, and is published as retained and persistent. All publications are global and can be collected by a subscriber that is registered anywhere in the network. They can also be collected by more than one subscriber.

One JSON publication is generated for each message flow that is producing data for the time period that you choose. For example, if MessageFlowA and MessageFlowB are both producing archive data over a period of 60 minutes, both MessageFlowA and MessageFlowB produce a JSON publication every 60 minutes.

If you are concerned about the safe delivery of these messages (for example, for charging purposes), use a secure delivery mechanism such as IBM MQ.

The folders and subfolders in the JSON publication have the following identifiers:

- WMQIStatisticsAccounting
- MessageFlow
- ThreadStatistics
- NodesStatistics
- TerminalStatistics

The tables provided here describe the contents of each of these folders.

The following table describes the general accounting and statistics information, created in folder WMQIStatisticsAccounting.

Field	Data type	Details
RecordType	Character	Type of output, one of: • Archive • Snapshot
RecordCode	Character	Reason for output, one of: • MajorInterval • Snapshot • Shutdown • ReDeploy • StatsSettingsModified

Field	Data type	Details
NumberOfThreads	Numeric	Number of thread statistics subfolders in WMQIStatisticsAccounting folder
NumberOfNodes	Numeric	Number of node statistics subfolders in WMQIStatisticsAccounting folder

The following table describes the message flow statistics information, created in folder MessageFlow.

Field	Data type	Details
BrokerLabel	Character (maximum 32)	Integration node name
BrokerUUID	Character (maximum 32)	Integration node universal unique identifier
ExecutionGroupName	Character (maximum 32)	Integration server name
ExecutionGroupUUID	Character (maximum 32)	Integration server universal unique identifier
MessageFlowName	Character (maximum 32)	Message flow name
StartDate	Character	Interval start date (YYYY-MM-DD)
StartTime	Character	Interval start time (HH:MM:SS:NNNNNN)
GMTStartTime	Character	Interval start date and time (universal timestamp in ISO8601)
EndDate	Character	Interval end date (YYYY-MM-DD)
EndTime	Character	Interval end time (HH:MM:SS:NNNNNN)
GMTEndTime	Character	Interval end date and time (universal timestamp in ISO8601)
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
MaximumElapsedTime	Numeric	Maximum elapsed time that is spent processing an input message (microseconds)
MinimumElapsedTime	Numeric	Minimum elapsed time that is spent processing an input message (microseconds)

Field	Data type	Details
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)
MaximumCPUTime	Numeric	Maximum processor time that is spent processing an input message (microseconds)
MinimumCPUTime	Numeric	Minimum processor time that is spent processing an input message (microseconds)
CPUTimeWaitingForInputMessage	Numeric	Total processor time spent waiting for input messages (microseconds)
ElapsedTimeWaitingForInputMessage	Numeric	Total elapsed time that is spent waiting for input messages (microseconds)
TotalInputMessages	Numeric	Total number of messages processed TotalInputMessages records only those messages that are propagated from input node terminals.
TotalSizeOfInputMessages	Numeric	Total size of input messages (bytes)
MaximumSizeOfInputMessages	Numeric	Maximum input message size (bytes)
MinimumSizeOfInputMessages	Numeric	Minimum message input size (bytes)
NumberOfThreadsInPool	Numeric	Number of threads in pool
TimesMaximumNumberofThreadsReached	Numeric	Number of times the maximum number of threads is reached
TotalNumberOfMQErrors	Numeric	Number of MQGET errors (MQInput node) or web services errors (HTTPInput node) For example, a conversion error occurs when the message is got from the queue.
TotalNumberOfMessagesWithErrors	Numeric	Number of messages that contain errors These errors include exceptions that are thrown downstream of the input node, and errors that are detected by the input node after it successfully retrieves the message from the queue, but before it propagates it to the output terminal (for example, a format error). TotalNumberOfMessagesWithErrors can include messages that are not included in TotalInputMessages.
TotalNumberOfErrorsProcessingMessages	Numeric	Number of errors when processing a message

Field	Data type	Details
TotalNumberOfTimeOutsWaitingForRepliesToAggregateMessages	Numeric	Number of timeouts when processing a message (AggregateReply node only)
TotalNumberOfCommits	Numeric	Number of transaction commits
TotalNumberOfBackouts	Numeric	Number of transaction backouts
AccountingOrigin	Character (maximum 32)	Accounting origin

The following table describes the thread statistics information for each individual thread, created in folder ThreadStatistics.

Field	Data type	Details
Number	Numeric	Relative thread number in pool
TotalNumberOfInputMessages	Numeric	Total number of messages that are processed by a thread
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)
CPUTimeWaitingForInputMessage	Numeric	Total processor time spent waiting for input messages (microseconds)
ElapsedTimeWaitingForInputMessage	Numeric	Total elapsed time that is spent waiting for input messages (microseconds)
TotalSizeOfInputMessages	Numeric	Total size of input messages (bytes)
MaximumSizeOfInputMessages	Numeric	Maximum size of input messages (bytes)
MinimumSizeOfInputMessages	Numeric	Minimum size of input messages (bytes)

The following table describes the node statistics information for each individual node, created in folder NodesStatistics.

Field	Data type	Details
Label	Character	Name of node (Label)
Type	Character	Type of node
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
MaximumElapsedTime	Numeric	Maximum elapsed time spent processing input messages (microseconds)
MinimumElapsedTime	Numeric	Minimum elapsed time spent processing input messages (microseconds)
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)
MaximumCPUTime	Numeric	Maximum processor time spent processing input messages (microseconds)

Field	Data type	Details
MinimumCPUTime	Numeric	Minimum processor time spent processing input messages (microseconds)
CountOfInvocations	Numeric	Total number of messages that are processed by this node
NumberOfInputTerminals	Numeric	Number of input terminals
NumberOfOutputTerminals	Numeric	Number of output terminals

The following table describes the terminal statistics information, created in folder TerminalStatistics.

Field	Data type	Details
Label	Character	Name of terminal
Type	Character	Type of terminal, one of: • Input • Output
CountOfInvocations	Numeric	Total number of invocations

XML publication for message flow accounting and statistics data
Certain information is written to the XML publication for message flow accounting and statistics data.

The data is created in the folder `WMQIStatisticsAccounting`, which contains subfolders that provide more detailed information. All folders are present in the publication even if you set current data collection parameters to specify that the relevant data is not collected.

Snapshot data is used for performance analysis, and is published as retained and not persistent. Archive data is used for accounting where an audit trail might be required, and is published as retained and persistent. All publications are global and can be collected by a subscriber that is registered anywhere in the network. They can also be collected by more than one subscriber.

One XML publication is generated for each message flow that is producing data for the time period that you choose. For example, if MessageFlowA and MessageFlowB are both producing archive data over a period of 60 minutes, both MessageFlowA and MessageFlowB produce an XML publication every 60 minutes.

If you are concerned about the safe delivery of these messages (for example, for charging purposes), use a secure delivery mechanism such as IBM MQ.

The folders and subfolders in the XML publication have the following identifiers:

- WMQIStatisticsAccounting
- MessageFlow
- Threads
- ThreadStatistics
- Nodes
- NodesStatistics
- TerminalStatistics

The tables provided here describe the contents of each of these folders.

The following table describes the general accounting and statistics information, created in folder WMQIStatisticsAccounting.

Field	Data type	Details
RecordType	Character	Type of output, one of: • Archive • Snapshot
RecordCode	Character	Reason for output, one of: • MajorInterval • Snapshot • Shutdown • ReDeploy • StatsSettingsModified

The following table describes the message flow statistics information, created in folder MessageFlow.

Field	Data type	Details
BrokerLabel	Character (maximum 32)	Integration node name. For an independent integration server, it is `integration_server`.
BrokerUUID	Character (maximum 32)	Integration node universal unique identifier (not used in IBM App Connect Enterprise Version 11.0)
ExecutionGroupName	Character (maximum 32)	The value set on the **--name** parameter of the **IntegrationServer** command.
ExecutionGroupUUID	Character (maximum 32)	Integration server universal unique identifier (not used in IBM App Connect Enterprise Version 11.0)
MessageFlowName	Character (maximum 32)	Message flow name
StartDate	Character	Interval start date (YYYY-MM-DD)
StartTime	Character	Interval start time (HH:MM:SS:NNNNNN)
GMTStartTime	Character	Interval start date and time (universal timestamp in ISO8601)
EndDate	Character	Interval end date (YYYY-MM-DD)
EndTime	Character	Interval end time (HH:MM:SS:NNNNNN)
GMTEndTime	Character	Interval end date and time (universal timestamp in ISO8601)
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)

Field	Data type	Details
MaximumElapsedTime	Numeric	Maximum elapsed time that is spent processing an input message (microseconds)
MinimumElapsedTime	Numeric	Minimum elapsed time that is spent processing an input message (microseconds)
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)
MaximumCPUTime	Numeric	Maximum processor time that is spent processing an input message (microseconds)
MinimumCPUTime	Numeric	Minimum processor time that is spent processing an input message (microseconds)
CPUTimeWaitingForInputMessage	Numeric	Total processor time spent waiting for input messages (microseconds)
ElapsedTimeWaitingForInputMessage	Numeric	Total elapsed time that is spent waiting for input messages (microseconds)
TotalInputMessages	Numeric	Total number of messages processed TotalInputMessages records only those messages that are propagated from input node terminals.
TotalSizeOfInputMessages	Numeric	Total size of input messages (bytes)
MaximumSizeOfInputMessages	Numeric	Maximum input message size (bytes)
MinimumSizeOfInputMessages	Numeric	Minimum message input size (bytes)
NumberOfThreadsInPool	Numeric	Number of threads in pool
TimesMaximumNumberofThreadsReached	Numeric	Number of times the maximum number of threads is reached
TotalNumberOfMQErrors	Numeric	Number of MQGET errors (MQInput node) or web services errors (HTTPInput node) For example, a conversion error occurs when the message is got from the queue.

Field	Data type	Details
TotalNumberOfMessagesWithErrors	Numeric	Number of messages that contain errors These errors include exceptions that are thrown downstream of the input node, and errors that are detected by the input node after it successfully retrieves the message from the queue, but before it propagates it to the output terminal (for example, a format error). TotalNumberOfMessagesWithErrors can include messages that are not included in TotalInputMessages.
TotalNumberOfErrorsProcessingMessages	Numeric	Number of errors when processing a message
TotalNumberOfTimeOutsWaitingForRepliesToAggregateMessages	Numeric	Number of timeouts when processing a message (AggregateReply node only)
TotalNumberOfCommits	Numeric	Number of transaction commits
TotalNumberOfBackouts	Numeric	Number of transaction backouts
AccountingOrigin	Character (maximum 32)	Accounting origin

The following table describes the thread statistics information, created in folder `Threads`.

Field	Data type	Details
Number	Numeric	Number of thread statistics subfolders in Threads folder

The following table describes the thread statistics information for each individual thread, created in folder ThreadStatistics, a subfolder of Threads.

Field	Data type	Details
Number	Numeric	Relative thread number in pool
TotalNumberOfInputMessages	Numeric	Total number of messages that are processed by a thread
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)
CPUTimeWaitingForInputMessage	Numeric	Total processor time spent waiting for input messages (microseconds)
ElapsedTimeWaitingForInputMessage	Numeric	Total elapsed time that is spent waiting for input messages (microseconds)
TotalSizeOfInputMessages	Numeric	Total size of input messages (bytes)
MaximumSizeOfInputMessages	Numeric	Maximum size of input messages (bytes)

Field	Data type	Details
MinimumSizeOfInputMessages	Numeric	Minimum size of input messages (bytes)

The following table describes the node statistics information, created in folder Nodes.

Field	Data type	Details
Number	Numeric	Number of node statistics subfolders in Nodes folder

The following table describes the node statistics information for each individual node, created in folder NodesStatistics, a subfolder of Nodes.

Field	Data type	Details
Label	Character	Name of node (Label)
Type	Character	Type of node
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
MaximumElapsedTime	Numeric	Maximum elapsed time spent processing input messages (microseconds)
MinimumElapsedTime	Numeric	Minimum elapsed time spent processing input messages (microseconds)
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)
MaximumCPUTime	Numeric	Maximum processor time spent processing input messages (microseconds)
MinimumCPUTime	Numeric	Minimum processor time spent processing input messages (microseconds)
CountOfInvocations	Numeric	Total number of messages that are processed by this node
NumberOfInputTerminals	Numeric	Number of input terminals
NumberOfOutputTerminals	Numeric	Number of output terminals

The following table describes the terminal statistics information, created in folder TerminalStatistics.

Field	Data type	Details
Label	Character	Name of terminal
Type	Character	Type of terminal, one of: • Input • Output
CountOfInvocations	Numeric	Total number of invocations

For an example of an XML publication, see "Example of an XML publication for message flow accounting and statistics" on page 2723.

Example of an XML publication for message flow accounting and statistics
This example shows an XML publication that contains message flow accounting and statistics data.

The following example shows what is generated for a snapshot report. The content of this publication message shows that the message flow is called *XMLflow*, and that it is running in an integration server that is named *default* on integration node *MQ02BRK*. The message flow contains the following nodes:

- An MQInput node called *INQueue3*.
- An MQOutput node called *OUTQueue*.
- An MQOutput node called *FAILQueue*.

The MQInput node's Out terminal is connected to the OUTQueue node. The MQInput node's Failure terminal is connected to the FAILQueue node.

During the interval for which statistics are collected, this message flow processed no messages.

A publication that is generated for this data always includes the appropriate folders, even if there is no current data.

Blank lines are added between folders to improve readability.

The following command was run to achieve these results:

```
mqsichangeflowstats MQ02BRK -s -c active -e default -k XMLApp -f XMLFlow -n advanced -t basic -b basic -
o xml
```

The integration node takes information about statistics and accounting from the operating system. On some operating systems, such as Windows, UNIX, and Linux, rounding can occur because the system calls that are used to determine the processor times are not sufficiently granular. This rounding might affect the accuracy of the data.

The following example is the subscription message. The <psc> and <mcd> elements are part of the RFH header.

```
<psc>
  <Command>Publish</Command>
  <PubOpt>RetainPub</PubOpt>
  <Topic>IBM/$SYSBroker/MQ02BRK/StatisticsAccounting/SnapShot/default/XMLflow
  </Topic>
</psc>

<mcd>
  <Msd>xml</Msd>
</mcd>
```

The following example is the publication that the integration node generates:

```
<WMQIStatisticsAccounting RecordType="SnapShot" RecordCode="Snapshot">

```

CSV file format for message flow accounting and statistics data

Snapshot and archive data records are written to output files in comma-separated value (`.csv`) format.

The output files include a header with the field name. The fields for averages are optional, and are written only if the `averages` property of the statistics file writer is set to `true`. One line is written for each message flow that is producing data for the time period that you choose. For example, if `MessageFlowA` and `MessageFlowB` are both producing archive data over a period of 60 minutes, both message flows produce a line of statistics data every 60 minutes.

The following table describes the general accounting and statistics information. These fields appear in all file types.

Field	Data type	Details
RecordType	Character	Type of output, one of: • Archive • Snapshot
RecordCode	Character	Reason for output, one of: • MajorInterval • Snapshot • Shutdown • ReDeploy • StatsSettingsModified

The following table describes the message flow statistics information, which is written to the `flowStats` files.

Field	Data type	Details
BrokerLabel	Character (maximum 32)	Integration node name
BrokerUUID	Character (maximum 32)	Integration node universal unique identifier
ExecutionGroupName	Character (maximum 32)	Integration server name
ExecutionGroupUUID	Character (maximum 32)	Integration server universal unique identifier
MessageFlowName	Character (maximum 32)	Message flow name
StartDate	Character	Interval start date (YYYY-MM-DD)
StartTime	Character	Interval start time (HH:MM:SS:NNNNNN)
GMTStartTime	Character	Interval start date and time (universal timestamp in ISO8601)
EndDate	Character	Interval end date (YYYY-MM-DD)
EndTime	Character	Interval end time (HH:MM:SS:NNNNNN)
GMTEndTime	Character	Interval end date and time (universal timestamp in ISO8601)
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
AverageElapsedTime	Numeric	Average elapsed time spent processing input messages (microseconds)
MaximumElapsedTime	Numeric	Maximum elapsed time that is spent processing an input message (microseconds)
MinimumElapsedTime	Numeric	Minimum elapsed time that is spent processing an input message (microseconds)
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)

Field	Data type	Details
AverageCPUTime	Numeric	Average processor time that is spent processing an input message (microseconds)
MaximumCPUTime	Numeric	Maximum processor time that is spent processing an input message (microseconds)
MinimumCPUTime	Numeric	Minimum processor time that is spent processing an input message (microseconds)
CPUTimeWaitingForInputMessage	Numeric	Total processor time spent waiting for input messages (microseconds)
ElapsedTimeWaitingForInputMessage	Numeric	Total elapsed time that is spent waiting for input messages (microseconds)
TotalInputMessages	Numeric	Total number of messages processed TotalInputMessages records only those messages that are propagated from input node terminals.
TotalSizeOfInputMessages	Numeric	Total size of input messages (bytes)
AverageSizeOfInputMessages	Numeric	Average size of input messages (bytes)
MaximumSizeOfInputMessages	Numeric	Maximum input message size (bytes)
MinimumSizeOfInputMessages	Numeric	Minimum message input size (bytes)
NumberOfThreadsInPool	Numeric	Number of threads in pool
TimesMaximumNumberofThreadsReached	Numeric	Number of times the maximum number of threads is reached
TotalNumberOfMQErrors	Numeric	Number of MQGET errors (MQInput node) or web services errors (HTTPInput node) For example, a conversion error occurs when the message is got from the queue.
TotalNumberOfMessagesWithErrors	Numeric	Number of messages that contain errors These errors include exceptions that are thrown downstream of the input node, and errors that are detected by the input node after it successfully retrieves the message from the queue, but before it propagates it to the output terminal (for example, a format error). TotalNumberOfMessagesWithErrors can include messages that are not included in TotalInputMessages.

Field	Data type	Details
TotalNumberOfErrorsProcessingMessages	Numeric	Number of errors when processing a message
TotalNumberOfTimeOutsWaitingForRepliesToAggregateMessages	Numeric	Number of timeouts when processing a message (AggregateReply node only)
TotalNumberOfCommits	Numeric	Number of transaction commits
TotalNumberOfBackouts	Numeric	Number of transaction backouts
AccountingOrigin	Character (maximum 32)	Accounting origin

The following table describes the thread statistics information, created in `threadStats` files.

Field	Data type	Details
Number	Numeric	Number of thread statistics subfolders in Threads folder

The following table describes the thread statistics information for each individual thread, created in `threadStats` files.

Field	Data type	Details
Number	Numeric	Relative thread number in pool
TotalNumberOfInputMessages	Numeric	Total number of messages that are processed by a thread
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
AverageElapsedTime	Numeric	Average elapsed time spent processing input messages (microseconds)
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)
AverageCPUTime	Numeric	Average processor time that is spent processing an input message (microseconds)
CPUTimeWaitingForInputMessage	Numeric	Total processor time spent waiting for input messages (microseconds)
ElapsedTimeWaitingForInputMessage	Numeric	Total elapsed time that is spent waiting for input messages (microseconds)
TotalSizeOfInputMessages	Numeric	Total size of input messages (bytes)
AverageSizeOfInputMessages	Numeric	Average size of input messages (bytes)
MaximumSizeOfInputMessages	Numeric	Maximum size of input messages (bytes)
MinimumSizeOfInputMessages	Numeric	Minimum size of input messages (bytes)

The following table describes the node statistics information, created in `nodeStats` files.

Field	Data type	Details
Number	Numeric	Number of node statistics subfolders in Nodes folder

The following table describes the node statistics information for each individual node, created in `nodeStats` files.

Field	Data type	Details
Label	Character	Name of node (Label)
Type	Character	Type of node
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
AverageElapsedTime	Numeric	Average elapsed time spent processing input messages (microseconds)
MaximumElapsedTime	Numeric	Maximum elapsed time spent processing input messages (microseconds)
MinimumElapsedTime	Numeric	Minimum elapsed time spent processing input messages (microseconds)
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)
AverageCPUTime	Numeric	Average processor time that is spent processing an input message (microseconds)
MaximumCPUTime	Numeric	Maximum processor time spent processing input messages (microseconds)
MinimumCPUTime	Numeric	Minimum processor time spent processing input messages (microseconds)
CountOfInvocations	Numeric	Total number of messages that are processed by this node
NumberOfInputTerminals	Numeric	Number of input terminals
NumberOfOutputTerminals	Numeric	Number of output terminals

Configuring the collection of message flow accounting and statistics data

You can configure the collection of message flow statistics and accounting data by modifying properties in .yaml configuration files, or by running the **`mqsichangeflowstats`** command.

Before you begin

- Read the concept topic "Message flow statistics and accounting data" on page 2699

About this task

You can configure message flow accounting and statistics data collection, either by modifying properties in the `server.conf.yaml` or `node.conf.yaml` configuration files, or by running the command. You can configure the collection of snapshot data, archive data, or both.

Procedure

Configure the collection of message flow accounting and statistics data by completing the steps in either of the following tasks:

- "Configuring the collection of message flow statistics by using a .yaml configuration file" on page 2729
- "Configuring the collection of message flow statistics by using the mqsichangeflowstats command" on page 2732

Configuring the collection of message flow statistics by using a .yaml configuration file

Configure the collection of accounting and statistics data for one or more active message flows by setting the statistics properties in the `node.conf.yaml` or `server.conf.yaml` configuration file for your integration node or integration server.

Before you begin

- Read the topics "Message flow statistics and accounting data" on page 2699 and "Configuring the collection of message flow accounting and statistics data" on page 2728.
- Configure an integration server, by following the instructions described in "Configuring an integration server by modifying the server.conf.yaml file" on page 172.
- Create your message flow and deploy it to your integration server. For more information, see "Creating a message flow" on page 574 and "Deploying integration solutions to a production environment" on page 2480.
- Ensure that the publication of events is enabled, and the pub/sub broker is correctly configured. For an integration node, the default configuration enables publication of events by using the built-in MQTT pub/sub broker. If IBM MQ is installed and there is a default IBM MQ queue manager that is specified on the integration node or independent integration server, the IBM MQ pub/sub broker is used for the publication of events. For more information, see "Configuring the publication of event messages" on page 2807 and "Configuring the built-in MQTT pub/sub broker" on page 2811.

About this task

You can configure message flow accounting and statistics data collection by modifying properties in the `server.conf.yaml` or `node.conf.yaml` files. For example, you can start collecting data for a new message flow that you deploy to an integration server for which you are already collecting data. When you restart the integration server, the new settings that you define in the `.yaml` configuration file come into effect.

You can configure the collection of snapshot data, archive data, or both, by setting properties in the Statistics section of the configuration file, as shown in the following example:

```
Statistics:
# All applications and message flows will inherit the Snapshot and Archive values set here,
 unless they have been set
# to a specific value other than inherit via the WebUI, mqsichangeflowstats command, Toolkit or
 apiv2 REST
# Notes
#  - values here can be overridden by 'overrides/server.conf.yaml'
#  - to publish on MQ or MQTT, also configure Events.OperationalEvents, and set outputFormat to
 include json and/or xml
#  - to display in the WebUI Snapshot.outputFormat must include json; nodeDataLevel needs to be
 set to basic or advanced

  Snapshot:
     publicationOn: 'active'     # Choose 1 of : active|inactive. Explictly set to 'active' by
 default. If unset, defaults to 'inactive'.
                                 # Also set Events.OperationalEvents.MQ|MQTT for outputFormat
 json,xml to be published to MQ/MQTT
    #accountingOrigin: 'none'    # Choose 1 of : none|basic. Default is 'none'.
    #nodeDataLevel: 'basic'      # Choose 1 of : none|basic|advanced. Explicitly set to 'basic'
 by default. If unset, defaults to 'none'.
     outputFormat: 'json'        # Choose comma-separated list, one or more of :
 csv,json,xml,usertrace. Explicitly set to 'json' by default (for web UI). If unset, defaults to
 ''.
    #threadDataLevel: 'none'     # Choose 1 of : none|basic. If unset, defaults to 'none'.
  Archive:
     archivalOn: 'active'        # Choose 1 of : active|inactive. Default is 'inactive'.
                                 # Also set Events.OperationalEvents.MQ|MQTT for outputFormat
 xml to be published to MQ/MQTT
    #accountingOrigin: 'none'    # Choose 1 of : none|basic
    #majorInterval: 60           # Sets the interval in minutes at which archive statistics are
 published
    #nodeDataLevel: 'none'       # Choose 1 of : none|basic|advanced
     outputFormat: 'usertrace'   # Comma-separated list of : csv,xml,usertrace
    #threadDataLevel: 'none'     # Choose 1 of : none|basic
```

Alternatively, you can configure the collection of message flow accounting and statistics data dynamically, by running the command. The settings that are specified by the command take effect immediately, without restarting the integration server. For more information, see "Modifying message flow accounting and statistics data collection settings by using the mqsichangeflowstats command" on page 2737.

Procedure

Complete the following steps to configure the collection of accounting and statistics data for message flows by uncommenting and setting the statistics properties in the configuration file for your integration node or server. This configuration is then applied to all message flows when they are deployed or when the integration server is restarted:

1. Open the appropriate `node.conf.yaml` or `server.conf.yaml` configuration file by using a YAML editor.

   If you are not able to access a YAML editor, you can edit the file by using a plain text editor. However, you must ensure that you do not include any tab characters. Tab characters are not valid in YAML files and they cause your integration server configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

You can start collection of snapshot data, archive data, or both, by setting properties in the Statistics section of the configuration file (`node.conf.yaml` or `server.conf.yaml`):

2. To turn on the collection of **snapshot** statistics data, uncomment and set the following properties in the appropriate `.yaml` file:
   a) Enable the collection of snapshot statistics data by setting the **publicationOn** property to `active`. This setting takes effect when the integration server is restarted. However, it can be changed dynamically (without restarting the integration server) by using the command.

      When a `node.conf.yaml` or `server.conf.yaml` file is created, the **publicationOn** property is explicitly set to `active` by default, and snapshot statistics for the integration node or server are published to the web user interface. If the **publicationOn** property is unset (with a value of `''`), the publication of snapshot statistics is turned off.

      In `node.conf.yaml` and `server.conf.yaml` files that were created prior to IBM App Connect Enterprise Version 11.0.0.8, the **publicationOn** property was set to `inactive` by default, so the publication of statistics was turned off. To enable the publication of snapshot statistics for those integration nodes or servers, edit the relevant `.conf.yaml` file and set the **publicationOn** property to `active`.

   b) Decide the target destination and specify the appropriate format in the **outputFormat** property.

      If you want to display statistics in the web user interface, you must specify `json` as one of the values in the **outputFormat** property. The web user interface can display message flow statistics

and accounting data for independent integration servers and integration servers that are managed by an integration node. The data that it receives must be in JSON format.

When a `node.conf.yaml` or `server.conf.yaml` file is created, the **outputFormat** property is explicitly set to `json` by default. If this property is unset, the output format is set to `''`.

You can choose multiple destinations by specifying multiple comma-separated values:

- `usertrace`

  The data is sent to the user trace log, which must be enabled before you can view the data.

- `csv`

  The data is sent to a set of cyclic files in the work directory of the integration node or integration server.

- `json`

  The data is sent to the IBM App Connect Enterprise web user interface. If IBM MQ and MQTT are enabled, data is also sent there. When a `node.conf.yaml` or `server.conf.yaml` file is created, the **outputFormat** property is explicitly set to `json` by default.

- `xml`

  If IBM MQ and MQTT are enabled, the data is also sent there.

c) Optional: Decide whether you want to associate data collection with a particular accounting origin. To report an accounting origin for the data, set the **accountingOrigin** property to `basic`.

Accounting and statistics data can be accumulated and reported about an identifier that is associated with a message in a message flow. This identifier is the accounting origin, which provides a method of producing individual accounting and statistics data for multiple accounting origins that generate input to message flows. The default for this property is `none` (no support). For more information, see "Setting message flow accounting and statistics accounting origin" on page 2735.

d) Optional: Decide whether you want to collect thread-related statistics. To include thread-related data, set the **threadDataLevel** property to `basic`. The default value for this property is `none`.

e) Optional: Decide whether you want to collect node-related statistics. If you do, you can also collect information about terminals for the nodes. To include node-related data, set the **nodeDataLevel** property to `basic`, or to include node-related and terminal-related data, specify `advanced`.

When the collection of snapshot statistics data is turned on, an up-to-date snapshot of information is collected every 20 seconds. You can view the snapshot data in the web user interface. For more information, see "Viewing message flow statistics and accounting data" on page 2738.

3. To configure the collection of **archive statistics data**, uncomment and set the following properties in the appropriate `.yaml` file:
   a) Set the **`archivalOn`** property to `active`.

      This setting takes effect when the integration server is restarted or when the message flow is deployed. However, it can be changed dynamically (without restarting the integration server) by using the command.

   b) Set the **`outputFormat`** property to one or more of the following values (separated by commas and enclosed by single quotation marks):

      - `usertrace`
      - `csv`
      - `xml`

      By default, the publication of archive statistics data is turned off. If you start collection (by setting the **`archivalOn`** property to `active`), the default output format is `usertrace`.

   c) Optional: Specify the interval (in minutes) at which archive statistics are published, by setting the **`majorInterval`** property. The default is `60` minutes.

   d) Optional: To report an accounting origin for the data, set the **`accountingOrigin`** property to `basic`.

      Accounting and statistics data can be accumulated and reported about an identifier that is associated with a message in a message flow. This identifier is the accounting origin, which provides a method of producing individual accounting and statistics data for multiple accounting origins that generate input to message flows. The default for this property is `none` (no support). For more information, see "Message flow accounting and statistics accounting origin" on page 2702.

   e) Optional: To include thread-related data in the statistics, set the **`threadDataLevel`** property to `basic`. The default value for this property is `none`.

   f) Optional: To include node-related data in the statistics, set the **`nodeDataLevel`** property to `basic`, or to include node-related and terminal-related data in the statistics, specify `advanced`.

4. Restart the integration node or integration server for the changes to take effect. Changes to the `server.conf.yaml` and `node.conf.yaml` files take effect only when the modified integration node or server is restarted.

   The state of statistics collection that is configured in the `.yaml` file is applied to all flows that are deployed when the integration server starts. It is also applied to any additional flows that are deployed after the integration server starts.

Configuring the collection of message flow statistics by using the `mqsichangeflowstats` command

You can configure the collection of accounting and statistics data for your message flows by using the **`mqsichangeflowstats`** command.

Before you begin

- Read the topics "Message flow statistics and accounting data" on page 2699 and "Configuring the collection of message flow accounting and statistics data" on page 2728.
- Configure an integration server by following the instructions described in "Configuring an integration server by modifying the server.conf.yaml file" on page 172.
- Create your message flow and deploy it to your integration server. For more information, see "Creating a message flow" on page 574 and "Deploying integration solutions to a production environment" on page 2480.
- Ensure that the publication of events is enabled, and the pub/sub broker is correctly configured. For an integration node, the default configuration enables publication of events that use the built-in MQTT pub/sub broker. If IBM MQ is installed and there is a default IBM MQ queue manager that is specified on the integration node or independent integration server, the IBM MQ pub/sub broker is used for the

publication of events. For more information, see “Configuring the publication of event messages” on page 2807 and “Configuring the built-in MQTT pub/sub broker” on page 2811.

About this task

You can configure the collection of message flow accounting and statistics data for one or more active message flows by using the command.

Alternatively, you can configure the statistics and accounting properties in the `.yaml` configuration file for your integration node or server, as described in “Configuring the collection of message flow statistics by using a .yaml configuration file” on page 2729.

If you want to view message flow statistics by using the web user interface, you must specify JSON as one of the output formats when you configure statistics collection. You can also report the statistics to the user trace, IBM MQ, or MQTT.

Procedure

If you use the **mqsichangeflowstats** command to start statistics collection and specify the required output formats, the specified formats replace the output formats that were previously emitted for the message flow. The specified formats are not added to the previously emitted formats. If you start statistics collection by running the **mqsichangeflowstats** command without specifying an output format on the command, the statistics data is emitted to the user trace log by default.

Select the granularity of the data that you want to be collected by specifying the appropriate parameters on the **mqsichangeflowstats** command.

To configure the collection of message flow accounting and statistics data, complete the following steps:

1. Identify the resource for which you want to collect statistics.

   You can collect statistics for a specific message flow, for all message flows in a specified application or library, or for all message flows on a specified integration server.
2. Decide whether you want to collect thread-related statistics.
3. Decide whether you want to collect node-related statistics.

   If you do, you can also collect information about terminals for the nodes.
4. Decide whether you want to associate data collection with a particular accounting origin.

   This option is valid for snapshot and archive data, and for message flows and integration servers. However, when active, you must set its origin value in each message flow to which it refers. If you do not configure the participating message flows to set the appropriate origin identifier, the data that is collected for that message flow is collected with the origin set to `Anonymous`.

   For more information, see “Setting message flow accounting and statistics accounting origin” on page 2735.
5. Decide the target destination. You can choose multiple destinations by specifying multiple comma-separated values for the output format property.
   - User trace log (the default setting).
   - XML format publication message. If you chose this target destination, register the following topic for the subscriber:
     - For publications on an IBM MQ pub/sub broker:

```
$SYS/Broker/integrationNodeName/StatisticsAccounting/recordType/integrationServerName/messageFlowLabel
```

     - For publications on an MQTT pub/sub broker:

```
IBM/IntegrationBus/integrationNodeName/
StatisticsAccounting/recordType/integrationServerName/messageFlowLabel
```

       where *integrationNodeName*, *integrationServerName*, and *messageFlowLabel* represent the integration node, integration server, and message flow on which you want to receive data. *recordType*

is the type of data collection on which you want to receive publications (SnapShot, Archive, or the topic wildcard "+" to receive both). The value that you specify for record type is case-sensitive, so if you choose to receive snapshot data, set the record type to `SnapShot`.

- JSON publication message. Register the following topic for the subscriber:
  - For publications on an IBM MQ pub/sub broker:

    ```
    $SYS/Broker/integrationNodeName/Statistics/JSON/recordType/integrationServerName/
    applications/application_name/libraries/library_name/messageflows/message_flow_name
    ```

  - For publications on an MQTT pub/sub broker:

    ```
    IBM/IntegrationBus/integrationNodeName/Statistics/JSON/recordType/integrationServerName/
    applications/application_name/libraries/library_name/messageflows/message_flow_name
    ```

  where *integrationNodeName*, *integrationServerName*, *application_name*, *library_name*, and *message_flow_name* represent the integration node, integration server, application, library, and message flow on which you want to receive data. The *recordType* is the type of data collection on which you want to receive publications (SnapShot, Archive, or the topic wildcard "+" to receive both). The value that you specify for record type is case-sensitive, so if you choose to receive snapshot data, set the record type to `SnapShot`.

6. Decide the type of data collection that you want:
   - Snapshot
   - Archive
   - Snapshot and archive
7. Run the **mqsichangeflowstats** command to activate or deactivate the collection of snapshot data, archive data, or both.

   For example, to turn on snapshot statistics for message flow `flow2` in application `app1`, on the specified integration server, use the following command:

   ```
   mqsichangeflowstats -c active -s -i localhost -p 7600 -k app1 -f flow2
   ```

   To turn off archive and snapshot statistics for all message flows in all applications and libraries on the specified integration server, use the following command:

   ```
   mqsichangeflowstats -c inactive -a -s -i localhost -p 7600 -k "*" -y "*" -f "*"
   ```

   By default, the settings that you specify with this command persist when the integration server or node is restarted and when the message flow is redeployed. If you do not want the settings to persist, you can specify the **--non-persist** parameter. The **--non-persist** parameter causes the settings to remain in effect only until a restart or redeploy, at which point the settings that are specified in the `server.conf.yaml` or `node.conf.yaml` configuration file take effect.

   For more information, see command.

Results

When the command completes successfully, data collection for the specified resources is started:

- If you requested snapshot data, information is collected for approximately 20 seconds, and the results are written to the output specified in the `node.conf.yaml` or `server.conf.yaml` file.
- If you requested archive data, information is collected for the interval that is defined for the integration node or server (in the `node.conf.yaml` or `server.conf.yaml` file). The results are written to the specified output. The interval is reset and data collection starts again.

What to do next

You can now view the message flow statistics and accounting data that is collected, as described in “Viewing message flow statistics and accounting data” on page 2738.

- “Setting message flow accounting and statistics accounting origin” on page 2735
- “Viewing message flow statistics and accounting data” on page 2738

Setting message flow accounting and statistics accounting origin

You can request accounting origin support for the collection of message flow accounting and statistics data, by setting properties in the configuration file for your integration node (`node.conf.yaml`) or integration server (`server.conf.yaml`). You must also configure your message flows to provide the correct identification values that indicate what the data is associated with.

Before you begin

- Ensure that you have created a message flow; for more information, see “Creating a message flow” on page 574.
- Read the concept topic, “Message flow accounting and statistics accounting origin” on page 2702

About this task

Accounting and statistics data is associated with an accounting origin. For more information, see “Message flow statistics and accounting data” on page 2699 and “Message flow accounting and statistics accounting origin” on page 2702.

You can set a different value for every message flow for which data collection is active, or the same value for a group of message flows (for example, those in a single integration server, or associated with a particular client, department, or application suite).

The accounting origin setting is not used until you deploy the message flow or flows to the integration nodes on which they are to run. You can activate data collection, or modify it to request accounting origin support, before or after you deploy the message flow. You do not have to stop collecting data when you deploy a message flow that changes accounting origin.

To configure a message flow to specify a particular accounting origin, complete the following steps.

Procedure

1. Open the message flow with which you want to work.
2. Click **Selection** above the palette of nodes.
3. Right-click a Compute, Database, or Filter node in the editor view, then click **Open ESQL**.

   The associated ESQL file is opened in the editor view, and your cursor is positioned at the start of the correct module. You can include the required ESQL in any of these nodes, so decide which node in each message flow is the most appropriate for this action.

   To take advantage of the accounting origin support, include one of these nodes in each message flow for which you want a specific origin set. If you have not configured one of these three nodes in the message flow, you must add one at a suitable point (for example, immediately following the input node) and connect it to other nodes in the flow.
4. Update the ESQL in the node module to set an accounting origin.

   The integration node uses the origin identifier that is set in the Environment tree. You must set a value in the field with correlation name `Environment.Broker.Accounting.Origin`. This field is not created automatically in the Environment tree when the message is first received in the integration

node. The field is created only when you set it in an ESQL module that is associated with a node in the message flow.

If you do not set a value in the message flow, the default value `Anonymous` is used for all output. If you set a value in more than one place in the message flow, the value that you set immediately before the message flow terminates is used in the output data.

The code that you must add has the following form:

```
SET Environment.Broker.Accounting.Origin = "value";
```

You can set the identifier to a fixed value (as shown previously), or you can determine its value based on a dynamic value that is known only at run time. The value must be character data, and can be a maximum of 32 bytes. For example, you might set its value to the contents of a particular field in the message that is being processed (if you are coding ESQL for a Compute node, you must use correlation name InputBody in place of Body in the following example):

```
IF Body.DepartmentName <> NULL THEN
   SET Environment.Broker.Accounting.Origin = Body.DepartmentName;
END IF;
```

5. Save the ESQL module, and check that you have not introduced any errors.
6. Save the message flow, and check again for errors.
7. Now that `Environment.Broker.Accounting.Origin` is set, you must enable the Accounting Origin collection function by setting the **`accountingOrigin`** property in the .yaml configuration file for your integration node or integration server.
   a) Open the `node.conf.yaml` or `server.conf.yaml` configuration file for your integration node or integration server by using a YAML editor.

      If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, because they are not valid characters in YAML files and would cause your integration server configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

   b) In the Statistics section of the `.yaml` configuration file, set the **`accountingOrigin`** property to `basic`.

   c) Restart the integration server for the changes to take effect.

      For information about how to start an integration server, see “Starting an integration server” on page 250.

Results

You are now ready to deploy the updated message flow; for more information, see “Deployment rules and guidelines” on page 2465. Accounting and statistics data records that are collected after the message flow has been deployed includes the origin identifier that you have set.

Viewing message flow accounting and statistics data collection parameters by using the `mqsireportflowstats` command

You can view the parameters that are currently in effect for message flow accounting and statistics data collection by using the **`mqsireportflowstats`** command.

Before you begin

- Read the concept topic about message flow accounting and statistics data.
- Ensure that message flow statistics and accounting data are being collected. For more information, see “Configuring the collection of message flow statistics by using the mqsichangeflowstats command” on page 2732.

Procedure

Issue the **mqsireportflowstats** command to view the parameters that are currently being used to control archive or snapshot data collection.

You can view the parameters for an integration node, an integration server, or an individual message flow.

For example:

```
mqsireportflowstats --admin-host localhost --admin-port 7600
--snapshot --verbose --all-applications --all-flows
```

Refer to the command for further examples.

Results

The command displays the current status.

What to do next

You can now modify the data collection parameters.

Modifying message flow accounting and statistics data collection settings by using the mqsichangeflowstats command

You can modify the parameters that you have set for message flow accounting and statistics data collection. For example, you can start collecting data for a new message flow that you have deployed to an integration server for which you are already collecting data. You can modify parameters while data collection is active; you do not have to stop data collection and restart it.

Before you begin

- Start collecting message flow statistics; see “Configuring the collection of message flow statistics by using the mqsichangeflowstats command” on page 2732
- Read the concept topic about “Message flow statistics and accounting data” on page 2699

About this task

To modify message flow accounting and statistics parameters:

Procedure

1. Decide which data collection parameters you want to change.

   You can modify the parameters that are in force for an integration node, an integration server, or an individual message flow.

2. Issue the **mqsichangeflowstats** command with the appropriate parameters to modify the parameters that are currently being used to control archive data collection or snapshot data collection.

   For example, to modify parameters to extend snapshot data collection to a new message flow MFlow2 in integration server IS2 for integration node INodeA, enter:

   ```
   mqsichangeflowstats INodeA -s -e IS2 -f MFlow2 -c active
   ```

   ```
   /F BrokerA,cs s=yes,e=EG2,f=MFlow2,c=active
   ```

   If you want to specify an accounting origin for archive data for a particular message flow in an integration server, enter:

   ```
   mqsichangeflowstats INodeA -a -e IS44 -f MFlowX -b basic
   ```

   ```
   /F BrokerA,cs a=yes,e=EG4,f=MFlowX,b=basic
   ```

   Refer to the command for further information.

Results

When the command completes successfully, the new parameters that you have specified for data collection are in effect. These parameters remain in effect until you stop data collection or make further modifications.

Viewing message flow statistics and accounting data

You can use the web user interface to view snapshot statistics and accounting data for independent integration servers and managed integration servers (which are managed by an integration node). You can also report statistics and accounting data for independent integration servers and managed integration servers to the user trace log, IBM MQ, and MQTT.

Before you begin

- Read the topic “Message flow statistics and accounting data” on page 2699.
- Start message flow statistics collection, as described in “Configuring the collection of message flow statistics by using a .yaml configuration file” on page 2729 and “Configuring the collection of message flow statistics by using the mqsichangeflowstats command” on page 2732.
- For information about how to subscribe to message flow statistics and accounting data, read “Subscribing to event message topics” on page 2813.

About this task

You can configure the statistics data to be published in a number of formats. For example, JSON, XML, CSV (for use in spreadsheets), and the user trace log.

Use the snapshot statistics and accounting data to monitor the performance of your integration servers at the message flow or message flow node level. You can view the statistics data for independent integration servers and managed integration servers in the App Connect Enterprise web user interface. The snapshot data that is displayed in the web user interface is updated automatically every 20 seconds. You can also report the data for independent integration servers or managed integration servers to the user trace log, IBM MQ, and MQTT.

For more information about how to start the web user interface for an integration server, see “Accessing the web user interface” on page 89.

You can display high-level statistical data that provides an overview of all the message flows in an integration server, or you can display statistical information that relates to a specific message flow. The level of information that is displayed depends on the type of resource that you select.

You can use the statistics data in these views to compare the performance of message flows in your applications. You can also use it to help you identify the possible reasons for reduced performance in a message flow.

Analyzing resource performance

You can collect statistics to assess the performance of resources used by integration servers.

Before you begin

Read the concept topic about resource statistics.

About this task

- “Managing resource statistics collection” on page 2741
- “Viewing resource statistics data” on page 2745

Resource statistics

Resource statistics are collected to record performance and operating details of resources that are used by integration servers.

As a system administrator, you can use the resource statistics to ensure that your systems are using the available resources in the most efficient manner. By monitoring systems and analyzing statistical trends, you can keep system resource usage within boundaries that you consider acceptable. You can also help to preempt situations where system resources are overstretched and might become unavailable. Analysis of the data that is returned potentially requires specialist skills and knowledge of each resource type.

If you detect that system resources are under pressure, you can examine the statistics to assess whether the cause of the concern is the use of those resources by processes in IBM App Connect Enterprise. You can collect data on one or more selected integration servers, or for all integration servers. When statistics collection is enabled, you might experience a minor degradation in operating performance of the integration servers for which you are collecting data.

When an integration node or server is created, the publication of resource statistics is enabled by default. The **reportingOn** property in the `node.conf.yaml` or `server.conf.yaml` file is explicitly set to `true`, which enables the publication of snapshot statistics to the web user interface. For integration nodes and servers that were created prior to IBM App Connect Enterprise Version 11.0.0.8, the publication of resource statistics was turned off by default. To enable the publication of statistics for your integration nodes or servers that were created prior to V11.0.0.8, edit the relevant `.conf.yaml` file and set the **reportingOn** property to `true`. For more information, see “Managing resource statistics collection” on page 2741.

Before resource statistics can be collected, you must ensure that the publication of events is enabled. If you are subscribing to resource statistics data, you must also ensure that a pub/sub broker is configured. For more information, see “Configuring the publication of event messages” on page 2807 and “Configuring the built-in MQTT pub/sub broker” on page 2811.

To start, stop, or check the status of resource statistics collection, you can also use the command and the command.

To set and check the properties that control where resource statistics are reported, use the command and the command.

You can view the resource statistics data for your integration nodes and servers by using the web user interface.

You can also specify that resource statistics data for the resource managers in your integration servers is written to files. For more information, see “Reporting resource statistics to files” on page 2744.

View statistics data by using the publish/subscribe method

You can view the output that is generated by statistics collection by using an application that subscribes to a publication message, which is published by the integration node every 20 seconds. The message contains the data that is collected for each integration server for which you activate statistics collection. The published message is available in XML format and in JSON format.

The topic for each message has the following structure:

- For XML format:
  - For an IBM MQ pub/sub broker:

    ```
    $SYS/Broker/integrationNodeName/ResourceStatistics/integration_server_name
    ```

  - For an MQTT pub/sub broker:

    ```
    IBM/IntegrationBus/integrationNodeName/ResourceStatistics/integration_server_name
    ```

- For JSON format:
  - For an IBM MQ pub/sub broker:

    ```
    $SYS/Broker/integrationNodeName/Statistics/JSON/Resource/integration_server_name
    ```

  - For an MQTT pub/sub broker:

    ```
    IBM/IntegrationBus/integrationNodeName/Statistics/JSON/Resource/integration_server_name
    ```

You can set up subscriptions for a specific integration server on a specific integration node. See the following examples:

- For XML format:
  - For an IBM MQ pub/sub broker:

    ```
    $SYS/Broker/INODE/ResourceStatistics/default
    ```

  - For an MQTT pub/sub broker:

    ```
    IBM/IntegrationBus/INODE/ResourceStatistics/default
    ```

- For JSON format:
  - For an IBM MQ pub/sub broker:

    ```
    $SYS/Broker/INODE/Statistics/JSON/Resource/default
    ```

  - For an MQTT pub/sub broker:

    ```
    IBM/IntegrationBus/INODE/Statistics/JSON/Resource/default
    ```

You can also use wildcards in the subscriptions to broaden the scope of what is returned. For example, to subscribe to reports for all integration servers on all integration nodes, use the following values:

- For XML format:
  - For an IBM MQ pub/sub broker:

    ```
    $SYS/Broker/+/ResourceStatistics/#
    ```

  - For an MQTT pub/sub broker:

    ```
    IBM/IntegrationBus/+/ResourceStatistics/#
    ```

- For JSON format:
  - For an IBM MQ pub/sub broker:

    ```
    $SYS/Broker/+/Statistics/JSON/Resource/#
    ```

  - For an MQTT pub/sub broker:

    ```
    IBM/IntegrationBus/+/Statistics/JSON/Resource/#
    ```

For more information about subscribing to an integration server, see "Subscribing to event message topics" on page 2813.

For more information about the statistics that are reported for each resource manager, and the publication content, see "Resource statistics data" on page 2746.

Managing resource statistics collection

Use resource statistics data to monitor the performance and resource usage of your integration servers.

Before you begin

- Configure an integration server, by following the instructions described in "Configuring an integration server by modifying the server.conf.yaml file" on page 172.
- Create your message flow, package it into a BAR file, and then deploy it to your integration server. For more information, see "Creating a message flow" on page 574 and "Deploying integration solutions to a production environment" on page 2480.
- Read the concept topic, "Resource statistics" on page 2739.

About this task

You can activate the collection of resource statistics by modifying a `node.conf.yaml` or `server.conf.yaml` configuration file, by using the IBM App Connect Enterprise web user interface, or by running the **`mqsichangeresourcestats`** command.

You can view the resource statistics data in the web user interface. Alternatively, you can configure your integration servers to write resource statistics to files, as described in "Reporting resource statistics to files" on page 2744.

You can manage the collection of resource statistics data for active integration servers by using one of the following methods:

- "Managing resource statistics collection by modifying a server.conf.yaml file" on page 2741
- "Managing resource statistics collection by using the web user interface" on page 2742
- "Managing resource statistics collection by using a command" on page 2743

Managing resource statistics collection by modifying a server.conf.yaml file

About this task

You can start collecting resource statistics data for resources that are used by any active message flows that are deployed in an integration server. To start collecting the data, set the resource statistics properties in the `server.conf.yaml` file for the integration server. Alternatively, you can configure the collection of resource statistics for the integration node by modifying the properties in the `node.conf.yaml` file.

When you configure the resource statistics settings for your integration server, you can start and stop the collection of resource statistics dynamically, without restarting the integration server, by using the command. You can also see the current options for gathering resource statistics by using the command.

Procedure

Complete the following steps to configure the collection of resource statistics:

1. Open the `server.conf.yaml` configuration file for your integration server, by using a YAML editor.

   If you cannot access a YAML editor, you can edit the file by using a plain text editor. Ensure that you do not include any tab characters, which are not valid in YAML and would cause your integration server configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file. The properties that you need to set are in the **Statistics** section of the `.yaml` configuration file:

   ```
   Statistics:
        ...
      Resource:
      reportingOn: true         # Choose 1 of : true|false. Explicitly set to 'true' by
    default. If unset, defaults to 'false'.
      #outputFormat: ''         # Choose 'csvFile' or 'file' (for IIB v10 compatibility). If
    unset, defaults to ''.
   ```

2. Uncomment the **reportingOn** property and set it to `true`. This setting takes effect when the integration server is restarted. However, it can be changed dynamically (without restarting the integration server) by using the command.

   When a node`.conf.yaml` or `server.conf.yaml` file is created, the **reportingOn** property is explicitly set to `true`, and resource statistics for the integration node or server are published to the web user interface. If the **reportingOn** property is unset (with a value of `''`), the publication of resource statistics is turned off.

   In node`.conf.yaml` and `server.conf.yaml` files that were created prior to IBM App Connect Enterprise V11.0.0.8, the **reportingOn** property was set to `false` by default, so the publication of resource statistics was turned off. To enable the publication of resource statistics for those integration nodes or servers, edit the relevant `.conf.yaml` file and set the **reportingOn** property to `true`.

3. Optional: If you want the resource statistics to be published to a file (in addition to the web user interface), set the **outputFormat** property to `csvFile`. For more information, about publishing resource statistics to a file, see “Reporting resource statistics to files” on page 2744.

4. Restart the integration server for the changes to take effect.

   For more information about how to start an integration server, see “Starting an integration server” on page 250.

Managing resource statistics collection by using the web user interface

Procedure

1. Start the web user interface for your integration node; see “Accessing the web user interface” on page 89.

   The integration servers that are owned by the integration node are displayed as tiles under the **Servers** tab.

2. Click the **Open List of Options** icon for the required integration server.

   - If you are viewing all the available servers under the **Servers** tab, the **Open List of Options** icon appears within the tile for each integration server.

3. Click **Open** in the drop-down menu to view the content of the integration server under the **Contents** tab.

4. Click the **Open List of Options** icon.

   - If you are viewing the content of an integration server under the **Contents** tab, the **Open List of Options** icon appears in the title bar for the integration server.

5. Click the required option in the drop-down menu.
   - To start collecting resource statistics for this integration server, click **Resource statistics on** in the drop-down menu.
   - To stop collecting resource statistics for this integration server, click **Resource statistics off** in the drop-down menu.

   If resource statistics collection is turned on for the integration server, data is displayed in the **Resource Statistics** tab.

Managing resource statistics collection by using a command

Procedure

1. If your integration server is running on Linux, UNIX, or Windows systems, set up the correct command environment.

   For more information about how to complete this task, see "Setting up a command environment" on page 64.
2. Run one of the following commands:
   - To start or stop collecting resource statistics for a specific integration server, or for all integration servers, run the **mqsichangeresourcestats** command with the appropriate parameters.

     For example, to start collecting resource statistics for the default integration server for an integration node that is named INODE, enter the following command:

     ```
     mqsichangeresourcestats INODE -c active -e default
     ```

     For example, to stop collecting resource statistics for all integration servers on an integration node that is named INODE, enter the following command:

     ```
     mqsichangeresourcestats INODE -c inactive
     ```

     By default, the settings that you specify with this command persist when the integration server or node is restarted and when the message flow is redeployed. If you do not want the settings to persist, you can specify the **--non-persist** parameter, which causes the settings to remain in effect only until a restart or redeploy. After a restart or redeploy, the settings that are specified in the `server.conf.yaml` or `node.conf.yaml` configuration file take effect.

     For more information, see command.
   - To check the status of resource collection, run the **mqsireportresourcestats** command with the appropriate parameters.

     For example, to view status for the default integration server on INODE, enter:

     ```
     mqsireportresourcestats INODE -e default
     ```

     For further examples, see the command.
   - To set and check the properties that control where resource statistics are reported, use the **mqsichangeproperties** and **mqsireportproperties** commands.

What to do next

You can view the resource statistics in the web user interface, as described in "Viewing resource statistics data" on page 2745.

You can write a program that subscribes to a publication (single XML message) that returns the resource statistics data. For an example of the publication message, see Example XML output.

Reporting resource statistics to files

You can configure an integration server or integration node to send resource statistics directly to files in the file system.

About this task

You can configure an integration server to send resource statistics directly to files in the file system, by modifying the `server.conf.yaml` configuration file for the integration server and setting the resource statistics properties. You can configure the collection of resource statistics for the integration node by modifying the properties in the `node.conf.yaml` file.

If you enable this option, each resource manager writes a separate file that contains its resource statistics. Limits apply to the size of each file and if the limit for a file is reached, a new file is created. Limits also apply to the number of files that can be written for each resource manager, and if the limit for the number of files for the resource manager is reached, the resource manager then writes to a previous file in a circular fashion.

When you have configured the resource statistics settings for your integration server or integration node, you can start and stop the collection of resource statistics dynamically, without restarting the integration server, by using the command. You can also see the current statistics gathering options for resources by using the command.

For information about publishing resource statistics to an MQ queue manager or MQTT pub/sub broker, see “Configuring the publication of event messages” on page 2807.

Procedure

Configure an integration server to write resource statistics to files, by completing the following steps:

1. Open the configuration file for your integration server (`server.conf.yaml`) by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, which are not valid in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

   The properties that you need to set are in the **`Statistics`** section of the `.yaml` configuration file:

   ```
   Statistics:
      # Application message flows will by default inherit Snapshot and Archive values set here
        ...
        Resource:
           reportingOn: true            # choose 1 of : true|false. Explicitly set to 'true' by
    default. If unset, defaults to 'false'.
           outputFormat: 'csvFile'      # choose 'csvFile' or 'file' (for IIB v10
    compatibility). If unset, defaults to ''.
   ```

2. Set the following properties:

   a) Set the **`reportingOn`** property to `true`.

   b) Set the **`outputFormat`** property to either `csvFile` or `file`:

   csvFile

   The CSV data is organized in rows with columns for reported metrics. The first column contains the resource name and the remaining columns contain the reported properties for the named

resource. For resource managers that produce sub-resource data, extra rows are written for the summary and for each sub-resource. For example:

- The **Parsers** resource manager emits a row for the `Summary` and for each *message flow*.*parser* sub-resource.
- The **JVM** resource manager emits a row for the `Summary` and rows for the `Heap Memory`, `Non-Heap Memory`, `Garbage Collection - scavenge`, and `Garbage Collection - global` sub-resources.

file

The `file` format is supported for compatibility with IBM Integration Bus Version 10. Each resource manager emits a single row for each reporting interval.

For resource managers that produce sub-resource data, additional columns are added. The column titles are formed by prefixing the metric name with the resource name. For example, the **Parsers** resource manager emits columns `Summary_`*`metric_name`*, and for each sub-resource another set of columns is emitted in the form *message flow*.*parser*`_`*metric_name*.

Only the first row in each resource manager file contains the column titles, so titles are shown only for the summary and sub-resources that exist when the new file is written. Additional columns with extra sub-resources can appear in the file without being written in the first title row. In App Connect Enterprise Version 11, components are not assigned UUIDs, so these columns are populated with zeros.

The integration server writes the data to files at the following location:

```
serverWorkDirectory/config/common/resourceStats/
ResourceStats_integration_server_serverName_resource.txt.n
```

where:

- *serverWorkDirectory* is the value of the **--work-dir** parameter.
- *serverName* is the value of the **--name** parameter.
- *resource* is the name of the reported resource, such as JVM or JDBCConnectionPools.

3. Restart the integration server for the changes to take effect.

   For information about how to start an integration server, see “Starting an integration server” on page 250.

Results

You can view the resource statistics by accessing the files that each resource manager has written. The files are in `.csv` format.

Use the links in “Resource statistics data” on page 2746 for information about the resource statistics data that is collected.

Viewing resource statistics data

You can view resource statistics for independent integration servers and managed integration servers (which are owned by an integration node) in the IBM App Connect Enterprise web user interface. If you specify that the statistics are to be written to the file system, you can also view them in a file format.

Before you begin

- Read the concept topic, “Resource statistics” on page 2739.
- Start resource statistics collection, as described in “Managing resource statistics collection” on page 2741.

About this task

You can also view resource statistics collection by subscribing to the topic on which statistics are published. For more information, see “Subscribing to event message topics” on page 2813.

To view resource statistics in the web user interface, start a browser and load the user interface for your integration server. You can then browse the statistics that you are interested in. For more information about how to start the web user interface, see “Accessing the web user interface” on page 89.

Resource statistics data

Learn about the measurements for which data is returned when you activate resource statistics collection.

Statistics information is collected for the following resource types:

You can then view these statistics in the web user interface. You can also specify that resource statistics are written to files in the file system, as described in “Reporting resource statistics to files” on page 2744

Example of an XML publication for resource statistics

This example message shows an XML publication that contains resource statistics data.

A single XML publication includes all the statistics information that is reported for the resource types listed in “Resource statistics data” on page 2746. The publication message starts with information that identifies the integration server to which the statistics apply.

For information about subscribing to these publication messages, see “Subscribing to event message topics” on page 2813.

The following message is an example that shows three sections, one for each of three different resource types, and the values that are returned for each type. The output lines in this example have been split to improve readability.

```

```

All times are reported in local time, and the timezone used is reported by the timezone attribute in the standard TZ Area/Location format. The date is in the format yyyy-MM-dd, and time is in the format HH:mm:ss, independent of locale and timezone.

The collectionStartDate and collectionStartTime specify when resource statistics collection started, typically when the integration server was last started.

The endDate and endTime specify when the statistics data in the current message was gathered. The startDate and startTime is when the previous set of data was reported.

Resource statistics data: .NET Application Domains

Learn about the data that is returned for the .NET Application Domains resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

High-level memory usage is shown for each application domain that is running in the integration server. Statistics are updated only after a full blocking garbage collection.

Measurements	Description
name	The name of the application domain.
CurrentlyInUseMB	The memory used by the domain at time of the last garbage collection.
TotalAllocatedInMB	The total amount of memory allocated by the application domain since it started (including any memory that has been garbage-collected).
Id	The numeric ID for this application domain.
ApplicationBase	The directory currently being used to load assemblies for this domain.

Resource statistics data: .NET Garbage Collection

Learn about the data that is returned for the .NET Garbage Collection resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

Gives detailed statistics on garbage collection, for the entire DotNet CLR. For details on interpreting these values, see the Microsoft documentation for .NET.

Measurements	Description
ExplicitGCCount	Indicates the number of garbage collections that were forced by external request.
Gen0CollectionsTaken	Indicates the number of garbage collections completed for generation 0.
Gen1CollectionsTaken	Indicates the number of garbage collections completed for generation 1.
Gen2CollectionsTaken	Indicates the number of garbage collections completed for generation 2.
CommittedInMB	The total number of Megabytes committed in all heaps.
ReservedInMB	The total number of Megabytes reserved in all heaps.
Gen0HeapSizeInMB	The size, in Megabytes, of the generation-zero heap.
Gen1HeapSizeInMB	The size, in Megabytes, of the generation-one heap.
Gen2HeapSizeInMB	The size, in Megabytes, of the generation-two heap.
LargeObjectHeapSizeInMB	The size, in Megabytes, of the large object heap.
PromotedFromGen0InMB	The size, in Megabytes, of the objects promoted from generation 0 to generation 1.
PromotedFromGen1InMB	The size, in Megabytes, of the objects promoted from generation 1 to generation 2.

Resource statistics data: CICS

Learn about the data that is returned for the CICS resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

A CICSRequest node calls CICS Transaction Server for z/OS programs. Use these resource statistics to review how many successful and unsuccessful calls the node is making to CICS, how many unsuccessful requests are related to security issues such as authentication failures, and how often connection attempts fail.

A statistics summary is returned for the whole integration server, followed by a breakdown for each named CICS Transaction Server for z/OS region.

The following table describes the measurements that are returned for each CICS region. Each row of statistics represents a CICS region, which is identified either by a policy, or by the CICSRequest node `CICS server` URL.

- In this example, the policy is identified by *myCICSConnectionService*, and the integration node is identified by APPLID*BRKApp* and qualifier *BRKQual*:

```
myCICSConnectionService.BRKApp.BRKQual
```

- In this example, the CICSRequest node `CICS server` URL is identified by *tcp://mycicsregion.com:12345*:

```
tcp://mycicsregion.com:12345
```

Measurements	Description
RequestSuccess	The number of requests to CICS that are successful.

Measurements	Description
RequestFailures	The total number of requests to CICS that fail. The value that is returned by this measurement does not include connection failures. Connection failure values are returned by the `ConnectionAttemptFailures` measurement.
RequestSecurityFailures	The number of failed requests to CICS that were caused by security issues, such as authentication failures.
ConnectionAttemptFailures	The number of connection attempts that fail.

Resource statistics data: Connect Direct

Learn about the data that is returned for the Connect Direct resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

Statistics are available for all Connect:Direct server activity, together with one line for each policy that is used.

The following table describes the measurements that are returned.

Measurements	Description
connectionDetails	The host name and port for the Connect:Direct server that is being connected to, in the format `<hostname>:port`. For the summary line, this property is set to an empty string.
inboundTransfers	The number of transfers received by the Connect:Direct server selected for processing in a message flow.
inboundBytes	Total number of bytes received in transfers, selected from Connect:Direct server.
nohitTransfers	The number of transfers received by the Connect:Direct server not selected for processing in a message flow. Reasons for not processing a transfer include: • The IBM App Connect Enterprise system has no access to the transferred file. • A deployed CDInput node has a filter that matches the transferred file. This number gives the total for the whole integration node and not just this integration server.
outboundTransfers	The number of transfers sent to the Connect:Direct server.
outboundBytes	Total number of bytes contained in transfers sent to the Connect:Direct server.

Resource statistics data: CORBA

Learn about the data that is returned for the CORBA resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

A CORBARequest node calls a CORBA server. Use these resource statistics to review how many calls the node is making to the CORBA server, and how many of those calls are successful or result in CORBA exceptions. A statistics summary is returned for the whole integration server.

The following table describes the measurements that are returned for each CORBA node. The measurements apply to the number of calls since the integration server started.

Measurements	Description
OutboundInvocations	The total number of calls made to a CORBA server.
OutboundSuccessfulInvocations	The number of calls to the CORBA server that are successful.
OutboundCorbaExceptions	The number of calls to the CORBA server that result in CORBA exceptions.

Resource statistics data: File

Learn about the data that is returned for the file resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

A summary is displayed for the local file system of any file actions done by any type of file node. It does not have any other entries; there is only one local file system. Remote file systems are reported in FTEAgent and FTP resource statistics.

Measurements	Description
FilesRead	The number of files successfully read by any file node
RecordsRead	The number of records read by either a file input node, FTE input node, or a file read node
BytesRead	The total number of bytes read by either a file input node, FTE input node, or a file read node
FilesCreated	The number of files successfully created by a file output node
RecordsWritten	The number of records written to files by a file output node or FTE output node
BytesWritten	The total number of bytes written by a file output node or FTE output node

Resource statistics data: FTE Agent

Learn about the data that is returned for the FTE Agent resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

The FTE agent is an embedded FTE component that allows IBM App Connect Enterprise to send and receive files by using IBM MQ File Transfer Edition. A one-to-one mapping exists between an integration server and its FTE agent. Therefore, the resource manager statistics provide an accurate picture of the IBM MQ File Transfer Edition activity of that integration server.

The following table describes the measurements that are returned for the agent.

Measurements	Description
inboundTransfers	The number of transfers received by the agent.
outboundTransfers	The number of transfers sent by the agent.
inboundBytes	The number of bytes received by the agent.

Measurements	Description
outboundBytes	The number of bytes sent by the agent.

Resource statistics data: FTP

Learn about the data that is returned for the FTP resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

A summary is displayed of file transfers that occur in the execution and a list for each server used.

Measurements	Description
Protocol	The protocol used: either FTP or SFTP
FTPGets	The number of transfers from a remote server to the file system of the integration node
BytesReceived	The number of bytes transferred from a remote server to the file system of the integration node
FTPPuts	The number of transfers from the file system of the integration node to a remote server
BytesSent	The number of bytes transferred from the file system of the integration node to a remote server **Note:** The FTPPuts counter can increase in two cases: either when a new file is transferred, or when an append is made to an existing file.

Resource statistics data: Global Cache

Learn about the data that is returned for the Global Cache resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

The global cache resource manager contains data about the interactions between message flows in a named integration server and the cache. Statistics are available for all activity in the embedded global cache and external WebSphere eXtreme Scale grids. One line of statistics is shown for each policy that is used to connect to an external grid.

The following table describes the measurements that are returned.

Measurements	Description
ConnectionFailures	The number of failed attempts to connect from this integration server to the named cache.
Connects	The number of successful attempts that were made from this integration server to the named cache.
FailedActions	The number of failed map operations by message flows in this integration server on the named cache.
MapReads	The total number of read operations that were completed by message flows in this integration server on the named cache.

Measurements	Description
MapRemoves	The total number of remove operations that were completed by message flows in this integration server on the named cache. This count is incremented by removing or updating an entry.
MapsUsed	The total number of maps that are used by message flows in this integration server in the named cache. This count is incremented each time a different map name is used in this integration server.
MapWrites	The total number of write operations that were completed by message flows in this integration server on the named cache. This count is incremented by putting or updating an entry.
Name	The name of the WebSphere eXtreme Scale grid for this cache. For the embedded global cache, this name is "WMB". For an external grid, this name consists of the name of the policy that is used to connect to the grid, and the name of the grid itself. For example, if you use a policy called "remoteCacheServer" to connect to a grid called "Grid1", this name property has the value `remoteCacheServer(Grid1)`.
TotalMapActions	The total number of map operations that were completed by message flows in this integration server on the named cache. This number includes reads, writes, removes, and key checks.

Resource statistics data: Java Virtual Machine (JVM)

Learn about the data that is returned for the JVM resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

Each integration server starts its own Java Virtual Machine (JVM), which provides support for all Java activities in that integration server. Some Java activity is present in the integration server even if you have not yet deployed or started message flows in that group. Use these resource statistics to review how much memory is in use by the JVM, and how often garbage collection might be occurring in the integration server.

Statistics are collected for the following JVM resources:

- Heap memory
- Non-heap memory
- Garbage collection

A summary is also provided, which adds the values in the three groups.

The special value `-1` is returned for measurements that are undefined or are not set.

The following table describes the measurements that are returned for each of the listed resources. The garbage collection measurements are cumulative, and continue to increase until you stop statistics collection.

Measurements	Resource	Description
InitialMemoryInMB	• Heap memory • Non-heap memory	The initial amount of memory that the JVM requests from the operating system for memory management during startup. Its value might be undefined.

Measurements	Resource	Description
UsedMemoryinMB	• Heap memory • Non-heap memory	The amount of memory that is currently in use.
CommittedMemoryInMB	• Heap memory • Non-heap memory	The amount of memory that is allocated to the JVM by the operating system.
MaxMemoryInMB	• Heap memory • Non-heap memory	The maximum amount of memory that can be used for memory management. Its value might be undefined.
CumulativeGCTimeInSeconds	Garbage collection	The accumulated garbage collection elapsed time in seconds for this instance of the JVM. Its value might be undefined.
CumulativeNumberOfGCCollections	Garbage collection	The total number of garbage collections that have occurred for this instance of the JVM. Its value might be undefined.

Resource statistics data: JDBC Connection Pools

Learn about the data that is returned for the JDBC Connection Pools resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

A statistics summary is returned for each JDBC provider defined in the integration node policy that is switched to use connection pools. The following examples are named JDBC data sources:

- DB2
- Oracle
- Microsoft SQLServer

The following table describes the measurements that are returned for each JDBC Providers policy.

Measurements	Description
NameOfJDBCProvider	The name of the JDBC Providers policy that is using connection pooling. If there are no connection pools started, this defaults to none.
MaxSizeOfPool	The maximum size of the connection pool.
ActualSizeOfPool	A snapshot of the number of connections currently in the pool when the statistics were reported.
CumulativeRequests	A count of the number of requests received by the connection pool during this accounting period.
CumulativeDelayedRequests	The number of times a request for a connection could not be satisfied immediately, because the number of allocated connections reached the maximum pool size and no connections are currently available.
MaxDelayInMilliseconds	The maximum time a caller waited for a connection to be allocated, in milliseconds.
CumulativeTimedOutRequests	A count of the number of requests for connections that could not be satisfied within 15 seconds.

Resource statistics data: JMS

Learn about the data that is returned for the JMS resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

Statistics are reported for each JMS connection factory and JNDI bindings location. XA connections are distinguished from non-XA connections for the same connection factory and JNDI bindings location. Each resource is named either *ConnectionFactoryName_JNDIBindingsLocation* or *ConnectionFactoryName_JNDIBindingsLocation* (XA).

The following table describes the measurements that are returned for each of the listed resources.

Measurements	Description
NumberOfOpenJMSConnections	The current number of open JMS connections.
NumberOfClosedJMSConnections	The total number of JMS connections that were closed since the last integration server restart.
NumberOfOpenJMSSessions	The current number of open JMS sessions.
NumberOfClosedJMSSessions	The total number of JMS sessions that were closed since the last integration server restart.
NumberOfMessagesReceived	The total number of messages received by JMSInput or JMSReceive nodes.
NumberOfMessagesSent	The total number of messages sent by JMSOutput nodes.
NumberOfMessagesBrowsed	The total number of messages browsed by JMSReceive nodes.
NumberOfJMSConnectionFailures	The total number of attempted JMS connections that failed since the last integration server restarts.

Resource statistics data: MQTT

Learn about the data that is returned for the MQTT resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

Statistics are reported for each MQTT server to which a connection exists.

The following table describes the measurements that are returned.

Measurements	Description
OpenConnections	The current number of open connections to an MQTT server.
ClosedConnections	The total number of connections to an MQTT server that were closed since the last integration server restart.
MessagesReceived	The total number of MQTT messages received by MQTTSubscribe nodes.
MessagesSent	The total number of MQTT messages sent by MQTTPublish nodes.
BytesReceived	The total amount of data received by MQTTSubscribe nodes.
BytesSent	The total amount of data sent by MQTTPublish nodes.

Measurements	Description
FailedConnections	The total number of attempted connections to an MQTT server that have failed since the last integration server restart.

Resource statistics data: ODBC

Learn about the data that is returned for the ODBC resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

Statistics are reported for each ODBC DSN that was accessed since the integration server started. XA connections are distinguished from non-XA connections from the same DSN. Each resource is named either *DSN* or *DSN* (XA).

Measurements	Description
ExecuteSuccess	The total number of times any statement was run against this DSN.
ExecuteFailure	The total number of times any statement failed against this DSN.
ActiveConnections	The number of connections currently open to this DSN.
ClosedConnections	The number of connections to this DSN that were ever open, but are now closed. This figure includes connections closed due to an error, forced closed by the DBMS or closed by integration node because it was no longer required (for example, thread idle for 60 seconds).
ConnectionErrors	The number of times a connection to this DSN was detected to have a connection error (which would have caused the error to be closed and therefore also contributed to the closed connections measurement).

Resource statistics data: ODM

Learn about the data that is returned for the ODM resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

Statistics are reported as an overall summary and for each unique ODM ruleset since the integration server started. A sub-resource statistics record is issued for each ruleset, in the form *ODM Policy*(*ruleset path*). For example, {PolicyProject}:ODM(/RuleSet1/1.0/Rule1/1.0).

Measurements	Description
SuccessfulExecutions	The number of successful executions of a ruleset.
FailedExecutions	The number of failed executions of a ruleset.
RulesMatched	The total number of rules matched during all executions of a ruleset.

For more information about using resource statistics, see “Resource statistics” on page 2739, and for information about using ODM rules with IBM App Connect Enterprise, see “Using Operational Decision Manager (ODM) business rules” on page 1241.

Resource statistics data: Parsers

Learn about the data that is returned for the parsers resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

All message flows in an integration server create parsers to parse and write input and output messages. Use the Parsers statistics to see how much resource is being used by the message trees and bit streams that these parsers own.

A statistics summary is returned, followed by an entry for accumulation by parser type for each message flow. The rows are named in the style *<Message Flow>.<Parser>*. A row is shown for every parser type used by that message flow. Additional instances are included in the accumulated statistics for each message flow.

The following table describes the statistics that are returned for each message flow parser since the integration server was last restarted.

Measurements	**Description**
Threads	The number of message flow threads that contributed to the statistics for a message flows parser type accumulation.
ApproxMemKB	The approximate amount of user data-related memory used for the named message flow parser type. It is not possible to calculate the exact amount of memory used by a parser.
MaxReadKB	Shows the largest bit stream parsed by the parser type for the named message flow.
MaxWrittenKB	Shows the largest bit stream written by the parser type for the named message flow.
Fields	Shows the number of message fields associated with the named message flow parser type. These fields are retained by the parser and are used for constructing the message trees.
Reads	The number of successful parses that were completed by the named message flow parser type.
FailedReads	The number of failed parses that occurred for the named message flow parser type.
Writes	The number of successful writes that were completed by the named message flow parser type.
FailedWrites	The number of failed writes that occurred for the named message flow parser type.

Resource statistics data: Security

Learn about the data that is returned for the Security resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

When a message flow is configured with a security profile, requests are typically made to a security provider or Security Token Service (STS) to process and approve authentication, mapping, or authorization. Use the security resource statistics to review the number of requests that are made, how many of those requests are successful, and how many are being serviced from the security cache.

A statistics summary is returned for the whole integration server, followed by a breakdown for each named security provider. Examples of named security providers are WS-Trust v1.3 STS and LDAP.

The following table describes the measurements that are returned for each provider.

Measurements	Description
TotalOperations	The number of security operations (authentication, mapping, or authorization) since collection started. A security profile with both authentication and authorization counts as two operations.
TotalSuccessfulOperations	The number of security operations (authentication, mapping, or authorization) that were approved.
TotalOperationsServicedByCache	The number of security operations (authentication, mapping, or authorization) that were serviced from the security cache (without accessing the STS directly).
TotalCacheEntries	The total number of security operation result entries in the security cache. A security operation is defined in the security profile as authentication, mapping, or authorization. A cache entry might include a returned security token.

Resource statistics data: SOAP Input

Learn about the data that is returned for the SOAP Input resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

The SOAPInput and SOAPReply nodes send and receive SOAP messages. Use the SOAPInput resource statistics to review how many inbound messages the SOAPInput node is receiving, how many replies the SOAPReply node is sending, and how many of those calls are successful or result in SOAP Faults, on a per-operation basis. Statistics for the SOAP nodes are collected with both HTTP and JMS transport. You can review the name of the applied policy set if one is defined. A statistics summary is returned for the whole integration server.

The following table describes the measurements that are returned for the SOAPInput and SOAPReply nodes. These statistics do not include messages which timed out.

Measurements	Description
Name	This measurement takes one of the following values: • "Summary" • *Flow*.*Node*.*Operation* • [Undeployed].*Flow*.*Node*.*Operation* where *Flow* is the name of your message flow, *Node* is the node name, and *Operation* is the name of the operation.
InboundMessagesTotal	The total number of SOAP messages received from the client. This measurement is equal to the sum of `InboundMessagesMadeFlow` and `InboundMessagesFaultedBeforeFlow`.
RepliesSentTotal	The total number of SOAP replies sent back to the client. This measurement is equal to the sum of `SuccessfulRepliesSent` and `FaultRepliesSent`.
InboundMessagesMadeFlow	The number of messages that made the flow without faulting.

Measurements	Description
InboundMessagesFaultedBeforeFlow	The number of messages that faulted before reaching the flow. This measurement includes input messages that are sent down the Failure terminal.
SuccessfulRepliesSent	The number of successful replies, without SOAP Fault, sent to the client.
FaultRepliesSent	The number of SOAP Fault replies sent to client. These faults can be user-defined faults or integration node exceptions.
PolicySetApplied	The name of the policy set if one was defined.

Resource statistics data: Sockets

Learn about the data that is returned for the Sockets resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

Outbound sockets are used by the integration server when a message is sent out through a SOAP, SCA, or HTTP request node. SOAP and SCA nodes always use keepalive sockets; therefore outbound sockets are reused for many requests. HTTPRequest nodes use keepalive sockets only if you set the property Enable HTTP/1.1 keep-alive. Use these resource statistics to review whether you are reusing outbound sockets, and to see the size and volume of message data that is flowing through those sockets.

A statistics summary is returned, followed by an entry for each outbound socket endpoint, which is defined by its URL. Examples of endpoints are `localhost:7080` and `www.soaphub.org:80`.

The following table describes the measurements that are returned for each endpoint that was accessed since the integration server was last restarted.

Measurements	Description
TotalSockets	The number of outbound sockets that have been opened since the last integration server restart.
TotalMessages	The number of requests for a socket; for example, from a SOAPRequest node.
TotalDataSent_KB	The number of bytes sent, in kilobytes (KB).
TotalDataReceived_KB	The number of bytes received, in kilobytes (KB).
SentMessageSize_0-1KB SentMessageSize_1KB-10KB SentMessageSize_10KB-100KB SentMessageSize_100KB-1MB SentMessageSize_1MB-10MB SentMessageSize_Over10MB	The number of messages sent in each size range. For example, a message of 999 bytes is counted in SentMessageSize_0-1KB; a message of 1000 bytes is counted in SentMessageSize_1KB-10KB.
ReceivedMessageSize_0-1KB ReceivedMessageSize_1KB-10KB ReceivedMessageSize_10KB-100KB ReceivedMessageSize_100KB-1MB ReceivedMessageSize_1MB-10MB ReceivedMessageSize_Over10MB	The number of messages received in each size range.

Resource statistics data: TCPIP Client Nodes

Learn about the data that is returned for the TCPIP Client Nodes resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

Use these statistics to get a view of the level of activity and health of TCP/IP nodes in an integration server. You can see how many connection managers are active and reporting statistics, and the following details from each:

Measurements	Description
OpenConnections	The current number of open connections
ClosedConnections	The total number of connections that were closed since the last integration server restart
MessagesReceived	The total number of messages received (by TCPIPClientInput or TCPIPClientReceive nodes)
MessagesSent	The total number of messages sent (by TCPIPClientOutput nodes)
BytesSent	The total amount of data sent (by TCPIPClientOutput nodes), excluding SSL wrappers.
BytesReceived	The total amount of data received (by TCPIPClientInput or TCPIPClientReceive nodes), excluding SSL wrappers.
FailedConnections	The total number of attempted connections that failed since the last integration server restarts.

Resource statistics data: TCPIP Server Nodes

Learn about the data that is returned for the TCPIP Server Nodes resource type when you activate resource statistics collection.

You can view these statistics in the web user interface, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

Use these statistics to get a view of the level of activity and health of TCP/IP nodes in an integration server. You can see how many connection managers are active and reporting statistics, and the following details from each:

Measurements	Description
OpenConnections	The current number of open connections
ClosedConnections	The total number of connections that were closed since the last integration server restart
MessagesReceived	The total number of messages received (by TCPIPServerInput or TCPIPServerReceive nodes)
MessagesSent	The total number of messages sent (by TCPIPServerOutput nodes)
BytesSent	The total amount of data sent (by TCPIPServerOutput nodes), excluding SSL wrappers.
BytesReceived	The total amount of data received (by TCPIPServerInput or TCPIPServerReceive nodes), excluding SSL wrappers.

Measurements	Description
FailedSSLConnections	The total number of attempted inbound SSL connections from external clients that failed or were refused since the last integration server restart.

Tuning the integration node

You can complete several tasks that enable you to tune different aspects of the integration node performance.

Before you begin

Ensure that the following requirements are met:

- Your user ID has the correct authorizations to perform the task. Refer to Security requirements for administrative tasks.

About this task

Select the tasks that are relevant to your enterprise:

Procedure

- "Setting the JVM heap size" on page 2762
- "Increasing the stack size on Windows, Linux, and UNIX systems" on page 2762

Setting the JVM heap size

When you start an integration server, it creates a Java virtual machine (JVM) for executing a Java user-defined node.

Before you begin

- Check the resource statistics data to monitor resource usage and identify potential problems with performance; for more information, see "Resource statistics" on page 2739.

About this task

You can pass parameters to the JVM to set the minimum and maximum heap sizes; the default maximum heap size is 256 MB. To give more capacity to a message flow that is going to process large messages, reduce the minimum JVM heap size to allow the main memory heap to occupy more address space.

Increase the maximum heap size only if you use Java intensively with, for example, user-defined nodes.

Use caution when you set the maximum heap size, because the Java Runtime Environment takes the values for its initial, maximum, and current heap sizes to calculate how frequently it drives garbage collection. A large maximum heap size drives garbage collection less frequently. If garbage collection is driven less frequently, the heap size associated with the integration server continues to grow.

Use the information on JVM parameter values on the **mqsichangeproperties** command to set the heap size that you require.

Increasing the stack size on Windows, Linux, and UNIX systems

Increase the stack size on Windows, Linux, and UNIX systems by setting the **MQSI_THREAD_STACK_SIZE** environment variable to an appropriate value.

About this task

When you restart integration nodes that are running on the system, they use the new value.

The value, in bytes, of **MQSI_THREAD_STACK_SIZE** that you set is used for every thread that is created in a DataFlowEngine process. If the integration server has many message flows assigned to it, and you set a large value for **MQSI_THREAD_STACK_SIZE**, the DataFlowEngine process needs a large amount of storage for the stacks.

Set this environment variable to at least 48 KB. The default values are:

Linux and UNIX
1 MB

AIX
2 MB

z/OS
50 KB

Windows
Determined by the operating system.

Optimizing message flow throughput

Each message flow that you design must provide a complete set of processing for messages received from a particular source. This design might result in very complex message flows that include large numbers of nodes that can cause a performance overhead, and might create potential bottlenecks. You can increase the number of message flows that process your messages to provide the opportunity for parallel processing and therefore improved throughput.

About this task

The operation mode of your integration servers can affect the number of message flows that you can use; see features and “Restrictions that apply in each operation mode” on page 5 for more information.

You can also consider the way in which the actions taken by the message flow are committed, and the order in which messages are processed.

The web user interface enables you to view message flow statistics and accounting data, including the message flow throughput and the CPU and elapsed times for transactions in the flow. See “Viewing message flow statistics and accounting data” on page 2738 for more information about how you can access the statistical data.

Consider the following options for optimizing message flow throughput:

Multiple threads processing messages in a single message flow
When you deploy a message flow, the integration server automatically starts an instance of the message flow for each input node that it contains. This behavior is the default. If you have a message flow that handles a very large number of messages, you can enable more messages to be processed by allocating more instances of the flow.

You can update the `Additional Instances` property of the deployed message flow in the BAR file; the integration server starts additional copies of the message flow on separate threads, providing parallel processing. This option is the most efficient way of handling this situation if you are not concerned about the order in which messages are processed.

If the message flow receives messages from an IBM MQ queue, you can influence the order in which messages are processed by setting the `Order Mode` property of the MQInput node:

- If you set `Order Mode` to By User ID, the node ensures that messages from a specific user (identified by the UserIdentifier field in the MQMD) are processed in guaranteed order. A second message from one user is not processed by an instance of the message flow if a previous message from this user is currently being processed by another instance of the message flow.
- If you set `Order Mode` to By Queue Order, the node processes one message at a time to preserve the order in which the messages are read from the queue. Therefore, this node behaves as though you have set the `Additional Instances` property of the message flow to zero.

- If you set `Order Mode` to `User Defined`, you can order messages by any message element, by setting an XPath or ESQL expression in the Order field location property. The node ensures that messages with the same value in the order field message element are processed in guaranteed order. A second message with the same value in the order field message element is not processed by an instance of the message flow if a previous message with the same value is currently being processed by another instance of the message flow.

  If the field is missing, an exception is raised, and the message is rolled back. NULL and empty values are processed separately, in parallel.

  If you set `Order Mode` to By User ID or `User Defined`, and the message flow uses transformation nodes, it is advisable to set the `Parse Timing` to Immediate.

The scope of the message flow

You might find that, in some circumstances, you can split a single message flow into several different flows to reduce the scope of work that each message flow performs. If you do split your message flow, be aware that it is not possible to run the separate message flows in the same unit of work, and if transactional aspects to your message flow exist (for example, the updating of multiple databases), this option does not provide a suitable solution.

The following two examples show when it might be beneficial to split a message flow:

1. In a message flow that uses a RouteToLabel node, the input queue might increase in size, indicating that work is arriving faster than it is being processed; this might indicate a need for increased processing capacity. You can use another copy of the message flow in a second integration server, but this option is not appropriate if you want all of the messages to be handled in the order in which they are shown on the queue. You can consider splitting out each branch of the message flow that starts with a Label node by providing an input queue and input node for each branch. This option might be appropriate, because when the message is routed by the RouteToLabel node to the relevant Label node, it has some level of independence from all other messages.

   You might also need to provide another input queue and input node to complete any common processing that the Label node branches connect to when unique processing has been done.
2. If you have a message flow that processes very large messages that take a considerable time to process, you might be able to:

   a. Create other copies of the message flow that use a different input queue (you can set this option up in the message flow itself, or you can update this property when you deploy the message flow).

   b. Set up IBM MQ queue aliases to redirect messages from some applications to the alternative queue and message flow.

   You can also create a new message flow that replicates the function of the original message flow, but only processes large messages that are immediately passed on to it by the original message flow, that you modified to check the input message size and redirect the large messages.

The frequency of commits

If a message flow receives input messages on an IBM MQ queue, you can improve its throughput for some message flow scenarios by modifying its default properties after you have added it to a BAR file. (These options are not available if the input messages are received by other input nodes; commits in those message flows are performed for each message.)

The following properties control the frequency with which the message flow commits transactions:

- `commitCount`. This property represents the number of messages processed from the input queue per message flow thread, before an MQCMIT is issued.
- `commitInterval`. This property represents the time interval that elapses before an MQCMIT is started.

Optimizing message flow response times

You can use different solutions to improve message flow response times.

Before you begin

Read the following concept topics:

- "Analyzing message flow performance" on page 2699
- "Message flow nodes" on page 484

About this task

When you design a message flow, the flexibility and functional capabilities of the built-in nodes often mean that there are several ways to achieve the processing and results that you require. You might find that different solutions deliver different levels of performance and, if performance is an important consideration for you, take it into account when designing your message flow

Your applications can perceive performance in either of these ways:

- The response time indicates how quickly each message is processed by the message flow. The response time is particularly influenced by how you design your message flows. Response time is discussed in this topic.
- The throughput indicates how many messages of particular sizes can be processed by a message flow in a specified time. The throughput is mainly affected by configuration and system resource factors, and is discussed in "Optimizing message flow throughput" on page 2763, with other domain configuration information.

The web user interface enables you to view message flow statistics and accounting data, including the message flow throughput and the CPU and elapsed times for transactions in the flow. See "Viewing message flow statistics and accounting data" on page 2738 for more information about how you can access the statistical data.

Several aspects influence message flow response times. However, as you create and modify your message flow design to arrive at the best results for your specific business requirements, also consider the eventual complexity of the message flow. The most efficient message flows are not necessarily the easiest to understand and maintain; experiment with the solutions available to arrive at the best balance for your needs.

Several factors influence message flow response times:

The number of nodes that you include in the message flow

Every node increases the amount of processing required in the integration server, therefore, consider the content of the message flow carefully, including the use of subflows.

Use as few nodes as possible in a message flow; every node that you include in the message flow increases the amount of processing required in the integration server. The number of nodes in a single flow has an upper limit, which is governed by system resources, particularly the stack size.

How the message flow routes and processes messages

In some situations, you might find that the built-in nodes, and perhaps other nodes that are available in your system, provide more than one way of providing the same function. Choose the simplest configuration. Where a message flow is required to process more than a single type of record, you can create an easily extendible framework by developing a message flow structure in which there is a parse of the message to determine the type, followed by a RouteToLabel node and Label nodes for each of the types. Where a higher number of label nodes is expected, consider implementing the message parse and Label selection in one message flow, and the processing of each of the label types into separate message flows. The interface between these two flows would be through a queue.

If your message flow includes loops
Avoid loops of repeating nodes, which can be very inefficient and can cause performance and stack problems. You might find that a Compute node with multiple PROPAGATE statements avoids the need to loop around a series of nodes.

The efficiency of the ESQL
Check all the ESQL code that you have created for your message flow nodes. As you develop and test a node, you might maintain statements that are not required when you have finalized your message processing. You might also find that something you have coded as two statements can be coded as one. Taking the time to review and check your ESQL code might provide simplification and performance improvements.

The use of persistent and transactional messages
Persistent messages are saved to disk during message flow processing. You can avoid this situation by specifying that messages are non-persistent on input, output, or both. If your message flow is handling only non-persistent messages, check the configuration of the nodes and the message flow itself; if your messages are non-persistent, transactional support might be unnecessary. The default configuration of some nodes enforces transactionality; if you update these properties and redeploy the message flow, response times might improve.

Message size
A larger message takes longer to process. If you can split large messages into smaller units of information, you might be able to improve the speed at which they are handled by the message flow.

Message format
Although IBM App Connect Enterprise supports multiple message formats, and provides facilities that you can use to transform from one format to another, this transformation increases the amount of processing required in the integration server. Make sure that you do not perform any unnecessary conversions or transformations.

Troubleshooting performance problems

Follow this guidance to resolve common problems with IBM App Connect Enterprise performance.

About this task

- **Scenario:** You are experiencing problems with performance, such as:
  - Poor response times in the IBM App Connect Enterprise Toolkit when developing message flows
  - Poor response time at deployment
  - Individual messages taking a long time to process
  - Poor overall performance, or performance that does not scale well
- **Solution:** Possible solutions are:
  - Tune the integration node
  - Speed up IBM MQ persistent messaging by optimizing the I/O (input/output)
  - Speed up database access by optimizing I/O
  - Increase system memory
  - Use additional instances or multiple integration servers
  - Optimize ESQL statements for best performance

The reports in IBM MQ Family Category 2 (freeware) SupportPacs contain additional advice about performance, and they are available for download from the IBM MQ SupportPacs web page.

The following topics contain information about dealing with some common performance problems:

- "You are experiencing poor startup times for the IBM App Connect Enterprise Toolkit" on page 2769
- "You are experiencing poor performance in the IBM App Connect Enterprise Toolkit when working with large projects" on page 2769

- "Performance is reduced when you run web services with small message sizes" on page 2770
- "The PutTime reported by IBM MQ on z/OS, and other times or timestamps are inconsistent" on page 2770

The following topics contain guidance to help you optimize the performance of your code and message flows:

- "Message flow design and performance" on page 2689
- "Code design and performance" on page 2690

The system is getting progressively slower

Follow this guidance to resolve the problem of a slow system.

Procedure

- **Scenario:** The system is getting progressively slower.
- **Explanation:** When a process ends abnormally, an entry is made in the local error log, and a dump data file might be written to the errors or z/OS log directory. This directory is unbounded, and if you do not clear it of unwanted files, you might find that your system performance degrades due to significant space being used by old abend files.
- **Solution:** Periodically clear the errors or z/OS log directory of unwanted files.

  On Windows, use the **-w** parameter of the **mqsicreatebroker** command to create the errors directory in a hard disk drive partition that does not contain IBM App Connect Enterprise or Windows itself.

You experience configuration problems with multiple components

Follow this guidance to resolve configuration problems with multiple components.

Procedure

- **Scenario:** You are experiencing configuration problems with many components.
- **Explanation:** If you are running IBM App Connect Enterprise with many configured components, the memory footprint of the integration node processes (particularly the integration servers or DataFlowEngines) might exceed their memory limits. In particular, the user process limit might be exceeded, or the address space limit might be reached.

  You might encounter problems, such as the BIP2106E or BIP2137E error messages, when running an integration node with:

  – Many message flows
  – Multiple databases
  – Large input or output messages
- **Solution:** Use tools that are specific to your operating system to check the maximum size of the failing process, then check for any user limits (if applicable) or computer limits on process size.

  On Windows, the maximum process size is 2 GB. Increasing user limits beyond this value does not make any difference. If your integration node processes regularly reach this size, consider spreading your message flows across more integration servers to reduce the size of each one below these limits.

Message flow performance is reduced when you access message trees with many repeating records

Follow this guidance to resolve the problem of reduced performance in message trees that have repeating records.

Procedure

- **Scenario:** Message flow performance is reduced when the following conditions are true:
  - You are using ESQL processing to manipulate a large message tree.
  - The message tree consists of repeating records or many fields.
  - You have used explicit SET statements with field reference paths to access or create the fields.
  - You have observed a gradual slowing of message flow processing as the ESQL processes more fields or repetitions.
- **Explanation:** This problem occurs when you use field references, rather than reference variables, to access or create consecutive fields or records.

  Consider the following example, in which independent SET statements use field reference paths to manipulate the message tree. The SET statement takes a source and target parameter, where either or both parameters are field references:

  ```
  SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field = '1';
  ```

  The problem arises when the SET statement is used to create many more fields, as shown in the following example:

  ```
  SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field1 = '1';
  SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field2 = '2';
  SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field3 = '3';
  SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field4 = '4';
  SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field5 = '5';
  ```

  In this example, the five fields that are created are all children of ParentA. Before the specified field can be created or modified, the integration node must navigate the named message tree to locate the point in the message tree that is to be altered. For example:

  - To access field 1, the SET statement navigates to ParentA, then to the first field, therefore involving two navigations.
  - To access field 5, the SET statement navigates to ParentA, then traverses each of the previous fields until it reaches field 5, therefore involving six navigations.

  Navigating over all the fields that precede the specified field causes the loss in performance.

  Now consider a scenario that accesses repeating fields in an input message tree; for example:

  ```
  DECLARE myChar CHAR;
  DECLARE thisRecord INT 0;
  WHILE thisRecord < 10000 DO
   SET thisRecord = thisRecord + 1;
   SET myChar = InputRoot.MRM.myParent.myRepeatingRecord[thisRecord];
  ```

```
END WHILE;
```

When index notation is used, as the count increases, the processing needs to navigate over all the preceding fields to get the one it wants; that is, it has to count over the previous records to get to the one that is represented by the current indexed reference.

- When accessing InputRoot.MRM.myParent.myRepeatingRecord[1], one navigation takes place to get to the first record.
- When accessing InputRoot.MRM.myParent.myRepeatingRecord[2], two navigations take place to get to the second record.
- When accessing InputRoot.MRM.myParent.myRepeatingRecord[N], *N* navigations take place to get to the N-th record.

Therefore, the total number of navigations for this WHILE loop is: 1 + 2 + 3 + ... + *N*, which is not linear.

- **Solution:** If you are accessing or creating consecutive fields or records, use reference variables. When you use reference variables, the statement navigates to the main parent, which maintains a pointer to the field in the message tree. The following example shows the ESQL that can be used to reduce the number of navigations when creating new output message tree fields:

```
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field1 = '1';
DECLARE outRef REFERENCE TO OutputRoot.XMLNS.TestCase.StructureA.ParentA;
SET outRef.field2 = '2';
SET outRef.field3 = '3';
SET outRef.field4 = '4';
SET outRef.field5 = '5';
```

When referencing repeating input message tree fields, you could use the following ESQL:

```
DECLARE myChar CHAR;
DECLARE inputRef REFERENCE TO InputRoot.MRM.myParent.myRepeatingRecord[1];
WHILE LASTMOVE(inputRef) DO
 SET myChar = inputRef;
 MOVE inputRef NEXTSIBLING NAME 'myRepeatingRecord';
END WHILE;
```

For further information, see “Creating dynamic field references” on page 1639.

You are experiencing poor startup times for the IBM App Connect Enterprise Toolkit

Follow this guidance to resolve the problem of poor startup times for the IBM App Connect Enterprise Toolkit.

Procedure

- **Scenario:** You are experiencing poor startup times for the IBM App Connect Enterprise Toolkit.
- **Explanation:** Poor startup times in the IBM App Connect Enterprise Toolkit can occur if you install all of the language packs.
- **Solution:** Install only those language packs that you require.

You are experiencing poor performance in the IBM App Connect Enterprise Toolkit when working with large projects

Follow this guidance to resolve the problem of reduced performance when you are working with large projects.

Procedure

- **Scenario:** You are experiencing poor performance in the IBM App Connect Enterprise Toolkit when working with large or complex projects.

- **Explanation:** Performance is reduced because of frequent project changes, such as adding and removing projects, or using **Project** > **Clean**. Complete project updates use large amounts of memory due to the size, number, and connections between files.
- **Solution:** Increase your system memory.

Performance is reduced when you run web services with small message sizes

Follow this guidance to resolve the problem of reduced performance when you run web services with small message sizes.

Procedure

- **Scenario:** You see poor response times and throughput rates when you run web services using HTTP, and send smaller messages sizes (typically less than 32 KB). Throughput rates can fluctuate with message size. IBM App Connect Enterprise running on the AIX platform might be affected.
- **Explanation:** The default configuration of HTTP enables the Nagle algorithm, which seeks to improve the efficiency of Internet Protocol networks by reducing the number of packets sent. It works by buffering small packets together, creating a smaller number of large packets. By default, the **`tcpnodelay`** setting on the sockets of the HTTPRequest is `true`. You can disable the Nagle algorithm at either the operating system level (system wide) or through IBM App Connect Enterprise (affecting only the IBM App Connect Enterprise HTTP sockets).
- **Solution:** Stop the integration node and use the following commands to disable the Nagle algorithm:

  HTTPRequest, SOAPRequest, and SCARequest nodes

  ```
  mqsichangeproperties integrationNodeName -e integrationServerName
        -o ComIbmSocketConnectionManager -n tcpNoDelay -v true|false -f
  mqsichangeproperties integrationNodeName -e integrationServerName
        -o ComIbmSocketConnectionManager -n tcpNoDelaySSL -v true|false -f
  ```

  To determine the value set, take the following steps:

  Report property values

  Start the integration node and use the following commands:

  ```
  mqsireportproperties integrationNodeName -e integrationServerName
        -o ComIbmSocketConnectionManager -r
  mqsireportproperties integrationNodeName -e integrationServerName
        -o HTTPConnector -r
  mqsireportproperties integrationNodeName -e integrationServerName
        -o HTTPSConnector -r
  mqsireportproperties integrationNodeName -b NodeHttpListener
        -o HTTPConnector -r
  mqsireportproperties integrationNodeName -b NodeHttpListener
        -o HTTPSConnector -r
  ```

The PutTime reported by IBM MQ on z/OS, and other times or timestamps are inconsistent

Follow this guidance to resolve the problem of inconsistently reported times and timestamps.

Procedure

- **Scenario:** The PutTime reported by IBM MQ on z/OS, and other times or timestamps are inconsistent. A difference of approximately 20 seconds is detected in:
  - Traces (including those obtained from the Trace node)
  - The MQPUTTIME timestamp in the message MQMD header
  - Timestamps obtained from ESQL (for example, in a Compute node)
- **Explanation:** IBM App Connect Enterprise reports the time using standard methods from the operating system, which do not account for leap seconds. However, on z/OS, the message putTime

that is reported by IBM MQ in the MQMD header of a message *can* account for leap seconds, using the value specified for the number of leap seconds in the CVT field.

This inconsistency can cause:

- Problems when debugging
- Problems with message flows if you use timestamps to control the flow of messages
- Misinformation

- **Solution:** Configure your system to synchronize with an NTP server, such that the CVT field is no longer relevant.

  Alternatively, add an offset to adjust a z/OS timestamp reading. For example, add 20 seconds when getting the CURRENT_TIME in ESQL.

You are experiencing reduced Java performance, or Java performance degrades after debugging a message flow

Follow this guidance to resolve the problem of reduced Java performance after debugging a message flow.

Procedure

- **Scenario:** The Java code in the JavaCompute, the Java user-defined node, or the XSLTransform node does not run as quickly as expected, or performance in these nodes degrades after debugging a message flow.

  This performance degradation might particularly affect the deployment of XML schemas. Other Java based nodes might also experience degraded performance; for example, adapter nodes (SAP, PeopleSoft, JD Edwards, Siebel), SOAP nodes, CORBA nodes, IMS nodes, CICS nodes and JMS nodes.
- **Explanation:** The integration node disables the Java JIT (just-in-time) compiler on the Java virtual machine (JVM) that is created when the integration server is started if you are debugging a message flow. A disabled Java JIT compiler provides a greater choice of debugging options, however any optimizations typically performed during JIT compilation are prevented, which might result in degraded performance.
- **Solution:** If you are not debugging a message flow:

  1. Set the JVM debug port to zero using this command:

     ```
     mqsichangeproperties integration_node_name -e integration_server_name
     -o ComIbmJVMManager -n jvmDebugPort -v 0
     ```

     For example:

     ```
     mqsichangeproperties TEST -e default
     -o ComIbmJVMManager -n jvmDebugPort -v 0
     ```

  2. Disable flow debugging.

Message flow monitoring

You can configure monitoring events on message flows, and these events can be published to IBM MQ or MQTT, to enable subscribers to receive them. You can also configure message flows to send monitoring events to a Logstash input in an Elasticsearch, Logstash, and Kibana (ELK) stack.

About this task

You can configure monitoring events on message flows, and then monitor the events as they are processed by the flows, as described in “Message flow monitoring overview” on page 2772.

You can also monitor business transactions, by creating business transaction definitions and then viewing the status of the business transactions in the web user interface. For more information, see "Monitoring business transactions" on page 2817 and "Business transaction monitoring overview" on page 2818.

Message flow monitoring overview

You can monitor message flows, learn about monitoring basics and scenarios, and decide how to configure event sources.

A message flow can be configured to publish an event when something interesting happens. The events can be published to IBM MQ or MQTT, to enable subscribers to receive them. You can also configure a message flow to send monitoring events to a Logstash input in an Elasticsearch, Logstash, and Kibana (ELK) stack.

An event is a message that contains information about the source of the event, the time of the event, and the reason for the event. The event can include the message bit stream, and can also include selected elements from the message body. These fields can be used to correlate messages that belong to the same transaction, or to convey business data to a monitoring application. You can then use these events to monitor your message flows.

You can configure events by using either of the following methods:

- Use the Flow Editor in the IBM App Connect Enterprise Toolkit to configure the message flow monitoring events.
- Use a Monitoring profile to define monitoring events that can be applied to one or more message flows that are deployed to an integration server. A Monitoring profile is a special XML file that is stored and deployed in a Policy project.

The following topics describe the concepts behind monitoring and explain how to configure monitoring for your message flows.

- "Monitoring basics" on page 2772
- "Monitoring properties and monitoring profiles" on page 2786
- "Configuring monitoring for message flows" on page 2788

For information about using business events to monitor business transactions through one or more message flows, see "Business transaction monitoring overview" on page 2818.

Monitoring basics

You can configure message flows to emit events, which can then be read and used by other applications for transaction monitoring and auditing. Monitoring events are also used by the built-in business transaction monitoring capability that is provided by IBM App Connect Enterprise, and by the record and replay capability.

The following sections introduce the concepts of monitoring:

- "Monitoring events" on page 2772
- "Event sources" on page 2773
- "Transaction events" on page 2774
- "Event output options" on page 2774
- "Publishing monitoring events" on page 2774

For more information about business transaction monitoring, see "Monitoring business transactions" on page 2817 and "Business transaction monitoring overview" on page 2818.

Monitoring events

A monitoring event is a message that is published when a message flow that is configured with a monitoring event completes the source action on which the event is configured. Monitoring events can be configured on two source types:

- Transaction, including Transaction Started, Transaction Completed.
- Terminal, when a message flow node terminal propagates.

Monitoring event messages that are published MQ or MQTT are in the form of XML or JSON documents that conform to the monitoring event schema. Monitoring event messages that are sent to a Logstash input in an Elasticsearch, Logstash, and Kibana (ELK) stack are emitted in JSON format.

Each event contains the following information:

- The source of the event.
- The name of the event.
- A sequence number and creation time.
- A correlation ID for events that are emitted by the same transaction or unit of work.

Additionally, a monitoring event can contain the following items:

- Application data that is extracted from the message.
- Part or all of the message bit stream.

You can create a message model for the monitoring event by completing the following steps in the IBM App Connect Enterprise Toolkit:

1. Click **File**.
2. Click **New**.
3. Select **Message Model**.
4. Select **IBM supplied**.
5. Click **Next**.
6. Select **Create an XML schema file by importing an IBM supplied definition**.
7. Click **Next**.
8. Select an existing Application or Library, or create a new one.
9. Select **IBM App Connect Enterprise Monitoring Event** from the list of IBM supplied messages.
10. Click **Finish**.

You can also find the monitoring event schema at: *install_location*/server/sample/Monitoring/MonitoringEventV2.xsd or *install_location*/server/sample/Monitoring/MonitoringEventV1.json.

Event sources

A message flow can emit two kinds of event:

Transaction events
Transaction events are emitted from input nodes only.

Terminal events
Terminal events are emitted from any terminal of any node, including input nodes.

An individual message flow can emit transaction events, terminal events, or both kinds of event. You can configure, enable, and disable both types of event by using the monitoring properties of the message flow, or by using a monitoring profile.

An event source address identifies an event source in a message flow.

Terminal events can be emitted from any node in a message flow. Therefore, these events can be used as an alternative to dedicated event-emitting nodes or subflows, such as the example supplied in SupportPac IA9V.

Event sources emit events only if monitoring is activated for the message flow.

Transaction events

Each input node in a message flow contains three events sources, in addition to terminal events.

Event source	Event source address	Description
Transaction start	*Nodename*.transaction.Start	The event is emitted when the message is read from the transport.
Transaction end	*Nodename*.transaction.End	The event is emitted when IBM App Connect Enterprise completes all processing of the message.
Transaction rollback	*Nodename*.transaction.Rollback	The event is emitted instead of transaction end if the message flow issues an exception that is not caught and processed in the flow.

Events are emitted subject to the evaluation of the `eventFilter` expression, as described in "Event output options" on page 2774.

If a message flow handles its own exceptions, a transaction end event is issued instead of a transaction rollback event because the flow takes control of the error and terminates normally. In this case, if you need to distinguish errors, you can configure terminal events at appropriate nodes in the flow.

Terminal events

Any terminal in a message flow can be an event source. If the event source is active, it emits an event each time a message passes through the terminal, subject to the evaluation of the `eventFilter` expression. This expression is described in "Event output options" on page 2774.

Event output options

When you configure an event source, you can define a filter to control whether the event is emitted. You can tailor event emission to your business requirements by filtering out events that do not match a set of rules. For example, you might decide to emit events only for transactions over a minimum amount:

```
$Body/StockTrade/Details/Value > 10000
```

The use of a filter can reduce the number of events that are emitted, and reduce the workload on your monitoring application.

You might filter out the transaction.Start and transaction.End events that are emitted by the MQInput node for IBM MQ Backout transaction events after a backout threshold is reached. An event monitoring application can then collect appropriate data.

```
3 >= $Root/MQMD/BackoutCount
```

Publishing monitoring events

Events are published to a topic, where they can be read by multiple subscribers. They can be published to IBM MQ or MQTT to enable subscribers to receive them. The topic name has the following structure:

- For events published on the IBM MQ pub/sub broker:
  - XML:

    ```
    $SYS/Broker/integrationNodeName/Monitoring/integrationServerName/flow_name
    ```

  - JSON:

    ```
    $SYS/Broker/integrationNodeName/MonitoringEvents/JSON/integrationServerName/flow_name
    ```

- For events published on the MQTT pub/sub broker:
  - XML:

    ```
    IBM/IntegrationBus/integrationNodeName/Monitoring/integrationServerName/flow_name
    ```

  - JSON:

    ```
    IBM/IntegrationBus/integrationNodeName/MonitoringEvents/JSON/integrationServerName/flow_name
    ```

Events can also be written to the file system in rotatable log files. The monitoring events are written to the *workDir*/Common/MonitoringEvents subdirectory.

Monitoring events can also be published to a Logstash input plug-in in an Elasticsearch, Logstash, and Kibana (ELK) stack, so that you can display the reported information in a Kibana dashboard. For more information, see "Reporting logs and monitoring events to a Logstash input in an ELK stack" on page 2869.

For more information about configuring the publication of event messages, see "Configuring the publication of event messages" on page 2807.

The hierarchical structure allows subscribers to filter the events that they receive. One subscriber can receive events from all message flows in the integration node, while another receives only the events from a single integration server. For more information about publishing and subscribing to events, see "Publish/subscribe overview" on page 1236.

You decide whether events participate in transactions when you configure a monitoring event source:

- If you want an event to be emitted only if the message flow transaction commits, configure the event source to coordinate the events with the message flow transaction.
- If you want an event to be emitted regardless of whether the message flow transaction commits or rolls back, configure the event source to emit events out of sync point. Such events are available immediately.
- A group of events can be emitted together regardless of whether the message flow transaction commits or rolls back. If you want this option, you must configure the event source to emit events in an independent unit of work.

Note:

The monitoring event is not emitted if a parser exception occurs in the following situations:

- Constructing the monitoring event from the Event Name, Event Filter, or Event Payload.
- Including the bit stream in the payload.

In these situations, the parser exception is thrown again and the message is rolled back.

Monitoring profiles

To customize events after a message flow is deployed, but without redeploying the flow, you can use a monitoring profile.

Before you can use a monitoring profile, you must deploy it to a policy project and then activate the monitoring profile on the message flow, application, or integration server. Activate the monitoring profile by using either the command or the administration REST API.

You can also configure a default monitoring profile for an integration server, by setting properties in the Defaults section of the server.conf.yaml file. This profile is then used if a message flow has no monitoring events that are configured and no specific monitoring profile applied. For example:

```
Defaults:
    monitoringProfile: 'myIS1MonitoringProfile'       # Default Monitoring profile
```

A monitoring profile is an XML document that specifies the event sources in a message flow that emits events, and the properties of those events. The monitoring profile XML must conform to XML schema file MonitoringProfile.xsd, which you can find in the samples directory of the

IBM App Connect Enterprise installation (*Install_root*/server/sample/Monitoring/MonitoringProfile.xsd). The XML file must have an extension of .monprofile.xml (for example, *monitoringProfileName*.monprofile.xml) and must be contained in a policy project.

The monitoring profile must be deployed before you start the message flows that use it. If a message flow is configured to use a monitoring profile that is not deployed, a warning is issued. You must manually stop and start the message flow after the monitoring profile is deployed in order for it to be used by the message flow. If you redeploy a monitoring profile, all message flows that use that monitoring profile are stopped and restarted to use the new values.

You can attach, change, or detach monitoring profiles from a message flow by using the **mqsichangeflowmonitoring** command. For more information, see "Applying and activating a monitoring profile" on page 2798.

The following example of a monitoring profile XML document contains a single event source to illustrate the structure.

```
<p:monitoringProfile
xmlns:p="http://www.ibm.com/xmlns/prod/websphere/messagebroker/10.0.0.0/monitoring/profile"
 p:version="2.0">
    <p:eventSource p:enabled="true" p:eventSourceAddress="SOAPInput.transaction.Start">
        <p:eventPointDataQuery>
            <p:eventIdentity>
                <p:eventName p:literal="" p:queryText=""/>
            </p:eventIdentity>
            <p:eventCorrelation>
                <p:localTransactionId p:queryText="" p:sourceOfId="automatic"/>
                <p:parentTransactionId p:queryText="" p:sourceOfId="automatic"/>
                <p:globalTransactionId p:queryText="" p:sourceOfId="automatic"/>
            </p:eventCorrelation>
           <p:eventFilter p:queryText="true()"/>
           <p:eventUOW p:unitOfWork="messageFlow" />
        </p:eventPointDataQuery>
        <p:applicationDataQuery>
            <p:simpleContent p:dataType="boolean" p:name="" p:targetNamespace="">
                <p:valueQuery p:queryText=""/>
            </p:simpleContent>
            <p:complexContent p:name="">
                <p:payloadQuery p:queryText=""/>
            </p:complexContent>
        </p:applicationDataQuery>
        <p:bitstreamDataQuery p:bitstreamContent="all" p:encoding="base64Binary"/>
    </p:eventSource>
</p:monitoringProfile>
```

The root element is p:monitoringProfile. It contains one or more p:eventSource elements, each of which specifies an event source and defines its properties. Each p:eventSource element contains:

- A p:eventPointDataQuery element that provides key information about the event.
- Optional: A p:applicationDataQuery element if the event payload includes data fields that are extracted from a message.
- Optional: A p:bitstreamDataQuery element if the event payload includes bitstream data from a message.

Creating a monitoring profile

If you have a deployed message flow with monitoring properties that were configured by using the Message Flow editor in the IBM App Connect Enterprise Toolkit, you can use either the command or the administration REST API to extract those monitoring properties from the deployed flow and create the equivalent monitoring profile (.monprofile.xml file) for the message flow. You can then use this profile as a starting point for creating other monitoring profiles.

Alternatively, you can create the .monprofile.xml file manually, by following the steps described in "Creating a monitoring profile" on page 2793.

XPath queries and XML namespaces

If an XPath query contains a component that has an XML namespace, the XPath contains a namespace prefix for the namespace. The namespace prefix in all `prefixMapping` elements in a monitoring profile must be unique. For example, the following XPath refers to components in two different namespaces:

```
<p:localTransactionId p:sourceOfId="query" p:queryText="$Body/soapenv:Header/wsa:messageID" />
```

For the integration node to resolve the namespace prefix, the namespace URL must also be provided. Supply a `prefixMapping` element for each namespace:

```
      <p:localTransactionId p:sourceOfId="query" p:queryText="$Body/soapenv:Header/wsa:messageID">
        <p:prefixMapping p:prefix="soapenv" p:URI="http://www.w3.org/2003/05/soap-envelope" />
        <p:prefixMapping p:prefix="wsa" p:URI="http://www.w3.org/2005/08/addressing" />
      </p:localTransactionId>
```

Monitoring profile examples

The following XML documents conform to the monitoring profile schema.

Monitoring profile 1: Two event sources, each supplying an event name

```
<p:monitoringProfile
xmlns:p="http://www.ibm.com/xmlns/prod/websphere/messagebroker/10.0.0.0/monitoring/profile"
 p:version="2.0">
 <p:eventSource p:eventSourceAddress="SOAPInput.transaction.Start">
  <p:eventPointDataQuery>
    <p:eventIdentity>
      <p:eventName p:literal="SOAP start event"/>
    </p:eventIdentity>
  </p:eventPointDataQuery>
 </p:eventSource>
 <p:eventSource p:eventSourceAddress="SOAPInput.transaction.End">
  <p:eventPointDataQuery>
    <p:eventIdentity>
      <p:eventName p:literal="SOAP end event"/>
    </p:eventIdentity>
  </p:eventPointDataQuery>
 </p:eventSource>
</p:monitoringProfile>
```

Monitoring profile 2: Supply an alternative local correlator

```
<p:monitoringProfile
xmlns:p="http://www.ibm.com/xmlns/prod/websphere/messagebroker/10.0.0.0/monitoring/profile"
 p:version="2.0">
 <p:eventSource p:eventSourceAddress="SOAPInput.transaction.Start">
  <p:eventPointDataQuery>
    <p:eventCorrelation>
      <p:localTransactionId p:queryText="$Body/soapenv:Header/wsa:messageID" p:sourceOfId="query">
        <p:prefixMapping p:prefix="soapenv" p:URI="http://www.w3.org/2003/05/soap-envelope"/>
        <p:prefixMapping p:prefix="wsa" p:URI="http://www.w3.org/2005/08/addressing"/>
      </p:localTransactionId>
    </p:eventCorrelation>
  </p:eventPointDataQuery>
 </p:eventSource>
</p:monitoringProfile>
```

Monitoring profile 3: Include two simple fields from the message

```
<p:monitoringProfile
xmlns:p="http://www.ibm.com/xmlns/prod/websphere/messagebroker/10.0.0.0/monitoring/profile"
 p:version="2.0">
 <p:eventSource p:eventSourceAddress="MQInput.terminal.out">
  <p:applicationDataQuery>
    <p:simpleContent p:dataType="integer" p:name="InvoiceNumber">
      <p:valueQuery p:queryText="$Body/invoice/invoiceNo"/>
    </p:simpleContent>
    <p:simpleContent p:dataType="string" p:name="BatchID">
      <p:valueQuery p:queryText="$Body/batch/batchNo"/>
    </p:simpleContent>
```

```
  </p:applicationDataQuery>
 </p:eventSource>
</p:monitoringProfile>
```

Monitoring profile 4: Include the bitstream, encoded as CDATA

By default, bitstreams are encoded in base64Binary format. The following monitoring profile changes the encoding to CDATA.

```
<p:monitoringProfile
xmlns:p="http://www.ibm.com/xmlns/prod/websphere/messagebroker/10.0.0.0/monitoring/profile"
 p:version="2.0">
 <p:eventSource p:eventSourceAddress="MQInput.terminal.out">
    <p:bitstreamDataQuery p:bitstreamContent="body" p:encoding="CDATA"/>
 </p:eventSource>
</p:monitoringProfile>
```

CDATA encoding is not suitable for all types of data. Use CDATA only when `@p:bitstreamContent="body"`. Do not use CDATA if your message bitstreams might contain characters that are not allowed in XML (see http://www.w3.org/TR/2006/REC-xml-20060816/#charsets).

Monitoring profile 5: One *eventSource* that applies to all transaction events for a message flow and includes the available bitstream as *base64binary*.

```
<p:monitoringProfile
xmlns:p="http://www.ibm.com/xmlns/prod/websphere/messagebroker/10.0.0.0/monitoring/profile"
 p:version="2.0">
    <p:eventSource p:enabled="true" p:eventSourceAddress="transaction.all">
        <p:eventPointDataQuery>
            <p:eventCorrelation>
                <p:localTransactionId p:queryText="" p:sourceOfId="automatic"/>
                <p:parentTransactionId p:queryText="" p:sourceOfId="automatic"/>
                <p:globalTransactionId p:queryText="" p:sourceOfId="automatic"/>
            </p:eventCorrelation>
        </p:eventPointDataQuery>
        <p:bitstreamDataQuery p:bitstreamContent="all" p:encoding="base64Binary"/>
    </p:eventSource>
</p:monitoringProfile>
```

The monitoring event

You can configure IBM App Connect Enterprise to emit a monitoring event, in XML or JSON format, when something significant happens. Events are typically emitted to support transaction monitoring and auditing, and business transaction monitoring.

You can configure the source of the event and the content of the event by using either the monitoring properties of a message flow or a monitoring profile.

Each event contains the following information:

- Source of the event.
- Name of the event.
- Creation time and sequence number.
- Correlation ID for events that are emitted by the same transaction or unit of work.
- Details of the message flow.

A terminal emits an event only if the message passes through that terminal. In particular, the output terminal of an output node emits events only if it is connected.

A monitoring event can also contain the following items:

- Application data extracted from the message.
- Part or all of the message bit stream. All nodes can produce bit streams, which can be included in monitoring events.

You can configure monitoring events to be formatted in XML or JSON format. By default, event XML in IBM App Connect Enterprise conforms to the monitoring event schema `MonitoringEventV2.xsd`. Alternatively, you can configure monitoring events to be formatted in JSON format, as defined by the

MonitoringEventV1.json schema. For compatibility with IBM Integration Bus Version 10.0, you can configure monitoring events to use the WMBEvent.xsd schema.

For information about the monitoring event formats, see the following sections:

- “XML MonitoringEventV2 format” on page 2779
- “JSON MonitoringEventV1” on page 2779
- “XML WMB format” on page 2780

For information about the sequencing of events and the default values that are assigned to monitoring events, see “Event sequencing” on page 2781 and “Default content of monitoring events” on page 2781.

For information about configuring monitoring events that contain complex content, see “Including complex content in the event payload of a monitoring event ” on page 2802.

For more information about how to configure monitoring events to be emitted and formatted according to these schema definitions, see “Activating monitoring” on page 2804.

XML MonitoringEventV2 format

The XML schema definition file is MonitoringEventV2.xsd, which is provided in the server/sample/Monitoring subdirectory of your IBM App Connect Enterprise installation directory.

To access the schema from the IBM App Connect Enterprise Toolkit, click **File** > **New** > **Message Model**. Select **IBM supplied** . Click **Next**, then select **Create an XML file by importing an IBM supplied definition** . Click **Next**, and then select **IBM App Connect Enterprise Monitoring Event**.

The following example shows a monitoring event in XML MonitoringEventV2 format:

```
<mon:event xmlns:mon="http://www.ibm.com/xmlns/monitoring/event/v2">
 <mon:eventPointData>
  <mon:eventData mon:productVersion="110010"
   mon:profileVersion="11" mon:eventSourceAddress="HTTP Input.transaction.Start">
   <mon:eventIdentity mon:eventName="HTTP Input.TransactionStart" />
   <mon:eventSequence mon:creationTime="2020-07-20T16:20:21.776758Z"
    mon:counter="1" />
   <mon:eventCorrelation mon:localTransactionId="40ddc412-f102-4840-a212-8b793d12b6bf-1"
    mon:parentTransactionId="" mon:globalTransactionId="" />
  </mon:eventData>
  <mon:messageFlowData>
   <mon:integrationServer mon:name="110010"
    mon:hostName="DESKTOP-7Q9JIP6" />
   <mon:application mon:name="Transformation_Map" />
   <mon:messageFlow mon:uniqueFlowName="110010.Transformation_Map.Transformation_Map"
    mon:name="Transformation_Map" mon:threadId="12244" />
   <mon:node mon:nodeLabel="HTTP Input" mon:nodeType="ComIbmWSInputNode" />
  </mon:messageFlowData>
 </mon:eventPointData>
 <mon:bitstreamData>
  <mon:bitstream mon:serializationEncoding="base64Binary"
   mon:dataCCSID="1208"

</mon:event>
```

JSON MonitoringEventV1

The JSON schema definition file is MonitoringEventV1.json, which is provided in the server/sample/Monitoring subdirectory of your IBM App Connect Enterprise installation directory.

The following example shows a monitoring event in JSON MonitoringEventV1 format:

```
{
 "type": "ace_monitoring_event",
 "ibm_product": "IBM App Connect Enterprise",
 "ibm_recordtype": "monitor",
 "host": "DESKTOP-7Q9JIP6",

  "dataCCSID": "1208",
  "dataEncoding": "546"
 },
 "ibm_sequence": "1"
}
```

XML WMB format

The XML schema definition file is `WMBEvent.xsd`, which is provided in the `server/sample/Monitoring` subdirectory of your IBM App Connect Enterprise installation directory.

To access the schema from the IBM App Connect Enterprise Toolkit, click **File** > **New** > **Message Model**. Select **IBM supplied**. Click **Next**, then select **Create an XML file by importing an IBM supplied definition** . Click **Next**, and then select **IBM Integration Bus Monitoring Event**.

The following example shows a monitoring event in XML WMB format:

```
<wmb:event
 xmlns:wmb="http://www.ibm.com/xmlns/prod/websphere/messagebroker/6.1.0/monitoring/event">

 </wmb:bitstreamData>
</wmb:event>
```

Event sequencing

To enable event-processing software to sequence the events correctly, both an ISO 8601 timestamp and a counter attribute are produced. The counter attribute is in the EventSequence element of the monitoring event. This counter starts at 1 for the first event that is produced by the processing of a message (typically the transaction.Start event) and is incremented for each subsequent event produced. It is reset to 1 at the start of the next message. The creation time and counter are always produced on all monitoring events. The software that processes the events can choose which field, or a combination of the two, to use to sequence the events.

If a message is processed successfully, the monitoring events that are generated have a contiguous, incrementing set of counter values. The value starts at 1 and is assigned at the time when the event is created. If a message fails and is rolled back, gaps can occur in the counter sequence. The missing values are the values that were used for events that were produced as part of the message flow unit of work that was rolled back.

Monitoring events can be included in the main unit of work of a message flow, an independent unit of work, or outside of a unit of work. Therefore, if a message flow fails, the sequence numbers are not necessarily contiguous. For example, consider the following scenario:

- Sequence 1. The transaction start event.
- Sequence 2, 3, 4. Events in the message flow unit of work.
- Sequence 5. The independent unit of work.
- Sequence 6. An event outside of a unit of work.
- Sequence 7. An event in the message flow unit of work.
- Sequence 8. An event outside of a unit of work.
- The flow then fails and is rolled back.
- Sequence 9. The transaction rollback event in the independent unit of work.

Only sequence numbers 1, 5, 6, 8 and 9 are sent to the monitoring application.

Default content of monitoring events

When an event is emitted, the fields for the event are created by using the information that is provided by the monitoring properties of the message flow or the monitoring profile. Any event field that is not explicitly specified is given a default value, as shown in the following table:

Field in event	Default value MonitoringEventV2	Default Value WMB
bitstreamData.bitstream@wmb:codedCharSetId	The coded character set identifier of the message data provided in the bitstream	Not applicable
bitstreamData.bitstream@wmb:encoding	The data encoding of the message data provided in the bitstream	Not applicable
eventData/@wmb:eventSourceAddress	No default; you must provide this information.	No default; you must provide this information.

Field in event	Default value MonitoringEventV2	Default Value WMB
eventData/@wmb: eventSchemaVersion	Not applicable	`6.1.0.3`
eventData/ @wmb:productVersion		`7000`
eventData/ eventIdentity/ @wmb:eventName	The default is derived from @eventSourceAddress.	The default is derived from @eventSourceAddress.
eventData/ eventSequence/ @counter	The counter is set to 1 for first event that is emitted and increased by 1 for each subsequent event.	The counter is set to 1 for first event that is emitted and increased by 1 for each subsequent event.
eventData/ eventSequence/ @creationTime	The date and time when the event was created.	The date and time when the event was created.
eventData/ eventCorrelation/ @localTransactionId	A generated unique identifier. This identifier is not generated if only transaction rollback or end events, or both, are configured, unless a transaction start event is configured as well.	A generated unique identifier. This identifier is not generated if only transaction rollback or end events, or both, are configured, unless a transaction start event is configured as well.
eventData/ eventCorrelation/ @parentTransactionId	No default. Unless you set this value, an empty string is used.	No default. Unless you set this value, an empty string is used.
eventData/ eventCorrelation/ @globalTransactionId	No default. Unless you set this value, an empty string is used.	No default. Unless you set this value, an empty string is used.
messageFlowData/ @application	Application name	Not applicable
messageFlowData/ @library	Library name	Not applicable
messageFlowData/ broker/@name	Not applicable.	The name of the integration node.
messageFlowData/ executionGroup/ @name	Not applicable.	The name of the integration server.
messageFlowData/ integrationNode/ @name	The name of the integration node.	Not applicable.
messageFlowData/ integrationServer	The name of the integration server.	Not applicable.
messageFlowData/ messageFlow/@name	The name of the message flow.	The name of the message flow.
messageFlowData/ messageFlow/ @uniqueFlowName	A string composed of the names of the integration node, integration server, and flow in the form: *integrationNodeName*`.`*integrationServerName*`.`*messageFlowName*	A string composed of the names of the integration node, integration server, and flow in the form: *integrationNodeName*`.`*integrationServerName*`.`*messageFlowName*

Field in event	Default value MonitoringEventV2	Default Value WMB
messageFlowData/ messageFlow/ @threadId	The thread ID of the message flow. The format depends on the operating system.	The thread ID of the message flow. The format depends on the operating system.
messageFlowData/ node/@nodeLabel	The label of the node that emitted the event.	The label of the node that emitted the event.
messageFlowData/ node/@nodeType	The type of the node that emitted the event.	The type of the node that emitted the event.
messageFlowData/ node/@nodeDetail	Optional information about the node. **MQInput** The name of the queue. **Other nodes** Omitted.	Optional information about the node. **MQInput** The name of the queue. **Other nodes** Omitted.
applicationData	No default; omitted if not provided.	No default; omitted if not provided.
bitstreamData	No default; omitted if not provided.	No default; omitted if not provided.

Correlation and monitoring events

A monitoring application uses correlation attributes to identify events that belong to the same business transaction.

A business transaction can be any of the following scenarios:

- A single invocation of a message flow.
- Multiple invocations of the same message flow from a parent application. The parent application might be another message flow.
- Multiple invocations of various message flows from a parent application. The parent application might be another message flow.

Three correlation attributes are available for you to use in your events: *local correlator*, *parent correlator* and *global correlator*. The exact usage of the correlation attributes varies depending on the requirements. For example, a parent application can pass its transaction identifier to the child message flow (perhaps in a header) so that the child message flow can report it in the event as a parent correlator.

Every emitted monitoring event can contain a local correlator, a parent correlator, and a global correlator. Correlation information is placed in the following attributes of the event:

```
wmb:eventPointData/wmb:eventCorrelation/@wmb:localTransactionId
wmb:eventPointData/wmb:eventCorrelation/@wmb:parentTransactionId
wmb:eventPointData/wmb:eventCorrelation/@wmb:globalTransactionId
```

You can specify correlation information when you configure the event.

If you do not specify any correlation information when you configure your events, no correlation attributes will be used.

If you do specify correlation information, you must configure the correlation attributes to be used, and where they will read their value from. Typically you need to specify correlation information only for the first event source in the message flow; by default all later event sources retrieve the same value from the Environment tree.

The exact steps for specifying correlation information depend on whether you are using monitoring properties or a monitoring profile to configure your events, but the principle is the same for both techniques:

Local correlator

If you want to reuse the local correlator from the Environment tree, specify `Automatic`. If no local correlator exists yet, a new unique value will be generated and saved in the Environment tree.

If you want to use a value contained in a location in the message, specify the location of the correlator by supplying an XPath into the message tree. Ensure that the specified location contains a correlator value unique to this invocation of the message flow. The extracted value is saved in the Environment tree as the local correlator.

Parent correlator

If you want to reuse the parent correlator from the Environment tree, specify `Automatic`. If no parent correlator exists yet, no parent correlator will be used.

If you want to use a value contained in a location in the message, specify the location of the correlator by supplying an XPath into the message tree. Ensure that the specified location contains a suitable value for the parent correlator. The extracted value is saved in the Environment tree as the parent correlator.

Global correlator

If you want to reuse the global correlator from the Environment tree, specify `Automatic`. If no global correlator exists yet, no global correlator will be used.

If you want to use a value contained in a location in the message, specify the location of the correlator by supplying an XPath into the message tree. Ensure that the specified location contains a suitable value for the global correlator. The extracted value is saved in the Environment tree as the global correlator.

A global correlator must be present if the event is to be used by the built-in business transaction monitoring capability of App Connect Enterprise.

When a correlator value has been set, it is saved in the Environment tree. Later event sources can reuse the saved value by specifying `Automatic`. There is no need to use the same XPath in all the event sources in your message flow, and doing so might adversely affect performance.

The locations in the Environment tree used to save correlator values for use by later events are:

```
Environment.Monitoring.EventCorrelation.localTransactionId
Environment.Monitoring.EventCorrelation.parentTransactionId
Environment.Monitoring.EventCorrelation.globalTransactionId
```

The following message tree locations often contain a value that can be used as a correlator:

```
$Root/MQMD/MsgId
$Root/MQMD/CorrelId
$Root/JMSTransport/Transport_Folders/Header_Values/JMSMessageID
$Root/JMSTransport/Transport_Folders/Header_Values/JMSCorrelationID
$LocalEnvironment/Destination/HTTP/RequestIdentifier
$LocalEnvironment/Wildcard/WildcardMatch
```

Tip: If the three available correlators are not sufficient, you can configure the event to extract other correlation fields from the message and place them in the `wmb:applicationData/wmb:simpleContent` section of the event.

Tip: The Collector node and the AggregateControl node do not preserve the Environment tree for later nodes in the message flow. If you want to use the same correlator value later in the flow, ensure that the correlator value is available in the message tree, and that the first event source after the Collector or AggregateControl node specifies the location of the correlator by supplying an XPath into the message tree.

Scenarios

Scenario 1: In this scenario, all three correlators are used to monitor data that starts in an external process. Several message flows then transform the data.

- The `globalTransactionID` field contains an identifier from the message header or payload. This identifier correlates events from the external process and IBM App Connect Enterprise.
- The `parentTransactionID` correlates events in IBM App Connect Enterprise from different message flows.
- The `localTransactionID` correlates events from the same message flow.

Scenario 2: In this scenario, the `parentTransactionID` field is used to correlate request and reply messages between two message flows:

- The Request flow sends a **`purchaseOrder`** request to an external application for processing.
- The Reply flow receives a confirmation reply from the external application when the **`purchaseOrder`** has been processed.

You need to correlate the request and replies belonging to the same purchase order. You can do this by setting the `parentTransactionID` to a field in the **`purchaseOrder`**, such as a **`purchaseOrderID`**, which is available in both the request and reply.

Example XPath expressions for event filtering

Use numeric, string, or Boolean expressions when configuring an event source, to determine whether the event is emitted.

When you configure an event source, using either monitoring properties or a monitoring profile, you use an XPath expression to determine whether the event is emitted.

- If the event is always required, use `true()`.
- If the event is required only in certain circumstances, use an expression of the form

```
xpath-query relational-operator value
```

Comparing numeric values

To emit an event only when the value is greater than 10 000, for example, enter an expression such as this:

```
$Body/StockTrade[1]/Details[1]/Value[1] > 10000
```

The [1] suffixes in the query specify that the first occurrence of the element within its parent is required. If these suffixes are not specified, the XPath engine searches the message for other occurrences of each element. This search might adversely affect performance.

Comparing string values

To emit an event only when the company is "Stock Co" for example:

```
$Body/StockTrade[1]/Details[1]/Company[1] = 'Stock Co'
```

Comparing Boolean values

Consider the example of a shares transfer approval. The approval flag in the message tree is a Boolean value. You cannot simply specify the element name, because this always returns true if the element exists. Instead, you query the value of the element, and compare the value to the string 'true' to yield the actual true or false result. The XPath query is:

```
$Body/StockTrade[1]/Shares[1]/Transfer[1]/Approved[1] = 'true'
```

XPath queries that return a nodeset, such as `$Body/StockTrade[1]/Details[1]`, are always evaluated as false, because they cannot be converted to a Boolean value.

Monitoring properties and monitoring profiles

Customize the events that are produced by a message flow by using monitoring properties or a monitoring profile. To customize events when you are designing the message flow, or to apply generic monitoring events to a flow without having to configure at design time, use monitoring properties. To customize events after a message flow is deployed, but without redeploying, use a monitoring profile.

If you have a deployed message flow with monitoring properties that were configured by using the Message Flow editor in the IBM App Connect Enterprise Toolkit, you can use the command or the administration REST API to extract those properties. You can then use the extracted properties to create the equivalent monitoring profile (`.monprofile.xml`) for the message flow, and use this profile as a starting point for creating other monitoring profiles.

Monitoring properties

By using the IBM App Connect Enterprise Toolkit Message Flow editor, you can configure event sources on most nodes in a message flow. A message flow node that supports the configuration of event sources has a Monitoring tab on its Properties view. Use this tab to add events and to set their properties. When you deploy the message flow in a BAR file, the monitoring properties are included as part of the message flow.

Key facts about monitoring properties:

- Use monitoring properties when you want to configure events at message flow design time.
- Monitoring properties apply only to the message flow in question. You can share monitoring properties between message flows by creating reusable subflows.
- Monitoring properties are deployed in a BAR file as part of the message flow.
- Use the **mqsichangeflowmonitoring** command to activate a message flow, or all message flows in an application or integration server to emit monitoring events.
- To change any other properties of a monitoring event, alter the monitoring properties in the message flow editor and then save and redeploy the flow in a BAR file.
- Use the **mqsireportflowmonitoring** command to report a list of the names of the event sources for a message flow.

Monitoring profiles

When you create a monitoring profile, you deploy it to a policy project and then activate it on a specific message flow, application, or integration server. You can activate the profile by using either the command or the administration REST API. Alternatively, you can specify the monitoring profile as a BAR file override, as described in Configurable properties in a file.

Key facts about monitoring profiles:

- You can configure a default monitoring profile for an integration server, by setting properties in the `Defaults` section of the `server.conf.yaml` file. This profile is then used when a message flow has no monitoring events that are configured and no specific monitoring profile applied. For example:

```
Defaults:
    monitoringProfile: 'myIS1MonitoringProfile'       # Default Monitoring profile
```

- You can override a deployed monitoring profile by putting an updated `.monprofile.xml` file in the integration server's overrides directory, as described in “Order of precedence for overrides” on page 326.
- You can use a monitoring profile when you want to configure events for a message flow that is deployed and for which no events are configured.

- You can use a monitoring profile to override the monitoring properties of a message flow that is deployed, as an alternative to redeploying the BAR file. The monitoring profile replaces all monitoring properties.
- A single monitoring profile can be applied to many message flows. Each flow that it is applied to issues events only if the event sources that are defined in the profile match the message flow. Transaction sources always apply, but terminal sources apply only if the node names are matched.
- A monitoring profile must be deployed in a policy project. The XML file must have an extension of `.monprofile.xml`

  For more information, see “Creating a monitoring profile” on page 2793, and “Deploying and redeploying a monitoring profile” on page 2797.
- Use the command to associate the monitoring profile with a message flow, or to activate the message flow to emit monitoring events.
- Use the REST API to associate the monitoring profile with a message flow. Use a POST to make a change that applies until the message flow is restarted or redeployed. For example, for a message flow deployed in a managed integration server:

  ```
  curl -v -X POST "http://<host>:<port>/apiv2/servers/<server name>/applications/<app
   name>/messageflows/<flow name>/attach-monitoring-profile?project=<policy project
   name>&profile=<profile-name>
  ```

  Use a PATCH to have the change persisted though restart or redeploy. For example:

  ```
  curl -v -X PATCH -H "Content-Type: application/json" -d Monitoring\monProf.json "http://
  <host>:<port>/apiv2/servers/<server name>/applications/<app name>/messageflows/<flow name>
  ```

- Use the command in the following situations:
  - To report a list of event sources for a message flow.
  - To report the monitoring profile for a message flow. You can edit the profile, by adding or changing event sources, then update it by using the **mqsichangeproperties** command.
  - To extract and create the equivalent monitoring profile `monprofile.xml` file for a message flow. If the monitoring properties for the message flow were configured in the IBM App Connect Enterprise Toolkit flow editor, you can place the monitoring profile `monprofile.xml` file into a Policy Project and edit the monitoring profile with an XML editor. Then, you can add it to a BAR file and deploy it. You can then associate the new monitoring profile with the original message flow, or other suitable message flows by using the **mqsichangeflowmonitoring** command. You can use this technique to override the monitoring properties for a message flow, without having to edit the message flow in the IBM App Connect Enterprise Toolkit toolkit and redeploy the BAR file.
- Use the REST API to extract a monitoring profile. For example, for a flow in an independent integration server:

  ```
  curl -v -X POST -H "Accept: application/xml" http://<host>:<port>/apiv2/applications/<app
   name>/messageflows/<flow name>/extract-monitoring-profile
  ```

  Use a PATCH to have the change persisted though a restart or deploy. For example:

  ```
  curl -v -X PATCH -H "Content-Type: application/json" -d Monitoring\monProf.json "http://
  <host>:<port>/apiv2/servers/<server name>/applications/<app name>/messageflows/<flow name>
  ```

where the content of the `Monitoring\monProf.json` file is: `{"properties": {"monitoringProfile":"{<policy project name>}:<monitoring profile name>"}}`

Configuring monitoring for message flows

You can configure your message flow to emit event messages that can be used to support transaction monitoring and auditing, and business process monitoring.

Before you begin

- To learn about the basic concepts of monitoring, see “Monitoring basics” on page 2772.
- To learn about monitoring IBM App Connect Enterprise event messages, see “Configuring and subscribing to performance and monitoring events” on page 2807.
- To decide whether to use monitoring properties or a monitoring profile, see “Monitoring properties and monitoring profiles” on page 2786.
- If you are using the default configuration with the built-in MQTT broker, the `BusinessEvents` group, which includes monitoring events, is disabled for MQTT. Check your pub/sub broker configuration. For more information, see “Configuring the built-in MQTT pub/sub broker” on page 2811.

About this task

Note: Monitoring messages are published to IBM MQ pub/sub brokers by using the persistent as topic option. Publications resolve to be nonpersistent by default, but you can change a publication to be persistent by configuring named topics in IBM MQ. For more information, see the Subscriptions and message persistence topic in the IBM MQ product documentation online.

Monitoring messages are published to MQTT brokers as nonpersistent by default. However, subscribers to MQTT brokers specify the maximum quality of service (QoS) that they require, which determines whether the message is delivered only once or more than once, and whether a confirmation of receipt is required. For more information, see http://mosquitto.org/man/mqtt-7.html.

To receive monitoring events, complete the following tasks.

Procedure

1. Configure event sources on the flow by using either monitoring properties or a monitoring profile.
   - “Configuring monitoring event sources by using monitoring properties” on page 2788
   - “Configuring monitoring event sources by using a monitoring profile” on page 236
2. Enable event sources by using the monitoring properties on the node.
3. Ensure that event publication for monitoring messages is enabled and is correctly configured.
   For more information, see “Configuring the publication of event messages” on page 2807.
4. Subscribe to the topic for the flow; see “Subscribing to event message topics” on page 2813.
5. Optional: Optionally, you can collect monitoring messages for all message flows in a server as described in “Collecting monitoring messages for all message flows in a server” on page 2806.

Configuring monitoring event sources by using monitoring properties

In the Message Flow editor, use the **Monitoring** tab on the properties of a message flow node to add one or more monitoring events.

Before you begin

Read the following topics:

- “Monitoring basics” on page 2772
- “Configuring monitoring for message flows” on page 2788

Ensure that you have a message flow that contains a node to which you want to add a monitoring event.

You cannot use monitoring properties to configure transaction events on the following nodes:

node
node

For these nodes, use a monitoring profile instead, as described in "Configuring monitoring event sources by using a monitoring profile" on page 236.

About this task

An event source is a point in a message flow from which a monitoring event can be emitted. Each event source has a set of properties that control the contents of the monitoring events that it emits. To create an event, complete the following steps.

Procedure

1. In the Message Flow editor, select the relevant node to display the properties for that node.
2. Select the **Monitoring** tab.
3. Click **Add**.

   The **Add event** window is displayed.
4. In the **Event Source** field, select the source of the event.

   When you select the event source, the corresponding value for `Event Source Address` is displayed as a read-only property. The event source information is used to populate the attributes of the `wmb:eventPointData/wmb:messageFlowData/wmb:node` element of the event.

   Tip: If you decide to enable or disable events by using the **mqsichangeflowmonitoring** command, you must specify a value for `Event Source Address`, not `Event Name`.
5. In the **Event Name** field, select either **Literal** or **Data location**.

   Every monitoring event has a name that is placed in the `wmb:eventPointData/wmb:eventIdentity/@wmb:eventName` attribute of the event. The default names are shown in the following table:

Event source	Default event name	Example
Transaction start	*nodeLabel*.TransactionStart	MQInput.TransactionStart
Transaction end	*nodeLabel*.TransactionEnd	MQInput.TransactionEnd
Transaction rollback	*nodeLabel*.TransactionRollback	MQInput.TransactionRollback
Terminal	*nodeLabel.terminal_label*.Terminal	MQInput.OutTerminal

   You can override the default value in the following ways:

   - By specifying an alternative literal string.
   - By specifying an XPath query. The query extracts the event name from a field in the input message. Click **Edit** to use the XPath Expression Builder.
6. Optional: In the **Event Filter** section, provide an XPath expression to control whether the event is emitted.

   Type in the expression (for example, `$Body/StockTrade/Details/Value > 10000`) or click **Edit** to launch the XPath Expression Builder.

   The expression must evaluate to true or false, and can reference fields in the message tree, or elsewhere in the message assembly. The default value is `true()`, which means that the event is always produced.

7. Optional: Complete the **Event Payload** field if the event must contain selected data fields that are extracted from the message.

   Click **Add** to launch the **Add Data Location** dialog box. You can then type in the location (for example, `$LocalEnvironment/File/Name`) or click **Edit** to launch the XPath Expression Builder.

   You can extract one or more fields from the message data and include them with the event. The fields can be simple or complex. Simple content is contained in the `wmb:applicationData/wmb:simpleContent` field of the event; complex data is contained in the `wmb:applicationData/wmb:complexContent` field.

   This facility is used commonly for communicating significant business data in a business event. If the event contains the input bit stream, this facility can also be used to extract key fields. You can then use another application to provide an audit trail or to resubmit failed messages.

   For more information about configuring monitoring events that contain complex content, see “Including complex content in the event payload of a monitoring event ” on page 2802.
8. Optional: Select **Include bitstream data in payload** if the event must capture message bitstream data.

   If you select this option, you must provide the following information:

   Content
   Select from `Headers`, `Body`, and `All`.

   Encoding
   Select from `CData` (the original text, without encoding), `HexBinary`, and `base64Binary`.

   When this option is selected, it is possible that the bitstream that is included is not the same as the message that is written from a transport output node. Monitoring serializes the whole message tree, whereas transport output nodes use the parts of the message tree that they recognize. The bitstream that is included in a monitoring message is generated from all the headers that occur before the first message body in the message tree. Any headers that occur after the message body are not included.

9. Optional: Select the **Correlation** tab to provide details for event correlation.

   Every monitoring event must contain at least one correlation attribute, and can contain up to three. If you do not specify any correlation information, the first event source in the message flow allocates a unique identifier that all later event sources in the same transaction use.

   a) In the **Local transaction correlator** field, select one of the following options.

      Automatic
      The local correlator that is used by the most recent event for this invocation of the message flow is used. If no local correlator exists, a new unique value is generated.

      Specify location of correlator
      Enter a value, or click **Edit** to launch the XPath Expression Builder. The local correlator is read from the specified location in the message tree. Ensure that the specified location contains a correlator value that is unique to this invocation of the message flow.

   b) In the **Parent transaction correlator** field, select one of the following options to extract a correlation field from the parent transaction.

      Automatic
      The parent correlator that is used by the most recent event for this invocation of the message flow is used. If no parent correlator exists, no parent correlator is used.

      Specify location of correlator
      Enter a value, or click **Edit** to launch the XPath Expression Builder. The parent correlator is read from the specified location in the message tree. Ensure that the specified location contains a suitable value for the parent correlator.

   c) In the **Global transaction correlator** field, select one of the following options to extract a correlation field from a global transaction.

      Automatic
      The global correlator that is used by the most recent event for this invocation of the message flow is used. If no global correlator exists, no global correlator is used.

      Specify location of correlator
      Enter a value, or click **Edit** to launch the XPath Expression Builder. The global correlator is read from the specified location in the message tree. Ensure that the specified location contains a suitable value for the global correlator.

10. Optional: On the **Transaction** tab, choose how the emission of monitoring events by a message flow is coordinated. You can choose to coordinate with the message flow transaction, in an independent unit of work, or not in a unit of work.

    Select one of the following options.

    Message flow
    The event, and all other events with this setting, are emitted only if the message flow commits its unit of work successfully.

    If the transaction start event is included in the message flow unit of work, but the message processing fails and this unit of work is not published, the transaction start event is included in an independent unit of work. This behavior ensures that your monitoring application receives a pair of events (start and rollback), rather than receiving a rollback event in isolation.

    Independent
    The event is emitted in a second unit of work, independent of the main unit of work. The event, and all other events with this setting, are emitted regardless of whether the main unit of work commits successfully.

    An independent transaction can be started only if the main transaction is either committed or rolled back. If the **`Commit count`** property of the flow is greater than one, or the **`Commit by`**

message group property is set, the events that are targeted for the independent transaction are emitted out of sync point. A message is also issued with this information.

None
The event is emitted out of sync point (not in any unit of work.) The event is emitted when the message passes through the event source, and is available for reading immediately.

Not all of these options are available on all event types. The default and allowed values are shown in the following table:

Event source	Allowed values	Default
Transaction start	Message flow Independent None	Message flow
Transaction end	Message flow None	Message flow
Transaction rollback	Independent None	Independent
Terminal	Message flow Independent None	Message flow

11. Click **Finish**.

    The **Events** table in the Monitoring tab of the Properties view for the node is updated with details of the event that you added, and the event is enabled.
12. Save the message flow.
13. When all events are added to the flow, add the message flow to the BAR file, and deploy the BAR file.

    Monitoring is inactive for the flow; deploying the BAR file does not activate monitoring.

What to do next

The monitoring properties for a node show all monitoring events that are defined for that node. You can edit the monitoring properties of a node to do the following tasks:

- Enable or disable a monitoring event.
- Add, delete, or change the monitoring events for the node.

Configuring monitoring event sources by using a monitoring profile

You can create a monitoring profile to configure your message flows to emit monitoring events.

Before you begin

Read the following topics:

- "Monitoring basics" on page 2772
- "Configuring monitoring for message flows" on page 2788

You must have a message flow that contains a node to which you want to add a monitoring event.

You can use XPath 1.0 expressions to configure a monitoring event.

About this task

To configure monitoring events by using a monitoring profile, complete the following tasks.

1. “Creating a monitoring profile” on page 2793
2. “Applying and activating a monitoring profile” on page 2798

Creating a monitoring profile

A monitoring profile XML file lists the event sources in the message flow that emits events, and defines the properties of each event.

Before you begin

A monitoring profile is an XML document that must be saved to a policy project. If you have a suitable policy project already, you can create a new XML file to save in that project. Otherwise, create a new policy project as described in “Creating policies with the IBM App Connect Enterprise Toolkit” on page 327.

About this task

A monitoring profile is an XML document that specifies the event sources in a message flow that emits events, and the properties of those events. The monitoring profile XML must conform to the XML schema file `MonitoringProfile.xsd`, which you can find in the samples directory of your IBM App Connect Enterprise installation:

```
Install_root/server/sample/Monitoring/MonitoringProfile.xsd
```

The XML file must have an extension of `.monprofile.xml`; for example, `monitoringProfileName.monprofile.xml`.

You can use either of the following methods to create a monitoring profile:

- Extract a monitoring profile from an existing message flow that is configured to use monitoring events. If you have a deployed message flow that was configured through the IBM App Connect Enterprise Toolkit Message Flow editor to use monitoring events, you can use either the command or the administration REST API to extract those monitoring properties from the deployed flow and create the equivalent monitoring profile (`.monprofile.xml` file) for the message flow. You can then use this profile as a starting point for other monitoring profiles, and edit them as required.

  For example, to extract a monitoring profile from a flow in an application that is running on an independent integration server, you can run a command similar to the following example:

  ```
  mqsireportflowmonitoring-i localhost -p 7600 -k <Application_name> -f <Flow_name>  -x <Path to
   your Toolkit Policy Project Folder>/<filename>.monprofile.xml
  ```

  After you successfully run the **mqsireportflowmonitoring** command, you must right-click on the Toolkit Policy Project in the IBM App Connect Enterprise Toolkit, and select **refresh**. The file appears in the **Navigator** view, in the **Other Resource** section. Alternatively, run the **mqsireportflowmonitoring** with the **-x** parameter set to the full path name of a file in a temporary location. Then use the Eclipse menu options **File**, and then **Import** to add `<filename>.monprofile.xml` into the Policy Project.
- Manually create a monitoring profile XML file (`.monprofile.xml`) from scratch, by completing the following steps.

Procedure

The following steps describe how to manually create a monitoring profile XML. Follow these steps for each `p:eventSource` element:

1. Use a text editor to create the monitoring profile XML file.

   For example, in the Toolkit right-click your policy project and then select **New** > **Other** > **XML / XML File**. Give the XML file a name with an extension of `.monprofile.xml` (for example,

monitoringProfileName.monprofile.xml). You can then use the Source view of the XML file to edit the monitoring profile.

The following example of a monitoring profile XML document contains a single event source to illustrate the structure.

```
<p:monitoringProfile
xmlns:p="http://www.ibm.com/xmlns/monitoring/11/profile" p:version="2.0">
    <p:eventSource p:enabled="true" p:eventSourceAddress="SOAPInput.transaction.Start">
        <p:eventPointDataQuery>
            <p:eventIdentity>
                <p:eventName p:literal="" p:queryText=""/>
            </p:eventIdentity>
            <p:eventCorrelation>
                <p:localTransactionId p:queryText="" p:sourceOfId="automatic"/>
                <p:parentTransactionId p:queryText="" p:sourceOfId="automatic"/>
                <p:globalTransactionId p:queryText="" p:sourceOfId="automatic"/>
            </p:eventCorrelation>
           <p:eventFilter p:queryText="true()"/>
           <p:eventUOW p:unitOfWork="messageFlow" />
        </p:eventPointDataQuery>
        <p:applicationDataQuery>
            <p:simpleContent p:dataType="boolean" p:name="" p:targetNamespace="">
                <p:valueQuery p:queryText=""/>
            </p:simpleContent>
            <p:complexContent p:name="">
                <p:payloadQuery p:queryText=""/>
            </p:complexContent>
        </p:applicationDataQuery>
        <p:bitstreamDataQuery p:bitstreamContent="all" p:encoding="base64Binary"/>
    </p:eventSource>
</p:monitoringProfile>
```

The root element is p:monitoringProfile. It contains one or more p:eventSource elements, each of which specifies an event source and defines its properties. Each p:eventSource element contains:

- A p:eventPointDataQuery element that provides key information about the event.
- Optional: A p:applicationDataQuery element if the event payload includes data fields that are extracted from a message.
- Optional: A p:bitstreamDataQuery element if the event payload includes bitstream data from a message.

2. Specify the p:eventSource/@p:eventSourceAddress attribute.

   This string uniquely identifies the event source in the message flow. The string must follow the fixed format for transaction events and terminal events, as shown in the following table:

Event type	Event source address
Transaction Start event	*nodelabel*.transaction.Start
Transaction End event	*nodelabel*.transaction.End
Transaction Rollback event	*nodelabel*.transaction.Rollback
Terminal event	*nodelabel*.terminal.<Terminal>
All transaction events	transaction.all

The *nodelabel* attribute is the label of the node as known by the IBM App Connect Enterprise runtime components. The label also indicates whether the node is in a subflow. For example, flow A contains an instance of flow B as a subflow that is labeled myB. Flow B contains an instance of a Compute node that is labeled myCompute. The *nodelabel* for the Compute node is myB.myCompute.

In the emitted event, the address string of the event source is set in the wmb:eventData/@wmb:eventSourceAddress attribute.

The event type *All transaction Events* means that all nodes that can emit transaction events do emit start events, end events, or rollback events.

3. Optional: In the p:eventPointDataQuery/p:eventIdentity/p:eventName element, specify the name by which events from this event source are known.

   - If the event name is a fixed string, complete the p:eventName/@p:literal attribute.
   - If the event name is extracted from a field in the message, complete the p:eventName/@p:queryText attribute by specifying an XPath query.

   In the emitted event, the event name is set in the wmb:eventPointData/wmb:eventIdentity/@wmb:eventName attribute.

   If the p:eventName element is not supplied, @wmb:eventName in the emitted event defaults to @p:eventSourceAddress.
4. Optional: Complete the p:eventPointDataQuery/p:eventFilter/@p:queryText attribute by specifying an XPath expression to control whether the event is emitted. The expression must evaluate to true (the event is emitted), or false (the event is not emitted). The expression can reference fields in the message tree, or elsewhere in the message assembly. If an event does not contain an eventFilter element, the event is always emitted.

   By using this facility, you can tailor event emissions to your business requirements, by filtering out events that do not match a set of rules. This facility can reduce the number of events that are emitted, and reduce the workload on your monitoring application.
5. Optional: If the event is to contain selected data fields that are extracted from the message, complete the p:applicationDataQuery element.

   You can extract one or more fields from the message data and include it with the event. The fields can be simple or complex.

   - For each simple data field, complete a p:simpleContent element:
     - Complete the p:simpleContent/p:valueQuery/@p:queryText attribute by specifying an XPath query.
     - Complete the p:simpleContent/@p:name, @p:namespace, and @p:dataType attributes. The @p:dataType value must be one of boolean, date, dateTime, decimal, duration, integer, string, or time.
   - For each complex data field, complete a p:complexContent element:
     - Complete the p:complexContent/p:payloadQuery/@p:queryText attribute by specifying an XPath query.
     - Complete the p:complexContent/@p:name attribute.

   This facility is commonly used for communicating significant business data in a business event. If the event contains the input bit stream, this facility can also be used to extract key fields. You can then use another application to provide an audit trail or to resubmit failed messages.

   In the emitted event, the extracted data is set in the wmb:applicationData/wmb:simpleContent and wmb:applicationData/wmb:complexContent elements.
6. Optional: If the event is to capture message bitstream data, complete the p:bitstreamDataQuery element.

   - Complete the @p:bitstreamContent attribute. The attribute value must be one of headers, body, or all.
   - Complete the @p:encoding attribute. The attribute value must be one of CDATA, base64Binary, or hexBinary.

   In the emitted event, the extracted bitstream data is set in the wmb:bitstreamData/wmb:bitstream element.

7. Optional: Complete the p:eventPointDataQuery/p:eventCorrelation element.

   Every emitted monitoring event can contain up to three correlation attributes. If no correlation information is specified in the monitoring profile, no correlation attributes are used.

   a. Complete the p:localTransactionId element.

      - To reuse the local correlator from the environment tree, set the p:localTransactionId/@p:sourceOfId attribute to automatic. If no local correlator exists yet, a new unique value is generated and saved in the environment tree.
      - To use a value that is contained in a location in the message, set the p:localTransactionId/@p:sourceOfId attribute to query, then complete the p:localTransactionId/@p:queryText attribute by specifying an XPath query. Ensure that the specified location contains a correlator value that is unique to this invocation of the message flow. The value is saved in the environment tree.

   b. Complete the p:parentTransactionId element.

      - To reuse the parent correlator from the environment tree, set the p:parentTransactionId/@p:sourceOfId attribute to automatic. If no parent correlator exists, no parent correlator is used.
      - To use a value that is contained in a location in the message, set the p:parentTransactionId/@p:sourceOfId attribute to query, then complete the p:parentTransactionId/@p:queryText attribute by specifying an XPath query. Ensure that the specified location contains a suitable value for the parent correlator. The value is saved in the environment tree.

   c. Complete the p:globalTransactionId element.

      - To reuse the global correlator from the environment tree, set the p:globalTransactionId/@p:sourceOfId attribute to automatic. If no global correlator exists, no global correlator is used.
      - To use a value that is contained in a location in the message, set the p:globalTransactionId/@p:sourceOfId attribute to query, then complete the p:globalTransactionId/@p:queryText attribute by specifying an XPath query. Ensure that the specified location contains a suitable value for the global correlator. The value is saved in the environment tree.

8. Complete the p:eventPointDataQuery/p:eventUOW element. This element determines how the emission of monitoring events by a message flow is coordinated. You can choose to coordinate with the message flow transaction, in an independent unit of work, or not in a unit of work.

   Set the p:eventUOW/@p:unitOfWork attribute to one of the following values:

   Message flow
   The event, and all other events with this setting, are emitted only if the message flow commits its unit of work successfully.

   If the transaction start event is included in the message flow unit of work, but message processing fails and this unit of work is not published, the transaction start event is included in an independent unit of work. This behavior ensures that your monitoring application receives a pair of events (start and rollback), rather than receiving a rollback event in isolation.

   Independent
   The event is emitted in a second unit of work, independent of the main unit of work. The event, and all other events with this setting, are emitted regardless of whether the main unit of work commits successfully.

   An independent transaction can be started only if the main transaction is either committed or rolled back. If the **Commit count** property of the flow is greater than one, or the **Commit by**

message group property is set, the events that are targeted for the independent transaction are emitted out of sync point. A message is also output with this information.

None
The event is emitted out of sync point (not in any unit of work.) The event is emitted when the message passes through the event source, and is available for reading immediately.

Not all of these options are available on all event types. The allowed values are shown in the following table.

Event Type	Allowed values
transaction.Start	messageFlow independent none
transaction.End	messageFlow none
transaction.Rollback	independent none
terminal	messageFlow independent none

If you do not include the `eventUOW` element for an event source, transactionality for all events that are output from that source (except transaction.rollback events) defaults to `messageFlow`. Transactionality for transaction.rollback events defaults to `independent`.

9. If you use XPath to select the value of a field, and if the XPath query contains a component that has an XML namespace, the XPath will contain a namespace prefix for the namespace. The namespace prefix in all `prefixMapping` elements in a monitoring profile must be unique.
10. Ensure that the monitoring profile XML conforms to the XML schema file `MonitoringProfile.xsd`, which you can find in the samples directory of the IBM App Connect Enterprise installation (*Install_root*`/server/sample/Monitoring/MonitoringProfile.xsd`).
11. Save the XML file with an extension of `.monprofile.xml` (for example, *monitoringProfileName*`.monprofile.xml`) to your policy project.

What to do next

Deploy the monitoring profile, as described in Deploying and redeploying a monitoring profile.

Deploying and redeploying a monitoring profile

Deploy or redeploy a monitoring profile in a Policy Project.

Before you begin

Create a monitoring profile and save it to a Policy Project by following the instructions in "Creating a monitoring profile" on page 2793.

About this task

If you deploy a monitoring profile, it must be deployed in a policy project, and the XML file must have an extension of `.monprofile.xml`. To deploy a monitoring profile, complete step 1 and step 2 in the Procedure.

You can redeploy a monitoring profile by completing step 3 in the Procedure.

You can override a deployed monitoring profile by completing step 4 in the Procedure.

As an alternative to deploying the monitoring profile, you can place the `monprofile.xml` file in the integration server's overrides directory, as described in step 5 in the Procedure.

Procedure

1. Create a BAR file to contain your Policy Project by completing the following steps:
   a. In the IBM App Connect Enterprise Toolkit, switch to the Integration Development perspective.
   b. In the Application Development view, right-click the BAR file that contains the message flows, then click **Open with** > **BAR Editor**.
   c. Click the **Manage** tab.
   d. Click the message flow on which you want to set the monitoring profile configurable service. The properties that you can configure for the message flow are displayed in the **Properties** view.
   e. In the **Monitoring Profile Name** field, enter the name of a monitoring profile.
   f. Save the BAR file.
2. Deploy the BAR file to your integration server.
3. Optional: If you make further changes to the monitoring profile, you can save it to the Policy Project, edit the BAR file, and redeploy it to your integration server. All message flows that use the monitoring profile are stopped and restarted to use the new values.

   For more information, see Monitoring profiles.
4. Optional: You can also override a deployed monitoring profile by putting an updated `.monprofile.xml` file in the integration server's `overrides` directory, as described in "Order of precedence for overrides" on page 326.

   You must restart the integration server to pick up any newly added or changed `monprofile.xml` file in the integration server's `overrides` directory.

As an alternative to deploying the monitoring profile, you can place the `monprofile.xml` file in the integration server's overrides directory, by completing the following step:

5. Optional: As an alternative to deploying the monitoring profile, you can place the `monprofile.xml` file in the integration server's `overrides` directory.

   For integration servers that are managed by an integration node, the location of the `overrides` directory is `$MQSI_WORKPATH/components/<Node name>/overrides/node.conf.yaml`.

   For independent integration servers, the location of the `overrides` directory is `<work directory>/overrides`.

   You must restart the integration server to pick up any newly added or changed `monprofile.xml` file in the integration server's `overrides` directory.

What to do next

Monitoring for the flow is inactive. Deploying the BAR file does not activate monitoring for the flow. After you create and deploy the monitoring profile in a policy project, you must apply and activate the monitoring profile by using either the command or the administration REST API. For more information, see Applying and activating a monitoring profile.

Alternatively, you can specify the monitoring profile as a BAR file override as described in Configurable properties in a file.

Applying and activating a monitoring profile

After you create and deploy a monitoring profile, apply it to one or more message flows and then activate monitoring for the flows.

Before you begin

Create a monitoring profile by following the instructions in "Creating a monitoring profile" on page 2793.

Deploy or redeploy a monitoring profile by following the instructions in "Deploying and redeploying a monitoring profile" on page 2797.

About this task

Applying means associating a deployed monitoring profile with a message flow. Applying can be done statically or dynamically.

Activating means enabling monitoring. Activating can be done statically or dynamically.

Apply and activate your monitoring profile by completing the following steps:

Procedure

1. Apply the monitoring profile to one or more message flows by completing one of the following steps:

   Statically. Before you deploy the message flow, use the BAR File editor to apply a monitoring profile to one or more message flows. Set the message flow property **`Monitoring Profile Name`**, and then deploy the BAR file by completing the following steps:

   a. In the IBM App Connect Enterprise Toolkit, switch to the Integration Development perspective.
   b. In the Application Development view, right-click the BAR file that contains the message flows, then click **Open with** > **BAR Editor**.
   c. Click the **Manage** tab.
   d. Click the message flow on which you want to set the monitoring profile configurable service. The properties that you can configure for the message flow are displayed in the **Properties** view.
   e. In the **Monitoring Profile Name** field, enter the name of a monitoring profile.
   f. Save the BAR file.
   g. Deploy the BAR file. The monitoring profile must be deployed in the same BAR file as the message flow.

   You can also apply a default monitoring profile for any message flow in an integration server, by setting properties in the *Defaults* section of the `server.conf.yaml` file. For example:

```
Defaults:
```

```
            monitoringProfile: 'myIS1MonitoringProfile'       # Default Monitoring profile
```

A default monitoring profile is applied only to message flows that do not have either a configured monitoring profile, or any toolkit monitoring events defined on it.

Dynamically. You can choose from two alternative methods to apply the monitoring profile. You can run the **mqsichangeflowmonitoring** command, or use the IBM App Connect Enterprise administration REST API with the `curl` command:

- Run the **mqsichangeflowmonitoring** command with the **--monitoring-profile** parameter. For example, to apply monitoring to a single message flow *messageflow1* in application *Application1* in integration server *IS1* of the integration node *myBroker*, run the following command:

```
mqsichangeflowmonitoring myBroker -e IS1 -k Application1 -f messageflow1 -c active --
monitoring-profile profileName
```

Where *profileName* is either *{policyProject}:profileName* or *profileName*. If you do not include the prefix *{policyProject}:*, then you must deploy the *profileName* in the configured default policy project.

For more information about the **mqsichangeflowmonitoring** command, see command.

- Use the REST API to associate the monitoring profile with a message flow. Use a POST to make a change that applies until the message flow is restarted or redeployed. For example, for a message flow deployed in a managed integration server:

```
curl -v -X POST "http://<host>:<port>/apiv2/servers/<server name>/applications/<app
 name>/messageflows/<flow name>/attach-monitoring-profile?project=<policy project
 name>&profile=<profile-name>
```

Use a PATCH to have the change persisted though restart or deploy. For example:

```
curl -v -X PATCH -H "Content-Type: application/json" -d Monitoring\monProf.json "http://
<host>:<port>/apiv2/servers/<server name>/applications/<app name>/messageflows/<flow name>
```

2. Activate the monitoring profile by completing one of the following steps:

Statically.

- You can activate monitoring, and optionally set the event format, for all applications and message flows in an integration server, by setting properties in the *Monitoring.MessageFlow* section of the `server.conf.yaml` file. For example:

```
Monitoring:
           MessageFlow:
           publicationOn: 'active'         # choose 1 of : active|inactive, default
 inactive
                                           # Ensure Events.BusinessEvents.MQ|MQTT is set
```

```
            #eventFormat: 'MonitoringEventV2'  # choose 1 of : MonitoringEventV2|WMB
```

This integration server level setting is used by applications and message flows only if they are left with the default setting of *inherit*. If you use the following dynamic option to set monitoring to *active* or *inactive*, it overrides the integration server level setting.

Dynamically. You can choose from two alternative methods to activate the monitoring profile. You can run the **mqsichangeflowmonitoring** command, or use the IBM App Connect Enterprise administration REST API with the `curl` command:

- Use the **mqsichangeflowmonitoring** command. For example, to activate monitoring for a single message flow *messageflow1* in application *Application1* in integration server *IS1* of the integration node *myBroker*, run the following command:

```
mqsichangeflowmonitoring myBroker -e IS1 -k Application1 -f messageflow1 -c active --
monitoring-profile profileName
```

Where *profileName* is either *{policyProject}:profileName* or *profileName*. If you do not include the prefix *{policyProject}:*, then you must deploy the *profileName* in the configured default policy project.

- Use the IBM App Connect Enterprise administration REST API to activate the monitoring profile. For example, to activate monitoring on a single message flow `MonitoringAppFlow1` in the application `MonitoringApp` that is deployed to an independent integration server, run the following command:

```
curl -X POST http://hostname:port/apiv2/applications/MonitoringApp/messageflows/
MonitoringAppFlow1/start-monitoring
```

For more information about activating monitoring by using the IBM App Connect Enterprise administration REST API, see "Activating monitoring by using the administration REST API" on page 364.

Enabling and disabling event sources

When events are configured for a message flow and deployed to the integration node, you can enable and disable individual events. If you enable and disable events from the command line, you do not need to redeploy the message flow. If you use the Message Flow editor to enable or disable events, you must redeploy the flow.

About this task

To enable or disable events, follow the instructions in one of the following sections:

- "Enabling and disabling events from the command line" on page 2801
- "Enabling and disabling events from the Message Flow editor" on page 2802

Enabling and disabling events from the command line

Before you begin

Configure events by using monitoring properties in the Message Flow editor:

- "Configuring monitoring event sources by using monitoring properties" on page 2788

About this task

To enable or disable events from the command line, complete the following steps:

Procedure

Use the **mqsichangeflowmonitoring** command, as shown in the following examples.

- To enable monitoring for all message flows in library `lib1` in application `app1`, on the specified integration server:

```
mqsichangeflowmonitoring -c active -i localhost -p 7600 -k app1 -y lib1 -f "*"
```

- To disable monitoring for message flow `flow3` in application `app0`, which is on integration server `server0` on integration node `broker1`:

```
mqsichangeflowmonitoring -c inactive broker1 -e server0 -k app0 -f flow3
```

You can enable or disable multiple events at the same time. The change of state takes effect immediately.

If you configured events by using monitoring properties, the change persists if the message flow is restarted, but is lost if the message flow is redeployed. To make the change permanent, you must also update the monitoring properties.

Enabling and disabling events from the Message Flow editor

Before you begin

Configure events by using monitoring properties in the Message Flow editor (see "Configuring monitoring event sources by using monitoring properties" on page 2788).

About this task

To enable and disable event sources by using the Message Flow editor, complete the following steps.

Procedure

1. Open the message flow in the editor.
2. Click the canvas.
3. Select the **Monitoring** tab in the Properties view.

   The monitoring events that you defined are shown.
4. Select **Enabled** for each event that you want to enable.

   To disable a single event, clear the checkbox for that event. To disable all events, click **Uncheck All**.
5. Save the message flow.
6. Rebuild and redeploy the BAR file.

Including complex content in the event payload of a monitoring event

You can include parts of a message assembly in a monitoring event, by configuring an XPath expression in the event payload of a monitoring event.

Most events contain data that is taken from fields in the message tree or from elsewhere in the message assembly. You specify the **`Data location`** in the **`Event Payload`** section of the Monitoring Event editor.

If the configured XPath in the **`Data Location`** of the **`Event Payload`** resolves to a simple element (`"name:value"`), the monitoring event includes a `"simpleContent"` section. For example, with an XPath `"$Root/DFDL/CSV/header/head_field2"`, where `"head_field2"` is a simple string element, the monitoring event formatted in JSON could contain the following code:

```
"applicationData": {
"simpleContent": [{
"elementName": "head_field2",
"elementValue": "h2",
"elementDataType": "string"
}],
```

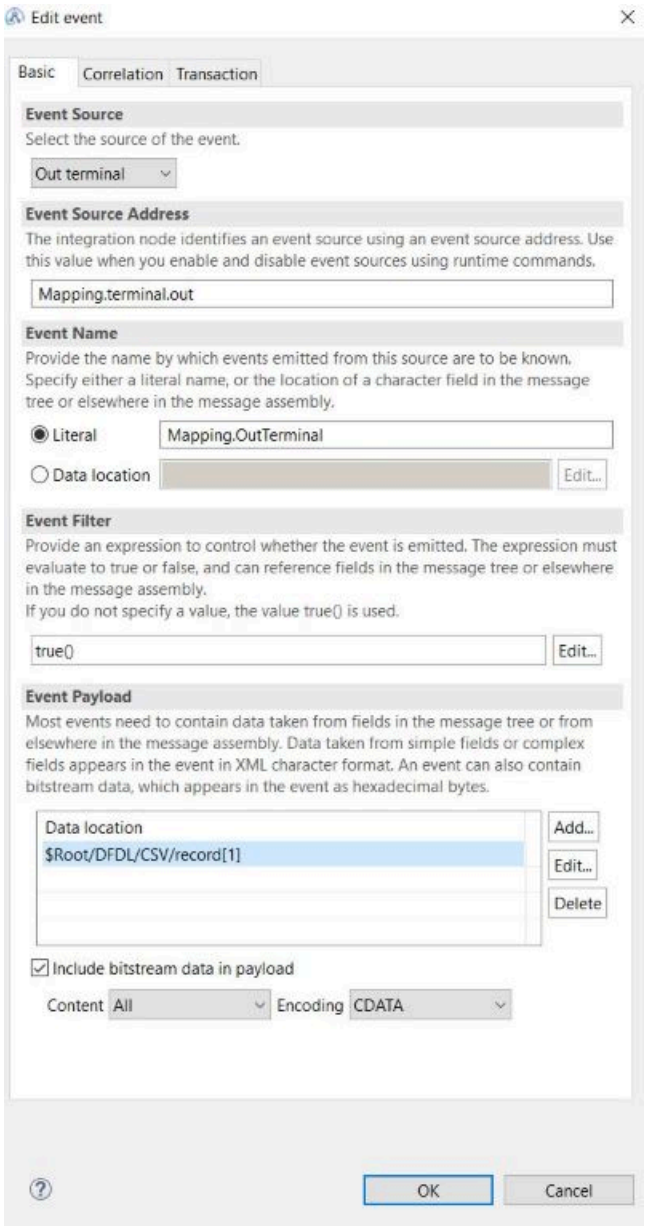

Figure 38. Monitoring Event editor

If the configured XPath in the **Data Location** of the **Event Payload** resolves to a complex element (a sub-tree), the monitoring event includes a `"complexContent"` section. For example, with an XPath `"$Root/DFDL/CSV/record[1]"`, where`"record"` is a complex element that has child elements, the monitoring event formatted in JSON could contain the following:

```
"applicationData": {
"complexContent": [{
"elementName": "record",
"elementValue": {
"bitstream": {
"field1": "Field1Val",
"field2": "Field2Val"
}
}
}]
```

If the configured XPath in the **Data Location** of the **Event Payload** resolves to a repeating simple or complex element, there is a `"simpleContent"` or `"complexContent"` section for each instance.

If an XPath query ends in a wildcard, each element node or attribute node appears in a separate `complexContent` or `simpleContent` folder in the emitted event.

If required, you can configure the **`Data Location`** of the **`Event Payload`** to resolve to a complex element in a message assembly that is in a message domain that does not match the format of the monitoring event. For example, the XPath in the **`Data Location`** could be `"$Root/XML/... "` and the monitoring event format could be JSON, or the XPath in the **`Data Location`** could be `"$Root/DFDL/... "` and the monitoring event format could be JSON or XML. However, if the message domain of the complex element and the format of the monitoring event are different, consider the following points:

- XML monitoring event format:
  - The names of elements resolved by the **`Event Payload Data Location`** XPath must be valid XML element names.
  - MRM XML attributes become elements in the monitoring event. The resolved element must not have an attribute and a child element with the same name.
- JSON monitoring event format:
  - The names of elements resolved by the **`Event Payload Data Location`** XPath must be valid JSON key fields.
  - XMLNSC, XMLNS, and MRM attributes become JSON fields. The resolved element must not have an attribute and a child element with the same name.
  - If the resolved element has a child element that repeats, the JSON monitoring event will have an object with repeating keys, which might lead to a "duplicate key" error.

Activating monitoring

Use the **`mqsichangeflowmonitoring`** command to activate monitoring after you configure monitoring event sources.

Before you begin

Configure monitoring event sources by using either monitoring properties or a monitoring profile:

- “Configuring monitoring event sources by using monitoring properties” on page 2788
- “Configuring monitoring event sources by using a monitoring profile” on page 236

About this task

If monitoring is activated for a message flow, and monitoring properties or a monitoring profile are not configured for the flow, transaction events are emitted. You must ensure that event publication for monitoring messages is enabled and is correctly configured, including specifying whether events are emitted in XML, JSON, or both. For more information, see “Configuring the publication of event messages” on page 2807.

You can start or stop monitoring and specify the appropriate event format by setting properties in the configuration file for your integration server (`server.conf.yaml`.

```
Monitoring:
  MessageFlow:
    #publicationOn: inactive           # Choose 1 of : active|inactive, default inactive
                                       # Ensure Events.BusinessEvents.MQ|MQTT is set
    #eventFormat: MonitoringEventV2    # When BusinessEvents output format is 'xml', set
 'MonitoringEventV2' or 'WMB'. Default 'MonitoringEventV2'.
```

Changes that you make to the properties in the `.conf.yaml` file take effect when the integration server is restarted, and apply to every flow in the integration server.

When you configure monitoring for your flows, you can use the command to activate or deactivate monitoring without restarting the integration server. The options that you set with this command remain in

effect until you run the command again or restart the integration server. When you restart the integration server, the settings that are specified in the `server.conf.yaml` file take effect.

To activate monitoring, specify the **`-c active`** parameter on the **mqsichangeflowmonitoring** command. To deactivate monitoring, specify **`-c inactive`**. You can activate or deactivate monitoring for all message flows in all integration servers. Alternatively, you can specify the integration servers, applications, libraries, or message flows for which monitoring is to be turned on or off.

For more information, see the command.

You can also use a monitoring profile to configure your message flows to emit monitoring events. When you create a monitoring profile, you deploy it to a policy project and then activate it on a specific message flow, application, or integration server. Activate the monitoring profile by using either the **mqsichangeflowmonitoring** command or the administration REST API. Alternatively, you can specify a monitoring profile as a BAR file override, as described in Configurable properties in a file. You can override a deployed monitoring profile by putting an updated `.monprofile.xml` file in the integration server's overrides directory, as described in “Order of precedence for overrides” on page 326.

You can check the monitoring options that are set for a message flow, application, or library, by using the **mqsireportflowmonitoring** command. For more information, see command.

Procedure

Configure monitoring options for a message flow by setting properties in the Monitoring section of the configuration file for your integration node or server (`node.conf.yaml` or `server.conf.yaml`):

1. Open the appropriate `node.conf.yaml` or `server.conf.yaml` configuration file by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor. However, you must ensure that you do not include any tab characters, which are invalid in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
2. To configure message flow monitoring options, set the following properties in the configuration file:
   a) Enable message flow monitoring by setting the **publicationOn** property to `active`. By default, message flow monitoring is turned off.
   b) Specify the correct format of monitoring events by setting the **eventFormat** property.
      Valid options are `MonitoringEventV2` and `WMB`.

   `MonitoringEventV2` is the default format that is used by default in IBM App Connect Enterprise 12.0. It provides some additional data that relates to Shared Libraries and the CCSID of encoded message bodies.

   Specify `WMB` if you want the monitoring events to be emitted in the same format as is used in IBM Integration Bus 10.0.

   For more information, see “The monitoring event” on page 2778.
3. Save the file and restart the integration server for the changes to take effect.

   Changes that you make to the properties in `.conf.yaml` files take effect when the integration server is restarted. For more information about how to start an integration server, see “Starting an integration server” on page 250.

When monitoring is configured, you can use the command to dynamically start or stop message flow monitoring, without restarting the integration server:

4. Optional: To activate monitoring, use the **-c active** parameter. You can activate monitoring for all message flows in all integration servers, or you can specify the integration servers, applications, libraries, message flows for which monitoring is to be activated.
   For example,

   To turn on monitoring for all message flows in library `lib1` in application `app1`, on the specified integration server, use the following command:

   ```
   mqsichangeflowmonitoring -c active -i localhost -p 7600 -k app1 -y lib1 -f "*"
   ```

   By default, the settings that you specify with this command persist when the integration server or node is restarted and when the message flow is redeployed. If you do not want the settings to persist, you can specify the **--non-persist** parameter. The **--non-persist** parameter causes the settings to remain in effect only until a restart or redeploy, at which point the settings that are specified in the `server.conf.yaml` or `node.conf.yaml` configuration file take effect.
5. Optional: To deactivate monitoring, use the **-c inactive** parameter. You can deactivate monitoring for all message flows in all integration servers, or you can specify the integration servers, applications, libraries, message flows for which monitoring is to be turned off.
   For example,

   To turn off monitoring for message flow `flow3` in application `app0`, which is on integration server `server0` on integration node `broker1`, use the following command:

   ```
   mqsichangeflowmonitoring -c inactive broker1 -e server0 -k app0 -f flow3
   ```

Collecting monitoring messages for all message flows in a server

You can collect monitoring messages for all message flows in a server by deploying a monitoring profile in a policy project, and configuring the `server.conf.yaml` file.

Before you begin

Create a monitoring profile that uses the **Event type** *All transaction events*, and the **Event source address** *transaction.all* as described in “Creating a monitoring profile” on page 2793.

About this task

You can collect monitoring messages for all message flows in a server by creating a monitoring profile that is configured for all transaction events. You must then add the profile to a policy project before you deploy it to the server. You must then configure the `server.conf.yaml` file for all transactions, enable the collection of the events, and enable the writing of the events to a file.

To collect monitoring messages for all message flows in a server, complete the following tasks.

Procedure

1. If you do not have a monitoring profile that uses the **Event type** *All transaction events*, and the **Event source address** *transaction.all*, create one as described in “Creating a monitoring profile” on page 2793.
2. Add the monitoring profile to a policy project and deploy it to the integration server. For more information, see “Deploying and redeploying a monitoring profile” on page 2797.
3. Configure the default monitoring profile for all flows in the `server.conf.yaml` file. In the following example, the monitoring profile is called *AllTransactions_Test* and is in a policy project called *PolProj* :

   ```
   Defaults:
     Policies:
       monitoringProfile: '{PolProj}:AllTransactions_Test'       # Default Monitoring profile
   ```

4. Configure the `server.conf.yaml` file to enable the collection of monitoring events:

```
Monitoring:
  MessageFlow:
    publicationOn: 'active'         # choose 1 of : active|inactive, default inactive
                                       # Ensure Events.BusinessEvents.MQ|MQTT is set
    #eventFormat: 'MonitoringEventV2'  # choose 1 of : MonitoringEventV2|WMB
```

5. Configure the `server.conf.yaml` file to enable the writing to file of monitoring events:

```
Events:
  BusinessEvents: # Monitoring events
    File:
      enabled: true            # Set true or false, default false
      #outputFormat: 'json'      # Set comma separated list of one or more of : json,xml.
 Defaults to 'json'
```

The publishing of the events can be done over WebSphere MQ, MQTT, or ELK.

Configuring and subscribing to performance and monitoring events

Integration servers use a pub/sub broker to publish event messages (as fixed topics) in response to changes in configuration, state, or operational status. You can then monitor these events by subscribing to the topics.

Operational events are required by the message flow statistics and resource statistics features of IBM App Connect Enterprise. If you want to collect and view statistics, you must ensure that event publication is enabled and that a pub/sub broker has been configured. For more information, see the following topics:

- “Configuring the publication of event messages” on page 2807
- “Configuring the built-in MQTT pub/sub broker” on page 2811

To monitor the events, you subscribe to the appropriate topics. For more information, see “Subscribing to event message topics” on page 2813.

For detailed information on the architecture of the event messages, see “IBM App Connect Enterprise event messages” on page 2816.

Configuring the publication of event messages

You can configure the publication of event messages to specify the pub/sub broker to which the messages are published, whether messages are published for an event message group, and whether events are emitted in XML, JSON, or both.

Before you begin

Read the following topics:

- “Publish/subscribe overview” on page 1236
- “Configuring and subscribing to performance and monitoring events” on page 2807

About this task

- You need to enable your required publication of events as follows:

  For Operational Events or Statistics and Accounting, use the **mqsichangeflowstats** command or set Statistics.Snapshot.publicationOn or Statistics.Archive.archivalOn in the `.conf.yaml` file.

  For Business Events or Message Flow Monitoring, use the **mqsichangeflowmonitoring** command, or set Monitoring.MessageFlow.publicationOn to `active` in the `.conf.yaml` file.

  Integration node and independent integration server event messages can be published to the following destinations:

  – The default IBM MQ queue manager of an integration node or independent integration server
  – The integration node MQTT pub/sub broker (not available for independent integration servers)
  – An external IBM MQ queue manager, by configuring an MQEndpoint policy
  – An external MQTT pub/sub broker, by configuring an MQTTPublish policy
  – The file system, in rotatable log files
  – A Logstash input plug-in in an Elasticsearch, Logstash, and Kibana (ELK) stack

  You can configure both IBM MQ and MQTT pub/sub brokers.

  The default pub/sub broker that is used for each group of event messages (`OperationalEvents` and `BusinessEvents`) depends on your IBM App Connect Enterprise deployment:

  IBM MQ is not installed, or IBM MQ is installed but a queue manager is not specified on the integration node.
  By default, the messages are published to the following locations:

  – `OperationalEvents` messages are published to the built-in MQTT pub/sub broker.
  – `BusinessEvents` messages are not published.

  IBM MQ is installed and a default queue manager is specified on the integration node or independent integration server.
  By default, the messages are published to the following locations:

  – `OperationalEvents` messages are published to the IBM MQ queue manager, and for the integration node only, to the built-in MQTT pub/sub broker.
  – `BusinessEvents` messages are published to the IBM MQ pub/sub broker.

  In either configuration, if you want to publish `BusinessEvents` messages to the built-in MQTT pub/sub broker, you must explicitly enable the publication of the `BusinessEvents` group to the built-in MQTT pub/sub broker.

  You can change the settings for the publication of `OperationalEvents` and `BusinessEvents`, and the integration node built-in MQTT broker, either by using the **mqsichangeproperties** command or by editing the `node.conf.yaml` or `server.conf.yaml` configuration file. You can configure specific IBM MQ or MQTT connection policies, for each of the `OperationalEvents` and `BusinessEvents` event message groups.

  If you want to use an external MQTT server instead of the built-in MQTT broker, you can create a policy that contains the connection details that you want to use. For more information about creating policies, see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327.

  If you want to use the IBM MQ pub/sub broker and you want to use a different queue manager to the queue manager that is specified on the integration server, you can create a policy that contains the connection details that you want to use. For more information about creating policies, see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327.

  To use a secured IBM MQ pub/sub broker or an MQTT server that requires a username and password, use the **mqsisetdbparms** command to define the credentials to use for the connection. If a specific identity is not defined in the configured policy, the integration node uses the security identity **pubsubDefault** when event messages are published. If **pubsubDefault** is associated with security

credentials by using the **mqsisetdbparms** command, then these credentials are used; otherwise, no credentials are used. For more information, see command.

For more information about of all the event messages that can be published, see "Subscribing to event message topics" on page 2813.

You can configure whether events are published, and where they are published to, either by using the **mqsichangeproperties** command, or by setting properties in the `server.conf.yaml` or `node.conf.yaml` configuration file. Configure the publication of events by completing the steps in one of the following tasks:

- "Using the mqsichangeproperties command" on page 2809
- "Modifying the server.conf.yaml or node.conf.yaml file" on page 2810

Using the `mqsichangeproperties` command

About this task

Follow these steps to configure the publication of event messages by using the **mqsichangeproperties** command:

Procedure

1. Use the **enabled** property of the **mqsichangeproperties** command to enable or disable the publication of event messages by the specified pub/sub broker.

   All integration node events are categorized by event message group (`OperationalEvents` and `BusinessEvents`). You can enable or disable the publication of event messages that are based on the event message group. For example, enter the following command to enable the publication of event messages to an MQTT broker for the publication of `BusinessEvents` messages:

   ```
   mqsichangeproperties INODE -b pubsub -o BusinessEvents/MQTT -n enabled -v true
   ```

2. If you want to use an external MQTT server for the publication of event messages, or if you want to use a specific IBM MQ queue manager, use the **policy** property of the **mqsichangeproperties** command. You can use the **policy** to specify the location of the policy that contains the connection details.
   For example:

   ```
   mqsichangeproperties INODE -b pubsub -o BusinessEvents/MQTT -n policy -v
    {DefaultPolicies}:example_mqtt_policy
   ```

3. Optional: If you want to publish the event messages to rotatable log files in the file system, complete the following steps:

   a) Enable output to a file by using the **mqsichangeproperties** command, as shown in the following example:

   ```
   mqsichangeproperties INODE -b pubsub -o BusinessEvents/File -n enabled -v true
   ```

   b) Set the output format of the event messages to either `json`, `xml`, or `json.xml` as shown in the following example:

   ```
   mqsichangeproperties INODE -b pubsub -o BusinessEvents/File -n outputFormat -v json
   ```

4. Optional: If you want to publish the event messages to a Logstash input plug-in in an Elasticsearch, Logstash, and Kibana (ELK) stack, complete the following steps:
   a) Enable output to a Logstash input plug-in in an Elasticsearch, Logstash, and Kibana (ELK) stack by using the **mqsichangeproperties** command, as shown in the following example:

```
mqsichangeproperties INODE -b pubsub -o BusinessEvents/ELK -n enabled -v true
```

   b) Set the ELK "elkConnections" to match a name of a ELKConnections section by using the **mqsichangeproperties** command, as shown in the following example:

```
mqsichangeproperties INODE  -b pubsub -o BusinessEvents/ELK -n elkConnections -v
 elkConnection1
```

   The referenced ELKConnections named section must be configured as described in "Reporting logs and monitoring events to a Logstash input in an ELK stack" on page 2869.
5. Ensure that the subscription is configured correctly so that the required event messages are received correctly following the configuration of the publication details.

   For example, if subscription was previously turned off in the web user interface, you must turn it on before published event messages can be received and processed for functions. For example, message flow statistics.

Modifying the server.conf.yaml or node.conf.yaml file

About this task

Follow these steps to configure the publication of event messages by setting properties in the `server.conf.yaml` or `node.conf.yaml` configuration file:

Procedure

1. Use a YAML editor to open the `.yaml` file.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor. However, you must ensure that you do not include any tab characters, which are not accepted in YAML and would cause your configuration to fail. If you choose to use a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

   For more information about working with YAML, see http://www.yaml.org/start.html.
2. Set the appropriate property values in the Events section of the `.yaml` file:

```
Events:
  OperationalEvents: # Message flow and Resource statistics plus Workload management
    MQ:
      #policy: ''      # Specify a {policy project}:policy if not using
 'defaultQueueManager'
      #enabled: true   # Set true or false, default false
      #format: ''      # Set string or none
    MQTT:
      #policy: ''      # Specify a {policy project}:policy
      #enabled: false  # Set true or false, default false
      #format: ''      # Set string or none
  BusinessEvents:    # Business monitoring events
    MQ:
      #policy: ''      # Specify a {policy project}:policy if not using
 'defaultQueueManager'
      enabled: true    # Set true or false, default false
      #format: ''      # Set string or none
      #outputFormat: 'xml' # Set comma separated list of one or more of : json,xml. Defaults
 to 'xml'
    MQTT:
      #policy: ''      # Specify a {policy project}:policy
      #enabled: true   # Set true or false, default false
      #format: ''      # Set string or none
      #outputFormat: 'xml' # Set comma separated list of one or more of : json,xml. Defaults
 to 'xml'
```

```
    ELK:
      #enabled: false            # Set true or false, default false
      #outputFormat: 'json'      # Set json, default json
      #elkConnections: ''        # Name of the ELK connection to use, for example
 'elkConnection1', must be defined in the ELKConnections section below.
    File:
      #enabled: false       # Set true or false, default false
      #outputFormat: 'json' # Set comma separated list of one or more of : json,xml. Defaults
 to 'json'
```

The business transaction monitoring capability requires your monitoring events to be published as MQ publications in `xml` format. If you intend to use business transaction monitoring, either set the **outputFormat** property in the `Events.BusinessEvents.MQ` section of the `.yaml` file to include `'xml'`, or leave it commented out so that `xml` format is assigned by default.

The referenced ELKConnections named section must be configured as described in "Reporting logs and monitoring events to a Logstash input in an ELK stack" on page 2869.

3. Save the changes to the `.yaml` file.
4. Restart the integration node or integration server for the changes to take effect. The properties that you set in the `.yaml` file take effect when the integration node or server is started. If you modify these properties again, you must also start the integration node or server again for the later changes to be applied.

Configuring the built-in MQTT pub/sub broker

Configure the built-in MQTT pub/sub broker for an integration node, by using the **mqsichangeproperties** command, or by updating the configuration file in the *work_path*\components*integrationNodeName*\config directory.

Before you begin

Read the following topics:

- "Publish/subscribe overview" on page 1236
- "Configuring and subscribing to performance and monitoring events" on page 2807

About this task

The built-in MQTT broker is enabled by default. It is the default transport for the publication of operational and admin events by an integration node, unless:

- IBM MQ is installed.
- An IBM MQ queue manager is specified on the integration node.

For more information, see "Configuring the publication of event messages" on page 2807.

The built-in MQTT pub/sub broker is only applicable to an integration node. If you want to publish event messages for an independent integration server, you must configure an MQTTPublish policy to use an external MQTT pub/sub broker. For more information, see "Configuring and subscribing to performance and monitoring events" on page 2807.

You can modify the configuration of the built-in MQTT broker by using the **mqsichangeproperties** command. Use the **enabled** property for the MQTTServer object in the pub/sub component to enable or disable the built-in MQTT broker, and the **port** property to specify the port to be used by the broker. By default, the **enabled** property is set to `true` and the port is set to 11883. When an integration node starts, the built-in MQTT broker starts on the port that is configured by the **port** property for the MQTTServer object in the pub/sub component.

If more than one integration node is configured with the same MQTTServer port, only one MQTT broker starts. All integration nodes that are using the same MQTTServer port, use the same MQTT broker to publish their events. Subscribers that connect to the MQTT broker receive all the events that are published by the broker, unless the subscriber includes the name of the integration node in their subscriptions.

You can modify the IP address that the MQTT broker process starts by updating the value of `bind_address` in the configuration file in the *work_path*`\components\`*integrationNodeName*`\config` directory. By default, the MQTT broker process starts on the same host as the integration node; the default content of the file is `bind_address localhost`.

You can view the current configuration of the built-in MQTT broker by using the **mqsireportproperties** command. For example, use the following command to view the port that is used by the built-in MQTT broker:

```
mqsireportproperties INODE -b pubsub -o MQTTServer -n port
```

Complete the following steps to change the MQTT pub/sub broker port:

Procedure

1. Use the **mqsichangeproperties** command to stop the built-in MQTT broker.

   For example,

   ```
   mqsichangeproperties INODE -b pubsub -o MQTTServer -n enabled -v false
   ```

2. Use the **mqsichangeproperties** command to restart the built-in MQTT broker on a port other than the default port.

   For example,

   ```
   mqsichangeproperties INODE -b pubsub -o MQTTServer -n enabled,port -v true,11885
   ```

Results

When **QoS** is set to 1 or 2, the default number of messages that are held in queue is `100`. If you alter the message count, then you must alter the integration node's config file to have the following property.

```
max_queued_messages count
```

The maximum number of **QoS** 1 or 2 messages to hold in the queue above those messages that are currently in flight. The default is `100`. Set to `0` for no maximum (this value is not advised).

The value of **max_queued_messages count** is set in the configuration file. The configuration file that is used by the bipMQTT can be found under the `work_path\components\integrationNodeName \config` directory, which contains a file with the same name as Integration Node name.

For example,

If the Integration Node name is *BRK1* and you are running Windows, then a file by name `BRK1` is found under `C:\ProgramData\Application Data\IBM\MQSI\components\BRK1\config` with the following details in it:

```
bind_address localhost
```

Use the following steps to alter the built-in configuration:

1. Stop the Node.
2. Append the following line to the file.

   ```
   max_queued_messages <count>
   ```

   Where *count* is the number of inflight messages to be held.
3. Restart the Node for the built-in MQTT broker to pick up the changes.

If more complicated configurations are required, then you must use your own MQTT broker.

What to do next

By default, all event groups except the `BusinessEvents` group are enabled for MQTT transport. The `BusinessEvents` group is enabled by default for the IBM MQ pub/sub broker. The `BusinessEvents` group includes monitoring events. If you want to publish monitoring events to the built-in MQTT broker, you must configure the `BusinessEvents` group to enable MQTT publication by using the **mqsichangeproperties** command. For an example, and more information about how to specify a pub/sub broker for specific types of event, see "Configuring the publication of event messages" on page 2807.

Subscribing to event message topics

You can subscribe to topics that return messages about the configuration, state, or operational status of your integration server, integration node, or message flows.

About this task

A subscriber can send a subscription request to the pub/sub broker that specifies the event messages that the subscriber wants to receive.

Note: You can use wildcards when you subscribe to statistics reports. For example, to receive message flow statistics reports for all integration nodes and all integration servers, subscribe to the following topic:

```
topicRoot/+/StatisticsAccounting/#
```

where *topicRoot* is `IBM/IntegrationBus` for an MQTT pub/sub broker and `$SYS/Broker` for an IBM MQ pub/sub broker. For more information about how you can use wildcards, see Special characters in topics. For more information about the use of *topicRoot*, see Topic semantics and usage.

You can subscribe to IBM App Connect Enterprise messages in the following categories:

Message flow performance

If you enable message flow accounting and statistics collection for an integration node, the integration node publishes messages (JSON or XML publications) at an interval that you can control by setting the `statsInterval` property of the integration node. You can subscribe to these messages on the following topics:

- For JSON publications:

```
topicRoot/integrationNodeName/Statistics/JSON/recordType/integrationServerName/messageFlowName
```

- For XML publications:

```
topicRoot/integrationNodeName/StatisticsAccounting/recordType/integrationServerName/messageFlowName
```

For messages published by an independent integration server, subscribe to the following topics:

- For JSON publications:

```
topicRoot/integration_server/Statistics/JSON/recordType/integrationServerName/messageFlowName
```

- For XML publications:

```
topicRoot/integration_server/StatisticsAccounting/recordType/integrationServerName/messageFlowName
```

where *recordType* specifies the type of record (SnapShot or Archive), and *integrationServerName* is the value that is specified by the **--name** parameter when the IntegrationServer process is started.

Note: For an IBM MQ pub/sub broker, each message is a JMS TextMessage that contains the statistics report in XML format. If you want the message in a JMS BytesMessage format, use one of the following methods:

- Set the environment variable **MQSI_STATS_MQSTR=false**.

- Run the **mqsichangeproperties** command with the pubsub component to change the format. For example:

```
mqsichangeproperties INODE -b pubsub -o OperationalEvents/MQ -n format -v none
```

The pubsub component change overrides the use of environment variables. For more information, see Parameter values for the pubsub component.

Resource performance

If you enable resource statistics collection for one or more integration servers on an integration node, the integration node publishes messages (JSON or XML publications) at 20-second intervals. You can subscribe to these messages on the following topics:

- For JSON publications:

```
topicRoot/integrationNodeName/Statistics/JSON/Resource/integrationServerName
```

- For XML publications:

```
topicRoot/integrationNodeName/ResourceStatistics/integrationServerName
```

For messages published by an independent integration server, subscribe to the following topics:

- For JSON publications:

```
topicRoot/integration_server/Statistics/JSON/Resource/integrationServerName
```

- For XML publications:

```
topicRoot/integration_server/ResourceStatistics/integrationServerName
```

where *integrationServerName* is the value that is specified by the **--name** parameter when the IntegrationServer process is started.

Note: For an IBM MQ pub/sub broker, each message is a JMS TextMessage that contains the resource statistics report in XML format. If you want the message in a JMS BytesMessage format, use one of the following methods:

- Set the environment variable **MQSI_STATS_MQSTR=false**.
- Run the **mqsichangeproperties** command with the pubsub component to change the format.

For more information about how to interpret the resource statistics that are included in the publication, see "Viewing resource statistics data" on page 2745.

Monitoring

You can configure your message flow to emit event messages that can be used to support transaction monitoring and auditing, and business process monitoring; see "Configuring monitoring for message flows" on page 2788. To receive event messages from your message flows, subscribe to the following topics:

- For JSON publications:

```
topicRoot/integrationNodeName/MonitoringEvents/JSON/integrationServerName/applicationName/messageFlowName
```

- For XML publications:

```
topicRoot/integrationNodeName/Monitoring/integrationServerName/applicationName/messageFlowName
```

Where *applicationName* is the name of the deployment container. For example:

- Application name.
- RESTAPI name.
- Integration Service name.

Note: When you use the built-in MQTT pub/sub broker, Monitoring events are not published by default. You must enable the publication of Monitoring events to the built-in MQTT pub/sub broker.

For messages published by an independent integration server, subscribe to the following topic:

```
topicRoot/integration_server/
Monitoring/integrationServerName/applicationName/messageFlowName
```

Workload management

The message rate statistics are collected at a checkpoint that occurs every 20 seconds. The total message rate is calculated at this checkpoint, and if the total message rate exceeds the notification threshold, the out of range XML message is published. If the total message rate continues to stay above the notification threshold, then no further out of range messages are published.

If you enable the notification threshold, you can subscribe to the following topics:

- Message flow is in a library within an application:

  ```
  topicRoot/integrationNodeName/WorkloadManagement/
  AboveThreshold/integrationServerName/applicationName/libraryName/messageFlowName
  ```

- Message flow is in a library that is not within an application:

  ```
  topicRoot/integrationNodeName/WorkloadManagement/
  AboveThreshold/integrationServerName/libraryName/messageFlowName
  ```

- Message flow is directly in an application (not in a library within the application):

  ```
  topicRoot/integrationNodeName/WorkloadManagement/
  AboveThreshold/integrationServerName/applicationName/messageFlowName
  ```

- Message flow is not in an application or a library:

  ```
  topicRoot/integrationNodeName/WorkloadManagement/
  AboveThreshold/integrationServerName/messageFlowName
  ```

For messages published by an independent integration server, subscribe to the following topics:

- Message flow is in a library within an application:

  ```
  topicRoot/integration_server/WorkloadManagement/
  AboveThreshold/integrationServerName/applicationName/libraryName/messageFlowName
  ```

- Message flow is in a library that is not within an application:

  ```
  topicRoot/integration_server/WorkloadManagement/
  AboveThreshold/integrationServerName/libraryName/messageFlowName
  ```

- Message flow is directly in an application (not in a library within the application):

  ```
  topicRoot/integration_server/WorkloadManagement/
  AboveThreshold/integrationServerName/applicationName/messageFlowName
  ```

- Message flow is not in an application or a library:

  ```
  topicRoot/integration_server/WorkloadManagement/
  AboveThreshold/integrationServerName/messageFlowName
  ```

Results

Subscribers receive statistics reports only from those integration servers that are enabled to produce statistics.

IBM App Connect Enterprise event messages

Event messages are published by an integration server in response to certain conditions that occur while it is active.

The events are published on a series of system-defined topics. The body of the message contains additional information in XML format. Every message is generated in code page 1208.

Event messages are published in response to operational events, such as the publication of statistics, and business events, such as monitoring.

For more information about events, see the following topics:

- "Event message architecture" on page 2816
- "Configuring the publication of event messages" on page 2807.

Event message architecture

Integration servers publish messages on reserved topics after significant events within the integration server. By subscribing to these topics, a client is informed when these events occur.

For each topic, the type of event and message body are explained. The body of these messages is either in JSON or XML format, depending on the topic.

An event publication can contain more than one entry if the topic is the same.

The general notation of the system topics on which events are published is as follows:

```
$SYS/Broker/integrationNodeName/event_type/integrationServerName
/applications/application_name/libraries/library_name/messageflows/message_flow_name
```

For an integration server that is managed by an integration node, *integrationNodeName* is the name of the integration node that manages the integration server. For an independent integration server, specify the literal string `integration_server` in place of an integration node name.

For example:

- For an integration server that is managed by an integration node:

```
$SYS/Broker/myIntegrationNode1/Statistics/JSON/SnapShot/myIntegrationServer3/applications/
myApplicationA
/libraries/myLibraryD/messageflows/myMessageFlow6
```

- For an independent integration server:

```
$SYS/Broker/integration_server/Statistics/JSON/SnapShot/myIntegrationServer3/applications/
myApplicationA
/libraries/myLibraryD/messageflows/myMessageFlow6
```

For events that are published using MQTT as the transport, the notation is as follows:

```
IBM/IntegrationBus/integrationNodeName/event_type/integrationServerName
/applications/application_name/libraries/library_name/messageflows/message_flow_name
```

integrationNodeName
The name of the integration node that issues or raises this event, or, in the case of an independent integration server, the literal string `integration_server`.

event_type
event_type is the type of the event. The possible event types are shown in the following table:

Table 92. Types of event and how they are represented in publication topics. The table describes the event groups, event types, and the equivalent notation for *event_type*.		
Event group	**Event type**	**Notation format for *event_type***
OperationalEvents	• Resource statistics (JSON) • Resource statistics (XML) • Message flow statistics (JSON) • Message flow statistics (XML) • Workload Management	• `Statistics/JSON/Resource` • `ResourceStatistics` • `Statistics/JSON` • `StatisticsAccounting` • `WorkloadManagement`
BusinessEvents	• Monitoring	• Monitoring

Message flow statistics and resource statistics event types are published in both JSON and XML format. All other event types are published in XML format. For more information, see "Output formats for message flow accounting and statistics data" on page 2704.

When you subscribe to events, the topic structure enables you to filter the events by integration node, integration server, and type of event. For specific events, additional information is included in the topic to help filter on the specific object that raised the event. The inclusion of the string `Broker` (or for MQTT, `IntegrationBus`) at the second level of the topic hierarchy allows for future extension to additional subsystems that publish system management events through the integration node or server. For more information, see "Subscribing to event message topics" on page 2813.

Monitoring business transactions

Monitor business transactions through one or more flows in your enterprise.

Before you begin

Read the introductory information about monitoring business transactions, in "Business transaction monitoring overview" on page 2818.

About this task

You can use the App Connect Enterprise web user interface to view the results of business transactions, and to create or delete business transaction definitions.

Procedure

Complete the following steps to configure integration servers for business transaction monitoring, to create business transaction definitions, and to view the results of business transaction monitoring:

1. Configure your integration server and message flows to enable business transaction monitoring, by following the instructions in "Configuring business transaction monitoring" on page 2820.
2. Enable security for business transaction monitoring, by following the instructions in "Enabling security for business transaction monitoring" on page 2824.
3. Create a business transaction definition, by following the instructions in "Creating a business transaction definition" on page 2826.
4. Start the business transaction definition, by following the instructions in "Starting and stopping a business transaction definition" on page 2827.
5. View the status and results of business transactions, by following the instructions in "Viewing the results of business transaction monitoring" on page 2830.
6. Optional: Update an existing business transaction definition, by following the instructions in "Updating a business transaction definition" on page 2828.

7. Optional: Delete a business transaction definition, by following the steps in "Deleting a business transaction definition" on page 2830.

Business transaction monitoring overview

Business transaction monitoring involves monitoring a message across multiple message flows, so you can track and report the lifecycle of a payload message through an end-to-end enterprise transaction.

Business transaction monitoring enables you to track the outcomes of work passing through a message flow, allowing you to see which aspects of your business transaction are working correctly and which aspects are failing.

Video: Business Transaction Monitoring

This video demonstrates the capability called Business Transaction Monitoring. The video describes the key concepts and demonstrates an overview of how to configure and use Business Transaction Monitoring.

The following terms describe aspects of business transaction monitoring:

Business transaction
A set of business events or actions that form a self-contained business use case, such as the booking of an airline ticket. A business transaction might be implemented as multiple user transactions or activities.

Business transaction instance
One instance of a business transaction. Multiple instances of a business transaction can be running concurrently, such as when multiple customers are booking airline tickets.

Business transaction definition
The definition of the business transaction, which you create by using the web user interface. The business transaction definition specifies the flows that are part of the business transaction. It also specifies which monitoring events signify the start and end of the business transaction, which events show that a business transaction is in progress, and which events signify a failure in the transaction.

The business transaction definition comprises information that is specified in a business transaction policy, and configuration properties that are set in the integration server's `server.conf.yaml` file. The business transaction policy defines the events that will be monitored as part of the business transaction, and the configuration properties in the integration server's `server.conf.yaml` file specify the name of the policy and the data store.

When you create the business transaction definition in the web user interface, you specify the name of a business transaction policy and select the business events that will be monitored as part of the business transaction. If the policy already exists, it is updated automatically with the business events that you have specified. If the policy does not exist, it is created for you. The `BusinessTransactionDefinitions` section of the integration server's `server.conf.yaml` file is updated automatically with the name of the policy that you selected.

Business transaction event
A monitoring event that signifies the start, end, or failure of a business transaction or shows how the transaction is progressing. Monitoring events are defined for the message flows in your business transaction. When you create a business transaction definition, you select appropriate monitoring events and flag them as start, end, failure, or progress business transaction events. Not all monitoring events need to be flagged as business transaction events.

A *start* business transaction event typically corresponds with an input node in a message flow. This event signifies that when a message is received on that input node, the business transaction starts.

An *end* business transaction event typically corresponds with a transaction end event for an input node. This event signifies that when a message reaches the end of that flow, the business transaction is complete.

A *failure* business transaction event typically corresponds with a node that handles error processing. This event signifies that when a message reaches this node, the business transaction has failed.

A *progress* business transaction event can correspond with any type of node in a message flow. This event signifies that a message has reached a particular node in the flow.

These business transaction events are used to show the progress of a business transaction on the Monitor tab of the business transaction monitor:

- If a start event is issued for a business transaction, but the end event or failure event is not yet issued, that business transaction instance is shown as being `In progress`.
- If an end event is issued for a business transaction, that business transaction instance is shown as being `Complete`.
- If a failure event is issued for a business transaction, that business transaction instance is shown as having `Failed`.
- If an in-progress event is received after an end event, the business transaction is shown as being `Inconsistent`. Other situations can also result in an inconsistent business transaction.

You can use business transaction monitoring to track the lifecycle of a message through an end-to-end enterprise transaction. Business transaction monitoring uses events that are emitted from message flows, and a transaction is correlated across a set of events using the global transaction ID that is defined in an event. The global transaction ID can be inferred from an upstream node by using the **`Automatic`** property, or you can set it explicitly with an XPath expression.

Tip: It is not necessary to flag all monitoring events in a business transaction as business events, and doing so can adversely affect the performance of business transaction monitoring. The extent to which performance is affected depends on the number and complexity of business transaction events, and the rate at which they are being processed. When business events are emitted by the flows, they are read from MQ topics and put to an MQ queue, which is specified in the integration server's `server.conf.yaml` file (by default, this queue name is `SYSTEM.BROKER.DC.RECORD`). Performance of the business transaction monitor can be impacted if the business events are emitted to the queue faster than they can be written to the database. To improve performance, focus on flagging events that occur in error conditions, so that you can monitor when and why a business transaction might have failed.

For event monitoring, the presentation of data is event-oriented. For business transaction monitoring, presentation of data is transaction-oriented. Initially, business transaction data is presented as a summary of transactions. You can then view the details of the business transaction, the system-level transactions, and a list of events by inspecting individual transactions.

The web user interface is used to monitor business transactions. You create a *business transaction definition* to identify the message flows that form the business transaction, and define how they interact with each other. You can view the monitoring events that are defined for the message flows that make up the business transaction. Some of these events are significant to the business transaction. The business transaction definition defines how these events apply to the business transaction. Existing monitoring events can be selected as start, end, failure, and progress events in the business transaction.

A business transaction policy specifies the business events that will take part in the business transaction, and this policy forms one part of the business transaction definition. Additional configuration information, such as details of the data store that contains the business data for the business transaction, is specified in the integration server's `server.conf.yaml` configuration file. You set the database location by specifying the data store in the `server.conf.yaml` file, and the business transaction policy is updated with the new data source name as a result. It is not necessary to make any other changes to the business transaction policy; however, if you want to change any other properties in the policy, you can modify it by using an external editor. For more information, see “Creating a business transaction definition” on page 2826.

The results of business transactions can be viewed in the web user interface. You can see which instances of business transactions are in progress, which instances completed successfully, and which instances failed. Detailed information is also shown for the transaction-specific events of a business transaction.

The business transaction monitor in the web user interface has two tabs: **Configure** and **Monitor**. Use the Configure tab to create or modify a business transaction definition, and to define the business events that participate in the business transaction. Create a new business transaction definition by clicking the **Create a transaction definition** button, and specifying the business transaction policy in which the

business events are to be defined. For a monitoring event to be part of a business transaction, it must be explicitly added to the business transaction definition as a business event, by clicking the **Create an event** button in the Configure tab, and then selecting the monitoring event that you want to define as a business event. For more information, see "Creating a business transaction definition" on page 2826 and "Updating a business transaction definition" on page 2828.

Use the Monitor tab to view instances of the business transaction, and the status of those instances and associated events. To show all the latest business transactions, click the Refresh icon (). Alternatively, you can show only the instances that have a particular status, or instances that were last updated within a specified period of time. For more information, see "Viewing the results of business transaction monitoring" on page 2830.

Configuring business transaction monitoring

Configure your integration server and message flows to enable business transaction monitoring.

About this task

You configure the message flows that you want to participate in the business transaction, and create the business transaction definitions and policies that define the business events that will be monitored end-to-end throughout the business transaction. You must also configure your integration server to enable business transaction monitoring, and define the data stores that are to be used for recording and viewing the business events.

Video: Configure App Connect Enterprise to use Business Transaction Monitoring - detailed view

This video demonstrates in detail how to configure IBM App Connect Enterprise to use Business Transaction Monitoring.

Procedure

Configure your integration server and message flows to enable business transaction monitoring, by completing the following steps:

1. Configure monitoring on the message flows that are to participate in the business transaction, either by setting properties on the message flow nodes or by using a monitoring profile.

   Ensure that the correlation information is set correctly. To be part of a business transaction, a flow must have events that are correctly defined and enabled, and that contain a global transaction ID when they are emitted by the flow. The global transaction ID is a unique ID such as a reference number or an order processing number, which is used to correlate all the events for a single business transaction. The global ID can either be derived from a previous node in the flow by using the `automatic` setting, or it can be set explicitly by using an XPath expression to specify a location in the message. A global transaction ID links events from a message flow to one or more related message flows or external applications. For more information, see "Configuring monitoring event sources by using monitoring properties" on page 2788 and "Configuring monitoring event sources by using a monitoring profile" on page 236.
2. Enable monitoring for the integration servers on which the flows are running (and which will therefore be publishing the events), by setting properties in the `Monitoring/MessageFlow` section of the integration server's `server.conf.yaml` file. Set the **`publicationOn`** property to `active`, and the **`eventFormat`** property to `MonitoringEventV2`, as shown in the following example:

```
Monitoring:
  MessageFlow:
    publicationOn: 'active'           # choose 1 of : active|inactive, default is inactive
                                      # Ensure Events.BusinessEvents.MQ|MQTT is set
    eventFormat: 'MonitoringEventV2'  # choose 1 of : MonitoringEventV2|WMB
```

3. Enable business monitoring events for the integration servers on which the flows are running, by setting the **enabled** property to `true`, in the `Events/BusinessEvents/MQ` section of the integration server's `server.conf.yaml` file:

```
Events:
  BusinessEvents: # Business monitoring events
    MQ:
      policy: ''                # Specify a policy in the form {policy project}:policy if
 not using 'defaultQueueManager'
      enabled: true             # Set true or false, default is false
      format: ''                # Set string or none
      outputFormat: 'xml'       # Set to xml or json, default is xml
      publishRetryInterval: 0   # Set the retry interval (in milliseconds), to pause
 all publications and retry when publication failures are causing serious delay to the
 transaction.
```

   The integration servers that are publishing the events must point to the same queue manager that is recording the events, either by specifying the **defaultQueueManager** property or by setting the **policy** property in the `Events/BusinessEvents/MQ` section.

Install and configure a database for recording monitoring events and business transaction data, and configure the integration server to record and access the data:

4. Install and configure a DB2 or Oracle database for recording monitoring events and business transaction data, and configure a connection to the integration, as described in "Enabling ODBC connections to the databases" on page 184.

   For more information, see "Configuring databases" on page 182.

5. Run the `DataCaptureSchema.sql` script to create the monitoring events tables that are required for business transaction monitoring.

   If these tables have already been created for use by the record and replay function, you can use the same tables for business transaction monitoring events. However, if the tables do not exist, or if you want to use a different schema for business transaction monitoring from the one that you use for record and replay, you must run the `DataCaptureSchema.sql` script as described in the relevant topic:

   - "Creating and configuring a DB2 database for recording data" on page 2842
   - "Creating and configuring an Oracle database for recording data" on page 2843

   In addition to the `DataCaptureSchema.sql` script that you run as part of this configuration procedure, a file called `DataCaptureSchema_v2.sql` is stored in the same location in the file system. However, the `DataCaptureSchema_v2.sql` script can be used only if you are using V2 monitoring events exclusively, and cannot be used in any architecture that combines V1 and V2 monitoring events.

6. Run the BusinessCaptureSchema.sql script to create the database table that is required for recording and storing business transaction data, as shown in the following examples:

   - DB2:

     ```
     db2 -tvf BusinessCaptureSchema.sql
     ```

   - Oracle:

     ```
     sqlplus user/password @BusinessCaptureSchema.sql
     ```

   The script is stored in the following location, depending on your database and operating system:

   DB2

   - Windows: *install_dir*\server\ddl\db2\BusinessCaptureSchema.sql
   - Linux or UNIX: *install_dir*/server/ddl/db2/BusinessCaptureSchema.sql

   Oracle

   - Windows: *install_dir*\server\ddl\oracle\BusinessCaptureSchema.sql
   - Linux or UNIX: *install_dir*/server/ddl/oracle/BusinessCaptureSchema.sql

   where *install_dir* is the location of your IBM App Connect Enterprise installation.

   The database tables are now ready to be used for recording and storing your business transaction data.

7. Configure the Record and Replay store for the integration server, by setting properties in the Stores section of the integration server's server.conf.yaml file.

   The name of this data store must be unique. By default, business transaction definitions created in the web user interface are configured to reference a Record and Replay store called BTMDataStore, as shown in the following example:

```
Stores:
    BTMDataStore:
       dataSource: ''                    # The ODBC data source name (DSN) that is used to
 connect to the database that stores the recorded data. This property is mandatory and has
 no default value.
       schema: ''                        # The schema name that owns the database tables
 that are used for storing recorded data. This property has no default value. If no value
 is set, either the default database schema is used (if there is one), or no schema is used,
 depending on the database.
       storeMode: 'all'                  # The mode for the store to operate in. Valid
 values are record, view, and all. Default is all.
       queue: 'SYSTEM.BROKER.DC.RECORD'  # The name of the queue to which event messages
 will be published before being recorded to the database. The queue must exist.
                                          # Default is SYSTEM.BROKER.DC.RECORD. The queue
 SYSTEM.BROKER.DC.RECORD must be created manually if you use Record and Replay. The same
 queue can be specified for multiple Record and Replay stores.
                                          # Change the value of this property to distribute
 the data from multiple sources across multiple queues.
       backoutQueue: 'SYSTEM.BROKER.DC.BACKOUT'  # The name of the backout queue used by the
 recorder. Messages that cannot be processed (for example, because the specified database
 does not exist) are sent to this queue.
                                                  # Default is SYSTEM.BROKER.DC.BACKOUT.
 The queue SYSTEM.BROKER.DC.BACKOUT must be created manually if you use Record and Replay.
 If a data capture source refers to this data capture store, and no backoutQueue has been
```

```
specified, an error occurs. The same backoutQueue can be specified for multiple Record and
Replay stores.
```

a) Specify the ODBC data source name (DSN) that is used to connect to the database where the recorded data is stored, by setting the **dataSource** property.

b) Specify the schema name for the database tables that are used for storing recorded data, by setting the **schema** property.

   If you do not set this property, the default database schema is used.

c) Specify the names of the queue and backout queue to be used by the recorder, by setting the **queue** and **backoutQueue** properties. By default, these properties are set to SYSTEM.BROKER.DC.RECORD and SYSTEM.BROKER.DC.BACKOUT.

   If you specify non-default queues in the **queue** and **backoutQueue** properties, you must also specify them in the Record and Replay store in which the ODBC data source name is specified (using the **dataSource** property), and the Record and Replay store must be the one that is referenced from the business transaction definition (by default, BTMDataStore).

8. Enable Record and Replay for the integration server, by editing the server.conf.yaml file and setting the **recordReplayEnabled** property to true.

```
# Record and Replay requires a default queue manager to be associated with the integration
 server.
   RecordReplay:
     recordReplayEnabled: true           # Set to true to enable all Record and Replay
 functionality. Default is true.
```

Configure the integration server to use a default queue manager, and create the default system queues on the queue manager:

9. Configure the integration server to use a local or remote default queue manager, by specifying either the **defaultQueueManager** or **remoteDefaultQueueManager** property in the integration server's server.conf.yaml file. For example:

```
# The remoteDefaultQueueManager and defaultQueueManager properties are mutually exclusive.
 Uncomment only one of these two options.
      defaultQueueManager: 'defaultQM'            # Set non-empty string to specify a
 default queue manager
```

or

```
# The remoteDefaultQueueManager and defaultQueueManager properties are mutually exclusive.
 Uncomment only one of these two options.
      remoteDefaultQueueManager: '{myPolicyProject}:myMQEndpointPolicy'      # Specify an
 MQEndpoint policy in the format {policy project}:policy
```

10. Ensure that the SYSTEM.BROKER.DC.RECORD and SYSTEM.BROKER.DC.BACKOUT system queues have been created on the queue manager. If they do not exist, you can create them by running the iib_createqueues script, as described in “Creating the default system queues on an IBM MQ queue manager” on page 99.

Configure the required security permissions for users of the web user interface:

11. If administration security has been enabled on the integration server, ensure that users have the required permissions, by setting properties in the `Security` section of the integration server's `server.conf.yaml` file:
    - For viewing transactions, users require **`read`** access on the `DataPermissions` object and the `Permissions` object.
    - For creating and editing business transaction definitions and business transaction policies, users require **`write`** access on the `Permissions` object.
    - For starting and stopping the recording of business transactions, users require **`execute`** access on the `Permissions` object.

```
Security:
  Permissions:
    # Set Admin Security Authorization file permissions by web user role using 'read+:write
+:execute+' , or 'all+'
    # '+' grants permission, '-' denies permission
    # e.g. define the following web user roles 'viewRole' and 'adminRole'
    #viewRole:  'read+:write-:execute-'
    #adminRole: 'all+'
  DataPermissions:
    # Set Admin Security Authorization file permissions for Record and Replay web user role
 using 'read+:write+:execute+' , or 'all+'
    # '+' grants permission, '-' denies permission.  Record and Replay roles also require
 'read+' permission to be defined
    # in the Permissions section above.
    # e.g. define the following web user roles 'dataViewer', 'dataReplayer' and 'adminRole'
    #dataViewer:  'read+:write-:execute-'
    #dataReplayer: 'read+:write-:execute+'
    #adminRole: 'all+'
```

12. Ensure that the web user interface is configured. For more information, see “Configuring the IBM App Connect Enterprise web user interface” on page 87.

Enabling security for business transaction monitoring

You can restrict the users who can view and configure business transaction monitoring for an integration server, by enabling administration security and setting permissions for specified roles.

Before you begin

Read the following topics:

- “Authorizing users for administration” on page 2516
- “Monitoring business transactions” on page 2817

About this task

If you do not enable administration security, any user can complete any action against an integration node and its resources, or against an integration server and its resources. You can enable administration security and specify the authorization mode for an integration node or server, by using the **`mqsichangeauthmode`** command.

Procedure

To enable security for business transaction monitoring, complete the following steps:

1. Stop the integration node or server:
    - To stop an integration node or a managed integration server, stop the integration node by using the web user interface or by running the **`mqsistop`** command.
    - For an independent integration server, stop the integration server by stopping its **`IntegrationServer`** process. For more information, see “Stopping an integration server” on page 254.

2. Enable administration security for an integration node, or an integration server, and specify an authorization mode by using the **mqsichangeauthmode** command.

   For example, to enable administration security with the file-based authorization mode for the ACE12NODE integration node, enter the following command:

   ```
   mqsichangeauthmode ACE12NODE -s active -m file
   ```

   where `-s active` enables administration security for the integration node, and `-m file` specifies the file-based authorization mode.

   For more information, see "Enabling administration security" on page 2504.
3. Define the roles and their associated permissions:

   - If the integration node or integration server is configured to use file-based authorization (**file** mode), you define the roles and associated permissions on the integration node or integration server, by using the **mqsichangefileauth** command. For information about setting permissions for file-based authorization, see "Setting file-based permissions" on page 2530.
   - If the integration node or integration server is configured to use queue-based authorization (**mq** mode), you must create a system user ID on the operating system that is running your integration node, or integration server. You must then assign permissions to the system user ID, which is then used as a role. For information about setting permissions for queue-based authorization, see "Setting queue-based permissions" on page 2533.

   One or more web user IDs can be assigned to each role, and the permissions that were granted to the role are automatically granted to all web user IDs that are assigned to it. For more information, see "Role-based security" on page 2503 and "Managing web user accounts" on page 2510.
4. To allow users with an assigned role to view the results of business transaction monitoring on the integration server, set the required permissions for the role, using either file-based or queue-based permissions, depending on the authorization mode that is set for the integration node or integration server:

   - If you are using file-based authorization, set `read+` permission for the role for actions on the integration node or the integration server. For more information about file-based authorization, see "Setting file-based permissions" on page 2530.
   - If you are using queue-based authorization, set `+inq` permission for the role for actions on the queues SYSTEM.BROKER.AUTH and SYSTEM.BROKER.AUTH.*EG*. For more information about queue-based authorization, see "Setting queue-based permissions" on page 2533.
5. You must also set the required permissions for configuring business transaction monitoring, control the actions that users with a specified role (such as `ibmuser`) can complete on the integration node or server. Ensure that the role has the appropriate authorization to complete the required actions, as described in "Controlling access to data and resources in the web user interface" on page 2544.

   To change permissions for an integration node or server that is using file-based authorization, see "Setting file-based permissions" on page 2530. To change permissions for an integration node or server that is using queue-based permissions, see "Setting queue-based permissions" on page 2533.
6. Create a web user account by using the **mqsiwebuseradmin** command, and specify a role for the account. This account is the one that you will use to log on to the web user interface for using business transaction monitoring.

   For more information, see "Managing web user accounts" on page 2510.
7. Start the integration node or server:

   - Start an integration node or managed integration server by using the web user interface or by running the **mqsistart** command.
   - For an independent integration server, start the integration server by using the **IntegrationServer** command. For more information, see "Starting an integration server" on page 250.

What to do next

For information about how to configure business transaction monitoring, see “Configuring business transaction monitoring” on page 2820. For information about how to view the results of business transaction monitoring, see “Viewing the results of business transaction monitoring” on page 2830.

Creating a business transaction definition

Create a business transaction definition in the App Connect Enterprise web user interface, by specifying message flows and defining business events in an associated business transaction policy.

Before you begin

- Read the information in “Monitoring business transactions” on page 2817 and “Business transaction monitoring overview” on page 2818.
- Configure business transaction monitoring, as described in “Configuring business transaction monitoring” on page 2820.
- Ensure that IBM MQ is installed.

About this task

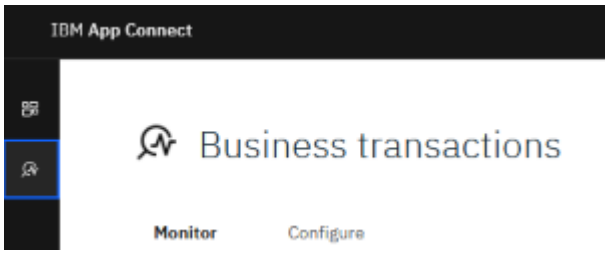
The business transaction definition contains information about the flows that participate in the transaction and the events that are monitored during the transaction. This definition includes information such as which events mark the beginning and end of a transaction, which events indicate that the transaction is in progress, and which events correspond to a failure in the transaction.

Procedure

To create a business transaction definition, complete the following steps:

1. Access the web user interface, as described in “Accessing the web user interface” on page 89.
2. Click the **Business transactions** icon to display the Business Transactions view for the integration server or integration node.

   The **Business transactions** icon is located in the side navigation links in the web user interface.

3. In the Business Transactions view, click the **Configure** tab.
4. In the Configure tab, click **Create a transaction definition**.

   The **Create a business transaction definition** panel is displayed.
5. Enter a name for the business transaction in the **Name** field.

   The name of the business transaction must be unique for the integration server. The name can contain only letters, numbers, and underscore (_) characters.
6. In the **Policy project** field, either select the policy project that will contain the business transaction policy for the new business transaction definition, or click **Create new policy project** and enter the name of a a new policy project.
7. In the **Policy** field, select the name of the business transaction policy in which the business events will be defined, or click **Create new policy** and enter the name of a new policy.

8. Click **Create** to create the new business transaction definition and, if applicable, a new business transaction policy.

   A new business transaction definition is created in the `stopped` state.
9. Add a new business event to the business transaction policy, by clicking **Create an event**.

   The **Create a business event** panel is displayed.
10. Enter the name of the business event in the **Name** field, and then select the event type that identifies the start, end, failure, or progress of the event, from the **Type** field:
    - A *start* business transaction event signifies that when a message is received on that node, the business transaction starts. You can choose any monitoring event to represent the start of a business transaction.
    - An *end* business transaction event signifies that when a message is received on that node, the business transaction is complete. You can choose any monitoring event to represent the end of a business transaction.
    - A *failure* business transaction event typically corresponds with a node that handles error processing. This event signifies that when a message reaches this node, the business transaction has failed.
    - A *progress* business transaction event can correspond with any type of node in a message flow. This event is used to monitor the progress of a transaction instance and signifies that a message has reached a particular node in the flow.

    Each business transaction definition requires a start event and an end event (in addition to any progress or failure events), and a warning message is displayed if they have not been defined. A warning message is also displayed if the flows have no monitoring events defined, or if no global transaction ID has been specified for the events.
11. When you have specified the name and type of the business event, specify the monitoring event that will be used for the business event, by selecting an integration, library, message flow, and monitoring event source, in the **Create a business event** panel. Then click **Create**.

    The business event is defined in the business transaction policy, and is displayed in the event definitions table for the business transaction definition.
12. Repeat steps “9” on page 2827, “10” on page 2827, and “11” on page 2827, until you have defined all the business events for your business transaction definition.

What to do next

Start the business transaction definition, as described in “Starting and stopping a business transaction definition” on page 2827. You can then view the results of a business transaction on the Monitor tab, as described in “Viewing the results of business transaction monitoring” on page 2830.

Starting and stopping a business transaction definition

Start or stop a business transaction definition by using the App Connect Enterprise web user interface.

Before you begin

Read the following topics:

- “Monitoring business transactions” on page 2817
- “Configuring business transaction monitoring” on page 2820

About this task

Before you can view the results of business transaction monitoring, you must start the business transaction definition. Before you can delete a business transaction definition, or make changes to its events, it must be stopped.

Procedure

- Start a business transaction definition by completing the following steps:
  1. Access the web user interface, as described in "Accessing the web user interface" on page 89.
  2. Click the **Business transactions** icon () to display the Business Transactions view for the integration server or integration node.
  3. In the Business Transactions view, click the **Configure** tab.
  4. Select the business transaction definition that you want to start, from the business transactions list on the left side of the panel.
  5. Click the actions icon (⋮) to display a list of options for the selected business transaction definition, and then click **Start monitoring**.
- Stop a business transaction definition by completing the following steps:
  1. Access the web user interface, as described in "Accessing the web user interface" on page 89.
  2. Click the **Business transactions** icon () to display the Business Transactions view for the integration server.
  3. In the Business Transactions view, click the **Configure** tab.
  4. Select the business transaction definition that you want to stop, from the business transactions list on the left side of the panel.
  5. Click the actions icon (⋮) to display a list of options for the selected business transaction definition, and then click **Stop monitoring**.

Updating a business transaction definition

Update the business events in a business transaction definition by using the web user interface or a text editor to modify the associated business transaction policy.

Before you begin

Before you update a business transaction definition, ensure that it is stopped, by following the instructions in "Starting and stopping a business transaction definition" on page 2827.

About this task

You can update the business events in a business transaction definition by using the web user interface. Alternatively, you can use a text editor to modify the business transaction policy in which the events for the business transaction are defined. The business transaction policy is typically created in the web user interface when the business transaction definition is created, as described in "Creating a business transaction definition" on page 2826.

If you move the policy from one deployment location to another, ensure that the integration node and server details for the business events are still correct for the new deployment location. For more information about the format of business transaction policies, see "Example business transaction policy" on page 2833.

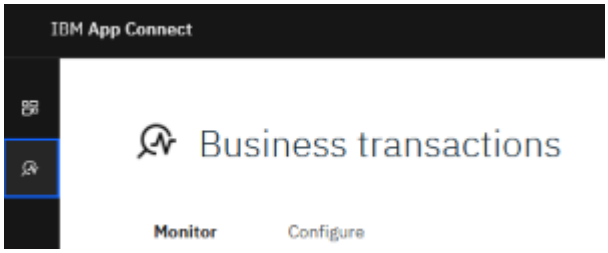
Procedure

Use the web user interface to update the business events in a business transaction definition, by completing the following steps:

1. Access the web user interface, as described in "Accessing the web user interface" on page 89.

2. Click the **Business transactions** icon to display the Business Transactions view for the integration server or integration node.

   The **Business transactions** icon is located in the side navigation links in the web user interface.



3. In the Business Transactions view, click the **Configure** tab.
4. Select the business transaction definition that you want to update, from the list on the left side of the panel.

   The business events that have been defined for the selected business transaction definition (if any) are displayed.

You can add, update, or delete business events in the selected business transaction definition, by completing the following steps:

5. Optional: **Add a business event** to the business transaction definition by completing the following steps:

   a) Click **Create an event**.

      The **Create a business event** panel is displayed.

   b) Enter the name of the business event in the **Name** field, and then select the event type that identifies the start, end, failure, or progress of the event, from the **Type** field:

      - A *start* business transaction event signifies that when a message is received on that node, the business transaction starts. You can choose any monitoring event to represent the start of a business transaction.
      - An *end* business transaction event signifies that when a message is received on that node, the business transaction is complete. You can choose any monitoring event to represent the end of a business transaction.
      - A *failure* business transaction event typically corresponds with a node that handles error processing. This event signifies that when a message reaches this node, the business transaction has failed.
      - A *progress* business transaction event can correspond with any type of node in a message flow. This event is used to monitor the progress of a transaction instance and signifies that a message has reached a particular node in the flow.

   c) When you have specified the name and type of the business event, specify the monitoring event that will be used for the business event, by selecting an integration, library, message flow, and monitoring event source, in the **Create a business event** panel. Then click **Create**.

      The business event is added to the business transaction policy, and is displayed in the event definitions table for the business transaction definition.

6. Optional: **Update a business event** by completing the following steps:

   a) Click the Edit icon ( ) in the row that contains the details of the event that you want to update.

      The **Edit a business event** panel is displayed.

   b) Modify the details that you want to update, such as the name or type of the business event, or the details of the monitoring event that will be defined as a business event, as described in step “5” on page 2829. When you have finished making the required changes, click **Save**.

7. Optional: **Delete a business event** from the business transaction definition by clicking the delete icon ( ) in the row that contains the details of the event that you want to delete, and then click the **Delete** button to confirm.

What to do next

Start the business transaction definition, as described in "Starting and stopping a business transaction definition" on page 2827. You can then view the results of a business transaction on the Monitor tab, as described in "Viewing the results of business transaction monitoring" on page 2830.

Deleting a business transaction definition

Delete a business transaction definition and its associated policy by using the App Connect Enterprise web user interface.

Before you begin

Before you delete a business transaction definition, ensure that it is stopped, by following the instructions in "Starting and stopping a business transaction definition" on page 2827.

About this task

When you delete a business transaction definition, you can choose whether to delete the associated business transaction policy, if there is one. However, if the policy is in use by other business transaction definitions, only the selected business transaction definition is deleted and the policy is retained.

Procedure

To delete a business transaction definition, complete the following steps:

1. Access the web user interface, as described in "Accessing the web user interface" on page 89.
2. Click the **Business transactions** icon ( ) to display the Business Transactions view for the integration server or integration node.
3. In the Business Transactions view, click the **Configure** tab.
4. Select the business transaction definition that you want to delete, from the list on the left side of the panel.
5. Click the actions icon ( ) to display a list of options for the selected business transaction definition, and then click **Delete**.
6. Confirm the deletion of the business transaction definition, by clicking **Delete** in the confirmation message.

   If the business transaction definition has a business transaction policy attached to it, you are prompted to delete that policy as long as it is not being used by other business transaction definitions. If an attached business transaction policy is in use by other business transaction definitions, it is retained when the selected business transaction definition is deleted.

Results

The business transaction definition and policy are removed from the Business Transactions view, but the business transaction results remain in the database until you remove them by using another method.

Viewing the results of business transaction monitoring

View the results of business transaction monitoring in the App Connect Enterprise web user interface.

Before you begin

- Read the information in "Monitoring business transactions" on page 2817 and "Business transaction monitoring overview" on page 2818.
- Create a business transaction definition, as described in "Creating a business transaction definition" on page 2826.

About this task

To see the results of the business transaction, complete the following steps:

Procedure

1. In the App Connect Enterprise web user interface, click the **Business Transactions** icon ().
   The Business Transactions window is displayed, containing a **Monitor** tab and a **Configure** tab.
2. Click the **Monitor** tab.
3. Select the required business transaction definition from the displayed list.

   The data for the selected business transaction is presented in charts and in a results table. The donut chart shows the total number of instances of the business transaction, and the number of instances that are in each state (In progress, Complete, Inconsistent, and Failed). You can display the data for transaction instances that have occurred during a specified time period, from the last 15 minutes to the last 365 days, by selecting a value from the pull-down menu above the donut chart.

   You can also choose whether to view a chart showing the number of transactions in each state, or a chart showing the duration of transactions in each state, by selecting either **Number of transactions** or **Transaction duration** from the pull-down menu. The **Number of Transactions** chart shows the number of instances of the business transaction in each state, by date. The **Transaction duration** chart shows the duration of the business transaction instances in each state, by date. In both charts, you can display the transaction instances that occurred within a specific time frame, from the last 15 minutes to the last 365 days, by selecting a value from the pull-down menu. A maximum of 1000 transaction instances can be displayed.

   The results table shows the transaction ID of each individual transaction instance, its status, the time that it started, when it was last updated, and the duration. You can reorder the information in the table by clicking the heading above a column. For example, to arrange the transaction instances in the table based on their status, click the **Transaction status** column heading.

   By default, all instances of the selected business transaction in the last 365 days are displayed, including those that have failed, those that have completed successfully, those that are still in progress, and those that have been marked as inconsistent. If a transaction instance has a status of `Inconsistent`, it means that a problem occurred during the transaction that prevented it from being resolved as `In progress`, `Complete`, or `Failed`. For example, if a transaction passed through your flows twice, two start events and two end events would be received, and the transaction would be marked `Inconsistent`.

4. Optional: You can filter the data in the results table to include a subset of transaction instances, based on their status, transaction ID, start time, and the date of their last update, by clicking the **Filter** button above the table.

   The **Build a query** dialog is displayed, in which you can add one or more of the following conditions to the filter:

   - **Transaction status:** To display only the transaction instances that are in a particular state, complete the following steps:
     a. In the **Build a query** dialog, click **Add condition**
     b. Select **Transaction status** from the first pull-down menu, then select the required status from the subsequent menus.
     c. Click **Apply**.

     The results table is updated to display only the transaction instances with the specified transaction status, which can be one or more of `Complete`, `In progress`, `Inconsistent`, or `Failed`.
   - **Transaction ID:** To display only the transaction instance with a specified ID, complete the following steps:
     a. In the **Build a query** dialog, click **Add condition**
     b. Select **Transaction ID** from the first pull-down menu, then define the search criteria for the required transaction IDs by specifying details in the subsequent menus.
     c. Click **Apply**.

     The results table is updated to display only the transaction instances that match the specified condition. For example, if you specify a transaction ID of `trans-id1`, all transaction IDs that include that string are displayed, including `trans-id1`, `trans-id10`, `trans-id100`, and `trans-id1000`, if they exist.
   - **Start time:** To display only transaction instances that started before or after a specified time, complete the following steps:
     a. In the **Build a query** dialog, click **Add condition**
     b. Select **Start time** from the first pull-down menu, then select either `Before` or `After`, then specify the required date and time from the subsequent menus.
     c. Click **Apply**.

     The results table is updated to display only the transaction instances that started during the specified time period.
   - **Last updated:** To display only the instances that were last updated before or after a specified time, complete the following steps:
     a. In the **Build a query** dialog, click **Add condition**
     b. Select **Last updated** from the first pull-down menu, then select either `Before` or `After`, and then specify the required date and time from the subsequent menus.
     c. Click **Apply**.

     The results table is updated to display only the transaction instances that were last updated during the specified time period.

5. To see the latest updates at any time, click the Refresh icon ().
6. You can display more detailed information about any individual transaction instance, by clicking the transaction ID in the table.

   A table is displayed, containing information about each of the business events that were received during the transaction instance. This information includes the time that the business event was received, the event name, the event type, the message flow, and the integration.

   You can display more detailed information about the monitoring event, including any message payload that was included in the event, by clicking on the timestamp.

Example business transaction policy

Example business transaction policy file.

You can update the business events in a business transaction definition by using the web user interface or a text editor to modify the associated business transaction policy.

If you move the policy from one deployment location to another, ensure that the integration node and server details for the events are still correct for the new deployment location.

The following example shows the type of information that might be contained in a business transaction policy:

```
{
  "eventSources": {
    "startEventSources": [
      {
        "name": "Start overall business transaction - FILE",
        "integrationNodeName": "DemoNode",

      },
      {
        "name": "Fail - rollback business transaction - FILE",
        "integrationNodeName": "DemoNode",
        "integrationServerName": "default",
        "integrationName": "IN-OUT",
        "libraryName": null,
        "flowName": "INOUT",
        "eventSourceAddress": "fileinput.transaction.Rollback"
      }
    ]
  }
}
```

For more information, see “Monitoring business transactions” on page 2817 and “Creating a business transaction definition” on page 2826.

Recording, viewing, and replaying data

Record data that is processed by a message flow and replay the data.

About this task

If you configured your message flow to emit event messages, the monitoring events publish selected message data, which you can then view or replay (resubmit for processing). The record function subscribes to the published monitoring data, and stores the data in a database. You can then view the data, or replay it by resending the message to an IBM MQ queue through the web user interface or by using the administration REST API.

For more information about recording and replaying data, see “Record and replay” on page 2835. For more information about monitoring events, see “Configuring monitoring for message flows” on page 2788.

To record, view, and replay data, follow these steps:

Procedure

1. Configure IBM App Connect Enterprise to record data. For more information, see “Recording data” on page 2837.
2. Configure the monitoring event points in the message flow.

   For more information, see “Configuring monitoring for recording” on page 2847.
3. Deploy your message flow.

   For more information, see “Deployment rules and guidelines” on page 2465.
4. Configure IBM App Connect Enterprise to view recorded data through the web user interface or the administration REST API. For more information, see “Viewing recorded data” on page 2849.
5. Replay data to an IBM MQ queue by using the web user interface or the administration REST API. For more information, see “Replaying data” on page 2850.
6. (Required if security is enabled.) If you want to view or replay recorded data through the web user interface, you must create a web user account by using the **mqsiwebuseradmin** command. See “Managing web user accounts” on page 2510 and command.
7. If you want to control users' ability to record, view, and replay data, you must enable integration node administration security, and also configure security for recording. For information, see “Enabling administration security” on page 2504 and “Enabling security for record and replay” on page 2835.
8. If you want to use different integration nodes or different independent integration servers for deploying your message flows and for recording data from those message flows to a database, you

must configure a publish/subscribe relationship between the integration nodes or integration servers. For more information, see “Using multiple integration nodes and multiple independent integration servers for record and replay” on page 2851.

Record and replay

For audit or problem determination purposes, you can record data to a database, then view it, and replay it.

Video: Record and Replay

This video describes the key concepts of Record and Replay, and demonstrates an overview of how to configure and use Record and Replay.

If you need an audit record of messages that pass through the message flows, you can record those messages. You might also want to record messages if you need to keep a history of messages for development and test purposes, or to help in problem determination. For more information, see “Recording data” on page 2837.

To determine which data is recorded, you must configure monitoring on the message flow. For more information, see “Configuring monitoring for recording” on page 2847. Data is stored in a database, which can be an Oracle, Microsoft SQL Server, or DB2 database. For more information, see “Creating and configuring a database for recording data” on page 2841. You must create a data source, then use a policy to define the data source name to use when recording data.

After you have recorded data, you can view it in several ways. By using the web user interface, you can view a list of recorded messages, or you can view details of a specific message. You can also view recorded data by using the IBM App Connect Enterprise REST API. For more information, see “Viewing recorded data” on page 2849.

You can replay a message to an IBM MQ queue by using the web user interface or the REST API. You can also replay the message to another message flow for testing or problem determination. For more information, see “Replaying data” on page 2850.

Enabling security for record and replay

You can restrict the users who can view and replay data for an integration server manged by an integration node, or an independent integration server, by enabling administration security and setting permissions for specified roles.

Before you begin

Read the following topics:

- “Authorizing users for administration” on page 2516
- “Recording data” on page 2837

About this task

If you do not enable administration security, any user can complete any action against an integration node and its resources, or an integration server and its resources. You can enable administration security and specify the authorization mode for an integration node, or an integration server by using the **mqsichangeauthmode** command.

Procedure

To enable security for record and replay, complete the following steps:

1. Stop the integration node or integration server:
   - To stop an integration node or an integration server managed by an integration node, stop the integration node by using the web user interface or by running the **mqsistop** command.
   - For an independent integration server, stop the integration server by stopping its **IntegrationServer** process. For more information, see "Stopping an integration server" on page 254.
2. Enable administration security for an integration node, or an integration server, and specify an authorization mode by using the**mqsichangeauthmode** command.

   For example, to enable administration security with the file-based authorization mode for the ACE11NODE integration node, enter the following command:

   ```
   mqsichangeauthmode ACE11NODE -s active -m file
   ```

   where `-s active` enables administration security for the integration node, and `-m file` specifies the file-based authorization mode.

   For more information, see "Enabling administration security" on page 2504.
3. Define the roles and their associated permissions:
   - If the integration node or integration server is configured to use file-based authorization (**file** mode), you define the roles and associated permissions on the integration node or integration server, by using the **mqsichangefileauth** command. For information about setting permissions for file-based authorization, see "Setting file-based permissions" on page 2530.
   - If the integration node or integration server is configured to use queue-based authorization (**mq** mode), you must create a system user ID on the operating system that is running your integration node, or integration server. You must then assign permissions to the system user ID, which is then used as a role. For information about setting permissions for queue-based authorization, see "Setting queue-based permissions" on page 2533.

   One or more web user IDs can be assigned to each role, and the permissions that were granted to the role are automatically granted to all web user IDs that are assigned to it. For more information, see "Role-based security" on page 2503 and "Managing web user accounts" on page 2510.
4. To allow users with an assigned role to run record and replay queries on the integration server, set the required permissions for the role, using either file-based or queue-based permissions, depending on the authorization mode that is set for the integration node or integration server:
   - If you are using file-based authorization, set `read+` permission for the role for actions on the integration node or the integration server. For more information about file-based authorization, see "Setting file-based permissions" on page 2530.
   - If you are using queue-based authorization, set `+inq` permission for the role for actions on the queues SYSTEM.BROKER.AUTH and SYSTEM.BROKER.AUTH.*EG*. For more information about queue-based authorization, see "Setting queue-based permissions" on page 2533.
5. You must also set the required permissions for recording to control the record and replay actions that users with a specified role (such as `ibmuser`) can complete on the integration node or integration server. Ensure that the role has the appropriate authorization to complete the required actions, as described in "Controlling access to data and resources in the web user interface" on page 2544.

   To change permissions for an integration node, or integration server that is using file-based authorization, see "Setting file-based permissions" on page 2530. To change permissions for an integration node, or integration server that is using queue-based permissions, see "Setting queue-based permissions" on page 2533.
6. Create a web user account by using the **mqsiwebuseradmin** command, and specify a role for the account. This account is the one that you will use to log on to the web user interface for viewing and replaying data.

   For more information, see "Managing web user accounts" on page 2510.

7. Start the integration node or integration server:
   - Start an integration node or an integration server managed by an integration node, by using the web user interface or by running the **mqsistart** command.
   - For an independent integration server, start the integration server by using the **IntegrationServer** command. For more information, see “Starting an integration server” on page 250.

What to do next

To view data that has been recorded, see “Viewing recorded data” on page 2849. To replay data that has been recorded, see “Replaying data” on page 2850.

Recording data

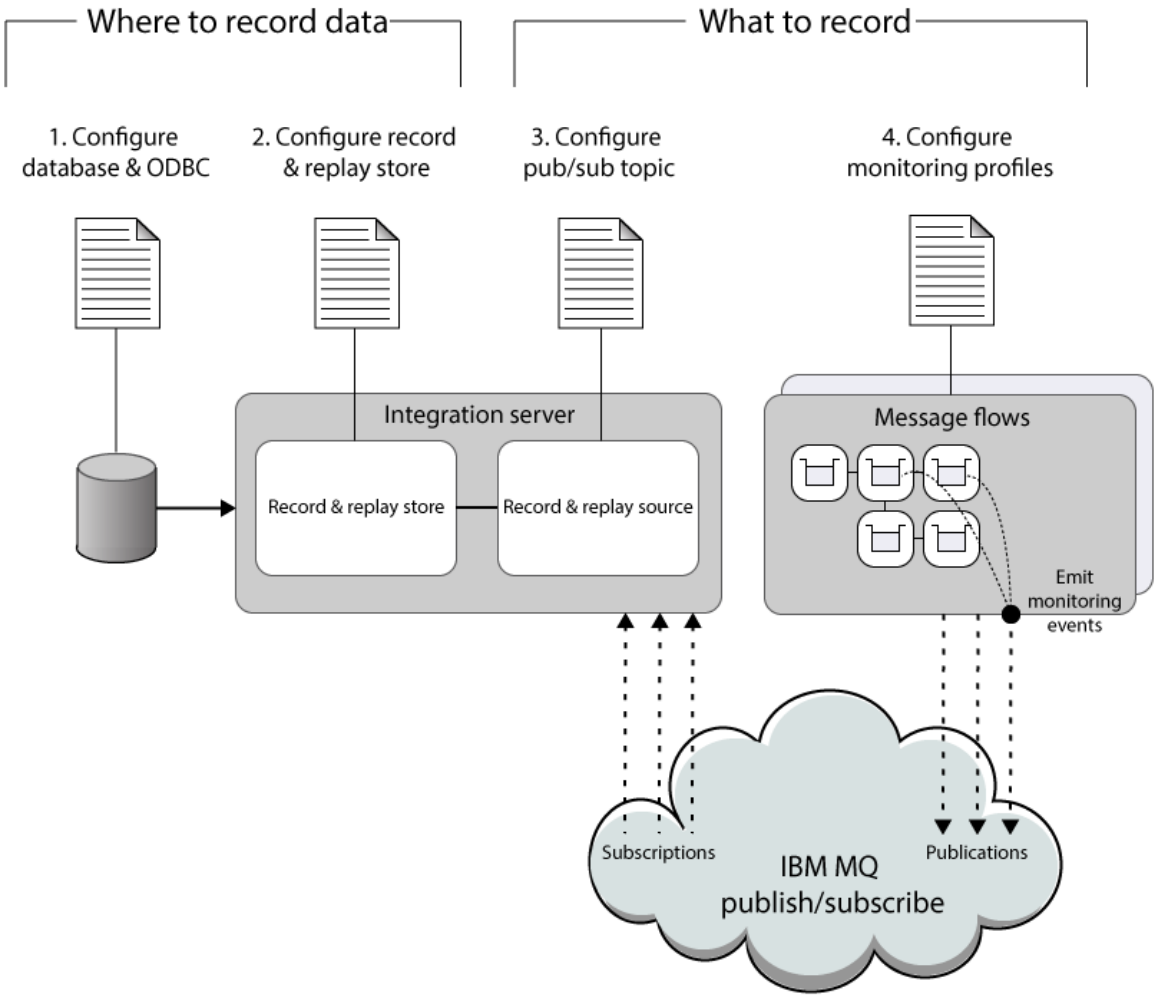
Record data that is flowing through a message flow.

Before you begin

Ensure that the message flow for which you want to record data has been deployed. For more information, see “Deployment rules and guidelines” on page 2465.

About this task

You can record data to a database for audit purposes, or to help with problem determination. To record data, you must identify the source of the data that you want to record and the place that you want to record it to. The steps that you take to record data are shown in the following diagram:



Procedure

Complete the following tasks to set up data recording. The sequence of these tasks is important. If they are not completed exactly as shown, BIP message BIP2194 is generated on startup.

1. Create and configure your database, and define an ODBC definition for the data source name (DSN). Specify an ID and password for your integration node to use when connecting to the database. See “Creating and configuring a database for recording data” on page 2841.
2. Configure the record and replay store for your integration server. See “Configuring data recording” on page 2839.

   Your record and replay topology can include more than one independent integration server or integration node. See “Using multiple integration nodes and multiple independent integration servers for record and replay” on page 2851.

3. Specify a publish/subscribe topic that identifies the source of the data that you want to record, by modifying the **topic** property of your record and replay source in the `server.conf.yaml` file for the integration server. For more information, see "Configuring data recording" on page 2839.

   Test that your subscription to the topic was successful by retrieving the subscriptions on the queue manager for your integration server.

   Use the **runmqsc** command to check the subscription. Complete the following steps:

   a. At a command prompt, type `runmqsc` *qmName*, where *qmName* is your queue manager name.

   b. To display all the queue manager subscriptions, type `dis sub(*)`

   c. Check that the topic name is returned in the list of subscription topics, for example SUB(*integrationServerName*:myTopic)

   d. To exit the **runmqsc** environment, type end

4. To generate the data that you want to record, configure monitoring on your message flows. See "Configuring monitoring for recording" on page 2847.

What to do next

- You can enable security for recording data by following the instructions in "Enabling security for record and replay" on page 2835.
- After you have recorded data, you can view it. For more information, see "Viewing recorded data" on page 2849.
- You might want to turn off recording for a particular integration server temporarily (for performance reasons, for example). For more information, see "Disabling and enabling Recording" on page 2853.
- For more information about tuning recording, See "Tuning data recording" on page 2848.
- If you use different integration nodes or independent integration servers for deploying your message flows and for recording data from those message flows to a database, then you must configure a publish/subscribe relationship between the integration nodes or integration servers . For more information, see "Using multiple integration nodes and multiple independent integration servers for record and replay" on page 2851.

Configuring data recording

Recording of data is enabled by default but takes effect only if you configure it by modifying the `server.conf.yaml` file for the integration server.

Before you begin

You must associate a queue manager with the independent integration server or the integration node that is managing integration servers. For more information, see "Creating an integration node" on page 114 and command.

About this task

You can modify the `server.conf.yaml` file to configure recording for your integration server.

Procedure

Modify the `server.conf.yaml` file to configure recording for your integration server by completing the following steps:

1. Stop the integration server. See "Stopping an integration server" on page 254.
2. Open the `server.conf.yaml` configuration file for your integration server by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, because they are invalid in YAML and

would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
The properties that you need to set are in the **RecordReplay** section of the `server.conf.yaml` configuration file:

```
RecordReplay:
  recordReplayEnabled: true  # Set to true to enable all Record and Replay functionality.
 Default is true.
```

3. Set the **recordReplayEnabled** property to `true`.
4. Copy and customize the StoreTemplate section for each record and replay store that you want to create. For example:

```
RecordReplay:
....
  Stores:
    ..
    MBRECORD_store:
      dataSource: 'MBRECORD' # The ODBC data source name (DSN) that is used to connect to the
 database that stores the recorded data. This property is mandatory and has no default value.
      schema: 'myschema'                       # The schema name that owns the database
 tables that are used for storing recorded data. This property has no default value. If no
 value is set, either the default database schema is used (if there is one), or no schema is
 used, depending on the database.
      storeMode: 'all'  # The mode for the store to operate in. Valid values are record,
 view, and all. Default is all.
```

   a) Change the heading **StoreTemplate** to the name of your store. For example, `MBRECORD_store`.
   b) Set the **dataSource** property to the ODBC name of your database. For example, `MBRECORD`.
   c) Set the **schema** property to the name of your schema for the database tables. For example, `myschema`.
   d) Set the **storeMode** property to `all`.

   Specifying `all` for the **storeMode** property lets you use the store for recording and viewing/replaying.

   If you only want to use the store for recording:

   a. Set the **storeMode** property to `record`.
   b. Create another store, perhaps on a different integration server, for viewing/replaying.
   c. Set the **storeMode** property of the new store to `view`.

   There are other store properties you can set. For more information, see “Tuning data recording” on page 2848.
5. Copy and customize the SourceTemplate section for each record and replay source that you want to create. For example:

```
RecordReplay:
....
  Sources:
    ..
    MBRECORD_source:
      topic: '$SYS/Broker/[nodename]/Monitoring/[servername]/[applicationname]/[flowname]'  #
 Sets the subscription topic that is used for business-level monitoring of a message flow.
```

```
      store: 'MBRECORD_store' # The Record and Replay store that is used to configure record
and replay for the message flows specified in the topic property. Multiple instances of
Record and Replay source can refer to one instance of a Record and Replay store.
```

a) Change the heading **SourceTemplate** to the name of your source. For example, `MBRECORD_source`.

b) In the **topic** property, set the *nodename* to the name of your integration node.

c) In the **topic** property, set the *servername* to the name of your integration server.

d) In the **topic** property, set the *applicationname* to the name of your application.

e) In the **topic** property, set the *flowname* to the name of your message flow.

f) Set the **store** property to the name of your record and replay store. For example, `MBRECORD_store`.

A durable subscription is created for each source and is created with an id of *nodename*:*servername*:*sourcename*. If multiple independent integration servers share the same queue manager, you must ensure that each subscription has unique values for *nodename*, *servername* and *sourcename*. If you delete a source, you must manually delete the durable subscription for that source to avoid messages being published to the record and replay store's queue. For more information, see Deleting a local subscription in the IBM MQ product documentation.

6. Start the integration server. See "Starting an integration server" on page 250.

What to do next

You are now ready to start recording, viewing, and replaying your data. See "Recording data" on page 2837, "Viewing recorded data" on page 2849, and "Replaying data" on page 2850.

Creating and configuring a database for recording data

To record data, create a database and configure an ODBC definition to it. Configure your integration server so that it can connect to the database.

Before you begin

Read the concept topic "Record and replay" on page 2835. For an overview of tasks that you must complete to record data, see "Recording data" on page 2837.

About this task

You can record data to a database for audit purposes, or to help with problem determination.

A script is provided with IBM App Connect Enterprise that you can use to create the database and database tables. You can run this script unmodified, or you can customize it. The script creates a database called MBRECORD with a default schema. After creating the database, you create an ODBC definition to identify the data source name (DSN) for the database. You use the **mqsisetdbparms** command to set a user identifier and password for the integration server to use when connecting to the database. The script creates some tables that are not currently used, and are reserved for future use, such as WMB_EVENT_FIELDS and WMB_EVENT_TYPES.

You can record data to DB2, Microsoft SQL Server, and Oracle databases. For information about how to create and configure your database, see the following topics:

- "Creating and configuring a DB2 database for recording data" on page 2842
- "Creating and configuring an Oracle database for recording data" on page 2843
- "Creating and configuring a Microsoft SQL Server database for recording data" on page 2844
- "Using Integrated Windows Authentication when recording data with a Microsoft SQL Server database" on page 2845

What to do next

Continue to follow the steps for recording data; see "Recording data" on page 2837.

Creating and configuring a DB2 database for recording data

To record data to a DB2 database, create the database and configure an ODBC definition to it. Configure your integration server so that it can connect to the database.

Before you begin

Read the following topics:

- "Record and replay" on page 2835
- "Recording, viewing, and replaying data" on page 2834
- "Creating and configuring a database for recording data" on page 2841

Procedure

1. Use the script that is provided with IBM App Connect Enterprise to create and configure a DB2 database to store your recorded data. Note that the script creates some tables that are not currently used, and are reserved for future use, such as WMB_EVENT_FIELDS and WMB_EVENT_TYPES.
   a) Locate the script for your operating system:
      - Windows: *install_dir*`\server\ddl\db2\DataCaptureSchema.sql`
      - Linux or UNIX: *install_dir*`/server/ddl/db2/DataCaptureSchema.sql`

      install_dir is the location of your IBM App Connect Enterprise installation.
   b) Optional: To specify your own database or schema, customize the provided `DataCaptureSchema` script, and save your changes.

      If you modify the SQL to specify a particular schema, you must also set the same schema name in the `server.conf.yaml` file. See "Configuring data recording" on page 2839.

      You might also want to edit the script for the following reasons:

      - If you ran the script, and want to run it again, you must drop the database MBRECORD first. Insert the command `drop database MBRECORD` before the line that reads `create database MBRECORD`.
      - The maximum message body size that you can record (after encoding has taken place) is 5 MB. The default size is 5 MB, but you can increase this size by editing the script to make the value in the WMB_BINARY_DATA.DATA column larger.
   c) At a command line, navigate to the script location and run it.

      On Windows, use a **DB2 Command Window** to ensure that the command environment is set up correctly. Click **Start** > **IBM DB2** > ***databaseInstance*** > **Command Line Tools**, and select **Command Window**, where *databaseInstance* is the DB2 installation name.

      On Linux and UNIX, a script called `db2profile` is provided for setting up the environment; for more information, see "Running database setup scripts before starting an integration node" on page 83.

      When the command environment is set up, you can run the script.

      For example, on Windows, UNIX, or Linux, enter the following command:

      ```
      db2 -tvf DataCaptureSchema.sql
      ```
2. Create an ODBC definition for the database.

   If you used the supplied script to create your database without modifications, create an ODBC definition for the database called MBRECORD, with MBRECORD as the data source name (DSN). For more information, see "Enabling ODBC connections to the databases" on page 184.

3. Use the **mqsisetdbparms** command to set a user identifier and password for the integration server to use when connecting to the database; for example:

```
mqsisetdbparms -w workDir -n dataSourceName -u userID -p password
```

   - *workDir* is the name of the work directory for your integration server.
   - *dataSourceName* identifies the database to which you want to record data.
   - *userID* and *password* specify the user identifier and the password that the integration server uses to connect to the database.
4. To ensure that the changes to the **mqsisetdbparms** command take effect, restart the integration server.

   For more information, see "Starting an integration server" on page 250.
5. Test the connection to your database by using the **mqsicvp** command.

   For more information, see command.

What to do next

Continue to follow the steps for recording data; for more information, see "Recording data" on page 2837.

Creating and configuring an Oracle database for recording data

To record data to an Oracle database, create the database tables and configure an ODBC definition. Configure your integration server so that it can connect to the database.

Before you begin

Read the following topics:

- "Record and replay" on page 2835
- "Recording, viewing, and replaying data" on page 2834
- "Creating and configuring a database for recording data" on page 2841

About this task

Procedure

1. Use the script that is provided with IBM App Connect Enterprise to create and configure the Oracle database tables in the default table space, which is where your recorded data will be stored. Note that the script creates some tables that are not currently used, and are reserved for future use, such as WMB_EVENT_FIELDS and WMB_EVENT_TYPES.

   a) Locate the script for your operating system:

   - Windows: *install_dir*\server\ddl\oracle\DataCaptureSchema.sql
   - Linux or UNIX: *install_dir*/server/ddl/oracle/DataCaptureSchema.sql

   install_dir is the location of your IBM App Connect Enterprise installation.

   b) On Oracle, enter the following command to run the script:

```
sqlplus user/password @DataCaptureSchema.sql
```

2. Create an ODBC definition for the database.

   If you used the supplied script to create your database without modifications, create an ODBC definition for the database called MBRECORD, with MBRECORD as the data source name (DSN). For more information, see "Enabling ODBC connections to the databases" on page 184.

3. Use the **mqsisetdbparms** command to set a user identifier and password for the integration node to use when connecting to the database; for example:

   ```
   mqsisetdbparms -w workDir -n dataSourceName -u userID -p password
   ```

   - *workDir* is the name of the work directory for your integration server.
   - *dataSourceName* identifies the database to which you want to record data.
   - *userID* and *password* specify the user identifier and the password that the integration server uses to connect to the database.
4. To ensure that the changes to the **mqsisetdbparms** command take effect, restart the integration server.

   For more information, see "Starting an integration server" on page 250.
5. Test the connection to your database by using the **mqsicvp** command.

   For more information, see command.

What to do next

Continue to follow the steps for recording data; for more information, see "Recording data" on page 2837.

Creating and configuring a Microsoft SQL Server database for recording data

To record data to a Microsoft SQL Server database, create the database, and configure an ODBC definition to it. Configure your integration server so that it can connect to the database.

Before you begin

Read the following topics:

- "Record and replay" on page 2835
- "Recording, viewing, and replaying data" on page 2834
- "Creating and configuring a database for recording data" on page 2841

About this task

The following steps describe how to create the SQL Server database, create an ODBC definition, and set a user ID and password for the database.

You can use Integrated Windows Authentication to specify a Windows user account to be used for authentication when using Microsoft SQL Server to record and replay data. For more information, see "Using Integrated Windows Authentication when recording data with a Microsoft SQL Server database" on page 2845.

Procedure

1. Use the script that is provided with IBM App Connect Enterprise to create and configure an SQL Server database to store your recorded data. Note that the script creates some tables that are not currently used, and are reserved for future use, such as WMB_EVENT_FIELDS and WMB_EVENT_TYPES.
   a) Locate the script at *install_dir*`\server\ddl\sqlServer\DataCaptureSchema.sql`, where *install_dir* is the location of your IBM App Connect Enterprise installation.
   b) Optional: Customize the provided DataCaptureSchema script.

      If you modify the SQL to specify a particular schema, you must also set the same schema name in the `server.conf.yaml` file. See "Configuring data recording" on page 2839.
   c) To run the script, at a command line, navigate to the script location and enter the following command:

      ```
      sqlcmd -d databaseName -i DataCaptureSchema.sql
      ```

2. Create an ODBC definition for the database.

   If you used the supplied script to create your database without modifications, create an ODBC definition for the database that is called MBRECORD, with MBRECORD as the data source name (DSN). For more information, see "Enabling ODBC connections to the databases" on page 184.
3. Use the **mqsisetdbparms** command to set a user identifier and password for the integration server to use when it connects to the database.
   For example:

   ```
   mqsisetdbparms -w workDir -n dataSourceName -u userID -p password
   ```

   - *workDir* is the name of the work directory for your integration server.
   - *dataSourceName* identifies the database to which you want to record data.
   - *userID* and *password* specify the user identifier and the password that the integration server uses to connect to the database.

   Windows If Integrated Windows Authentication is being used for SQL Server database access, then the service user ID under which the process runs is used by Windows to access the SQL Server database. That is, it ignores any user ID and password credentials that are set using the **mqsisetdbparms** command.
4. To ensure that the changes to the **mqsisetdbparms** command take effect, restart the integration server.

   For more information, see "Starting an integration server" on page 250.
5. Test the connection to your database by using the **mqsicvp** command.

   For more information, see command.

What to do next

Follow the steps for recording data. See "Recording data" on page 2837.

Using Integrated Windows Authentication when recording data with a Microsoft SQL Server database

Integrated Windows Authentication (IWA) refers to a set of authentication protocols that are used by Windows clients and servers. You can use IWA with IBM App Connect Enterprise to provide transport-level security when you are recording data with a Microsoft SQL Server database.

Before you begin

Read the following topics:

- "Record and replay" on page 2835
- "Recording, viewing, and replaying data" on page 2834
- "Creating and configuring a database for recording data" on page 2841

About this task

You can use IWA to specify a Windows user account to be used for authentication when using Microsoft SQL Server to record and replay data. The following steps describe how to create the SQL Server database, create a Windows user account, and give that user account permission to access the SQL Server.

For more information about how to set up Microsoft SQL Server for record and replay without using IWA, see "Creating and configuring a Microsoft SQL Server database for recording data" on page 2844.

Procedure

1. Use the script that is provided with IBM App Connect Enterprise to create and configure an SQL Server database to store your recorded data. Note that the script creates some tables that are not currently used, and are reserved for future use, such as WMB_EVENT_FIELDS and WMB_EVENT_TYPES.
   a) Locate the script at *install_dir*\server\ddl\sqlServer\DataCaptureSchema.sql, where *install_dir* is the location of your IBM App Connect Enterprise installation.
   b) Optional: Customize the provided DataCaptureSchema script.
   c) To run the script, at a command line, navigate to the script location and enter the following command:

   ```
   sqlcmd -d databaseName -i DataCaptureSchema.sql
   ```

2. Create a Windows user account to be used for authentication.
   a) Ensure that you are logged on as the administrator, then create a new user account with non-administrator privileges. Provide a user name and password, ensuring that the user name has fewer than 12 characters.
   b) Add this user to the mqbrkrs group by using the **mqsisetsecurity** command.
3. Create an integration node and set the serviceUserId and servicePassword to the user name and password of the authenticating Windows user account.
4. Ensure that you are logged on as the SQL Server administrator, then give the Windows user account permission to access the SQL Server instance.
   a) Start the SQL Server Management Studio.

      For more information, see your SQL Server documentation.
   b) Connect to the database instance for which you want to set up authentication.
   c) In the instance tree, navigate to **Security** > **Logins**, right-click **Logins**, and select **New Login**.
   d) Ensure that **Windows Authentication** is selected.
   e) Click **Search**, locate the user ID to use, then click **OK**.

      The user ID typically has the format DOMAIN/USERNAME. To search the instance location, click **Advanced**, then click **Find Now**. You can then select the name from the list of possible options.
   f) To map the user ID to the databases that are used for recording and replaying data, navigate to the **User Mapping** page in the instance tree. Select the relevant databases and ensure that the correct DOMAIN/USERNAME combination and default database schema are specified.
   g) To create the user login, accept all other default values and click **OK**.
5. Create the necessary ODBC connections that target the databases that are used for recording and replaying data. This step involves defining the data source that the record and replay store uses.
   a) Open the Windows Control Panel and navigate to **System and Security** > **Administrative Tools** > **Data Sources (ODBC)**.
   b) On the **System DSN** tab, create a new data source by clicking **Add**.
   c) Select **SQL Server Native Client**, then click **Finish**.
   d) Provide a name for your ODBC data source, select the relevant SQL Server, then click **Next**.
   e) Ensure that SQL Server is set to verify authenticity by using Integrated Windows authentication, then click **Next**.
   f) Change the default database to use the database that is used as the store for recording and replaying data, then click **Next**.
   g) Accept the remaining default value, then click **Finish**.
   h) Test that the data source connects successfully to the SQL Server database by clicking **Test Data Source**.

      If the test is successful, a success message is issued. To complete setup, click **OK**.

What to do next

Next:

Create the record and replay store by following the steps in "Recording data" on page 2837. Ensure that the data source that you created in this task is used as the target for the record and replay store.

Configuring monitoring for recording

Determine which data you want to record, and configure your message flows to emit this data, by using monitoring events. Learn about the differences between how you configure event sources for record and replay and for business-level monitoring.

Before you begin

Create and configure a database, and specify the IBM App Connect Enterprise runtime properties that are required for recording data. See "Recording data" on page 2837.

About this task

Record and replay is based on a publish/subscribe model. To specify the data that you want to record to a database, you configure your message flows to emit event messages. These messages contain the data that you want to record. The messages are published to a topic that you specify when you update the `server.conf.yaml` file. See "Configuring data recording" on page 2839. The integration server subscribes to the topic and routes the published messages to the database.

The mechanism that is used for configuring message flows to emit event messages for record and replay is also used for business-level monitoring. This mechanism is summarized in the concept topic "Configuring monitoring for message flows" on page 2788, and is described further on in this topic. Because record and replay and business-level monitoring can share event sources and monitoring events, you must ensure that the configuration for one does not inadvertently affect the other. Before you begin to configure monitoring for record and replay, you need to be aware of some specific considerations that relate to the use of the monitoring mechanism for recording data for record and replay.

- When you view your recorded data in the web user interface, you might see one or more errors in the **Exception** column. You can retrieve the exception data for these errors only if you included the exception list (`$ExceptionList`) when you created your monitoring events.
- You can record messages from many different providers and sources. However, you can replay messages to IBM MQ destinations only.

  When you configure a monitoring event, you can choose to include all of the message bitstream data, the headers only, or the message body only. When an integration server replays a message, it needs to include an IBM MQ message header. It handles this requirement in one of the following ways:

  – If the recorded data includes an IBM MQ header, the integration node uses the existing IBM MQ message header.
  – If the recorded data does not include an IBM MQ header, the integration server generates an IBM MQ header. All other headers are appended to the message payload.

Procedure

To configure monitoring on a message flow to emit events for record and replay, use the following method:

- Configure and enable event sources, and activate monitoring for the message flow, by completing the steps in "Configuring monitoring for message flows" on page 2788.

The subscription to the monitoring events is durable, which results in messages being put to the queue specified in the `queueName` property of the `server.conf.yaml` file. Messages can be put to this queue even when the integration server is not running. For more information about how you can monitor the queue depth and tune data recording, see "Tuning data recording" on page 2848.

What to do next

Review the steps that you completed for recording data; see “Recording data” on page 2837. Now you are ready to view the data that you recorded; see “Viewing recorded data” on page 2849.

Tuning data recording

You can change the integration server configuration to improve performance and message throughput when you are recording data. You can configure the number of integration servers and queues used to process the data, the size of the thread pool that is used by each integration server, and how often data is committed. You can also use more than one database for storing data by creating multiple record and replay stores.

About this task

You can modify the `server.conf.yaml` file to tune recording for your integration server. See “Configuring data recording” on page 2839.
Consider each of the following factors of a record and replay store when designing your integration server configuration for record and replay.

threadPoolSize
: This property of a record and replay store determines the number of threads that are used by the recorder to process the monitoring topic subscriptions. The default value is 10.

commitCount
: The `commitCount` property of a record and replay store identifies the number of input messages that are processed on each thread before a sync point is taken. Decreasing the value of `commitCount` can improve performance.

commitIntervalSecs
: The `commitIntervalSecs` property of a record and replay store identifies the time interval at which a commit is taken when the `commitCount` property is greater than 1 but the number of messages processed has not reached the value of the `commitCount` property. Increasing the value of `commitIntervalSecs` can improve performance.

storeMode
: The `storeMode` property of a record and replay store sets the mode for the store to operate in. Valid values are `record`, `view`, and `all`. The default value is `all`, meaning that you can record, view, and replay the data. You can spread workload by specifying multiple stores with different integration servers for recording and viewing data specified for each one.

record and replay stores and record and replay sources
: The relationship between record and replay stores and record and replay sources is one-to-many. To use multiple sources for storing recorded data, you can define several sources. To increase the number of integration servers and queues used to process data for recording and viewing, you can change the ratio of sources to stores. For more information, see “Using multiple integration nodes and multiple independent integration servers for record and replay” on page 2851.

queue Name and backoutQueue
: The `queueName` property of a record and replay store specifies the queue that is used for holding data before it is recorded. The `backoutQueue` property of a record and replay store specifies the queue that is used for backing out messages that cannot be processed. You can use the default queues or you can create new queues so that the data is spread across multiple queues. The same `backoutQueue` can be specified for multiple record replay stores.

  You can configure IBM MQ to warn when queue depths are close to their maximum size. For more information, see the topics about "Event monitoring" in the IBM MQ documentation.

  You can also increase the maximum queue depth and the maximum message length for queues by using the **runmqsc** command.

  Complete the following steps:

1. At a command prompt, enter the following command, where *qmName* is the name of your queue manager:

```
runmqsc qmName
```

2. Confirm the current settings for your queue by running the following command, where *qName* is the name of the relevant queue; for example, SYSTEM.BROKER.DC.RECORD. If your queue name contains lowercase characters, you must enclose the queue name in single quotation marks.

```
dis qlocal(qName) maxdepth,maxmsgl
```

3. Enter the following command, where *qName* is the name of your queue, *newMaxDepth* is the new setting for maximum queue depth, and *newMaxMsgL* is the new setting for maximum message length:

```
alter qlocal(qName) maxdepth(newMaxDepth) maxmsgl(newMaxMsgL)
```

4. To exit the **runmqsc** environment, type end

Viewing recorded data

You can view a list of recorded messages, or details of individual messages.

Before you begin

Ensure that you have completed all the steps in "Recording data" on page 2837, "Configuring data recording" on page 2839, and "Configuring monitoring for recording" on page 2847.

About this task

You can view recorded data from the web user interface or from the administration REST API.

Procedure

To configure IBM App Connect Enterprise to view recorded data, complete the following steps:

1. Ensure your record and replay stores are configured to allow viewing. For more information, see "Configuring data recording" on page 2839.
2. Use one of the following methods to view your data:
   - View recorded data and administer your integration nodes or integration servers from the web user interface:
     a. Configure a web administration server, as described in "Configuring the IBM App Connect Enterprise web user interface" on page 87.
     b. Log on to the web user interface. For more information, see "Accessing the web user interface" on page 89.
     c. Select the **Data** tab of an integration node or integration server. All record and replay stores on the integration node or integration server that have been configured for viewing are displayed.
     d. Select the record and replay store containing the data that you want to view. Each row that is displayed represents a recorded message.
     e. You can select which columns will appear in the web user interface. The selection persists when you log out and when other users view the same record and replay store.
     f. You can download the bitstream data for a message by clicking the arrow in the **Data** column.
     g. You can create and apply a query to filter the list of messages in the record and replay store.
     h. You can show message creation times in either Coordinated Universal Time (UTC) or local time.
   - Use the administration REST API. For more information, see "Managing resources by using the administration REST API" on page 334.

Replaying data

When you have recorded data, you can replay it to a queue by using the web user interface or the administration REST API.

Before you begin

Configure your system to record data and to view the recorded data. See “Recording data” on page 2837 and “Viewing recorded data” on page 2849.

Procedure

To replay data to an IBM MQ queue, complete the following steps:

1. Ensure that your record and replay stores are configured to allow viewing. For more information, see “Configuring data recording” on page 2839.
2. Stop the integration server. See “Stopping an integration server” on page 254.
3. Open the `server.conf.yaml` configuration file for your integration server by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor. However, you must ensure that you do not include any tab characters, because they are invalid in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
4. Update the `server.conf.yaml` file to define the IBM MQ queues to which you can replay data. The properties that you need to set are in the **RecordReplay** section of the `server.conf.yaml` configuration file.
   Copy and customize the MQDestinationTemplate section for each Record and Replay destination that you want to create. For example:

   ```
   RecordReplay:
              ...
              Destinations:
                 MQDestination:
                 endpointType: 'WMQDestination'             # The type of the target destination
    to which messages will be replayed. The default is WMQDestination, which is the only valid
    value.
                 endpoint: 'wmq:/msg/queue/[QUEUE]@[QMGR]'  #
   ```

   a) Change the heading **MQDestinationTemplate** to the name of your data destination, for example, `MQDestination`.

   b) Set the **endpointType** property to `WMQDestination`.

   c) Set the **endpoint** property to include the name of the queue and, optionally, the queue manager.

   If the queue manager is not specified (`'wmq:/msg/queue/[QUEUE]'`), the default local or remote queue manager for the integration server is used.
5. Start the integration server. See “Starting an integration server” on page 250.

6. Use one of the following methods to replay your data:
   - Use the IBM App Connect Enterprise web user interface:
     a. Configure the web user interface, as described in "Configuring the IBM App Connect Enterprise web user interface" on page 87.
     b. Log on to the web user interface. For more information, see "Accessing the web user interface" on page 89.
     c. Select the **Data** tab of the integration node or integration server. Selecting the **Data** tab displays all the record and replay stores in the integration node or integration server that have been configured for viewing.
     d. Select the record and replay store that contains the data that you want to replay. Each row that is displayed represents a recorded message.
     e. Select the messages that you want to replay. You can replay only messages that have data.
     f. Click **Mark for replay**. The selected messages are added to the replay list in the **Replay** tab; they are not replayed at this stage.
     g. Select the destination for your data. The list of available destinations corresponds to the destinations that you defined when you updated the `server.conf.yaml` file.
     h. You can now select the messages to replay.
     i. Click **Replay**. The selected messages are sent to the specified destination. Messages that are not delivered are highlighted. You can replay messages multiple times. To remove a message from the list, select the message and click **Remove**.
   - Use the administration REST API. For more information, see "Managing resources by using the administration REST API" on page 334.

Using multiple integration nodes and multiple independent integration servers for record and replay

You can have multiple integration nodes or multiple independent integration servers in your record and replay topology. If you use different integration nodes or different integration servers for deploying your message flows, and for recording data from those message flows to a database, then you must configure a publish/subscribe relationship between the integrations nodes or integration servers.

Before you begin

Read the concept topic "Record and replay" on page 2835.

About this task

You can use separate integration nodes or integration servers for deploying the message flows from which you want to record data and for viewing the data from a database. The integration node or integration server that is used for viewing and replaying data does not interact with the integration node or integration server that is used to record data to a database. However, if the integration node or integration server to which you deploy your message flows is not the recording integration node or integration server, then you must set up a publish/subscribe relationship between these integration nodes or integration servers.

Data recording is based on a publish/subscribe model. You configure monitoring on message flows that you deployed to an integration node or integration server, for example, to integration server *MONSERV*. This publishes to the topic that you specify when you configure your monitoring events. The topic identifies the source of the data that you want to record. You specify this topic when you update the `server.conf.yaml` file. see "Configuring data recording" on page 2839

You can record on any integration node or integration server but view and replay must use the same integration server.

In this scenario, *MONSERV* publishes on the monitoring topic and *RECSERV* subscribes to the topic. If *MONSERV* runs on queue manager *MONQM* and *RECSERV* runs on queue manager *RECQM*, then you need to configure a publish/subscribe relationship between *MONQM* and *RECQM*.

You can choose to create either a cluster or a hierarchical publish/subscribe relationship between the two queue managers. If you plan to add queue managers to your topology frequently, then a cluster relationship is more appropriate. See the topics on "Publish/subscribe topologies" in the IBM MQ product documentation online. This example uses a hierarchical relationship. In the example, values enclosed in single quotation marks can be replaced with your preferred values, but keep the quotation marks if you use lowercase characters. Complete the following steps:

Procedure

1. Establish a point-to-point channel connection between *MONQM* and *RECQM*.
   a) On a command line on the server that hosts *MONQM*, enter `runmqsc MONQM`
   b) Define a transmission queue for *MONQM* to use when forwarding messages to *RECQM*:

```
DEFINE QLOCAL('RECQM') USAGE(XMITQ) TRIGGER TRIGDATA('MONQM.TO.RECQM')
 INITQ(SYSTEM.CHANNEL.INITQ)
```

   c) Define a sender channel:

```
DEFINE CHANNEL('MONQM.TO.RECQM') CHLTYPE(SDR) TRPTYPE(TCP) CONNAME('RECQM.SERVER')
 XMITQ(XMIT)
  DESCR('Sender channel from MONQM to RECQM')
```

   RECQM.SERVER is the name of the server that hosts *RECQM*.
   d) Define a receiver channel:

```
DEFINE CHANNEL('RECQM.TO.MONQM') CHLTYPE(RCVR) TRPTYPE(TCP)
   DESCR('Receiver channel from RECQM to MONQM')
```

   e) Configure a listener on the queue manager:

```
DEFINE LISTENER ('LISTENER.TCP') TRPTYPE(TCP) PORT(PORT) CONTROL(QMGR)
```

   PORT is the port number on which the listener listens.
   f) Start the listener. Enter `START LISTENER('LISTENER.TCP')`
   g) Enter END to finish the **RUNMQSC** session.
   h) Now configure *RECQM*. On the server that hosts *RECQM*, enter the following commands at a command line:

```
runmqsc RECQM

DEFINE QLOCAL('MONQM') USAGE(XMITQ) TRIGGER TRIGDATA('RECQM.TO.MONQM')
 INITQ(SYSTEM.CHANNEL.INITQ)
DEFINE CHANNEL('RECQM.TO.MONQM') CHLTYPE(SDR) TRPTYPE(TCP) CONNAME('MONQM.SERVER')
 XMITQ(MONQM)
  DESCR('Sender channel from RECQM to MONQM')
DEFINE CHANNEL('MONQM.TO.RECQM') CHLTYPE(RCVR) TRPTYPE(TCP)
  DESCR('Receiver channel from MONQM to RECQM')
DEFINE LISTENER ('LISTENER.TCP') TRPTYPE(TCP) PORT(PORT) CONTROL(QMGR)
START LISTENER ('LISTENER.TCP')
END
```

   MONQM.SERVER is the name of the server that hosts *MONQM*, and *PORT* is the port number on which the listener listens.

   For more information about configuring channels for publish/subscribe, see the topics on "Publish/subscribe topologies" in the IBM MQ product documentation online.

2. Configure the queue manager publish/subscribe hierarchy.

   Make *RECQM* a child of *MONQM* by completing the following steps:

   a) Open a command line on the server that hosts *RECQM*, and enter: `runmqsc RECQM`

   b) Make *RECQM* a child of *MONQM*:

   ```
   ALTER QMGR PARENT('MONQM')
   ```

   To make *RECQM* a child of *MONQM*, the Parent queue manager name must be given as *MONQM*.

   Confirm that the operation worked by listing all publish/subscribe relationships for this queue manager:

   ```
   DIS PUBSUB TYPE(ALL)
   ```

   The output shows that *MONQM* is now the parent of *RECQM*:

   ```
   AMQ8723: Display pub/sub status details.
      QMNAME(RECQM)                           TYPE(LOCAL)
   AMQ8723: Display pub/sub status details.
      QMNAME(MONQM)                           TYPE(PARENT)
   ```

   c) Type END to end the **RUNMQSC** session for *RECQM*.

   d) Start a **RUNMQSC** session for *MONQM* and display the publish/subscribe types, as you did for *RECQM*. The output shows that *RECQM* is a child of *MONQM*.

What to do next

Consider the performance implications of your record and replay topology; see "Tuning data recording" on page 2848.

Complete the steps for recording data; see "Recording data" on page 2837.

Disabling and enabling Recording

Recording of data is enabled by default but can be disabled by modifying the `server.conf.yaml` file.

About this task

You might want to temporarily stop recording for an integration server for performance reasons, or to modify the integration server. You can disable recording for your integration server by modifying the `server.conf.yaml file`.

Procedure

Modify the `server.conf.yaml` file to disable or enable recording for your integration server by completing the following steps:

1. Stop the integration server. See "Stopping an integration server" on page 254.
2. Open the `server.conf.yaml` configuration file for your integration server by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, because they are invalid in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
   The property that you need to set is in the **RecordReplay** section of the `server.conf.yaml` configuration file:

   ```
   RecordReplay:

       #recordReplayEnabled: 'true' # Valid values are true and false.
   ```

3. Set the **recordReplayEnabled** property to `false`.
4. Start the integration server. See "Starting an integration server" on page 250.

What to do next

You have now disabled recording for your integration server. When you are ready to start recording again, repeat the above procedure, and set the **recordReplayEnabled** property to `true` at step "3" on page 2853.

Activity Logs

Use Activity Logs as the first point of investigation when something unexpected happens in a message flow and associated external resources.

Before you begin

- Read the concept topic "Activity Log overview" on page 2854.
- Read the reference topic, "Activity Logs structure and types" on page 2858 for more information about the structure and content of Activity Logs, and about the *tags* that you can use to enrich the log data and filter its content.
- View and configure the runtime properties for Activity Logs, by following the steps described in "Viewing and setting runtime properties for Activity Logs" on page 2855.

About this task

Activity Logs provide immediate, basic information about what is happening in your message flows, and how they are interacting with external resources.

Procedure

- To view recent Activity Log information for individual message flows, use the Activity Log view in the web user interface.

  For more information, see "Viewing Activity Logs for message flows in the web user interface" on page 2856.
- If you would like to view activities over a longer period, you can use an Activity Log policy to write Activity Logs to files, to publish them to Logstash in an ELK stack, or both, as described in Activity Log policy (ActivityLog), and "Writing Activity Logs to files or to Logstash in an ELK stack" on page 2857.

Activity Log overview

Activity Logs help you to understand what your message flows are doing by providing a high-level overview of how IBM App Connect Enterprise interacts with external resources. They do not require detailed product knowledge, and can be used to enhance understanding of the overall system.

Activity Log messages are concise and avoid technical complexity, although more information is provided in the message detail. Because the log entries are short, uncomplicated, and focused on single activities, they can be quickly scanned and understood. Identifying patterns of behavior and changes in behavior can be done more easily with Activity Log messages than if you use more extensive product trace. The qualitative data about resources that are provided in Activity Logs complements the quantitative resource data that is provided by resource statistics. Because Activity Logs are enabled by default, they can be useful for troubleshooting. For example, if the Activity Log for a message flow shows a prolonged period of inactivity, review the Activity Logs for associated resource types. You might discover that a problem with an external resource is the reason why messages are no longer being processed by your message flow.

Activity Logs can be written to a circular file system. Use the Activity Log policy to set up file logging if you want continuous logging of activities over a long period. The policy has extensive filtering capabilities, based on *tags*. You can use tags to search or filter on various attributes, such as resource types or message flow names. All Activity Log messages have several tags, which are displayed in the log entries and can be used as search and filter keys. Individual resource types also have resource-specific tags that you can use to retrieve the data that you are interested in. For more information, see Activity Log policy (ActivityLog), and "Writing Activity Logs to files or to Logstash in an ELK stack" on page 2857.

Activity Logs can also be viewed in the web user interface. For more information, see "Viewing Activity Logs for message flows in the web user interface" on page 2856.

For more information about the types Activity Logs that are available in IBM App Connect Enterprise, see "Activity Logs structure and types" on page 2858.

Viewing and setting runtime properties for Activity Logs

Display and modify the runtime properties that govern the behavior of Activity Logs within the scope of a single integration server.

About this task

You can view and set properties for Activity Logs by modifying the `server.conf.yaml` configuration file for the integration server. For example, you can use these properties to change the number of Activity Log entries held in memory, or to limit log entries to error messages.

The properties that can be set are:

- activityLogEnabled

  This property takes a Boolean value that indicates whether Activity Log entries are kept in memory. The default value for this property is `true`.

- defaultLogSizePerThread

  This property takes an integer value that determines the maximum number of Activity Log entries that are written to memory before the log is recycled. The default value is `1000`. The property can have any positive integer value.

  If the thread on which the log is processed terminates (for example, because you redeploy or restart the integration server), the log entries that are held in memory are lost. When you diagnose a problem, save the current activity log before you redeploy or restart your integration server.

- minSeverityLevel

  This property takes an integer value that is used to specify the severity of messages that are written to the Activity Log.

  Only messages with a severity level higher than or equal to the specified value for this property are logged. The initial value of the property is `INFO`, which means that messages of all severities are written to the log.

  Valid values are `INFO`, `WARN`, and `ERROR`, where `ERROR` is the highest severity level and `INFO` the lowest.

  Specify a value of `WARN` to log messages of severity levels `WARN` and `ERROR`.

To display the current Activity Log configuration properties and then modify them, complete these steps:

Procedure

1. Open the `server.conf.yaml` configuration file for your integration server, by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor. However, you must ensure that you do not include any tab characters because they are invalid in YAML and would cause your integration server configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
2. Set the **`activityLogEnabled`** property to `true`.
3. Set the **`defaultLogSizePerThread`** property to the maximum number of Activity Log entries that you want to be written to memory before the log is recycled. The default value is `1000`.
4. Set the **`minSeverityLevel`** property to specify the minimum severity of messages that you want to be written to the Activity Log. The default is `INFO`.

5. Restart the integration server for the changes to take effect.

   For more information about how to start an integration server, see “Starting an integration server” on page 250.

Viewing Activity Logs for message flows in the web user interface

View Activity Log data for a message flow by using the web user interface.

Before you begin

- Read the concept topic “Activity Log overview” on page 2854.
- Start the web user interface for your integration node or integration server, as described in “Accessing the web user interface” on page 89.

About this task

Each row within a log represents an activity. For more information about what is displayed for each activity, see “Activity Logs structure and types” on page 2858.

Activity Logs are enabled by default. You can view the data in the web user interface if the message flow is deployed to an integration node or an integration server that is running.

To view Activity Logs in the web user interface:

- Browse to the message flow for which you want to view activity logs.
- Click the **Activity Log** tab.
- Click **Fetch Activity Log**.
- Optionally, customize the view by using the **Entries per page** field, or reordering the data in the columns.

The following procedure describes the process in more detail.

Procedure

To open the Activity Log view for a message flow, complete the following steps:

1. Click the **Open List of Options** icon for the required integration server. Then click Open in the menu.

   The **Open List of Options** icon appears within the tile for each integration server.
2. Click the **Open List of Options** icon for the required application, and then click Open in the menu.

   The **Open List of Options** icon appears within the tile for each deployed application.
3. Click the **Open List of Options** icon for the required message flow, and then click Open in the menu.

   The **Open List of Options** icon appears within the tile for each message flow.
4. Click the **Activity Log** tab to open the Activity Log view.

5. Click **Fetch Activity Log** to populate the Activity Log view.

   For each activity log entry, you can see the following information.

   - **Timestamp**: The date and time of the activity entry. Click the column header to change the sort order of the messages.
   - **Message**: The BIP message ID that is associated with the activity log entry.
   - **Thread ID**: The thread number that is associated with the activity log entry. Click the magnifying glass icon to see only messages with the same thread ID. To reset the activity log to show all messages, click the magnifying glass icon again.
   - **Node**: The message flow node that the activity log relates to.
   - **Resource Manager**: The resource manager (if any) that is associated with the activity log entry.
   - **Message Details**: A summary of the message. Click the message ID in the **Message** column in the same row to see the full contents of the message.
   - **Tag**: Information about the type of node the activity log relates to.

   Note: The activity log view loads only when you first click **Fetch Activity Log**. It does not reload if you leave the **Activity Log** tab and then return to it. To see the most up-to-date information, click **Refresh** in the tab header.
6. Optional: Use the menu in the **Entries per page** field to select the number of entries displayed on the page.

   The default value is `10`. Available values are `10`, `25`, `50`, `100`. `500`, and `1000`.
7. Optional: Use the menu in the **pages** field to select the required page number when the entries are displayed on more than one page.
8. Optional: Click one of the column headings that are listed in step “5” on page 2857 to reorder the data in forward or reverse order on the selected column.

   By default, the entries in the Activity Log view are ordered on the **Timestamp** column in chronological order.
9. Optional: Type a *Thread ID*, for example, `1234`, into the **Search** field to filter the entries in the Activity Log view to show only entries with the specified *Thread ID*. To revert to showing all entries, click the "x" in the **Search** field.

   If no activity logs match the specified *Thread ID*, the message "No activity logs match the current filter" appears.
10. Optional: Click the magnifying glass icon in one of the rows in the **Thread ID** column. If the magnifying glass icon displays a "+" sign before you click it, the Activity Log view changes to show only entries with the same *Thread ID* as the selected row. If the magnifying glass icon displays a "-" sign before you click it, the Activity Log view changes to show all activity log entries.
11. Optional: Click a message ID in the **Message** column to see the full details and the timestamp of the message.
12. Optional: Click **Export** to export the activity logs to a file. The file `activityLog.json` is created in the `Downloads` subdirectory of the user's home directory.

Writing Activity Logs to files or to Logstash in an ELK stack

You can define an Activity Log policy to write your Activity Logs to a file system, to a Logstash input in an ELK stack, or both. Configure the policy to capture the Activity Log data that you are interested in.

About this task

Use the filtering capabilities of this feature to customize the log content and make it relevant to your needs. You can configure the size and number of log files and the criteria by which the log rotates from one file to the next. You can also identify the location and file name of the log files.

You can use the Activity Log policy to configure the following Activity Log file characteristics:

- Whether file logging is enabled

- The maximum number of files used for each log
- The maximum size of the log files (before the log rotates to the next file)
- The maximum age of the log files (before the log rotates to the next file)
- Filters that determine the content of the logs
- The severity levels of messages logged
- The log path and file name
- Whether messages are formatted with inserts included in the message text
- The scope of the policy (which integration server it applies to)

You can also use the Activity Log policy to configure the following Activity Log ELK properties:

- Enable or disable publication to ELK
- Reference the ELk Connection configuration to be used

For more information about the properties that can be set and their possible values, see Activity Log policy (ActivityLog). The scope of the settings is the integration server. For example, if you set the **Number of log files** property to 5, each integration server has a maximum of five files for its Activity Log.

The files are in UTF-8 format.

Procedure

1. Create an Activity Log policy by using the Policy editor in the IBM App Connect Enterprise Toolkit (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).
2. Define appropriate values for the properties in the policy, as described in Activity Log policy (ActivityLog).

What to do next

Deploy the Activity Log policy before or with the message flows that it applies to.

Activity Logs structure and types

Activity Logs contain information about message flows and how they interact with external resources. They can be generated for a message flow or a resource type. Learn about the structure and content of Activity Logs, and about the *tags* that enrich the log data and can be used to filter its content.

You can choose to write activity logs to a file, as described in "Writing Activity Logs to files or to Logstash in an ELK stack" on page 2857.

You can also display Activity Log data in the Activity Log view of the web user interface, as described in "Viewing Activity Logs for message flows in the web user interface" on page 2856.

Activity Log columns

The data in Activity Logs is organized in columns. The following columns are displayed by default:

Table 93. Log Columns

Column title	Description
MessageNumber	The message identifier
Severity	The severity of the message (whether the message is informational, a warning or an error)
Timestamp	The date and time that the activity occurred (taken from the computer that is hosting the integration server)
ThreadID	The identifier of the thread on which the activity message was generated.

Table 93. Log Columns (continued)	
Column title	**Description**
FormattedMessage	The formatted activity message (with all inserts resolved)
Inserts	The message inserts
RM	A resource type name
MSGFLOW	A message flow name

Activity Log tags

One of the important features of the Activity Log is the use of *tags* to enrich the log data. *Tags* are strings that represent significant categories of data that can be used for filtering and for providing additional information.

In the Log Columns table, the column headings RM and MSGFLOW are examples of tags.

Some tags are generic across all types of log, but some are specific to individual resource types. The following tags apply to all types of Activity Log:

Table 94. Generic Activity Log tags.		
Name	**Description**	**Valid values**
RM	The name of the resource type to which the activity relates	• Aggregation • CICS • Connect:Direct • GlobalCache • JDEDWARDS • JMS • Kafka • Loopback • MQTT • ODBC • ODM • PEOPLESOFT • REST • Salesforce • SAP • SIEBEL
MSGFLOW	The name of the message flow to which the activity relates	Any valid message flow name
NODE	The name of the message flow node from where the Activity Log message is generated.	Any valid message flow node name

Table 94. Generic Activity Log tags. (continued)		
Name	**Description**	**Valid values**
NODETYPE	The type of the message flow node from where the Activity Log message is generated.	• INPUT • OUTPUT • READ • REQUEST • REPLY • RECEIVE
HOSTNAME	The name of the host server where the Activity Log message is generated.	Any valid hostname
PORT	The listening port of the host server where the Activity Log message is generated.	Any valid port
CONNECTION_EVENT	An event that relates to a change in the state of the connection.	• CONNECTION_EVENT.CONNECTED • CONNECTION_EVENT.PLANNED_DISCONNE • CONNECTION_EVENT.UNPLANNED_DISCON • CONNECTION_EVENT.FAILURE
FILENAME	A file name	Any valid file name
FILEPATH	The fully qualified path to the file specified using the `FILENAME` tag	Any valid file path

For more information about the types of activities that are logged for individual resource types, and about the additional tags for particular resource types, see the following topics:

- "Aggregation Activity Log" on page 2861
- "CICS Activity Log" on page 2861
- "Global Cache Activity Log" on page 2862
- "IBM Sterling Connect:Direct Activity Log" on page 2863
- "JMS Activity Log" on page 2864
- "Kafka Activity Log" on page 2865
- "LoopBack Activity Log" on page 2865
- "MQTT Activity Log" on page 2866
- "ODBC Activity Log" on page 2866
- "ODM Activity Log" on page 2867
- "REST Request Activity Log" on page 2868
- "Salesforce Activity Log" on page 2868
- "WebSphere Adapters Activity Log" on page 2869

Aggregation Activity Log

Provides a high-level overview of how IBM App Connect Enterprise processes aggregation requests with external systems to better understand which aggregations are in progress and waiting for responses from end systems.

Activity Log content

Activity Log entries for Aggregation include the following types of activity:

- An aggregation group is started.
- All the aggregation requests that have been sent to end systems.
- All the aggregation requests that have received responses from end systems.
- The successful completion of an aggregation, containing all expected replies.
- The timeout of an aggregation, containing all received replies.
- Any unknown replies received from end systems.

Activity Log tags

In addition to the generic Activity Log tags, there are additional tags that are specific to Aggregation. These tags enrich the logged information and can also be used for filtering.

For more information about the generic tags, see “Activity Logs structure and types” on page 2858. The following table lists the additional Aggregation tags.

Table 95. Activity Log tags.

Name	Description	Valid values
AGGREGATE_NAME	The name of the aggregation as defined on the aggregation control node.	Any valid aggregate name string.
FOLDER	The name of the aggregate request folder for a request.	Any valid aggregate folder name string.
AGGREGATE_ID	The unique id for an aggregation	A 24-byte binary field that is displayed as 48 hex characters.
REPLY_ID	The unique id for an aggregation request to an end system.	A 24-byte binary field that is displayed as 48 hex characters.
PROTOCOL	The type of transport that is used for sending the aggregate request.	Any protocol that is supported by the aggregate nodes.
REPLIES	The number of aggregate replies received.	Any valid positive integer.
TIMEOUT	The time in seconds for the aggregate timeout.	A positive decimal with only one decimal place.

CICS Activity Log

Learn about the specifics of CICS Activity Logs.

Activity Log content

Activity Log entries for CICS include the following types of activity:

- A CICS program was called successfully

- A call to a CICS program failed
- A security identity contained in a message was propagated to CICS
- A security failure occurred when calling CICS
- A communications failure occurred when connecting to a CICS server
- A new transaction was started during flow processing
- CICS resources were committed during a flow transaction
- CICS resources were rolled back during a flow transaction
- A CICS abend occurred
- A timeout occurred during a CICS request
- An SSL connection failed when connecting to a CICS server

Activity Log tags

In addition to the generic Activity Log tags, there are additional tags that are specific to CICS. These tags enrich the logged information and can also be used for filtering.

For more information about the generic tags, see "Activity Logs structure and types" on page 2858. The following table lists the additional CICS tags.

Table 96. Activity Log tags

Name	Description	Valid values
CICS_SERVER	The CICS system against which the activity has been performed	Any valid CICS system
CICS_PROGRAM	The initiated CICS program	Any valid CICS program

Global Cache Activity Log

The global cache activity log provides a high-level overview of how IBM App Connect Enterprise interacts with the global cache or external grid, so that you can understand what your message flows are doing.

Activity Log content

Activity Log entries for the global cache include the following types of activity:

- A message flow puts data into a map.
- A message flow gets data from a map.
- A message flow updates data in a map.
- A message flow removes data from a map.
- A message flow checks if a map contains a specified key.
- A message flow fails to complete an action on a map.
- An integration server connects successfully to an embedded cache or external grid.
- An integration server fails to connect to an embedded cache or external grid.
- A catalog server started successfully.
- A catalog server failed to start.
- A container server started successfully.
- A container server failed to start.

Activity Log tags

In addition to the generic Activity Log tags, more tags are specific to the global cache. These tags enrich the logged information and can also be used for filtering.

For more information about the generic tags, see "Activity Logs structure and types" on page 2858. The following table lists the additional global cache tags.

Name	Description	Valid values
CACHEMAP	The name of the map in the global cache.	Any valid map name.
CACHENAME	The name of the WebSphere eXtreme Scale grid for this cache.	For the embedded global cache, the cache name is WMB. For an external grid, this value is the grid name that is specified in the policy.

IBM Sterling Connect:Direct Activity Log

Learn about the specifics of Connect:Direct Activity Logs.

Activity Log content

Activity Log entries for Connect:Direct include the following types of activity:

- A file is sent from a CDOutput node.
- A file is received by a CDInput node.
- A node starts to process a file.
- A node finishes processing a file.

Activity Log tags

In addition to the generic Activity Log tags, there are additional tags that are specific to Connect:Direct. These tags enrich the logged information and can also be used for filtering.

For more information about the generic tags, see "Activity Logs structure and types" on page 2858. The following table lists the additional Connect:Direct tags.

Table 97. Activity Log tags.

Name	Description	Valid values
CDPNODE	The primary Connect:Direct server	Any valid Connect:Direct server
CDSNODE	The secondary Connect:Direct server	Any valid Connect:Direct server
CDPROCESSNAME	The name given to a process that is run in Connect:Direct	Any valid process name
CDPROCESSNUMBER	The identifier of the process specified in the *CDPROCESSNAME* tag	Any valid process number

JMS Activity Log

Learn about the specifics of JMS Activity Logs, including the types of activity logged and the tags that can be used for filtering on these activities.

Activity Log content

Here are some examples of the type of JMS node activities that are logged in a JMS Activity Log:

- Connected to a JMS provider
- Created a non-transactional session for a JMS provider
- Received a message from a queue
- Browsed a queue
- Sent a message to a queue
- Published to a topic
- Timed out, waiting for a message on a queue
- Sent a message to a backout queue
- Failed to connect to a JMS provider

Activity Log tags

In addition to the generic Activity Log tags, there are additional tags that are specific to JMS. These tags enrich the logged information and can also be used for filtering.

For more information about the generic tags, see “Activity Logs structure and types” on page 2858. The following table lists the additional JMS tags.

Table 98. Activity Log tags.

Name	Description	Valid values
JMSPROVIDER	The JMS provider configured on the JMS node	Any valid JMS provider
CONNECTIONFACTORYNAME	The name of the connection factory that is used to create a connection to the JMS provider	Any valid connection factory name
JNDIBINDINGSLOCATION	The location used to look up Java Naming and Directory Interface (JNDI) Administered objects such as connection factories and destinations	Any valid system path or Lightweight Directory Access Protocol (LDAP) location
INITIALCONTEXTFACTORY	The fully qualified class name of the class used to perform JNDI lookups	Any valid initial context factory
JMSTRANSACTIONMODE	The transaction mode configured on the JMS node	• yes • no

Kafka Activity Log

The Kafka Activity Log provides a high-level overview of how IBM App Connect Enterprise interacts with Apache Kafka servers by using the KafkaProducer and KafkaConsumer nodes.

Activity Log content

When a KafkaProducer node publishes a message, or a KafkaConsumer node receives a message, or a KafkaRead node reads a message, information is written to the activity log.

Activity Log messages for the KafkaProducer node contain the following information:

- Topic name
- Partition name
- Offset
- Client ID

Activity Log messages for the KafkaConsumer node contain the following information:

- Topic name
- Partition name
- Offset
- Client ID
- Group ID

Activity Log messages for the KafkaRead node contain the following information:

- Topic name
- Partition name
- Offset
- Client ID

This information enables you to review the interactions between your message flows and the Kafka servers.

LoopBack Activity Log

The LoopBack Activity Log provides a high-level overview of how IBM App Connect Enterprise interacts with LoopBack connectors by using the LoopBackRequest node.

Activity Log content

When a LoopBackRequest node issues a request for an operation through a LoopBack connector, information is written to the activity log for successful and failed processing.

The LoopBackRequest node activity log messages contain the following information:

- The name of the operation: create, retrieve, update, or delete.
- The data source name.
- The object name.
- The ID, where applicable; for example, it is provided for an operation to delete records by ID, but not for a retrieve operation without a filter.
- The status of the operation, indicating whether the operation is about to start, has completed successfully, or has failed.

Activity Log entries that are written by the LoopBackRequest node are not associated with a message flow and are not visible in the Activity Log Viewer in the web user interface; however, they are available when an Activity Log policy is used to write your activity logs to a file system (see Activity Log policy (ActivityLog)).

MQTT Activity Log

Learn about the types of activity that are logged in the MQTT Activity Log, and the tags that can be used for filtering these activities.

Activity Log content

Here are some examples of the type of MQTT node activities that are logged in an MQTT Activity Log:

- Successfully connected to an MQTT server
- Failed to connect to an MQTT server
- Reattempted the connection to an MQTT server
- Published a message to a topic
- Failed to publish a message to a topic
- Subscribed to a topic
- Received a message that was published to a topic
- Lost the connection to an MQTT server
- Successfully disconnected from an MQTT server
- Failed to disconnect from an MQTT server

Activity Log tags

In addition to the generic Activity Log tags, there are extra tags that are specific to MQTT. These tags enrich the logged information and can also be used for filtering.

For more information about the generic tags, see “Activity Logs structure and types” on page 2858. The following table lists the additional MQTT tags.

Table 99. Activity Log tags.

Name	Description	Valid values
TOPICNAME	The name of the topic that messages are published to, or the name of the topic that is subscribed to.	Any valid MQTT topic name. For more information, see MQTT Protocol Specification.
CONNECTIONURL	The URL of the MQTT server.	Any valid URL.

ODBC Activity Log

Provides a high-level overview of how IBM App Connect Enterprise interacts with databases so that you can better understand these interactions.

Activity Log content

Activity Log entries for ODBC include the following types of activity:

- A message flow connects to an ODBC datasource.
- A message flow prepares a database statement for execution.
- A message flow executes a database statement.

Activity Log tags

In addition to the generic Activity Log tags, there are additional tags that are specific to ODBC. These tags enrich the logged information and can also be used for filtering.

For more information about the generic tags, see “Activity Logs structure and types” on page 2858. The following table lists the additional ODBC tags.

Table 100. Activity Log tags.

Name	Description	Valid values
DATASOURCE	The name of the ODBC datasource which is suffixed with XA for globally coordinated connections.	Any valid ODBC datasource name.
ODBCOPERATION	The type of ODBC interaction.	CONNECT, PREPARE, and EXECUTE.

ODM Activity Log

The ODM Activity Log provides a high-level overview of the execution of Operational Decision Manager (ODM) rulesets through the ODMRules or JavaCompute node.

Activity Log content

ODM Activity Log entries are written when the following events are generated by an node or node:

- The execution of a ruleset completes successfully (BIP11200)
- The execution of a ruleset fails (BIP11201)
- A ruleset is about to be executed (BIP11203). This information enables you to see how long the ODM ruleset took to execute, by calculating the time between this event and the success or failure event.

The messages that are written to the ODM Activity Log also include the following information:

- The name of the ODM Server policy
- The ruleset path
- The number of rules matched
- The number of input parameters
- The number of output parameters

Activity Log tags

In addition to the generic Activity Log tags, there are tags that are specific to the execution of ODM business rules. These tags enrich the logged information and can also be used for filtering.

For information about the generic tags, see “Activity Logs structure and types” on page 2858. The following table lists the additional tags for the execution of ODM business rules:

Table 101. Activity Log tags.

Name	Description	Valid values
ODM	The ODM Server policy that specifies the details of either a remote Operational Decision Manager (ODM) rule execution server or a ruleset archive on the local file system.	The name of an ODM Server policy, in the form *{PolicyProject}:policyName*. For more information, see ODM Server policy (ODMServer).

Table 101. Activity Log tags. (continued)		
Name	**Description**	**Valid values**
RULESMATCHED	The number of rules that were matched in the ruleset. This tag is available only when the execution of a ruleset completes successfully (BIP11200).	Any value that is greater than or equal to 0.

For more information about using ODM rules with IBM App Connect Enterprise, see "Using Operational Decision Manager (ODM) business rules" on page 1241.

REST Request Activity Log

The REST API activity log provides a high-level overview of how IBM App Connect Enterprise interacts with REST APIs by using the RESTRequest and RESTAsyncRequest nodes.

Activity Log content

When a RESTRequest or RESTAsyncRequest node issues a request to a REST API, information is written to the activity log for successful and failed processing.

The activity log messages for the REST request nodes contain the following information:

- Operation name.
- HTTP method.
- URL used.
- HTTP status code of the response.
- Size of the request headers and body.
- Size of the response headers and body.
- Total time for the request.

  You can use the activity log to determine how much time is being spent outside of the REST request node when a request is issued to a remote REST API. The time written in the activity log includes only the time spent calling the operating system's send and receive system calls, and the time spent waiting for the remote REST API to process and respond to the request. The time written excludes the time spent elsewhere in the REST request node, such as time spent parsing or serializing message tree data. If this time is unexpectedly high, it indicates a performance problem with the network or the remote REST API rather than the REST request node. The time can be compared with the information available through message flow statistics to determine if a performance problem is occurring inside or outside of the REST request node.

Activity Log entries written by the RESTRequest and RESTAsyncRequest nodes are visible in the Activity Log Viewer in the web user interface. They are also available when an Activity Log policy is used to write your Activity logs to a file system.

Salesforce Activity Log

The Salesforce activity log provides a high-level overview of how IBM App Connect Enterprise interacts with Salesforce by using the SalesforceRequest node.

Activity Log content

When a SalesforceRequest node issues a request against Salesforce, information is written to the activity log for successful and failed processing. Activity Log entries for SalesforceRequest node operations include the following types of activity:

- A SalesforceRequest operation completed successfully.

- A SalesforceRequest operation failed.

Activity Log entries that are written by the SalesforceRequest node are not associated with a message flow and are not visible in the Activity Log Viewer in the web user interface. However, they are available when an Activity Log policy is used to write your activity logs to a file system (see Activity Log policy (ActivityLog)).

WebSphere Adapters Activity Log

Learn about the specifics of WebSphere Adapters Activity Logs.

Activity Log content

Activity Log entries for WebSphere Adapters include the following types of activity:

- An adapter connected to an Enterprise Information System (EIS).
- An adapter made an outbound request.
- An outbound request failed.
- An adapter received an inbound message.
- An adapter closed a connection.

Activity Log tags

In addition to the generic Activity Log tags, there are additional tags that are specific to WebSphere Adapters. These tags enrich the logged information and can also be used for filtering.

For more information about the generic tags, see "Activity Logs structure and types" on page 2858. The following table lists the additional WebSphere Adapters tags.

Table 102. Activity Log tags.

Name	Description	Valid values
ADAPTER	The adapter name	Any valid adapter name

Reporting logs and monitoring events to a Logstash input in an ELK stack

IBM App Connect Enterprise provides a facility to send any or all of your BIP message logs, message flow monitoring events, and activity logging events for your integration servers to a Logstash input in an Elasticsearch, Logstash, and Kibana (ELK) stack, so that you can view that data in a Kibana dashboard.

The ELK stack consists of three parts:

- **Elasticsearch** (a search and analytics engine)
- **Logstash** (a data processing pipeline that ingests data and sends it to a stash, such as Elasticsearch)
- **Kibana** (a visualization tool that can be used to display data in charts and graphs).

For more information about Elasticsearch, Logstash, and Kibana, see the Elastic stack web pages.

BIP message logs, message flow monitoring events, and activity logging events that are generated by IBM App Connect Enterprise integration servers (not integration nodes) can be sent to Logstash. However, you can enable logging at the level of an integration server or an integration node, by setting properties in the `server.conf.yaml` or `node.conf.yaml` file. To configure a specific integration server to send logs and events to Logstash, you set logging properties in the `server.conf.yaml` file for that integration server. If you enable logging for an integration node (by setting logging properties in the `node.conf.yaml` file), events that are generated by all of its managed integration servers are sent to Logstash.

App Connect Enterprise requires the ELK stack to include Logstash with either `beats` or `http` input plug-in configured. When you configure App Connect Enterprise to send to Logstash, you select the `beats`

or `http` protocol and specify connection and security parameters. When the reporting feature is active, logging and event data are sent to Logstash at regular intervals, which you can specify in the `.conf.yaml` file. You can also specify the Logstash input protocol to be used for sending the data (`beats`, `beatsTls`, `http`, or `https`). For more information about how to configure your integration servers to report logging and event data to Logstash, see "Configuring integration servers to send logs and events to Logstash in an ELK stack" on page 2870.

When you activate the IBM App Connect Enterprise logging capability and specify the Logstash input protocol, BIP message logs, message flow monitoring events, and activity logging events that are triggered by integration server events are sent to the Logstash input plug-in. The logs and events can be published from independent integration servers and from integration servers that are managed by an integration node. The logging data that is sent to Logstash contains information about the events that are issued by the integration server process. Events that are initiated by other components (such as an integration node) are not reported. If you compare the contents of the local event log relating to integration servers with the logging data that is published to Logstash, you see that a very small number of BIP message logs, message flow monitoring events (or both) at the beginning and end of the local log are not published to Logstash. These logs and events are typically messages about the startup and shutdown of the integration server. Publication of logs and events to Logstash begins after the integration server starts, which means that messages that relate to the integration server startup are not published to Logstash. The logs and events are then published until the integration server shutdown process begins, so any messages that relate to the shutdown are written to the local system log but are not published to Logstash. If an integration server does not appear to be delivering messages to Logstash, check the local system log for information. For more information about Logstash, see the Logstash reference documentation online.

- If you want to send data to a secured Logstash input, you can configure the security credentials, including the username, password, truststore, and keystore, by setting properties in the integration node's `node.conf.yaml` file or the integration server's `server.conf.yaml` file

. You can store the security credentials in the encrypted vault by using the command and the command. For more information about encrypted security credentials, see "Configuring encrypted security credentials" on page 177.

For more information about configuring an integration server, see "Configuring an integration server by modifying the server.conf.yaml file" on page 172. For more information about viewing data in a Kibana dashboard, see the Elastic stack online documentation.

Configuring integration servers to send logs and events to Logstash in an ELK stack

You can configure your integration servers to send any or all of your logging and event data, in the form of BIP message logs, message flow monitoring events, and activity logging events, to a Logstash input plug-in in an Elasticsearch, Logstash, and Kibana (ELK) stack. This configuration enables you to display the reported information in a Kibana dashboard.

Before you begin

Read the conceptual information that is provided in "Reporting logs and monitoring events to a Logstash input in an ELK stack" on page 2869.

About this task

To enable your IBM App Connect Enterprise integration servers to send logging and event information to a Logstash input in an ELK stack, you must configure the integration node or server by setting the properties in the `node.conf.yaml` or `server.conf.yaml` file.

For more information about configuring an integration node or server, see "Configuring an integration node by modifying the node.conf.yaml file" on page 118 or "Configuring an integration server by modifying the server.conf.yaml file" on page 172.

Procedure

Complete the following steps to enable your integration servers to send logging and event data to a Logstash input in an ELK stack:

1. Decide which of the following Logstash input protocols that you want to use:

   - `beats`
   - `beatsTls`
   - `http`
   - `https`

   This information determines the property values that you set in the following steps.

   For more information about the Logstash input protocols that you can use to connect IBM App Connect Enterprise to the ELK stack, see the Logstash reference documentation online.

2. Open the `node.conf.yaml` or `server.conf.yaml` configuration file for your integration node or server, by using a YAML editor.

   If you are not able to access a YAML editor, you can edit the file by using a plain text editor. However, you must ensure that you do not include any tab characters. Tab characters are not valid in YAML files and they would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

3. Configure the integration node or server to use your chosen Logstash input protocol (`beats`, `beatsTls`, `http`, or `https`), by setting properties in the `ELKConnections` section of the `node.conf.yaml` or `server.conf.yaml` file:

```
ELKConnections:
  # Description for ELK Connections.
  # elkConnection1:
  #   elkProtocol: 'beats'                      # Logstash input protocol. Valid values are:
 'beats', 'beatsTls', 'http', or 'https'.
  #   hostname: 'myhost.domain.com'             # Hostname for the elkProtocol endpoint.
  #   port: 0                                   # Port for the elkProtocol endpoint.
  #   uploadIntervalMilliSecs: 60000            # Interval between uploading cached data,
 set in milliseconds.
  #   elkCredential: ''                         # Set an 'elk' credential alias name to
 enable basic authentication, if it is required by the Logstash input protocol.
  #   keystoreFile: '/path/to/keystore.jks'     # Set the path to the keystore to be used,
 if it is required by the Logstash input protocol.
  #   keystorePass: 'P4s5w0rd'                  # Set the password, or 'keystore' credential
 alias to the password, of the keystore.
  #   keyAlias: ''                              # Set the alias name of the private key, if
 mutual authentication is required by the Logstash input protocol.
  #   KeyPassword: ''                             # Set the password, or 'keystorekey'
 credential alias to the password, for accessing the private mutual authentication key.
  #   truststoreFile: '/path/tp/truststore.jks'  # Set the path to the truststore to be used,
 if it is required by the Logstash input protocol.
  #   truststorePass: 'P4s5w0rd'                # Set the password, or 'truststore'
 credential alias to the password, for accessing the truststore.
```

   For example, to connect to an unsecured Logstash input plug-in by using the `beats` input protocol, on `localhost` port 5044, and to upload the log data every 30 seconds, set the following properties:

```
ELKConnections:
  elkbeats:
    elkProtocol: 'beats'
    hostname: 'localhost'
    port: 5044
    uploadIntervalMilliSecs: 30000
```

4. Optional: If you are connecting to a secured Logstash input plug-in, configure the security credentials that are required to access it. For example, if you are using HTTP to connect to a Logstash input plug-

in that requires a username and password, configure the integration node or server to use an `elk` credential for basic authentication (basicAuth), by completing the following steps:

a) Update the `node.conf.yaml` or `server.conf.yaml` file to specify a credential to be used for basic authentication (basicAuth), by specifying the credential name in the **elkCredential** property; for example:

```
elkCredential: 'elk_ID'
```

b) Use the command to create the security credential that you specified in the `.conf.yaml` file (`elk_ID`), setting the username and password, and a credential type of `elk`:

```
mqsicredentials --work-dir elk_work_dir --create --credential-name elk_ID --credential-
type elk --username user1 --password passw0rd1
```

5. Optional: Enable App Connect Enterprise BIP messages to be sent to the configured ELK Connection, by setting properties in the Log section of the `.conf.yaml` file:

```
Log:
  #consoleLog: true          # Control writing BIP messages to standard out. Set to true or
 false, default is true.
  #outputFormat: 'text'      # Control the format of BIP messages written to standard out and
 file. Set to ibmjson or text, default is text.
  #eventLog: '[iib.system-work-dir]/log/[iib.system-node-label].[iib.system-server-
label].events.txt'     # Control writing BIP messages to file. Set to '' to disable, default
 is as shown.
  #eventLogFileSize: 10      # The maximum size in MB of an event log file before it is
 rotated into a new file
  #eventLogFileCount: 10     # The maximum number of event log files that should be rotated
 between.
  #elkLog: false             # Control the publication of BIP messages to an ELK
 (Elasticsearch, Logstash, Kibana) stack. Set to true or false, default is false.
  #elkConnections: ''        # Name of the ELK connection to use, for example
 'elkConnection1'
                             # Each named ELK Connection must be defined in the
 ELKConnections section below.
```

For example, to enable logs data to be sent to the ELK Connection that was configured in the previous example (`elkbeats`), set the following properties:

```
Log:
  elkLog: true
  elkConnections: 'elkbeats'
```

6. Optional: Optionally, enable IBM App Connect Enterprise message flow monitoring events to be sent to the configured ELK Connection, by setting properties in the Events.BusinessEvents.ELK section of the `.conf.yaml` file:

```
Events:
  BusinessEvents:
    ELK:
      #enabled: false              # Set true or false, default false
      #outputFormat: 'json'      # Set json, default json
      #elkConnections: ''          # Name of the ELK connection to use, for example
 'elkConnection1', must be defined in the ELKConnections section below.
```

Also, ensure that Monitoring is enabled in the Monitoring.MessageFlow section of the `.conf.yaml file`:

```
Monitoring:
  MessageFlow:
    #publicationOn: 'inactive'         # choose 1 of : active|inactive, default inactive
```

7. Optional: Deploy an Activity Log policy to the integration server, with the **elkLog** property set to `true` and the **elkConnections** property set to match the name of an ELK connection configuration specified in ELKConnections section of the `.conf.yaml` file.

8. Restart the integration server for the changes to take effect.

   The integration server's log events in the form of BIP message logs, message flow monitoring events (or both), are sent to the configured Logstash input plug-in.

   When the integration server starts delivering BIP message logs, message flow monitoring events (or both), to the configured Logstash input, a confirmation message is written to the log; for example:

```
BIP6503I: ( CHECK.IS2 ) The integration server successfully sent data to ELK connection
 ''ELKbeats''
using elkProtocol ''beats'', hostname ''localhost'' and port ''5444''.
```

   If the integration server is unable to deliver event data to the configured Logstash input, a BIP message is logged to the integration server's local event log; for example:

```
BIP3888E: ( CHECK.IS2 ) The ELK connector ''ELKbeats'' failed to send data to
 ''localhost:5444''.
Error details: ''SocketException BIP3150E: ImbBasicSocket::connectTimeout "An error occurred
 whilst performing a socket operation:
getsockopt" [::connect::select(), 10061, No connection could be made because the target
 machine actively refused it.
```

Workload management

Workload management allows system administrators to monitor and adjust the speed that messages are processed, as well as controlling the actions taken on unresponsive flows and threads.

Before you can use workload management functions, you must ensure that the publication of events has been enabled and that a pub/sub broker has been configured. For more information, see “Configuring the publication of event messages” on page 2807 and “Configuring the built-in MQTT pub/sub broker” on page 2811.

The following topics explain the various options available under workload management:

Message flow notification

A common requirement is to be able to monitor the speed at which IBM App Connect Enterprise processes messages. Workload management allows the system administrator to express a notification threshold for individual message flows deployed. An out of range notification message is produced if the notification threshold is exceeded. A back in range notification message is produced if the notification threshold later drops back into range. For more information, see “Configure a message flow to cause notification threshold messages to be published” on page 2874.

Setting the maximum rate for a message flow

The system administrator can set the maximum rate that an individual message flow can run at. The maximum rate is specified as the total number of input messages processed every second. When set, the number of input messages that are processed across the flow is measured. This measure is irrespective of the number of additional instances in use, the number of input nodes in the message flow, or the number of errors that occur. If necessary, a processing delay is introduced to keep the input message processing rate under the maximum flow rate setting. For more information, see “Setting the maximum rate for a message flow” on page 2877.

Setting additional threads to service a message flow

You can set the number of additional threads that the integration node can use to service a message flow, and specify whether the additional threads start when the flow starts.

Unresponsive message flows

Allows you to specify and monitor the maximum amount of time that any message flow is allowed to process a message for, and to specify an action to be taken if the timeout is exceeded. Additionally, manual requests can be made to stop a message flow by restarting the integration server. For more information, see Unresponsive message flows.

Workload management policy configuration

Instead of defining properties on the message flow, you can specify a workload management policy within the Integration Registry for a message flow, so that message flows can refer to the policy to find properties at run time. You can change the values of attributes for a policy on the integration node, which then affects the behavior of a message flow without the need for redeployment. The workload management policy encompasses all of the properties available under workload management in one place, including the notification threshold and maximum rate, and therefore allows for easier tuning of message flow performance.

Configure a message flow to cause notification threshold messages to be published

How to configure and monitor the message flow notification threshold.

About this task

Details how a notification threshold can be set up on a message flow to cause a notification message to be sent if the message count for messages arriving in the flow exceeds the notification threshold. A further notification message is sent if later the message count drops back below the notification threshold.

Note: Unless otherwise stated, the notification threshold is a measure of the total messages every second.

The following sections provide further information about how you can configure the message flow notification threshold and monitor message flow performance:

- "Setting the notification threshold for a message flow" on page 2874
- "Message publication when the message rate for a message flow is out of range" on page 2875
- "Message publication when the message rate for a message flow goes back into range" on page 2876

Setting the notification threshold for a message flow

Describes how to calculate and set the message flow notification threshold.

About this task

Before activating the message flow notification threshold, the system administrator must first establish what message rate is required for the message flow in question. The message rate is a measure of the total number of messages arriving each second at the message flow from all input nodes of any type. It is the total rate and not the average rate. For example: A message flow contains two input nodes that are called A and B. If input node A received messages at the rate of 50 messages a second, and input node B received messages at the rate of 70 messages a second, then the total message rate for the message flow would be 120 messages per second.

There are two ways the notification threshold can be set for a message flow:

- Directly within a BAR file.
- As one of the attributes within a workload management policy that is defined within Integration Registry.

BAR file

The notification threshold is set within the BAR file under a property called *notificationThresholdMsgsPerSec*.

The property can be set in the following ways:

- Within the BAR file through the IBM App Connect Enterprise Toolkit editor.
- Within the BAR file through the **mqsiapplybaroverride** command line.

Additionally, once the BAR file is deployed, the property can be set dynamically within the flow through the IBM Integration API. Any change to the property is picked up immediately and does not require the flow to be restarted.

Workload management policy
Create and configure a workload management policy. For more information about workload management, see "Workload management" on page 2873.

A notification threshold value of zero, or not set, will cause the message flow notification threshold to be turned off. The default state is off.

Within the same integration server, a mixture of message flows can run along side each other, some with the notification threshold set, others with the notification threshold turned off.

Message publication when the message rate for a message flow is out of range

Lists the conditions that control the publishing of the message rate is out of range message.

Before you begin

- Ensure that the publication of events is enabled, and the pub/sub broker is correctly configured. For an integration node, the default configuration enables publication of events that use the built-in MQTT pub/sub broker. If IBM MQ is installed and there is a default IBM MQ queue manager that is specified on the integration node or independent integration server, the IBM MQ pub/sub broker is used for the publication of events. For more information, see "Configuring the publication of event messages" on page 2807 and "Configuring the built-in MQTT pub/sub broker" on page 2811.

About this task

The message rate statistics are collected at a checkpoint that occurs every 20 seconds. The total message rate is calculated at this checkpoint, and if the total message rate exceeds the notification threshold, the out of range XML message is published. If the total message rate continues to stay above the notification threshold, then no further out of range messages are published.

If you enable the notification threshold you can subscribe to the following topic:

- For publications on an MQ pub/sub broker:

```
$SYS/Broker/integrationNodeName/WorkloadManagement/AboveThreshold/integrationServerName
/application_name/library_name/message_flow_name
```

- For publications on an MQTT pub/sub broker:

```
IBM/IntegrationBus/integrationNodeName/WorkloadManagement/AboveThreshold/integrationServerName
/application_name/library_name/message_flow_name
```

where *integrationNodeName* is the name of the integration node, *integrationServerName* is the name of the integration server on that integration node, *application_name* is the name of the application on that integration server, *library_name* is the name of the library on that application, and *message_flow_name* is the name of the message flow that is deployed to the library.

In the situation where the message flow is not contained in either an application or a library, the *application_name* or *library_name* parameters must be omitted along with their enclosing forward slash (/). For example:

- If the message flow is not contained in an application or a library:

```
$SYS/Broker/integrationNodeName/WorkloadManagement/AboveThreshold/integrationServerName
/message_flow_name
```

or

```
IBM/IntegrationBus/integrationNodeName/WorkloadManagement/AboveThreshold/integrationServerName
```

```
/message_flow_name
```

- If the message flow is contained in an application and not in a library:

```
$SYS/Broker/integrationNodeName/WorkloadManagement/AboveThreshold/integrationServerName
/application_name/message_flow_name
```

or

```
IBM/IntegrationBus/integrationNodeName/WorkloadManagement/AboveThreshold/integrationServerName
/application_name/message_flow_name
```

Message publication when the message rate for a message flow goes back into range

Lists the conditions that control the publishing of the message rate is back in range message.

Before you begin

- Ensure that the publication of events is enabled, and the pub/sub broker is correctly configured. For an integration node, the default configuration enables publication of events that use the built-in MQTT pub/sub broker. If IBM MQ is installed and there is a default IBM MQ queue manager that is specified on the integration node or independent integration server, the IBM MQ pub/sub broker is used for the publication of events. For more information, see "Configuring the publication of event messages" on page 2807 and "Configuring the built-in MQTT pub/sub broker" on page 2811.

About this task

The message rate statistics are collected at a checkpoint that occurs every 20 seconds and the total message rate is calculated at this checkpoint. If the total message rate previously exceeded the notification threshold, and then later the total message rate drops back into range, the back in range XML message is published.

No state is stored when the message flow is stopped, restarted, or redeployed.

When a flow is terminated, the flow termination process checks to see whether the last message published was to report that the message rate exceeded the notification threshold. In this situation, the flow termination process automatically publishes a message to report that the message flow is now back in range.

If you enable the notification threshold you can subscribe to the following topic:

- For publications on an MQ pub/sub broker:

```
$SYS/Broker/integrationNodeName/WorkloadManagement/BelowThreshold/integrationServerName
/<applicationName>/<libraryName>/<messageFlowLabel>
```

- For publications on an MQTT pub/sub broker:

```
IBM/IntegrationBus/integrationNodeName/WorkloadManagement/BelowThreshold/integrationServerName
/<applicationName>/<libraryName>/<messageFlowLabel>
```

where *integrationNodeName* is the name of the integration node, *integrationServerName* is the name of the integration server on that integration node, *application_name* is the name of the application on that integration server, *library_name* is the name of the library on that application, and *messageFlowLabel* is the name of the message flow that is deployed to the library.

In the situation where the message flow is not contained in either an application or a library, the *application_name* or *library_name* parameters must be omitted along with their enclosing forward slash (/). For example:

- If the message flow is not contained in an application and a library:

```
$SYS/Broker/integrationNodeName/WorkloadManagement/BelowThreshold/integrationServerName
```

```
/<messageFlowLabel>
```

or

```
IBM/IntegrationBus/integrationNodeName/WorkloadManagement/BelowThreshold/integrationServerName
/<messageFlowLabel>
```

where *integrationNodeName* is the name of the integration node, *integrationServerName* is the name of the integration server on that integration node, and *messageFlowLabel* is the name of the message flow that is deployed to the integration server.

- If the message flow is contained in an application and not in a library:

```
$SYS/Broker/integrationNodeName/WorkloadManagement/BelowThreshold/integrationServerName
/<applicationName>/<messageFlowLabel>
```

or

```
IBM/IntegrationBus/integrationNodeName/WorkloadManagement/BelowThreshold/integrationServerName
/<applicationName>/<messageFlowLabel>
```

where *integrationNodeName* is the name of the integration node, *integrationServerName* is the name of the integration server on that integration node, *application_name* is the name of the application on that integration server, and *messageFlowLabel* is the name of the message flow that is deployed to the application.

Setting the maximum rate for a message flow

Allows system administrators to restrict the maximum rate at which a message flow can run at by setting the maximum rate property.

About this task

The system administrator is able to restrict the rate that an individual message flow can run at by setting the maximum rate property. The maximum rate is specified as the total number of input messages processed every second by all the threads that are running in the message flow.

To calculate the number of threads within a specific message flow:

1. Count the number of input nodes within the flow.
2. Add on the number of additional instances that are specified for each input node.

There are two ways the maximum rate can be set for a message flow:

- Directly within a BAR file.
- As one of the attributes within a workload management policy that is defined within Integration Registry.

BAR file

The maximum rate is set within the BAR file under a property called *maximumRateMsgsPerSec*.

The property can be set in the following ways:

- Within the BAR file through the IBM App Connect Enterprise Toolkit editor.

  Note: You must refresh the content of a migrated BAR file before you can see and configure the *maximumRateMsgsPerSec* property.

- Within the BAR file through the **mqsiapplybaroverride** command line.

  Note: For example, to set the *maximumRateMsgsPerSec* property for a message flow included in an application, you can use the following sample code:

  ```
  mqsiapplybaroverride -b BARfile -k applicationName -m
   sampleFlow#maximumRateMsgsPerSec=100
  ```

  For more information, see command.

Additionally, once the BAR file is deployed, the property can be set dynamically within the flow through the IBM Integration API. Any change to the property is picked up immediately and does not require the flow to be restarted.

Workload management policy
Create and configure a workload management policy. For more information about workload management, see “Workload management” on page 2873.

A maximum rate value of zero, or not set, causes the message flow maximum rate to be turned off. The default state is off.

Within the same integration server, a mixture of message flows can run along side each other, some with the maximum rate set, others with the maximum rate turned off.

Chapter 10. Troubleshooting and support

If you are having problems with your message flow applications, use the techniques described in this section to help you to diagnose and solve the problems.

About this task

This section contains information about the various techniques that you can use to diagnose problems with IBM App Connect Enterprise.

Procedure

- "Making initial checks" on page 2880
- "Using logs" on page 3023
- "Using trace" on page 3026
- "Using dumps and abend files" on page 3039
- "Contacting your IBM Support Center" on page 3040

What to do next

You can also read the general troubleshooting guidance in the following topics:

- "Troubleshooting overview" on page 2879
- "Searching knowledge bases" on page 3042
- "Getting product fixes" on page 3042
- "Contacting IBM Software Support" on page 3043
- "Collecting diagnostics" on page 3041

For information that is specific to debugging message flows, see "Testing and troubleshooting message flows" on page 647.

Troubleshooting overview

Troubleshooting is the process of finding and eliminating the cause of a problem. Whenever you have a problem with your IBM software, the troubleshooting process begins as soon as you ask yourself "what happened?"

A basic troubleshooting strategy at a high level involves:

1. "Recording the symptoms of the problem" on page 2879
2. "Re-creating the problem" on page 2880
3. "Eliminating possible causes" on page 2880

Recording the symptoms of the problem

Depending on the type of problem that you have, whether it be with your application, your server, or your tools, you might receive a message that indicates that something is wrong. Always record the error message that you see. As simple as this sounds, error messages sometimes contain codes that might make more sense as you investigate your problem further. You might also receive multiple error messages that look similar but have subtle differences. By recording the details of each one, you can learn more about where your problem exists.

Sources of error messages:

- Problems view

- Local error log
- Eclipse log
- Activity Log
- User trace
- Service trace
- Error dialog boxes
- **mqsiexplain** command

Re-creating the problem

Think back to what steps you were doing that led to the problem. Try those steps again to see if you can easily re-create the problem. If you have a consistently repeatable test case, it is easier to determine what solutions are necessary.

- How did you first notice the problem?
- Did you do anything different that made you notice the problem?
- Is the process that is causing the problem a new procedure, or has it worked successfully before?
- If this process worked before, what has changed? (The change can refer to any type of change that is made to the system, ranging from adding new hardware or software, to reconfiguring existing software.)
- What was the first symptom of the problem that you witnessed? Were there other symptoms occurring around the same time?
- Does the same problem occur elsewhere? Is only one machine experiencing the problem or are multiple machines experiencing the same problem?
- What messages are being generated that could indicate what the problem is?

You can find more information about these types of question in “Making initial checks” on page 2880.

Eliminating possible causes

Narrow the scope of your problem by eliminating components that are not causing the problem. By using a process of elimination, you can simplify your problem and avoid wasting time in areas that are not responsible. Consult the information in this product and other available resources to help you with your elimination process.

- Has anyone else experienced this problem? See: “Searching knowledge bases” on page 3042.
- Is there a fix you can download? See: “Getting product fixes” on page 3042.

Making initial checks

Before you start problem determination in detail, consider whether there is an obvious cause of the problem, or an area of investigation that is likely to give useful results. This approach to diagnosis can often save a lot of work by highlighting a simple error, or by narrowing down the range of possibilities.

About this task

This section contains a list of questions to consider. As you go through the list, make a note of anything that might be relevant to the problem. Even if your observations do not suggest a cause straight away, they might be useful later if you have to carry out a systematic problem determination exercise.

Procedure

- “Did you log off Windows while IBM App Connect Enterprise components were active?” on page 2881
- “Are the Linux and UNIX environment variables set correctly?” on page 2881
- “Are there any error messages or return codes that explain the problem?” on page 2882

Did you log off Windows while IBM App Connect Enterprise components were active?

How to avoid problems caused by logging off while components are active.

About this task

Windows On Windows, logging off when an IBM App Connect Enterprise component (an integration node) is active can cause a problem.

You might see messages, including BIP2070, BIP2642, BIP1102, and BIP1103, in the Windows Event log.

When you log off, any queue manager that supports the IBM App Connect Enterprise component is stopped unless it is defined to run as a Windows service. The component runs Windows services and remains active, but it finds that the queue manager and queue manager objects that are associated with it are no longer available.

Procedure

To avoid this problem, set the queue manager that is used by the integration node to run as a Windows service, so that logging off Windows from does not cause this problem.

Are the Linux and UNIX environment variables set correctly?

Use the **mqsiprofile** command to set a command environment.

About this task

UNIX On Linux and UNIX systems, the basic settings are made by the **mqsiprofile** command, which is located in the following directory:

```
install_dir/bin
```

What to do next

See “Setting up a command environment” on page 64 for information about setting up the command environment.

Are there any error messages or return codes that explain the problem?

You can find details of error messages and return codes in several places.

Procedure

- **BIP messages and reason codes**

  IBM App Connect Enterprise error messages have the prefix BIP. If you receive any messages with this prefix (for example, in the UNIX, Linux, or z/OS syslog), you can search for them in the product documentation for an explanation. You can also view the full content of a BIP message by using the **mqsiexplain** command. For more information, see command.

  Windows In the Windows Event log, references to BIP messages are identified by the source name "WebSphere Integration node v6000", where v6000 can be replaced by a number representing the exact service level of your installation, for example 6001.

  IBM App Connect Enterprise messages that have a mixture of identifiers such as BIPmsgs, BIPv700, BIPv610, BIPv500, WMQIv210, MQSIv202, and MQSIv201 indicate a mixed installation, which does not work properly.

- **Other messages**

  For messages with a different prefix, such as AMQ or CSQ for IBM MQ, or SQL for DB2, see the appropriate messages and codes documentation for a suggested course of action to help resolve the problem.

  Messages that are associated with the startup of IBM App Connect Enterprise, or were issued while the system was running before the error occurred, might indicate a system problem that prevented your application from running successfully.

  A large or complex IBM App Connect Enterprise integration node environment might require some additional configuration of the environment beyond what is recommended in “Installing and uninstalling complementary products” on page 96. The need for such configuration changes is typically indicated by warning or error messages that are logged by the various components, including IBM MQ, the databases, and the operating system. These messages are normally accompanied by a suggested user response.

Can you see all of your files and folders?

How to show all files in Windows Explorer:

About this task

If you are using Windows Explorer to view your files and you cannot see all of your files and folders, such as the integration node workpath directory, this is because Windows Explorer, by default, hides some files and folders.

Procedure

1. Click **Tools** > **Folder options**. The **Folder Options** dialog box opens.
2. Click the **View** tab and select **Show hidden files and folders**.

Can you reproduce the problem?

If you can reproduce the problem, consider the conditions under which you can do so.

Procedure

- **Is the problem caused by a particular message flow?**

  If so, use the debugging facility of the IBM App Connect Enterprise Toolkit and user tracing to identify the problem.
- **Is the problem caused by a command?**

  On distributed operating systems, you issue commands at the system command line.
- **Does a problem command work if it is entered by another user ID?**

  If the command works when it is entered by another user ID, check the environment of each user. Paths, especially shared library paths, might be different. On Windows, UNIX systems, and Linux verify that all users have set up their command environment correctly; refer to sample profile for more information.

  Windows On Windows, the environment for the integration node is determined by the system settings, not by a particular user's variables. However, the user's variables affect non-integration node commands.

  UNIX On LinuxUNIX systems, only the service ID that is specified when the integration node was created can start an integration node.

  Windows On Windows, any authorized user can start an integration node.

Has the message flow run successfully before?

Sometimes a problem appears in a message flow that has previously run successfully.

About this task

To identify the cause of the problem, answer the following questions:

Procedure

- **Have you made any changes to the message flow since it last ran successfully?**

  If so, it is likely that the error exists somewhere in the new or modified part of the flow. Examine the changes and see if you can find an obvious reason for the problem.
- **Have you used all the functions of the message flow before?**

  Did the problem occur when you used part of the message flow that had never been invoked before? If so, it is likely that the error exists in that part. Try to find out what the message flow was doing when it failed by using user tracing, trace nodes, and the debugger function of the IBM App Connect Enterprise Toolkit.

  If you have run a message flow successfully on many previous occasions, check the current queue status and the files that were being processed when the error occurred. It is possible that they contain some unusual data value that invokes a rarely-used path in the message flow.

- **Does the message flow check all return codes?**

  Has your system been changed, perhaps in a minor way, but your message flow does not check the return codes it receives as a result of the change? For example:

  – Does your message flow assume that the queues that it accesses can be shared? If a queue has been redefined as exclusive, can your message flow deal with return codes indicating that it can no longer access that queue?
  – Have any security profiles been changed? A message flow could fail because of a security violation.
- **Does the message flow expect particular message formats?**

  If a message with an unexpected message format has been put onto a queue (for example, a message from a queue manager on a different operating system) it might require data conversion or a different form of processing. Also, check whether you have changed any of the message formats that are used.
- **Does the message flow run on other IBM App Connect Enterprise systems?**

  Is there something different about the way that your system is set up that is causing the problem? For example, have the queues been defined with the same maximum message length or priority? Are there differences in the databases used, or their setup?
- **Are you using any user-defined extensions?**

  There might be translation or compilation problems with loadable implementation library (LIL) files. Before you look at the code, examine the output from the translator, the compiler or assembler, and the linkage editor, to see if any errors have been reported. Fix any errors to make the user-defined extension work.

  If the documentation shows that each of these steps was completed without error, consider the coding logic of the message flow, message set, or user-defined extension. Do the symptoms of the problem indicate which function is failing and, therefore, which piece of code is in error? See "User-defined extensions overview" on page 2321 for more information.
- **Can you see errors from IBM App Connect Enterprise or external resources, such as databases?**

  Your message flow might be losing errors because of incorrect use of the failure terminals on built-in nodes. If you use the failure terminals, make sure that you handle errors adequately. See "Handling errors in message flows" on page 1883 for more information about failure terminals.

Have you made any changes since the last successful run?

Have you changed IBM App Connect Enterprise, any related software, or any hardware?

About this task

When you are considering changes that might have been made recently, think not only about IBM App Connect Enterprise, but also about the other programs with which it interfaces, the hardware, device drivers, and any new applications.

Procedure

- **Have you changed your initialization procedure?**

  On z/OS, have you changed any data sets or library definitions? Has the operating system been initialized with different parameters? Check for error messages generated during initialization.
- **Has the profile of the user who is running the commands on Linux or UNIX systems been changed?**

  If so, this might mean that the user no longer has access to the required objects and commands.
- **Has any of the software on your system been upgraded to a later release?**

  Check that the upgrade completed successfully, and whether the new software is compatible with IBM App Connect Enterprise (check the product readme.html file).

- **Do your message flows deal with the errors and return codes that they might get as a result of any changes that you have made?**

  Check that your message flow can handle all possible error situations.

Is there a problem with descriptive text for a command?

On Linux and UNIX systems, be careful when including special characters (backslash (\) and double quotation mark (") characters) in descriptive text for some commands.

About this task

If you use either of these characters in descriptive text, precede them with the escape character backslash (\) ; that is, enter \\ or \" if you want \ or " in your text.

Is there a problem with a database?

If you have database problems, complete a set of initial checks to identify errors.

Procedure

- Check that the database is started.
- Check that you have correctly completed ODBC configuration:
  - Linux UNIX On Linux and UNIX systems, check that you have created a copy of the sample ODBC configuration file (`odbc.ini`), and have modified them for your environment, and that you have not added any extra unsupported parameters.
  - Windows On Windows systems, click **Start** > **Control Panel** > **Administrative Tools** > **Data Sources (ODBC)** to configure the connections you require.
- Check that you have correctly completed JDBC configuration.
- Check the number of database connections that are in use on DB2 for AIX. If you use local mode connections, a maximum of 10 is supported.
- If messages that indicate that `imbdfdb2v6.lil` failed to load, check that you have installed a supported database.

  Details of supported databases are given in IBM App Connect Enterprise system requirements.

Is there a problem with the network?

IBM App Connect Enterprise uses IBM MQ for inter-component communication. If components are on separate queue managers, they are connected by message channels.

About this task

Communication problems can arise between any of these resources:

Procedure

- integration nodes
- The IBM App Connect Enterprise Toolkit

What to do next

If any two components are on different queue managers, make sure that the channels between them are working. Use the IBM MQ **`display chstatus`** command to see if messages are flowing.

Use the **`ping`** command to check that the remote computers are connected to the network, or if you suspect that the problem might be with the network itself. For example, use the command **`ping`**

integrationNodeName, where *integrationNodeName* is a computer name. If you get a reply, the computer is connected. If you don't get a reply, ask your network administrator to investigate the problem. Further evidence of network problems might be messages building up on the transmission queues.

Does the problem affect all users?

On distributed systems, problems can be caused by different users having different environments.

About this task

Check whether there is a different user ID in an incoming message, or a different user ID issuing a command (or acting as the integration node's service ID).

Have you recently changed a password?

Check that you have updated passwords correctly.

About this task

If you have changed the operating system password for one of the following user IDs, the integration server or the deployed message flows might have access problems:

- The ID that you have specified for the **serviceUserId** of the integration server on Windows
- The ID that you have specified for access to a database

If these problems occur, complete one or more of the following steps:

Procedure

- Run the **mqsisetdbparms** command to redefine the correct values for the user ID and password.
- Run the **mqsireportdbparms** command to see the user ID that is defined. You can also run **mqsireportdbparms** using the **-n** and **-p** parameters and a possible password. If the entered password is correct, then the command returns information, including if the password was changed since the integration server was last started.
- Run **mqsireportdbparms** and check what user IDs are defined for the systems that require one. It might be that a security identity was not defined for the ID.
- Ensure that your passwords do not contain reserved keywords.
  For example, "IBM" is a reserved keyword in DB2.

Have you applied any service updates?

Check what service updates you have applied to your software.

About this task

If you have applied an APAR or a PTF to IBM MQ for z/OS, or an interim fix has been applied to a distributed operating system, check that no error message was produced. If the installation was successful, check with the IBM Support Center for any known error with the service update.

Procedure

- If a service update has been applied to any other product, consider the effect that it might have on IBM App Connect Enterprise.
- Ensure that you have followed any instructions in the service update that affect your system. For example, you might need to redefine a resource, or stop and restart a component.

- If you are not sure whether a service update has been applied to your system, search for and view the release notes stored in the product installation directory.

  These notes include the service level and details of the maintenance that you have applied.

Do you have a component that is running slowly?

If a particular component, or the system in general, is running slowly, you can take some actions to improve the performance.

About this task

Consider the following actions:

Procedure

- Check whether tracing is on.

  You might have started IBM App Connect Enterprise user tracing or service tracing, ODBC tracing, IBM MQ tracing, or native database tracing. If one or more of these traces are active, turn them off.
- Clear out all old abend files from your errors directory.

  If you do not clear the directory of unwanted files, you might find that your system performance degrades because significant space is used up.
- Increase your system memory.

Dealing with problems

Learn how to resolve some of the typical problems that can occur.

Before you begin

Make initial checks, see “Making initial checks” on page 2880, and check the following locations to see if you can rectify the problem:

- Logs, see “Using logs” on page 3023
- Trace, see “Using trace” on page 3026
- Dumps, see “Using dumps and abend files” on page 3039

About this task

This section contains the following topics:

Procedure

Resolving problems when you install IBM App Connect Enterprise

Work through the advice that is provided to help you to deal with problems that can arise when the product is installed on a distributed platform, such as on a Windows, or Linux system.

About this task

The following list describes problems that you might experience when you install IBM App Connect Enterprise on a distributed platform, with a corresponding solution or workaround.

You are prompted for the location of files during installation

Procedure

- **Scenario:** During the installation of IBM App Connect Enterprise, you are prompted to provide the location of certain installation files.
- **Explanation:** It is likely that your installation package is truncated and that files are missing.
- **Solution:** Check the size of the installation package and download another copy of the package if it is not the expected size.

The installation fails

Procedure

- **Scenario:** You have problems during the installation of IBM App Connect Enterprise.

- **Solution:** If the installation fails, you should receive an error message with an error code and a link to the log file where the error is explained. If you cannot identify the problem and need to contact your IBM Support Center for assistance, the following are the log files that you should send to your IBM Support contact:
  - `%LOCALAPPDATA%/Temp/IBM_App_Connect_Enterprise_11.0.0.n_`*`timestamp`*`.log`
  - `%LOCALAPPDATA%/Temp/IBM_App_Connect_Enterprise_11.0.0.n_`*`timestamp`*`_1_IIBCommonInstall.log`
  - `%LOCALAPPDATA%/Temp/IBM_App_Connect_Enterprise_11.0.0.n_`*`timestamp`*`_2_IIBServerInstall.log`
  - `%LOCALAPPDATA%/Temp/IBM_App_Connect_Enterprise_11.0.0.n_`*`timestamp`*`_3_IIBToolsInstall.log`

  where *timestamp* is the date and time of the installation.

The installation process is interrupted

Procedure

- **Scenario:** You are installing IBM App Connect Enterprise but the process is interrupted before the installation completes.
- **Explanation:** The process might be interrupted because of a problem, such as a power failure.
- **Solution:** Restart the installation wizard. If the installation was interrupted by a power failure, the installation wizard automatically restarts when you restart the computer. The installation process continues from the point where it was interrupted, and program files that are already installed are not reinstalled. Do not change the location of the installation directory when you restart the installation, otherwise the program files are split across the two directories, and IBM App Connect Enterprise will not work correctly.

Firewall software reports attempted internet access from an unexpected program

Procedure

- **Scenario:** During installation of the IBM App Connect Enterprise, your firewall software reports attempted internet access from an unexpected program.
- **Explanation:** Internet access is not required to complete the installation of the IBM App Connect Enterprise. However, the product might install an updated Microsoft C runtime library or updated version of the Microsoft.NET framework. These components might attempt internet access during the installation, which might cause firewall software to report a warning.
- **Solution:** This is normal behavior and the installation completes successfully whether you allow access or not.

`MSVCP120.dll missing` message is issued

Procedure

- **Scenario:** During installation of IBM App Connect Enterprise, a pop-up window is seen that states `mqsisetsecurity.exe has stopped working`. Clicking the details in the pop-up window shows that the MSVCP120.dll file is missing.
- **Solution:** Download and install the Microsoft Visual C++ 2010 Redistributable Package.

You experience display problems when you start the IBM App Connect Enterprise Toolkit

Procedure

- **Scenario:** You unpacked IBM App Connect Enterprise, started the IBM App Connect Enterprise Toolkit, and see one of two commonly reported errors.
- **Explanation:** Both errors typically occur if you log in remotely, or you switch user ID.
- **Solution:** Address the appropriate error with the following corresponding solution:

  `Can't open display localhost:1.0`
  Check that the DISPLAY variable is set to the correct value. If you are logged in locally, the typical value is `:0.0` or `localhost:0.0`.

  `Connection to ":0.0" refused by server`
  Run the following command, where *user* is the user ID you are logged in as:

  ```
  xauth merge ~user/.Xauthority
  ```

  If you are unable to correct these errors, contact your systems administrator for further help.

Resolving problems when you uninstall IBM App Connect Enterprise

Work through the advice provided to help you to deal with problems that can arise when the product is uninstalled.

About this task

The following list describes problems that you might experience when you uninstall IBM App Connect Enterprise on Windows, with a corresponding solution or workaround.

- On Windows: "The uninstallation process is interrupted" on page 2890

The uninstallation process is interrupted

Procedure

- **Scenario:** You are uninstalling IBM App Connect Enterprise but the process is interrupted before completion.
- **Explanation:** The process might be interrupted because of a problem, such as a power failure.
- **Solution:** Restart the uninstallation wizard. If the uninstallation was interrupted by a power failure, the uninstallation wizard automatically restarts when you restart the computer.

Resolving problems when running commands

Use the advice that is given here to help you to resolve common problems that can arise when you run commands.

About this task

- "MSVCP120.dll missing message is issued" on page 2891
- "Backing up or restoring the integration node returns error BIP1253 or BIP1262" on page 2891
- "ReportEvent() error message is issued on Windows when you attempt to run a command" on page 2891
- "A timeout error is issued when you attempt to run a command on AIX when Stack Execution Disable (SED) is enabled" on page 2892

- "A correct URL and password returns error BIP1939 when you attempt to connect to a remote host name" on page 2892
- "Running the mqsichangeproperties or mqsireportproperties commands on a resource manager returns error BIP2212" on page 2892

Windows MSVCP120.dll missing message is issued

Procedure

- **Scenario:** You are running commands and a pop-up window is seen that states `mqsisetsecurity.exe has stopped working`. Clicking the details in the pop-up window shows that the MSVCP120.dll file is missing.
- **Solution:** Download and install the Microsoft Visual C++ 2010 Redistributable Package.

Backing up or restoring the integration node returns error BIP1253 or BIP1262

Procedure

- **Scenario:** An error message is generated when you back up or restore an integration node:
  - The following message is returned when you run the **mqsibackupbroker** command:

    ```
    BIP1253E Failed to backup the integration node 'integrationNodeName' (error 'error_code')
    ```

  - The following message is returned when you run the **mqsirestorebroker** command:

    ```
    BIP1262E Could not delete the existing configuration of integration node
     'integrationNodeName'.
    ```

- **Explanation:** Both backup and restore commands require read/write access to the files that contain integration node configuration data. Access has failed and the command cannot complete its operation successfully.
- **Solution:** Typically, you might see one of these errors if you are running the backup or restore command against an active integration node, and a conflict of access has occurred.

  If your integration node is active, use the **mqsistop** command to stop the integration node, and try the operation again.

  You might also see one of these errors if the directory to which the command is writing, or from which it is reading, is temporarily inaccessible because of communications or authorization problems. Check that your user ID has access to the directory that you specified in the command.

ReportEvent() error message is issued on Windows when you attempt to run a command

Procedure

- **Scenario:** A ReportEvent () message is generated whenever you attempt to run any `mqsi*` command, The ReportEvent () message is followed by the result of the command itself.
- **Explanation:** The Windows Application Log has become full.
- **Solution:** Clear the Windows Application Log from the Event Viewer.

A timeout error is issued when you attempt to run a command on AIX when Stack Execution Disable (SED) is enabled

Procedure

- **Scenario:** You want to run an `mqsi*` command on AIX with Stack Execution Disable enabled, but the command times out even if the **-w** option is set to 360.
- **Explanation:** `mqsi*` commands attempt to create a JVM with Java Native Interface (JNI) calls. Because of Stack Execution Disable, the JVM creation fails.

  For more information about Stack Execution Disable, see IBM SDK, Java Technology Edition, product documentation online.
- **Solution:** Use the **sedmgr** command to create exemption records from Stack Execution Disable. For example, for **mqsilist**:

  ```
  sedmgr c exempt install_dir/server/bin/mqsilist
  ```

  The following commands might be affected by this issue:

  - **biphttplistener**
  - **bipbroker**
  - **bipservice**
  - **mqsideploy**
  - **mqsilist**
  - **mqsimode**
  - **mqsireloadsecurity**
  - **mqsireportresourcestats**
  - **mqsiwebuseradmin**

A correct URL and password returns error BIP1939 when you attempt to connect to a remote host name

Procedure

- **Scenario:** A BIP1939 message is generated whenever you attempt to run an `mqsi*` command where a URL and password were specified on the **-i** parameter to connect to a remote host name. The user name and password are correct, and the password contains non-alphanumeric characters.
- **Explanation:** The entered password contains URI Reserved characters. You cannot use URI Reserved characters within the URL.
- **Solution:** Convert URI Reserved characters to their equivalent percent-encoded format, and run the command again.
  For example, `@` becomes `%40`.

Running the mqsichangeproperties or mqsireportproperties commands on a resource manager returns error BIP2212

Procedure

- **Scenario:** A BIP2212 message is generated whenever you attempt to run an **mqsichangeproperties** or **mqsireportproperties** command for a valid resource manager.

- **Explanation:** The specified resource manager requires IBM MQ, but it is not available.

  There are a number of features in IBM App Connect Enterprise that require an IBM MQ installation, and for a queue manager to be associated with the integration node. For more information, see “Enhanced flexibility in interactions with IBM MQ ” on page 26.
- **Solution:** If you have not already done so, install IBM MQ. Create a new integration node, and specify a queue manager to associate with the new integration node by using the **mqsicreatebroker** command.

Resolving problems when creating resources

Use the advice given here to help you to resolve common problems that can occur when you create resources.

About this task

Look for the problem that you have encountered, and follow the guidance provided to recover from the error.

Problems when creating an integration node:

- “Message BIP8081 is issued when creating an integration node” on page 2893
- “Message BIP8246 is issued when creating an integration node that is configured to start as an IBM MQ service” on page 2893
- “Message BIP8087 is issued when creating an integration node on Windows” on page 2894
- “You cannot create files when creating an integration node on AIX” on page 2894

Problems when creating other resources:

- “Error message BIP2624 is issued when creating an integration server” on page 2894

Message BIP8081 is issued when creating an integration node

Procedure

- **Scenario:** Message BIP8081E is displayed when you are creating an integration node, the inserted message does not format correctly, and the integration node is not created.
- **Explanation:** This problem occurs because you are not a member of the correct group.
- **Solution:** Read the explanation of message BIP8081, and ask your IBM App Connect Enterprise administrator to give your user ID access to the mqbrkrs group.

Message BIP8246 is issued when creating an integration node that is configured to start as an IBM MQ service

Procedure

- **Scenario:** Message BIP8246E is displayed when you are creating an integration node that is configured to start and stop with the queue manager that is associated with the integration node.
- **Explanation:** You must be a member of the mqm group to run the **mqsicreatebroker** command with the **-d** parameter.
- **Solution:** Ask your IBM App Connect Enterprise administrator to give your user ID access to the mqm group.

Message BIP8087 is issued when creating an integration node on Windows

Procedure

- **Scenario:** When you create an integration node on Windows that has the same name as an integration node that you recently deleted, the following message might be displayed:

  ```
  BIP8087E integrationNode already exists and cannot be created.
  ```

- **Explanation:** The Windows service that is associated with the integration node that you deleted might be in a "Pending deletion" state. You cannot create an integration node with the same name, until the deletion of the Windows service has completed. The "Pending deletion" state can occur if a Windows system tool has a handle on the service.
- **Solution:** Close the system tool that has a handle on the Windows service and the service should be deleted.

You cannot create files when creating an integration node on AIX

Procedure

- **Scenario:** When you run the **mqsicreatebroker** command on IBM App Connect Enterprise for AIX, the following message is displayed:

  ```
  BIP8135E Unable to create files. Operating System return code 1
  ```

- **Explanation:** The user ID that you create for IBM App Connect Enterprise testing must have a primary group of mqbrkrs. The following example shows an AIX SMIT panel listing the **Change / Show Characteristics of a User**:

  ```
                    Change / Show Characteristics of a User

  Type or select values in entry fields.
  Press Enter AFTER making all desired changes.
  [TOP]                                  [Entry Fields]
  * User NAME                            peterc
    User ID                              [202]                    #
    ADMINISTRATIVE USER?                 false                    +
    Primary GROUP                        [mqbrkrs]                +
    Group SET                            [mqbrkrs,mqm,system,sys> +
  ```

Error message BIP2624 is issued when creating an integration server

Procedure

- **Scenario:** When you create an integration server, you get several BIP2624 messages (MQRC=2012 (MQRC_ENVIRONMENT_ERROR)), and no IBM MQ messages are processed.
- **Explanation:** You have created the integration node to run as an IBM MQ trusted application (that is, the integration node runs in the same process as the IBM MQ queue manager), but the user ID that you specified does not have the required authority.
- **Solution:** If you request the trusted application option on the **mqsicreatebroker** command by specifying the **-t** parameter, perform the appropriate steps for your operating system:

  Windows **Windows**

  Using the **-i** parameter on the **mqsicreatebroker** command, specify a service user ID that is a member of IBM MQ group mqm.

  Linux UNIX **Linux and UNIX systems**

  Specify the user ID mqm on the **-i** parameter on the **mqsicreatebroker** command.

Resolving problems when renaming resources

Use the advice in this topic to resolve common problems that can occur when you rename resources.

You rename a library that is referenced by an application or another library, but the containing project does not appear to contain the renamed library

Procedure

- **Scenario:** An application or library refers to a library. You rename that library, but the containing application or library now contains no reference to the original or renamed library in the Application Development view.
- **Explanation:** When you rename a library that is referenced by an application or library, the library reference in the containing application or library is not updated automatically.
- **Solution:** To refer to the renamed library, complete the following steps.
  a) Right-click the containing application or library and click **Manage library references**.
  The **Manage library references** dialog box opens.
  b) Select the renamed library and clear the original library, then click **OK**.
  The containing application or library now contains a reference to the renamed library. For more information, see “Referencing resources in other libraries” on page 1976.

Resolving problems when starting an integration node

Use the advice given here to help you to resolve common problems that can arise when you start an integration node.

About this task

When you start an integration node by using the **mqsistart** command, the **mqsicvp** command is run automatically to check that the environment is set up correctly (for example, the installed level of Java is supported). On Linux and UNIX, the **mqsicvp** command also verifies that the ODBC environment (if specified) is configured correctly. For more information, see command.

For advice about specific problems that can occur when you start an integration node, see the following sections.

- “Error messages AMQ7626 and BIP8048 are displayed when you try to start an integration node” on page 2899
- “Error messages BIP8048 and BIP8059 are displayed when you try to start an integration node” on page 2899

The integration node fails to start because there is not enough space in the Java TMPDIR directory or access permissions for the Java TMPDIR directory are inadequate

Procedure

- **Scenario:** The integration node fails to start and either an error message indicates that insufficient space is available or a BIP4512 exception indicates a java.lang.NoClassDefFoundError in the stack trace.
- **Explanation:** This error has two possible causes:
  - The integration node uses Java JAR files. When the integration node starts, the Java runtime environment extracts the JAR files into a temporary directory, Java TMPDIR. On Linux, and UNIX computers, the TMPDIR directory is typically `/tmp`; on Windows computers, it is `c:\temp`. If this directory is not large enough to hold the JAR files, the integration node does not start.
  - If the program is packaged as a PAR file, the user must have access to the system temporary directory and adequate space must be available in the temporary directory.
- **Solution:** Use one of the following methods to specify the location of this temporary JAR directory:
  - Use the environment variable `TMPDIR`.
  - Set the system property `java.io.tmpdir`.

  Allow at least 50 MB of space per integration server in this directory for IBM App Connect Enterprise components. You might need more space if you deploy large user-defined nodes or other JARs to the integration node. You should ensure that all the dependencies of the compute node class are deployed to the integration node.

Error message BIP2228 is issued when you try to start a second integration node on Linux or UNIX

Procedure

- **Scenario:** Error message BIP2228, which mentions `semctl` in the syslog, is displayed when you try to start a second integration node on Linux or UNIX.
- **Explanation:** This error typically indicates a permissions problem with a semaphore used by IBM App Connect Enterprise. A semaphore is created when the first integration node starts after a reboot (or after an initial installation), and only members of the primary group of the semaphore creator can access this semaphore. This problem is a consequence of the UNIX System V IPC primitives that are used by IBM App Connect Enterprise.

  The BIP2228 message is logged by any integration node that is started by a user who is not a member of the primary group of the semaphore creator. The integration node tries to access the semaphore, but fails with a permissions-related error. The integration node then terminates with the BIP2228 message.
- **Solution:** Avoid this problem by ensuring that all user IDs used to start IBM App Connect Enterprise have the same primary group. If this action is impractical, ensure that all user IDs are members of primary groups of all other user IDs. Contact your IBM Support Center for further assistance.

MQIsdp client connection is refused by the integration node

Procedure

- **Scenario:** When a new MQIsdp client tries to connect to the integration node, its connection is refused.
- **Explanation:** MQIsdp Client ID fields must be unique. If a client sends a CONN packet that contains the same Client ID as a currently connected client, the behavior is undefined.
- **Solution:** Ensure that Client IDs are unique.

When you start the integration node through the DataFlowEngine, it cycles continually

Procedure

- **Scenario:** When you start the integration node through the DataFlowEngine, it continually cycles, starts and stops, and errors BIP2801 and BIP2110 appear in the log:

```
Unable to load implementation file '/opt/IBM/DistHu b/v2/lib/libdhbNBIO.so',  rc=The file access
 permissions do not allow the specified action.
IBMibm Integration Bus internal program error.
```

- **Explanation:** The permissions on `/opt/IBM` have a value of 700, meaning that the integration node service user ID cannot read the disthub files.
- **Solution:** Set the permissions on `/opt/IBM` to 755, which is rwxr-xr-x.

The Java installation is at an incorrect level

Procedure

- **Scenario:** You issue the command to start an integration node , but the integration node does not start and the system log includes message BIP8892, for example:

```
Verification failed. The installed Java level 1.3.2 does not
   meet the required Java level 1.5.
```

- **Explanation:** The command performs a check on the level of the Java product installed on the computer to ensure that the Java product is at the required level.

  The check has failed, therefore the integration node is not started.
- **Solution:**
  - On distributed systems, you must use the JVM that is supplied with IBM App Connect Enterprise; no other Java product is supported. Check that you have run **mqsiprofile**, or (on Windows only) that you issued the **mqsistart** command from the correct command console.

    If you ran the profile command, check the settings of the environment variables in **mqsiprofile**; MQSI_JREPATH, PATH, and the appropriate library path environment variables for your operating system. Change these settings to point to the integrated JVM, and ensure that no other Java installation is in the path.

Error message BIP8875 is issued when you start an integration node

Procedure

- **Scenario:** You issue the **mqsistart** command to start an integration node, but the integration node does not start and the system log shows message BIP8875, for example:

```
The component verification for INODE has finished,
```

```
but one or more checks failed.
```

- **Explanation:** The command performs a series of checks to ensure that the integration node environment, IBM MQ queues, and Java are correct and accessible.

  One or more of the checks for the integration node identified in the message has failed, therefore the integration node is not started.

- **Solution:** Look in the system log, or in the Application log in the Event Viewer on Windows.

  Additional messages have been written before this message to indicate which checks have failed. All the checks are performed every time you issue **mqsistart**, therefore all errors are included in the log. Some messages are also returned when you run the command from the command line.

  Investigate the one or more errors that have been reported and check return codes and additional details. Look at the complete message content to check for typical causes of the error, and follow the advice given for the messages that you see in the log. View the complete message text in the Diagnostic Messages reference topics.

  For example, you might see one or more of the following messages:

  – BIP8875W: The component verification for '*component_name*' has finished, but one or more checks failed.
  – BIP8877W: The environment verification for component '*component_name*' has finished, but one or more checks failed.
  – BIP8883W: The IBM MQ verification for component '*component_name*' has finished, but one or more checks failed.
  – BIP8885E: Verification failed. Failed to connect to queue manager '*queue_manager_name*'. MQRC: *return_code* MQCC: *completion_code*
  – BIP8887E: Verification failed for queue '*queue_name*' on queue manager '*queue_manager_name*' while issuing '*operation*'. MQRC: *return_code* MQCC: *completion_code*
  – BIP8888E: Verification failed. Failed to disconnect from queue manager '*queue_manager_name*'. MQRC: *return_code* MQCC: *completion_code*
  – BIP8892E: Verification failed. The installed Java level '*level_installed*' does not meet the required Java level '*level_supported*'.
  – BIP8893E: Verification failed for environment variable '*variable_name*'. Unable to access file '*file_name*' with user ID '*user_ID*'. Additional information for IBM support: *data1 data2*.
  – BIP8895E: Verification failed. Environment variable '*variable_name*' is incorrect or missing.
  – BIP8896E: Verification failed. Unable to access the registry with user ID '*user_ID*'. Additional information for IBM support: *data1 data2*
  – BIP8897E: Verification failed. Environment variable '*variable_name*' does not match the component name '*component_name*'.
  – BIP8903E: Verification failed. The APF Authorization check failed for file '*file_name*'.
  – BIP8904E: Verification failed. Failed to start file '*file_name*' with return code '*return_code*' and errno '*error_number*'.

  If you cannot resolve the problems that are reported, and you receive a message such as BIP8893 that includes additional information, include these items in the information that you provide when you contact IBM Service.

Warning messages BIP8288-BIP8297 are shown in the syslog when you start an integration node

Procedure

- **Scenario:** Warning messages BIP8288-BIP8297 are shown in the syslog when you start an integration node on Linux and UNIX systems.

- **Explanation:** One or more problems were detected with the ODBC environment on Linux and UNIX systems.

  When you start an integration node by using the **mqsistart** command, the **mqsicvp** command is run automatically to check that the integration node environment is set up correctly. On Linux and UNIX systems, this command also verifies that the ODBC environment is configured correctly. Warning messages are written to the syslog in the following situations:

  - The file that is referenced by the ODBCINI environment variable does not exist, or the integration node does not have access to read or write to the file.
  - The ODBCSYSINI environment variable is not set.
  - The directory that is referenced by the ODBCSYSINI environment variable does not contain a file called `odbcinst.ini`, or the integration node does not have access to read or write to the file.
  - The IE02_PATH is not set.
- **Solution:** Examine the warning messages in the syslog. To view more information, run the **mqsicvp** command from the command line.

Error messages AMQ7626 and BIP8048 are displayed when you try to start an integration node

Procedure

- **Explanation:** You see these messages when using an integration node on a queue manager that is configured for global coordination with Oracle.
- **Solution:** Start the queue manager manually with the **-si** flag before starting the integration node.

Error messages BIP8048 and BIP8059 are displayed when you try to start an integration node

Procedure

- **Explanation:** You see these messages when starting an integration node that does not have an associated queue manager, or the queue manager is not started.
- **Solution:** If you do not have a queue manager associated with the integration node, create it. Start the queue manager by using the **strmqm** command, and then start the integration node.

Resolving problems when starting resources

Use the advice given here to help you resolve common problems that can arise when you start resources other than an integration node.

About this task

To learn how to resolve common problems when starting an integration node, see “Resolving problems when starting an integration node” on page 2895.

For advice about specific problems that can occur when you start resources, see the following sections.

- “Resources terminate during startup” on page 2900
- “Resources hang at startup on Windows” on page 2900
- “Error message BIP8048 is issued when you start a component” on page 2901
- “A "Not Found" error is issued when you click a link to a specific tutorial” on page 2901
- “Error message BIP0832 is issued on startup” on page 2902
- “Your integration servers restart repeatedly” on page 2902

- “After creating or changing a policy, you restart your integration server but your message flow does not start, and message BIP2275 is issued in the system log or Windows Event Viewer” on page 2902
- “A device allocation error is issued” on page 2903
- “Windows fails to recognize IBM App Connect Enterprise digital signatures: "Unknown Publisher"” on page 2904
- “The create command fails, and error message BIP8022 is issued” on page 2905
- “Your integration server restarts repeatedly with a JVM Startup failure” on page 2905

Resources terminate during startup

Procedure

- Windows

  Scenario: The following error message is displayed when you start an integration node on Windows:

  ```
  ServiceName - DLL initialization failure Initialization of the
  dynamic link library c:\windows\system32\user32.dll failed.
  The process is terminating abnormally.
  ```

- **Explanation:** This error is issued by Windows when it fails to start a service because it has insufficient storage.
- **Solution:** This error is an operating system problem. Information about how to recover from this problem is available in the Microsoft Developer Network (MSDN). You can access MSDN on the Web at `http://msdn.microsoft.com`.

Resources hang at startup on Windows

Procedure

- Windows

  Scenario: You try to start the integration node on Windows, but nothing happens in the Event log to show that a connection has started.

- **Explanation:** This problem is typically caused by processes having only one thread. To see if this is the cause, check the Windows Task Manager. If either of the processes `bipconfigmgr.exe` or `dataflowengine.exe` has started, check the number of threads owned by the process. If the process has only one thread, you are likely to encounter this problem.

- **Solution:**
  a) Shut down the integration node using the **mqsistop** command and end the process from within the Task Manager.
  b) From the Windows **Start** button, click **Settings** > **Control Panel**
  c) Double-click **Administrative Tools**
  d) Double-click **Services** to open the **Services** window. From the list of available services, locate and right-click the integration node resource that you want to start (the service name begins with IBM App Connect Enterprise component). Click **Properties** from the menu.
  e) Make a note of the **This Account** setting. Contact the system administrator to obtain the password associated with **This Account**, because these settings are lost when you change values.
  f) Select **System Account** as the **Log On As** option, and select **Allow Service to Interact with Desktop.** These selections allow you to see any hidden dialog messages. Click **OK** to accept the changes.
  g) Restart the resource that is failing and report any subsequent error messages and dialog box messages to your IBM Service Representative.
  h) When your IBM Service Representative has resolved this problem for you, make sure that you restore the **This Account**, **Password**, and **Confirm Password** entries to the values that you used when you created the integration node.

Error message BIP8048 is issued when you start a component

Procedure

- **Scenario:** Error message BIP8048 is issued when you start a component.
- **Explanation:** This message indicates that IBM MQ is not responding as expected when it tries to start the queue manager. This problem might be because of the following reasons:
  - Linux UNIX The **strmqm** executable file is not present on Linux or UNIX systems.
  - Windows The **amqmdain** executable file is not present on Windows
- **Solution:** Check that your IBM MQ installation is fully functional:
  - On Windows, start the "IBM MQSeries" service.
  - On UNIX or Linux, issue the **strmqm** command to start the queue manager that is associated with this component.

  If the check fails, your IBM MQ installation is incomplete. This error occurs typically because you have previously installed WebSphere Application Server, which installs an embedded IBM MQ component that does not support IBM App Connect Enterprise.

  Uninstall WebSphere Application Server, then install the full IBM MQ product that is provided with IBM App Connect Enterprise.

A "Not Found" error is issued when you click a link to a specific tutorial

Procedure

- **Scenario:** You see a "Not Found" error when you click a link to a specific tutorial, indicating that a URL is invalid.
- **Explanation:** You can view tutorial applications only when you use the product documentation that is integrated with the IBM App Connect Enterprise Toolkit. If you are viewing a stand-alone or online product documentation, you cannot access these resources.

- **Solution:** If you want to access tutorials, ensure that you are viewing the product documentation from within the IBM App Connect Enterprise Toolkit.

Error message BIP0832 is issued on startup

Procedure

- **Scenario:** The following error message is displayed on startup:

  ```
  BIP0832E: A class java.io.FileNotFoundException exception occurred which
  reported the following message: [filepath] (The process cannot access the
  file because it is being used by another process). Resolve the reason of
  error and try again.
  ```

- **Explanation:** An invalid IBM MQ Java Client trace output file has been specified on the Enqueue preferences screen.
- **Solution:**
  a) Open the Enqueue preferences screen by clicking **Windows** > **Preferences**, then clicking **Enqueue** on the left.
  b) In the **To file** field, specify a valid output file (one that is not read-only or already in use).

Your integration servers restart repeatedly

Procedure

- **Scenario:** Your integration servers restart repeatedly. The system log might show an error, such as BIP2060.
- **Explanation:** The problem might be caused by:
  - The integration node environment variables incorrectly defined
  - Incorrect Loadable Implementation Library directory permissions
  - Incorrect database permissions
  - Invalid user-written LILs
- **Solution:** Check:
  - Environment variables as described in "Setting up a command environment" on page 64
  - Group memberships as described in Integration servers and integration nodes

After creating or changing a policy, you restart your integration server but your message flow does not start, and message BIP2275 is issued in the system log or Windows Event Viewer

Procedure

- **Scenario:** After creating or changing a policy, you restart your integration server but your message flow does not start, and message BIP2275 is issued in the system log or Windows Event Viewer, indicating that an error occurred while loading the message flow from the persistent store.
- **Explanation:** When you change or create the policy, the connection properties are not fully validated at that point; the integration server does not attempt to use them to make a connection. For inbound adapters, the connection is made only when the associated message flow is deployed to the integration server and started. Therefore, the properties that you set on the policy might be invalid.

- **Solution:** Look at the messages following the BIP2275 message to determine if the message flow failed to start because of invalid connection properties.
  For example, in SAP you would see message BIP3414 with a reason such as:

```
Connect to SAP gateway failed
Connect_PM GWHOST= invalidhost.test.co, GWSERV=sapgw00, ASHOST= invalidhost.test.co,
  SYSNR=00
LOCATION CPIC (TCP/IP) on local host
ERROR partner not reached (host invalidhost.test.co, service 3300)
TIME Fri Nov 28 15:27:32 2008
RELEASE 640
COMPONENT NI (network interface)
VERSION 37
RC -10
MODULE nixxi_r.cpp
LINE 8728
DETAIL NiPConnect2
SYSTEM CALL SiPeekPendConn
ERRNO 10061
ERRNO TE'
```

  followed by a BIP3450 message with an adapter error message such as:

```
Connect to SAP gateway failed
Connect_PM GWHOST= invalidhost.test.co, GWSERV=sapgw00, ASHOST= invalidhost.test.co,
  SYSNR=00
LOCATION CPIC (TCP/IP) on local host
ERROR partner not reached (host invalidhost.test.co, service 3300)
TIME Fri Nov 28 15:27:32 2008
RELEASE 640
COMPONENT NI (network interface)
VERSION 37
RC -10
MODULE nixxi_r.cpp
LINE 8728
DETAIL NiPConnect2
SYSTEM CALL SiPeekPendConn
ERRNO 10061
ERRNO TE
```

  This error was detected by the adapter. The following message describes the diagnostic information that is provided by the adapter:

```
Connect to SAP gateway failed
Connect_PM GWHOST= invalidhost.test.co, GWSERV=sapgw00, ASHOST= invalidhost.test.co,
  SYSNR=00
LOCATION CPIC (TCP/IP) on local host
ERROR partner not reached (host invalidhost.test.co, service 3300)
TIME Fri Nov 28 15:27:32 2008
RELEASE 640
COMPONENT NI (network interface)
VERSION 37
RC -10
MODULE nixxi_r.cpp
LINE 8728
DETAIL NiPConnect2
SYSTEM CALL SiPeekPendConn
ERRNO 10061
ERRNO TE
```

  This message suggests that the **applicationServerHost** and **gatewayHost** properties are incorrect. When you have determined which properties are incorrect, use the **mqsichangeproperties** command to correct the properties.

A device allocation error is issued

Procedure

- **Scenario:** A device allocation error is issued.
- **Explanation:** A likely cause of this problem is that you do not have the correct permissions set on the component file system for the started task ID.

- **Solution:** Check the system log; if the problem is caused by having incorrect permissions set for the started task ID, you often see an RACF authorization failure message, as shown in the following example.

```
ICH408I USER(TASKID1 ) GROUP(TSOUSER ) NAME(FRED (FRED) 959
 /argo/MA11BRK/ENVFILE
 CL(DIRSRCH ) FID(01D7C7E2E3F0F8000F16000000000003)
 INSUFFICIENT AUTHORITY TO LOOKUP
 ACCESS INTENT(--X)  ACCESS ALLOWED(OTHER ---)
IEE132I START COMMAND DEVICE ALLOCATION ERROR
IEA989I SLIP TRAP ID=X33E MATCHED.  JOBNAME=*UNAVAIL, ASID=00A8.
D J,BPXAS
IEE115I 11.13.04 2001.212 ACTIVITY 601
```

  In this example, the started task ID does not have access to the file system component. The ICH408I message shows:

  – The file that the task is trying to access
  – The user ID that is trying to access the file
  – The permissions that the ID is expecting to have (INTENT in the message)
  – The permissions that the ID actually has (ALLOWED in the message)

  You can use this information to correct the permissions, then reissue, in this example, the request to start the integration node. This type of message is produced if the user who is issuing the command (which might be to start the integration node, or to submit JCL to start one of the utility jobs) does not have the correct file system permissions for the file system component. Use the ICH408I information to rectify the problem.

  Another possible reason for authorization failures is inconsistencies in the RACF definitions for a user ID in the MVS image and the OMVS segment. Also check with your system administrator that the RACF ID that is used on MVS has a corresponding OMVS image created.

Windows fails to recognize IBM App Connect Enterprise digital signatures: "Unknown Publisher"

Procedure

- **Scenario:** User A installs IBM App Connect Enterprise, and can run all programs (`mqsi*.exe`, `bip*.exe`, including the command console launcher). User B is created and given appropriate privileges. When User B runs an executable file such as the command console launcher, a window opens and reports that the executable file is from an unidentified publisher.
- **Explanation:** The operating system has not installed the appropriate digital certificates for User B.
- **Solution:** User B must manually install the certificates:

  1. In Windows Explorer, navigate to the `bin` directory for the IBM App Connect Enterprise installation; for example, on 32-bit systems, `C:\Program Files\IBM\MQSI\7.0\bin`
  2. Right-click any .exe file to open the **Properties** window.
  3. Click the **Digital Signatures** tab.
  4. Select the appropriate certificate from the list, then click **Details**. The **Digital Signature Details** window is displayed.
  5. Click **View Certificate**. The **Certificate** window is displayed.
  6. Click **Install Certificate** and complete the steps in the wizard. (Click **Next**, **Next**, **Finish**, then click **OK**.)
  7. Close the **Certificate** window. You return to the **Digital Signature Details**.
  8. Select the countersignature from the list, then click the **Details** button. A new **Digital Signature Details** window is displayed. You can repeat the preceding steps to install other certificates.

The create command fails, and error message BIP8022 is issued

Procedure

- **Scenario:** Error message BIP8022 is displayed when you use the **mqsicreatebroker** command on Windows, even if the supplied user name and password are correct.
- **Explanation:** The Microsoft component "Shared File and Printer Services" is required.
- **Solution:** Correct this error by installing the "Share File and Printer for Microsoft network" service on the Windows system.

Your integration server restarts repeatedly with a JVM Startup failure

Procedure

- **Scenario:** When you start the DataFlowEngine it continually starts and stops, displaying errors BIP2116E and BIP7409S in the log:

```
BIP2116E: IBM Integration Bus internal error: diagnostic information 'Fatal Error; exception
 thrown before initialisation completed', 'JVM Startup'
BIP7409S: The integration node was unable to create a JVM. The return code indicates that an
 unrecognized option was passed in to it.
```

- **Explanation:** When you start an integration server, it creates a Java virtual machine (JVM) for executing Java user-defined nodes, and its creation failed due to an incorrect JVM option.
- **Solution:** Correct the JVM option by completing the following steps:

  a) Stop the integration node.

  ```
  mqsistop integrationNodeName
  ```

  b) Check the jvmSystemProperty value of the failing integration server.

  ```
  mqsireportproperties brokerName -e egName -o ComIbmJVMManager -n
  jvmSystemProperty -f
  ```

  c) If the jvmSystemProperty has an invalid option, correct or reset its value.

  ```
  mqsichangeproperties brokerName -e egName -o ComIbmJVMManager -n
  jvmSystemProperty -v "" -f
  ```

  d) Start the integration node.

  ```
  mqsistart integrationNodeName
  ```

Resolving problems that occur when migrating or importing resources

Use the advice given here to help you to resolve common problems that can occur when you import or migrate resources.

About this task

Migration information is regularly updated on the IBM App Connect Enterprise support web page with the latest details available. Click **Troubleshoot**, then look for a document with a title like "Problems and solutions when migrating".

Procedure

- “Resolving problems when migrating or importing message flows” on page 2906
- “Resolving problems when migrating or importing message models” on page 2906
- “Resolving problems when migrating or importing other resources” on page 2908

Resolving problems when migrating or importing message flows

Use the advice given here to help you to resolve common problems that can occur when you import or migrate message flows.

Message flows that refer to a migrated user-defined node have connection errors

Procedure

- **Scenario:** After migration, all message flows that refer to a migrated user-defined node have errors indicating that connections cannot be made.
- **Explanation:** One possible cause is that the original user-defined node had space characters as part of one or more terminal names.

  The spaces are wrongly rendered as 'X20'.
- **Solution:**

  Edit the user-defined node `.msgnode` file, which is available in the same project as the flows that you have migrated. Correct any terminal names that are at fault. Ensure that the names are exactly as the message flow node implementation expects.

After migration, message flows cannot locate a user-defined node

Procedure

- **Scenario:** After migration, message flows cannot locate a user-defined node.
- **Explanation:** One possible cause is that the flows do not have the correct reference internally to a user-defined node.
- **Solution:** Select the **Locate subflow** menu for the node that cannot be located. Using the Browse dialog box, locate the user-defined node (which is in the same project as migrated flows).

  The message flow now links to the user-defined node correctly and the task list entry is removed when you save the flow.

Resolving problems when migrating or importing message models

Use the advice here to help you to resolve common problems that can occur when you import or migrate message models.

About this task

- "New instances of error message CTDV1534E" on page 2906
- "New instances of error messages CTDV1561E, CTDV1560E, CTDV1431E" on page 2907
- "New instances of error messages CTDV1150E, CTDV1118E, CTDV1432E, CTDV1446E, CTDV1466E, CTDV1467E" on page 2907
- "New instances of error message CTDV1625E" on page 2907
- "New instances of error message CTDV1458E" on page 2908
- "COBOL compiler errors when importing a copybook" on page 2908

New instances of error message CTDV1534E

Procedure

- **Scenario:** A DFDL schema that was created by a version of IBM App Connect Enterprise earlier than Version 10.0 is validated in the toolkit or during deployment. Extra instances of CTDV1534E are issued.

- **Explanation:** The IBM implementation of DFDL added a validation check to comply with the DFDL 1.0 specification. The DFDL property 'length' of an element must not exceed the capacity of the element's simple type. This check was being made for DFDL 'lengthUnits' = 'bits', it is now also being made for 'lengthUnits' = 'bytes'. The addition of this check can cause extra instances of CTDV1534E.
- **Solution:** Change the element's simple type so that it can cope with the length. For example, a two's complement binary number has DFDL 'length' = '8' and type is xs:int. Change the type to xs:long to clear the error.

New instances of error messages CTDV1561E, CTDV1560E, CTDV1431E

Procedure

- **Scenario:** A DFDL schema that was created by a version of IBM App Connect Enterprise earlier than Version 10.0 is validated in the toolkit or during deployment. Extra instances of CTDV1561E, CTDV1560E, CTDV1431E are issued.
- **Explanation:** The IBM implementation of DFDL added validation checks to comply with the DFDL 1.0 specification. Checks need to be made on elements and groups when DFDL property 'initiatedContent' = 'yes' on the parent sequence or choice. Some of these checks were missing, and have now been added. The addition of these checks can cause extra instances of CTDV1561E, CTDV1560E, or CTDV1431E.
- **Solution:** Set 'initiatedContent' = 'no' on the parent sequence or choice. If a new error CTDV1559E then appears, contact your IBM Support Center for further advice.

New instances of error messages CTDV1150E, CTDV1118E, CTDV1432E, CTDV1446E, CTDV1466E, CTDV1467E

Procedure

- **Scenario:** A DFDL schema that was created by a version of IBM App Connect Enterprise earlier than Version 10.0 is validated in the toolkit or during deployment. Extra instances of CTDV1150E, CTDV1118E, CTDV1432E, CTDV1446E, CTDV1466E, CTDV1467E are issued.
- **Explanation:** The IBM implementation of DFDL added validation checks to comply with the DFDL 1.0 specification. Cross-checks need to be made between DFDL properties of elements and groups and DFDL properties on the parent sequence or choice. Some of these checks were missing when the parent sequence or choice was the content of a global group and DFDL properties were placed on group references to the group. These checks have now been added. The addition of these checks can cause extra instances of CTDV1150E, CTDV1118E, CTDV1432E, CTDV1446E, CTDV1466E, or CTDV1467E.
- **Solution:** Correct the schema in accordance with the indicated error.

New instances of error message CTDV1625E

Procedure

- **Scenario:** A DFDL schema,that was created by a version of IBM App Connect Enterprise earlier than Version 10.0 is validated in the toolkit or during deployment. Extra instances of CTDV1625E are issued.
- **Explanation:** The IBM implementation of DFDL added validation checks to comply with the DFDL 1.0 specification. When the DFDL property 'occursCountKind' of an element is 'parsed' and the parent sequence has a separator, the DFDL property 'separatorSuppressionPolicy' of the parent sequence must be 'anyEmpty'. This new check is the result of a specification erratum.
- **Solution:** Correct the sequence so DFDL 'separatorSuppressionPolicy' is 'anyEmpty', or change the element so DFDL 'occursCountKind' is 'implicit'.

New instances of error message CTDV1458E

Procedure

- **Scenario:** A DFDL schema,that was created by a version of IBM App Connect Enterprise earlier than Version 10.0 is validated in the toolkit or during deployment. Extra instances of CTDV1458E are issued.
- **Explanation:** The IBM implementation of DFDL has added validation checks to comply with the DFDL 1.0 specification. The DFDL property '`fillByte`' must resolve to a single byte value. This check was not being made correctly when '`fillByte`' contained DFDL entities such as `%r00;`. The corrected check can cause extra instances of CTDV1458E.
- **Solution:** Correct the '`fillByte`' to use a single DFDL entity that resolves to a single byte value.

COBOL compiler errors when importing a copybook

Procedure

- **Scenario:** The report file that is generated by the import contains COBOL compiler errors.

  For example, you try to import the following copybook:

  01 AIRLINE-REQUEST.
  ....05 CUSTOMER.
  ....10 NAME.....PIC X(45).
  ....05 ADDRESS.
  ....10 STREET.....PIC X(30).
  ....10 CITY.....PIC X(25).
  ....10 STATE.....PIC X(20).
  ....10 ZIP-CODE.....PIC X(5).
  ....05 FLIGHT-NO.....PIC X(6).
  ....05 TRAN-DATE.....PIC X(10).
  ....05 COST.....PIC X(7).
  ....05 CC-NO.....PIC X(20).
  ....05 RESPONSE.
  ....10 STATUS.....PIC X(100).
  ....10 DETAILS.....PIC X(100).

  The report file contains errors:

```
Line No : 4 IGYDS1089-S "ADDRESS" was invalid. Scanning was resumed at the next area "A"
 item, level-number, or the start of the next clause.
Line No : 14 IGYDS1089-S "STATUS" was invalid. Scanning was resumed at the next area "A"
 item, level-number, or the start of the next clause.
```

- **Explanation:** The errors are caused by the copybook containing field names that are COBOL reserved keywords.
- **Solution:** Change the name of the fields in question, so that they are not COBOL reserved keywords, and retry the import.

Resolving problems when migrating or importing other resources

Use the advice given here to help you to resolve common problems that can arise when you import or migrate resources other than message flows.

About this task

- "You see an error message when you recompile a BAR file from a previous version" on page 2909
-

- "The FileImport menu provides only the option to import a compressed file inside an existing project" on page 2909

You see an error message when you recompile a BAR file from a previous version

Procedure

- **Scenario:** You have imported a BAR file with your resources from a previous version, and you then choose to refactor those resources to applications and libraries. You try to recompile a BAR file after the resources have been migrated to applications and libraries, but you see an error message similar to the following example:

```
TotalPurchaseOrderFlow.msgflow belongs in an application or library and should be deployed
 within that container and not independently.
Create a new BAR file and select the application or library in the Prepare tab of the BAR
 editor, then select Build and Save.
To deploy the resource separately from the application or library, it must be moved into a
 Message Broker project.
```

- **Explanation:** If you have reorganized your imported resources into applications and libraries, you cannot rebuild the original BAR file. If a message flow from your original BAR file has been moved into an application in IBM App Connect Enterprise, you must deploy the flow with the new container, or move it to an integration project, from which you can deploy it separately.
- **Solution:** Create a new BAR file and add the application or library that contains the resources that you want to deploy. To deploy a resource like a message flow on its own, move the flow to an integration project, then deploy the flow separately.

The File > Import menu provides only the option to import a compressed file inside an existing project

Procedure

- **Scenario:** You have a compressed file that contains message set projects and message flow projects. When you click **File** > **Import**, you have only the option to import the compressed file inside an existing project, but you want to re-create the message set projects and message flow projects.
- **Solution:** When you export and import files, do not export or import the root directory, which is created for you because of the project file. When you export your message flow and message set projects:
  a) Click **Create only selected directories**.
  b) Clear the project root folder.
  c) Select the files and subdirectories as required.
  The project root folder is selected, but is displayed as gray.

  Then, when you import the compressed file:
  a) Clear the root (/) folder.
  b) Select the files and subfolders as required.
  The project root folder is selected, but is displayed as gray.

Resolving problems when stopping resources

Use the advice given here to help you to resolve problems when you stop resources.

About this task

Procedure

- "You cannot stop the integration node" on page 2910
- "You cannot stop the integration node queue manager" on page 2910

- "The integration server ends abnormally" on page 2910

You cannot stop the integration node

Procedure

- **Scenario:** You run the **mqsistop** command to stop the integration node, but the system freezes, and does not stop any of the integration servers.
- **Explanation:** One possible cause is that a message flow is being debugged and it is currently stopped at a breakpoint. IBM App Connect Enterprise regards this as a message in flight situation, and refuses to stop the integration node through the normal command.
- **Solution:** Click **Stop debugging** in the Integration Development perspective of the IBM App Connect Enterprise Toolkit. After that operation has completed, the integration node stops.

  If you cannot stop the debug session, end all integration server processes that are associated with that integration node to allow the integration node to stop. Your messages are backed out. Click **Stop debugging** after the integration node restarts.

You cannot stop the integration node queue manager

Procedure

- **Scenario:** You are trying to use the IBM MQ **endmqm** command to stop an integration node queue manager on a distributed system, but it does not stop.
- **Explanation:** In certain circumstances, attempting to stop an integration node queue manager does not cause the queue manager to stop. This situation can occur if you have configured any message flows with multiple threads (you have set the message flow property Additional Instances to a number greater than zero).
- **Solution:** If you want to stop the integration node's queue manager, stop the integration node first by running the **mqsistop** command, and then stop the queue manager.

The integration server ends abnormally

About this task

Procedure

- **Scenario:** Your integration server processes end abnormally.
- **Explanation:** When integration server processes end abnormally, they are restarted automatically by the `bipbroker` process. If an integration server process fails, it is restarted three times during each five-minute interval. The first five-minute interval begins when the integration server is first started. RetryInterval defaults to 5

  Remove the integration server from the integration node configuration, deploy the integration node configuration, then later add the integration server, and redeploy the integration node configuration. The row is re-created and RetryInterval is set to its default value of 5.
- **Solution:** To change the default value:

  a) Stop the integration node.

  b) Change the value of the RetryInterval in the database table.

  c) Restart the integration node.

Resolving problems when deleting resources

Use the advice given here to help you to resolve problems when you delete resources.

About this task

The Windows service that is associated with an integration node is not deleted when the integration node is deleted

Procedure

- **Scenario:** When you delete an integration node on Windows, the Windows service that is associated with the integration node might remain in a "Pending deletion" state.
- **Explanation:** The "Pending deletion" state can occur if a Windows system tool has a handle on the service.
- **Solution:** Close the system tool that has a handle on the Windows service, and the service should be deleted.

You cannot delete a project from your workspace

Procedure

- **Scenario:** You cannot delete a project from your workspace. You get error messages indicating that the containing directory cannot be deleted, or the project file is missing.
- **Explanation:** If you attempt to delete a project, and the directory that contains the project is in use, or you have any files that are contained within the project that have been opened by programs other than the IBM App Connect Enterprise Toolkit, some of the resources in the project are not deleted, but others, including the project file, might be deleted.
- **Solution:** Before you delete a project, make sure that other applications do not have the files open, and that you do not have an open command prompt located in the directory. To recover from this problem, manually delete any remaining files and directories from your workspace directory, then click **Delete** from the project in the IBM App Connect Enterprise Toolkit.

Resolving problems when developing message flows

Use the advice given here to help you to resolve common problems that can arise when developing message flows.

About this task

- “Resolving appearance problems when developing message flows” on page 2912
- “Resolving problems when you use callable flow nodes” on page 2912
- “Resolving problems when you use CORBA nodes” on page 2915

Resolving appearance problems when developing message flows

This topic contains advice for dealing with some common appearance problems that can arise when developing message flows:

The task list does not update when you make corrections to your files

Procedure

- **Scenario:** The task list does not update any modifications that you make to an ESQL or mapping file. You have made corrections to the files, and while there are no error flags in the file or file icon, the error remains as a task list item.
- **Solution:** To work around this problem, set the following environment variable:

```
JITC_COMPILEOPT=SKIP{org/eclipse/ui/views/tasklist/TaskListContentProvider}
{resourceChanged}
```

You rename a flow that contains errors, but the task list entries remain

Procedure

- **Scenario:** When you rename a message flow in the IBM App Connect Enterprise Toolkit for which there are error icons (red crosses) displayed on nodes and connections, those error icons are removed when changes are made. However, the task list entries remain.
- **Solution:** Refresh the Message Flow editor by closing and reopening it.

Terminals on a subflow get out of sync as changes are made

Procedure

- **Scenario:** You have a message flow that contains subflow nodes. The name or number of terminals on the subflow gets out of sync when changes are made on the subflow itself. The same problem can happen with promoted properties.
- **Solution:** Refresh the Message Flow editor by closing and reopening it. Close the Message Flow editor that contains subflows while the subflows are being changed.

Resolving problems when you use callable flow nodes

Diagnose problems with callable flows by validating messages and running commands.

Before you begin

Read the concept information in "Callable message flows" on page 491.

About this task

To check the current operational status of IBM App Connect on IBM Cloud, see the status page: IBM App Connect status.

If problems occur when you develop callable flows, complete the following checks.

For all callable flows:

- "Validate messages before they reach the CallableFlowInvoke node" on page 2913

- “Ensure that application and endpoint name pairs are unique on a single integration server” on page 2913

For callable flows that are split between IBM App Connect Enterprise and IBM App Connect on IBM Cloud:

- “Check that the Switch server is running” on page 2913
- “Check that your callable flows are registered” on page 2914
- “Determine the status of the switch server for callable flows” on page 2914
-

Validate messages before they reach the CallableFlowInvoke node

About this task

The CallableFlowInvoke node parses the incoming message in full so that it is in a suitable format to send to the CallableInput node. Therefore, you should validate the message before it reaches the CallableFlowInvoke node. If the call fails due to a parsing failure, the message is rolled back with an exception.

Binary Large Object (BLOB) messages do not need to be parsed. Therefore, if you do not want to parse the message data before the CallableFlowInvoke node, you can send data to the callable flow by using the BLOB parser.

Ensure that application and endpoint name pairs are unique on a single integration server

About this task

Application and endpoint name pairs must be unique on a single integration server. You can have multiple callable flows that share the same application and endpoint names, but they must be in different integration servers. In this case, the Switch server acts as a load balancer.

Similarly, if you are splitting processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, any callable flows with the same application and endpoint names must be in different integrations in the cloud.

Check that the Switch server is running

About this task

The Switch server is a special integration server that runs in a special integration node called IIBSWITCH_NODE. This server routes data between your callable flows. You cannot deploy anything to this server. If your callable flows are deployed to different integration servers, you run the **iibcreateswitchcfg** command to create configuration files for the Switch server and for the agents that enable your flows to use the Switch server securely. You run the **iibswitch** command to create and start the Switch server by using the generated configuration file (`switch.json`).

After you run the **iibswitch** command, check that the Switch server is created and running by using the **mqsilist** command:

```
mqsilist IIBSWITCH_NODE
```

If the Switch server is running, you see the following response:

```
BIP1286I: Integration server 'IIBSWITCH_SERVER' on integration node 'IIBSWITCH_NODE' is running.
```

If the Switch server is stopped, start it by running the following command:

```
iibswitch /start switch
```

If the Switch server is not created, run the following commands:

```
iibcreateswitchcfg /output filepath
iibswitch /create switch /config filepath\switch.json
```

Determine the status of the switch server for callable flows

About this task

You can view the status of the switch server by running the following command (do not replace IIBSWITCH_NODE or IIBSWITCH_SERVER with the name of an integration node or integration server):

```
mqsireportproperties IIBSWITCH_NODE -e IIBSWITCH_SERVER -o ComIbmIIBSwitchManager/Switch -r
```

The output of this command also includes details of the callable flows that have been registered in this switch server, and the details of the callable flow invoke nodes that have been registered in this switch server.

Check that your callable flows are registered

About this task

The **mqsireportproperties** command lists the calling and callable flows that are registered for a specified integration server. Run the following **mqsireportproperties** command for each integration server:

```
mqsireportproperties integrationNodeName -e integrationServerName -o CallableFlowManager -r
```

The following example shows a typical response:

```
callable-flow-manager
  name='CallableFlowManager'
  identifier='CallableFlowManager'
  type='CallableFlowManager'
  delayReplyUntilFlowCommit='false'
  disableRemoteInputRegistration='false'
  redeployMessageTimeout='5'
  remoteRetryTimeout='60'
  retryLocalDuringDeploy='true'
  retryRemoteUntilTimeout='true'
  detailed
    registrations
      callableFlow
        applicationName='app2'
        endpointName='callableEndpoint1'
        inputNodeRegistered='0x0000000006AF8480'
        invokeNodeCount='1'
        queueDepth='0'
      callableFlow
        applicationName='app4'
        endpointName='callableEndpoint2'
        inputNodeRegistered='0x0000000000000000'
        invokeNodeCount='1'
        queueDepth='0'
```

A message flow that calls a callable flow contains a CallableFlowInvoke node. Therefore, if a calling flow is deployed to the server, the invoke node count is 1. The **mqsireportproperties** command also specifies the application name and endpoint name that the calling flow is using to call the callable node.

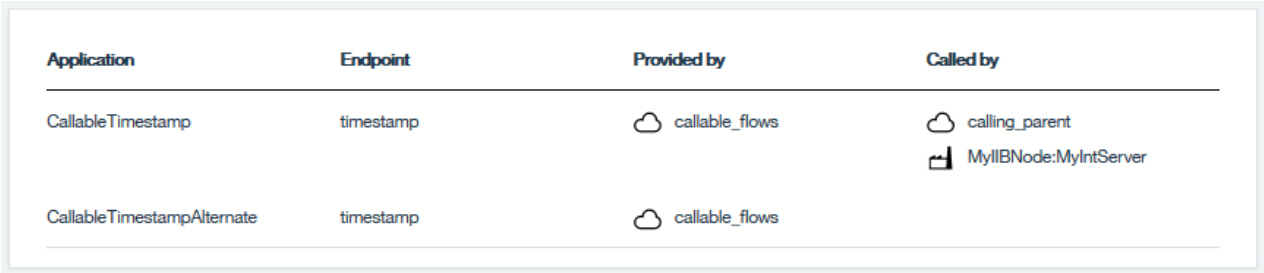
A callable flow contains a CallableInput node. If a callable flow is deployed to the server, the inputNodeRegistered value is greater than zero. The **mqsireportproperties** command also specifies the name of the application that contains the callable flow, and the endpoint name that is set on the CallableInput node of the callable flow.

If both the calling and the callable flow are deployed to the same integration server, the invokeNodeCount value is 1, and the inputNodeRegistered has a value that is greater than zero. In the example, the inputNodeRegistered value indicates that a callable flow with an endpoint name

of *callableEndpoint1* is deployed to this server in an application called *app2*. The `invokeNodeCount` value of 1 indicates that the flow that calls this callable flow is also deployed to this server. However, the `inputNodeRegistered` value is zero for the callable flow in application *app4* with an endpoint name of *callableEndpoint2*, but the invoke node count is 1. Therefore, the calling flow is deployed to this server, but the callable flow is not.

Using the Callable Flows view in IBM App Connect on IBM Cloud

If one of your callable flows is in IBM App Connect on IBM Cloud, you can check that your flows are registered with the Switch server in the Callable flows view. This view lists the callable flows that are running in IBM App Connect on IBM Cloud.



This example shows that a callable flow called *CallableTimestamp* is deployed to IBM App Connect on IBM Cloud in an integration server called *callable_flows*. This callable flow is called by a flow on another integration server in IBM App Connect on IBM Cloud, called *calling_parent*. The same flow is also called by an on-premises flow that is deployed to the integration server *MyIntServer* on the integration node *MyIIBNode*. You can also see the endpoint name that is used to link the calling and called flows.

If your on-premises flows are not listed in the Callable flows view, restart the IBM App Connect Enterprise integration server, then refresh the IBM App Connect on IBM Cloud web page in your browser.

Resolving problems when you use CORBA nodes

Advice for dealing with common problems that can arise when you develop message flows that contain CORBA nodes.

Before you begin

IBM App Connect Enterprise does not currently support all CORBA operations and types. Ensure that you are passing in a valid IDL file that contains supported operations and types. For a full list of what is supported, see "CORBA support" on page 1155. To ensure that the IDL file is valid, run it through an IDL parser.

About this task

Error message BIP4891 is issued when you include a CORBARequest node in a message flow

Procedure

- **Scenario:** You have created a message flow that contains a CORBARequest node, but error message BIP4891 is issued, indicating that the node did not receive a valid body.
- **Explanation:** This error message indicates that the CORBARequest node is trying to call an operation but cannot find the required input parameters in the incoming tree. IBM App Connect Enterprise uses

the DataObject parser to read and write message from CORBA applications. If you use an input node to pass XML into the CORBARequest node, ensure that it uses the DataObject domain.

- **Solution:** Ensure that the incoming message has the correct structure. If you are using an input node to pass XML into the CORBARequest node, set the `Message domain` property on the **Input Message Parsing** tab of the input node to `DataObject`.

A CORBA IDL file drop error is issued when you are using an IDL file that contains includes

Procedure

- **Scenario:** You have dragged a CORBA IDL file onto the canvas but a CORBA IDL file drop error is issued.
- **Explanation:** If you have imported an IDL file that contains includes, you must drag the top-level IDL file onto the canvas so that the CORBARequest node has all the relevant information. Similarly, when setting properties on the CORBARequest node, if you have imported an IDL file that contains includes, you must select the top-level IDL file in the `IDL file` property.
- **Solution:** Drag the top-level IDL file onto the canvas, or set the `IDL file` property on the CORBARequest node to the top-level IDL file.

Error message BIP4910 is issued during deployment when you are using an IDL file that contains includes

Procedure

- **Scenario:** You are deploying a message flow that contains a CORBARequest node, but error message BIP4910 is issued.
- **Explanation:** This error is issued when you have imported an IDL file that contains includes, but not all the included IDL files have been added to the BAR file. For example, you might have dragged only the message flow onto the integration server. If you have imported an IDL file that contains includes, you must ensure that all the included IDL files are added to the BAR file so that all the relevant information is available to the message flow.
- **Solution:** When you deploy a message flow that contains a CORBARequest node and an IDL file that contains includes, ensure that all included IDL files are added to the BAR file.

  If you are dragging a message flow that uses a multifile IDL file onto an integration server in the Integration Development perspective, included IDL files are not deployed. To deploy message flows that use multifile IDL files, you must create a BAR file.

Resolving problems when you use Email nodes

Advice for dealing with common problems that can arise when you develop message flows that contain Email nodes.

About this task

- "A negative email size displays in the local environment" on page 2917
- "A parsing error displays when you reparse an email attachment as XML" on page 2917
- "Removing unwanted null characters from an email" on page 2917

A negative email size displays in the local environment

Procedure

- **Scenario:** The EmailInput node receives an email from an email server that supports Post Office Protocol 3 (POP3) but the size of the email, including any attachments, might display a negative value in the `Root.EmailInputHeader.Size` Multipurpose Internet Mail Extensions (MIME) logical tree.
- **Explanation:** The email server provider that supports POP3 uses the **TOP** command to fetch the headers for the email message and the **LIST** command to determine the size of the entire message. The server then subtracts the two values to determine the size of the message body. If the server reports the size of the entire message incorrectly, you might see a negative number in the local environment Size field.
- **Solution:** You can use a Compute node to calculate the size of the email message and the size of any attachments. The following example ESQL can be used to calculate the size of the email content and attachments for a multipart MIME document. In this example, the result is stored in the LocalEnvironment:

```
DECLARE CURSOR REFERENCE TO InputRoot.MIME.Parts;
      DECLARE I INTEGER 0;

      FOR SOURCE AS CURSOR.Part[] DO
         SET I = I + LENGTH( SOURCE.Data.BLOB.BLOB);
      END FOR;

      SET OutputLocalEnvironment.Variables.EmailSize = I;
```

  For more information about messages that belong to the MIME domain, see "Manipulating messages in the MIME domain" on page 1742.

A parsing error displays when you reparse an email attachment as XML

Procedure

- **Scenario:** Your message flow retrieves emails from an email server by using an EmailInput node. The email contains an XML document attachment that you want to reparse. However, when you try to reparse the attachment you receive parsing errors from IBM App Connect Enterprise reporting that you have an invalid XML character.
- **Explanation:** Some email servers might insert carriage return (CR) and line feed (LF) characters at the end of an email. Typically you would want to keep these characters, but in this scenario you must remove them so that you can reparse your XML data.
- **Solution:** Use the following ESQL in a Compute node to remove the CR and LF characters:

```
DECLARE NEWEMAIL BLOB TRIM( TRAILING X'0d0a' FROM InputRoot.
MIME.Data.BLOB.BLOB );
```

Removing unwanted null characters from an email

Procedure

- **Scenario:** Your email attachment contains unwanted null characters that you would like to remove.
- **Explanation:** Your email attachment might contain null characters that you would like to remove; for example, you intend to reparse the data in the attachment.
- **Solution:** Use the following ESQL in a Compute node to remove the null characters:

```
DECLARE NEWEMAIL BLOB TRIM( TRAILING X'00' FROM InputRoot.MIME.
Data.BLOB.BLOB)
```

Resolving ESQL problems when developing message flows

This topic contains advice for dealing with some common ESQL problems that can arise when developing message flows:

A `Routine not defined` error message is issued in ESQL when you move a routine

Procedure

- **Scenario:** A `Routine not defined` error message is displayed in ESQL when you move a routine from one schema to another.
- **Explanation:** If a routine that was referenced by code in one schema is moved to another schema, where it is still visible, a false error is generated stating that the routine cannot be resolved.
- **Solution:** Clean the project by clicking **Project** > **Clean**.

The product fails to respond when you paste ESQL statements from Adobe Reader

Procedure

- **Scenario:** When you copy and paste certain ESQL statements from Adobe Reader into the ESQL editor, IBM App Connect Enterprise stops responding.
- **Explanation:** This problem occurs when you paste text directly from Adobe Reader into either the ESQL editor or the Java editor.
- **Solution:** To work around this problem, either enter the text manually, or copy and paste it to a text editor (such as Notepad), then perform another copy and paste action from there.

You do not know how message flows handle the code page of ESQL files

Procedure

- **Scenario:** You do not know how message flows handle the code page of ESQL files.
- **Solution:** The code page of an ESQL file is the code page of the IBM App Connect Enterprise Toolkit on which the file is created. You must deploy a message flow using an ESQL file on an IBM App Connect Enterprise Toolkit with the same code page setting as the ESQL file. When multiple ESQL files are involved in a single compiled message flow (`.cmf`) file, all these ESQL files must be in the same code page.

  See Editor preferences and localized settings for more information.

You do not know the naming restrictions for ESQL procedures and functions

Procedure

- **Scenario:** You do not know the restrictions for choosing names for ESQL modules or schema scope ESQL and mapping procedures and functions.
- **Solution:** Module and schema scope procedures and functions cannot have names starting with `IBM_WBIMB_` because `IBM_` is reserved for IBM use, and `IBM_WBIMB_` is reserved for IBM App Connect Enterprise.

Error message BIP5431 is issued and the integration node fails

Procedure

- **Scenario:** Error message BIP5431 is displayed and the integration node fails.
- **Explanation:** When setting output message properties, you have specified an incorrect physical format name for the message format.

- **Solution:** The name that you specify for the physical layer must match the name that you have defined for it. The default physical layer names are `Binary1`, `XML1` and `Text1`.

You are unable to call Java from ESQL

Procedure

- **Scenario:** Your Java class files are not being found.
- **Explanation:** When creating the class files, you have not placed them in the correct location within the system CLASSPATH.
- **Solution:** See the CREATE PROCEDURE statement for further information.

Error message BIP3203 is issued: Format expression is not a valid FORMAT expression for converting expression to type

Procedure

- **Scenario:** Your format expression contains an unrecognized character for the conversion.
- **Explanation:** Your format expression for a numeric conversion was used to convert to or from a *DATE*, *TIME*, *TIMESTAMP*, *GMTTIME* or *GMTTIMESTAMP* variable. Another possible explanation is that your format expression for a DateTime conversion was used to convert to or from an *INTEGER*, *DECIMAL* or *FLOAT* variable.
- **Solution:** Replace the format expression with one from the applicable types. For more information about valid data types and expressions, see the ESQL reference topic.

Error message BIP3204 is issued: Input expression does not match FORMAT expression. Parsing failed to match

Procedure

- **Scenario:** You have used an input string that does not match the format expression.
- **Explanation:** Your format expression contains data that does not match the current element of the format expression.
- **Solution:** Either rewrite the format expression to match the input data, or modify the input data to match the format expression. For more information about valid data types and expressions, see the ESQL reference topic.

The CAST function does not provide the expected DST offset for non-GMT time zones

Procedure

- **Scenario:** You are using the CAST function to convert a string to a TIME variable, in an integration node that is running in a time zone other than GMT. The daylight saving time (DST) offset is not correctly calculated.
- **Explanation:** If no time zone is associated with the time string passed to CAST, it is converted to GMT time. If no date is supplied, the current system date is assumed.
- **Solution:** Specify the correct time zone and date. See Formatting and parsing dateTimes as strings for more information.

Error message BIP3205 is issued: The use of a FORMAT expression is not allowed when converting

Procedure

- **Scenario:** You have used a format expression when it is not applicable, for example when converting from decimal to integer.
- **Explanation:** The use of format expressions is limited to casting between datetime and string values or numeric and string values. Your format expression cannot be applied in this case.
- **Solution:** Either remove the FORMAT clause, or change the parameters. For more information about valid data types and expressions, see the ESQL reference topic.

Problems when developing message flows with file nodes

Use the advice given here to help you to resolve some common problems that can arise when you develop message flows that contain file nodes.

About this task

- "A file node flow stops processing files and error message BIP3331 or BIP3332 is issued" on page 2920
- "During processing of a large file, error message BIP2106 is issued or the integration node stops because of insufficient memory" on page 2921
- "Missing or duplicate messages after recovery from failure in a flow attached to a FileInput node" on page 2922
- "No file is created in the output directory after FileOutput node processing" on page 2922
- "Output file name overrides have not been applied" on page 2923

A file node flow stops processing files and error message BIP3331 or BIP3332 is issued

Procedure

- **Scenario:** Files in the specified input directory are not being processed. Error message BIP3331 or BIP3332 is issued.
- **Explanation:** The error messages explain that the FileInput node encountered an exception and could not continue file processing.

  This problem can be caused when the FileInput node cannot move files from its input directory to the archive or backout directory because of file system permissions or another file in the target directory preventing the file to be transferred. In this situation, the node is unable to process input files without losing data so processing stops. Two messages are issued; the first is either BIP3331 or BIP3332 which specifies a second message which describes the cause of the problem in more detail.

- **Solution:** If the first error message issued is BIP3331, stop the flow and resolve the problem. The FileInput node is unable to complete successful processing of the file.

  1. Stop the flow.
  2. Find the error message referenced in the BIP3331. This second error message identifies the problem and the files and directories causing it.
  3. Ensure the integration node has the required access to these files and directories.
  4. You might need to move, delete or rename files in the archive or transit directories.
  5. Check whether the input file causing the problem has been successfully processed (except for being moved to the archive or backout directory). If it has been successfully processed, remove it from the input directory.
  6. Restart the flow.

  If the first error message issued is BIP3332, you do not need to stop the flow because the FileInput node has detected the problem before starting file processing. Find the error message referenced in the BIP3332 message. This second error message identifies the problem and the files and directories causing it.

During processing of a large file, error message BIP2106 is issued or the integration node stops because of insufficient memory

Procedure

- **Scenario:** Large input files cause the integration node to issue messages, or stop, because insufficient memory is available.
- **Explanation:** The FileInput node can process very large files. Subsequent processing in the flow attached to its Out terminal might require more memory than is available to the integration node.
- **Solution:** In most cases, the FileInput node imposes a limit of 100 MB on the records propagated to the attached flow. If your application needs to access large amounts of data, you might need to increase its available memory and reduce the number of available instances. See “Resolving problems with performance” on page 3010 for more information.

  If your application needs to process messages larger than 100 MB, you can override the FileInput node record size limit by taking the following actions:

  – Before starting the integration node, set the environment variable MQSI_FILENODES_MAXIMUM_RECORD_LENGTH to the required limit as an integer number of bytes, for example:

  ```
  SET MQSI_FILENODES_MAXIMUM_RECORD_LENGTH=268435456
  ```

  – When the integration node first initializes a FileInput node, it will use the environment variable value instead of the default value of 100 MB. Subsequent changes to the environment variable value will not affect the integration node limit until the integration node is restarted.

  – If the `Record detection` property is set to `Whole File`, the limit applies to the file size. If the `Record detection` property is set to `Fixed Length` or `Delimited`, the limit applies to the record size. The FileOutput node is not affected by changes to this limit.

  – **Note:** Increasing the FileInput node record size limit might require additional integration node resources, particularly memory. You must thoroughly test and evaluate your integration node's

performance when processing these files. The number of factors that are involved in handling large messages make it impossible to provide specific integration node memory requirements.

You can also reduce the memory required to process the file's contents in the following ways:

– If you are processing a whole file as a single BLOB, split it into smaller messages by specifying on the **Records and Elements** tab of the FileInput node's properties:

  - A value of `Fixed Length` in the `Record detection` property
  - A large value in the `Length` property, for example 1000000.

– If you are writing the file's contents to a single output file, specify `Record is Unmodified Data` in the FileOutput node's `Record definition` property; this reassembles the records in an output file of the same size as the input file. Wire the FileInput node's End of Data terminal to the FileOutput node's Finish File terminal. Configure the flow to have no additional instances to ensure that the output records arrive in sequence.

– If you are processing large records using the techniques shown in the Large Messaging sample, ensure that you do not cause the integration server to access the whole record. Avoid specifying a value of $Body in the `Pattern` property of a Trace node.

– If you have specified a value of `Parsed Record Sequence` in the FileInput node's `Record definition` property, the integration node does not limit the size of the record. If subsequent nodes in the message flow try to access an entire large record, the integration node might not have sufficient memory to allow this and stop.

Missing or duplicate messages after recovery from failure in a flow attached to a FileInput node

Procedure

- **Scenario:** After the failure of a message flow containing a FileInput node processing the input file as multiple records, a subsequent restart of the flow results in duplicate messages being processed. If the flow is not restarted, some input records are not processed.
- **Explanation:** If a record produces a message which causes the flow to fail and retry processing does not solve the problem, the node stops processing the file and moves it to the backout directory. Records subsequent to the failing message are not processed. The FileInput node is not transactional; it cannot roll back the file input records. Transactional resources in the attached flow can roll back the effects of the failing input record but not preceding records. Records before the failing record will have been processed but records subsequent to the failing record will not have been processed. If you restart the flow by moving the input file from the backout directory to the input directory, messages from records preceding the point of failure are duplicated.
- **Solution:** If the input messages have unique keys, modify your flow to ignore duplicate records. If the messages do not have unique keys but each input file has a unique name, you can modify your flow to form a unique key based on the file name and record number. Define a database table and add a Database node to your flow to record the key of each record that is processed. Add a DatabaseRoute node to filter input messages so that only records without keys already in the database are processed.

  If you cannot generate unique keys for each record, split your flow into two separate flows. In the first flow, wire the FileInput node to an MQOutput node so that each input record is copied as a BLOB to an IBM MQ queue. Ensure there are adequate IBM MQ resources, queue size for example, so that the first flow does not fail. In the second flow, wire an MQInput node to the flow previously wired to your FileInput node. Configure the MQInput and other nodes to achieve the desired transactional behavior.

No file is created in the output directory after FileOutput node processing

Procedure

- **Scenario:** A file created by the FileOutput node does not appear in the output directory. The node is configured so that the `Record definition` property has a value of `Record is Unmodified`

Data, Record is Fixed Length Data, or Record is Delimited Data and the flow runs one or more times.

- **Explanation:** The FileOutput node accumulates messages, record by record, in an incomplete version of the output file in the transit subdirectory of the output directory. It moves the file from the transit subdirectory to the output directory only when it receives a message on its Finish File terminal; at this point, the file is complete. If the node's input processing fails before a message is sent to the Finish file terminal, the file remains in the transit directory. The file might be completed by a subsequent flow if it uses the same file name and output directory; if this does not happen, the file is never moved to the output directory
- **Solution:** If you need to ensure that incomplete files are moved to the output directory if the input flow fails, wire the input node's Failure terminal to the FileOutput node's Finish File terminal, in addition to all other flows that are wired to this terminal.

  If you need all output files to be available for a downstream process at a particular time or after a particular event, wire a separate flow to the FileOutput node's Finish File terminal to send a message at that particular time or on that particular event. If duplicate messages which identify the same file are sent to the Finish File terminal, the FileOutput node ignores them.

  If your flows use the Request directory property location, Request file name property location (default Directory and Name in the $LocalEnvironment/Destination/File folder), or $LocalEnvironment/Wildcard/WildcardMatch, ensure that messages sent to the Finish File terminal contain the correct elements and values to identify the output file and directory.

Output file name overrides have not been applied

Procedure

- **Scenario:** The message elements set in the flow to override the output file name or directory values specified in the FileOutput node's **Basic** properties have not been applied. The output file is created using the name and directory set in the FileOutput node's **Basic** properties.
- **Explanation:** One of the following might be the cause of this problem:
  - The message sent to the FileOutput node does not contain the expected changes.
  - The FileOutput node is configured to use different elements in the message from the ones set to the new values.
  - Not all messages contain the overriding values.
- **Solution:** Use the debugger or a Trace node inserted in front of the FileOutput node's In terminal to check that the expected overriding values appear in the correct message elements. If they do not, check that the Compute mode property has been set correctly in Compute nodes that are upstream in the flow; for example, if $LocalEnvironment/File/Name has not changed following a Compute node, check that the Compute node has its Compute mode property set to LocalEnvironment and Message.

  If the message elements are set correctly, check that the FileOutput node's Request directory property location and Request file name property location properties identify the correct elements in the message.

  If you have specified Record is Unmodified DataRecord is Fixed Length Data, or Record is Delimited Data in the FileOutput node's Record definition property, ensure that messages that go to the Finish File terminal have the same override values as those that go to the in terminal. Unless you do this, the Finish file terminal message and the In terminal messages will apply to different files.

Resolving problems when you use HTTP and SOAP nodes

Use the advice that is given here to help you to resolve common problems that can arise when you develop web services message flows that contain HTTP and SOAP nodes.

About this task

If you experience problems when you use HTTP and SOAP nodes in message flows, complete the instructions for the following scenarios to diagnose and solve the problem.

- "Error message BIP3689 is issued when you deploy or restart an integration server" on page 2924
- "Warning message BIP3690 is issued when you deploy or restart an integration server" on page 2924
- "A HandshakeException is issued when you use an HTTPRequest node to make an HTTPS call" on page 2925

Use the replies to the following questions to assist you in diagnosing problems with HTTP or SOAP nodes:

- "How do I tell which listener the HTTP and SOAP nodes are using?" on page 2925
- "How do I collect HTTPListener trace?" on page 2926

Error message BIP3689 is issued when you deploy or restart an integration server

Procedure

- **Scenario:** You configure Web Services Reliable Messaging (WS-RM) on one or more message flow nodes in your message flow configuration. When you attempt to deploy the configuration to an integration server, or to restart the integration server, you see a BIP3689 error message.
- **Explanation:** Two or more message flow nodes in your deployment configuration have the same value for the `Path suffix for URL` property, and at least one of these nodes is using WS-RM. Using the same URL twice is not allowed, as one integration server might get messages intended for another integration server, therefore breaking the WS-RM message ordering.
- **Solution:** Review the values for the `Path suffix for URL` property in the message flow nodes that you plan to deploy to the same integration node. Ensure that the URL for a node that is using WS-RM is not used anywhere else in the deployment configuration.

Warning message BIP3690 is issued when you deploy or restart an integration server

Procedure

- **Scenario:** Your integration server contains SOAP or HTTP input nodes in one or more message flows. When you attempt to deploy the integration server, or to restart it, you see a BIP3690 warning message.
- **Explanation:** This warning message indicates that you are using the same value for the `Path suffix for URL` property in both SOAP and HTTP nodes in your deployed topology. You do not see the warning if you use the same URL in two or more HTTP nodes, or in two or more SOAP nodes.

  For example, you might deploy the same flow to multiple integration servers for scaling and performance reasons; this configuration is valid and does not trigger the warning. However, using the same URL across SOAP and HTTP nodes might result in unexpected behavior, and always triggers a warning, even if the configuration is valid.

  If you are using SOAP nodes and HTTP nodes in message flows on a single integration node, you can choose to handle HTTP messages by using either the integration node listener or embedded integration server listeners. If a listener in your configuration receives messages that both SOAPInput and HTTPInput nodes might get, you must carefully check the URL specifications in these nodes. If both URL specifications match an incoming message, the wrong type of node might get the message, and processing might fail or produce unexpected results. This situation occurs if you specify identical values for the Path suffix for URL properties of the HTTPInput node and the SOAPInput node. It can

also occur if you use wildcards in either or both specifications, and an incoming message matches both properties.

- **Solution:** Check the URL specifications in your HTTP and SOAP input nodes and confirm that message routing works as intended.

A HandshakeException is issued when you use an HTTPRequest node to make an HTTPS call

Procedure

- **Scenario:** You are trying to make an HTTPS call to an external web service from your IBM App Connect Enterprise message flow by using an HTTPRequest node. You receive the following error:

```
javax.net.ssl.SSLHandshakeException:
com.ibm.jsse2.util.h: PKIX path building failed:

java.security.cert.CertPathBuilderException:
PKIXCertPathBuilderImpl could not build a valid CertPath.;

internal cause is:
java.security.cert.CertPathValidatorException:
The certificate issued by OU=Class 3 Public Primary Certification Authority,
O="VeriSign, Inc.", C=US is not trusted;

internal cause is:
java.security.cert.CertPathValidatorException: Certificate chaining error
```

- **Explanation:** The integration node cannot build the entire certificate path. The keystore of this integration node must contain all the certificates in this chain of certificate authorities (CA). For an integration node to verify the digital signature on a signed certificate, the keystore must contain the public key of the certificate authority (CA) that issued that certificate. If this public key is itself issued on a signed certificate, the keystore must contain the public key of the CA that issued that certificate. This chain continues until the integration node reaches a root certificate authority that issues a self-signed certificate.
- **Solution:** Verify that you added all the required certificates to your keystore. If any of the components in the certificate chain are missing from your keystore, re-create your keystore by using keytool with the `genkey` option, then reimport your application certificates.

How do I tell which listener the HTTP and SOAP nodes are using?

Procedure

- **Scenario:** HTTP and SOAP nodes that you include in a message flow can use either the integration node listener or the embedded listener that is defined to the integration server to which the containing message flow is deployed.

  Both listeners can handle both HTTP and HTTPS messages by handling the different message types on different ports.

- **Solution:** Use the **mqsireportproperties** command to check the properties that define what listener is in use.

  1. Check whether the integration node listener is disabled:

     ```
     mqsireportproperties INODE -b httplistener -o HTTPListener -n startListener
     ```

     If this property is false, all HTTP and SOAP nodes in all integration servers are using an embedded listener.

  2. If the integration node listener is active, you must check the specific integration server.

     For example, check whether the listener in *integrationServerName* is being used to process HTTP messages for HTTP nodes:

     ```
     mqsireportproperties integrationNodeName -e integrationServerName -o ExecutionGroup  -n
      httpNodesUseEmbeddedListener
     ```

     If this property is true, all HTTP nodes that you deploy to this integration server are using the embedded listener.

     Check all integration servers for which you want to know this information.

     Check whether the listener in *integrationServerName* is being used to process HTTP messages for SOAP nodes:

     ```
     mqsireportproperties integrationNodeName -e integrationServerName -o ExecutionGroup  -n
      soapNodesUseEmbeddedListener
     ```

     If this property is true (the default value), all SOAP nodes that you deploy to this integration server are using the embedded listener.

     Check all integration servers for which you want to know this information.

  3. If both properties are false, all HTTP and SOAP nodes that you deploy to all integration servers are using the embedded listener. The value for the integration server property is ignored.

Results

If you are experiencing problems with message flows that contain HTTP or SOAP nodes, and you want to collect trace information to provide to your IBM Support Center, trace the integration server. If you are using the integration node listener for HTTP or SOAP nodes, also trace the HTTPListener component.

How do I collect HTTPListener trace?

About this task

To gather information about HTTP nodes and listeners, you must start trace, run your message flows, then retrieve and format the trace information.

Trace the integration server and the HTTPListener component:

Procedure

- Start trace for the integration server.

  For example:

  ```
  mqsichangetrace INODE -t -e integrationServerName -l debug
  ```

- If you are using the integration node listener for one or more integration servers, start trace for the HTTPListener component in one of the following two ways:
  - Trace all integration node components by running the **mqsichangetrace** command to start trace with the following options:

    ```
    mqsichangetrace component -t -b -l debug
    ```

    where *component* is the integration node name
  - Trace only the HTTPListener component by running the **mqsichangeproperties** command to start trace with the following options:

    ```
    mqsichangeproperties integrationNodeName -b httplistener -o HTTPListener
     -n traceLevel -v debug
    ```

What to do next

Save the trace output so that you can send it to the IBM Support Center, if requested.

Turn off trace when you finish collecting information to avoid affecting the performance of the integration node.

Resolving implementation problems when developing message flows

Use the advice given here to help you to resolve some common problems that can arise when running message flows.

About this task

Messages are directed to the Failure terminal of an MQInput node

Procedure

- **Scenario:** Messages that are received at a message flow are directed immediately to the Failure terminal on the MQInput node (if it is connected), or are rolled back.

- **Explanation:** When a message is received by IBM MQ, an error is signalled if the following conditions are all true:
  - The MQInput node requests that the message content is converted (the Convert property is set to `yes` on the node).
  - The message consists only of an MQMD followed by the body of the message.
  - The message format, as specified in the MQMD, is set to MQFMT_NONE.

  This error causes the message to be directed to the Failure terminal.
- **Solution:** In general, you do not need to request IBM MQ to convert the message content, because the integration node processes messages in all code pages and encodings that are supported by IBM MQ. Set the Convert property to no to ensure that messages flow from the MQInput node to successive nodes in the message flow.

Messages enter the message flow but do not exit

Procedure

- **Scenario:** You have sent messages into your message flow, and they have been removed from the input queue, but nothing appears at the other end of the message flow.

- **Explanation:** Several situations might cause this error to occur. Consider the following scenarios to try to identify the situation that is causing your failure:

  a) Check your message flow in the IBM App Connect Enterprise Toolkit.

     You might have connected the MQInput node Failure terminal to a successive node instead of the Out terminal. The Out terminal is the *middle* terminal of the three. Messages directed to an unconnected Out terminal are discarded.

  b) If the Out terminal of the MQInput node is connected correctly to a successive node, check the integration node's local error log for an indication that message processing has been ended because of problems. Additional messages give more detailed information.

     If the Failure terminal of the MQInput node has been connected (for example, to an MQOutput node), these messages do not appear.

     Connecting a node to a Failure terminal of another node indicates that you have designed the message flow to deal with all error processing. If you connect a Failure terminal to an MQOutput node, your message flow ignores all errors that occur.

  c) If the Out terminal of the MQInput node is connected correctly to a successive node, and the local error log does not contain error messages, turn user tracing on for the message flow:

     This action produces a user trace entry from only the nodes that the message visits.

     On distributed systems, you can retrieve the trace entries by using the **mqsichangetrace** command, and view the records to check the path of the message through the message flow.

  d) If the user trace shows that the message is not taking the expected path through the message flow, increase the user trace level to Debug by selecting the message flow, right-clicking it, and clicking **User Trace** > **Debug**.

     Send your message into the message flow again. Debug-level trace produces much more detail about why the message is taking a particular route, and you can then determine the reasons for the actions taken by the message flow.

     Do not forget to turn tracing off when you have solved the problem, because performance might be adversely affected.

  e) If the MQPUT command to the output queue that is defined on the MQOutput node is not successful (for example, the queue is full or **put** is disabled), the final destination of a message depends on:

     – Whether the Failure terminal of the MQOutput node is connected.
     – Whether the message is being processed transactionally (which in turn depends on the transaction mode setting of the MQInput node, the MQOutput node, and the input and output queues).
     – Whether the message is persistent or nonpersistent. When transaction mode is set to the default value of Automatic, message transactionality is derived from the way that it was specified at the

input node. All messages are treated as persistent if transaction mode=yes, and as nonpersistent if transaction mode=no.

In general, if a path is not defined for a failure (that is, neither the Catch terminal nor the Failure terminal of the MQInput node is connected):

– Non-transactional messages are discarded.

– Transactional messages are rolled back to the input queue to be tried again:

- If the backout count of the message is less than the backout threshold (BOTHRESH) of the input queue, the message is tried again and sent to the Out terminal.
- When the backout count equals or exceeds the backout threshold, one of the following might happen:
  - The message is placed on the backout queue, if one is specified (using the BOQNAME attribute of the input queue.)
  - The message is placed on the dead-letter queue, if there is no backout queue defined or if the MQPUT to the backout queue fails.
  - If the MQPUT to the dead-letter queue fails, or if there is no dead-letter queue defined, then the message flow loops continuously trying to put the message to the dead-letter queue.

– If a path is defined for the failure, then that path defines the destination of the message. If both the Catch terminal and the Failure terminal are connected, the message is propagated through the Catch terminal.

f) If your message flow uses transaction mode=yes on the MQInput node properties, and the messages are not appearing on an output queue, check the path of the message flow.

– If the message flow has paths that are not failures (but that do not end in an output queue), either:

- The message flow has not failed and the message is not backed out.
- The message flow is put to an alternative destination (for example, the Catch terminal, the dead-letter queue, or the queue's backout queue).

– Check that all possible paths reach a final output node and do not reach a dead end. For example, check that you have:

- Connected the Unknown terminal of a Filter node to another node in the message flow.
- Connected both the True and False terminals of a Filter node to another node in the message flow.

Your integration server is not reading messages from the input queues

Procedure

- **Scenario:** Your integration server has started, but is not reading messages from the specified input queues.
- **Explanation:** A started integration server might not read messages from the input queues of the message flows because previous errors might have left the queue manager in an inconsistent state.

- **Solution:** Complete the following steps:
  a) Stop the integration node.
  b) Stop the IBM MQ listener.
  c) Stop the IBM MQ channel initiator.
  d) Stop the IBM MQ queue manager.
  e) Restart the IBM MQ queue manager.
  f) Restart the IBM MQ channel initiator.
  g) Restart the IBM MQ listener.
  h) Restart the integration node.

The integration server ends while processing messages

About this task

Procedure

- **Scenario:** While processing a series of messages, the integration server (DataFlowEngine) process size grows steadily without levelling off.

  This situation might cause the DataFlowEngine process to end if it cannot allocate more memory, and restart. The error message BIP2106 might be logged to indicate the out of memory condition.

  In addition, if you are using DB2 on distributed systems, you might get the message:

  ```
  SQL0954C  Not enough storage is  available in the application heap to process
  the statement.
  ```

- **Explanation:** When a database call is made from within a message flow node, the flow constructs the appropriate SQL, which is sent using ODBC to the database manager. As part of this process, the SQL statement is prepared using the SQLPrepare function, and a statement handle is acquired so that the SQL statement can be executed.

  For performance reasons, after the statement is prepared, the statement and handle are saved in a cache to reduce the number of calls to the SQLPrepare function. If the statement is already in the cache, the statement handle is returned so that it can be re-executed with newly bound parameters.

  The statement string is used to perform the cache lookup. By using hardcoded SQL strings that differ slightly for each message, the statement is not found in the cache, and an SQLPrepare function is always performed (and a new ODBC cursor is opened). When using PASSTHRU statements, use parameter markers so that the same SQL prepared statement can be used for each message processed, with the parameters being bound at run time. This approach is more efficient in terms of database resources and, for statements that are executed repeatedly, it is faster.

  However, it is not always possible to use parameter markers, or you might want to dynamically build the SQL statement strings at run time. This situation potentially leads to many unique SQL statements being cached. The cache itself does not grow that large, because these statements themselves are generally not big, but many small memory allocations can lead to memory fragmentation.

- **Solution:** If you encounter these types of situations, disable the caching of prepared statements by setting the MQSI_EMPTY_DB_CACHE environment variable to an arbitrary value. When this environment variable has been created, the prepared statements for that message flow are emptied at the end of processing for each message. This action might cause a slight performance degradation because every SQL statement is prepared.

Your integration server hangs, or ends with a core dump

Procedure

- **Scenario:** While processing a message, an integration server either hangs with high CPU usage, or ends with a core dump. The stack trace from the core dump or abend file is large, showing many calls on the stack. Messages written to the system log might indicate "out of memory" or "bad allocation" conditions. The characteristics of the message flow in this scenario often include a hard-wired loop around some of the nodes.
- **Explanation:** When a message flow thread executes, it requires storage to perform the instructions that are defined by the logic of its connected nodes. This storage comes from the integration server's heap and stack storage. The execution of a message flow is constrained by the stack size, the default value of which differs depending on the operating system.
- **Solution:** If a message flow that is larger than the stack size is required, you can increase the stack size limit and then restart the integration nodes that are running on the system so that they use the new value.

  For information on setting the stack size for your operating system, see System resources for message flow development.

Your XSLTransform node is not working after deployment and errors are issued indicating that the style sheet could not be processed

Procedure

- **Scenario:** Your XSLTransform node is not working after deploying resources, and errors are displayed indicating that the style sheet could not be processed.
- **Solution:**
  - If the integration node cannot find the style sheet or XML files that are required, migrate the style sheets or XML files with relative path references.
  - If the contents of a style sheet or XML file are damaged and therefore no longer usable (for example, if a file system failure occurs during a deployment), redeploy the damaged style sheet or XML file.

Output messages are not sent to expected destinations

Procedure

- **Scenario:** You have developed a message flow that creates a destination list in the LocalEnvironment tree. The list might contain queues for the MQOutput node, labels for a RouteToLabel node, or URLs for an HTTPRequest node. However, the messages are not reaching these destinations, and there are no error messages.
- **Solution:**
  - Check that you have set Compute mode to a value that includes the LocalEnvironment in the output message, for example All. The default setting of Compute mode is Message, and all changes that you make to LocalEnvironment are lost.
  - Check your ESQL statements. The content and structure of LocalEnvironment are not enforced, so the ESQL editor (and content assist) does not provide guidance for field references, and you might have specified one or more of these references incorrectly.

    Some example procedures to help you set up destination lists are provided in “Populating Destination in the local environment tree” on page 1656. You can use these procedures unchanged, or modify them for your own requirements.

You experience problems when sending a message to an HTTP node's URL

Procedure

- **Scenario:** Sending a message to an HTTP node's URL causes a timeout, or the message is not sent to the correct message flow.
- **Explanation:** The following rules are true when URL matching is performed:
  - There is one-to-one matching of HTTP requests to HTTPInput nodes. For each HTTP request, only one message flow receives the message. This statement is true even if two message flows are listening on the same URL. Similarly, you cannot predict which MQInput node that is listening on a particular queue will receive a message.
  - Messages are sent to wildcard URLs only if no other URL is matched. Therefore a URL of /* receives all messages that do not match another URL.
  - Changing a URL in an HTTPInput node does not automatically remove the entry from the HTTP listener. For example, if a URL /A is used first, then changed to a URL of /B, the URL of /A is still used to listen on, even though there is no message flow to process the message. This incorrect URL does get removed after the integration node has been stopped and restarted twice.
- **Solution:** To find out which URL the integration node is currently listening on, look at the file `wsplugin6.conf` in the following location:
  - Linux UNIX On Linux and UNIX: `/var/mqsi/components/`*`integrationNodeName`*`/config`
  - Windows On Windows, `%ProgramData%\IBM\MQSI\components\`*`integrationNodeName`*`\config`, where %PROGRAMDATA% is the environment variable that defines the system working directory. The default directory depends on the operating system.

  If problems persist, empty `wsplugin6.conf`, restart the integration node, and redeploy the message flows.

When using secure HTTP connections, you change a DNS host's destination but the integration node is using a cached DNS host definition

Procedure

- **Scenario:** You are using an integration node with secure HTTP connections that use the Java virtual machine (JVM). You have changed a DNS destination, but the integration node is using a cached DNS host definition, therefore you have to restart the integration node to use the new definition.
- **Explanation:** By default, Java caches the host lookup from DNS, which is not appropriate if you want to look up the host name each time or if you want to cache it for a limited amount of time. This situation occurs only when you use SSL connections. (When using a secure HTTPS connection, the HTTPRequest node uses the SSL protocol, which issues Java calls, whereas a non-SSL protocol uses native calls.)

  To avoid this situation, you can empty the cache on the JVM by setting the **`networkaddress.cache.ttl`** property to zero. This property dictates the caching policy for successful name lookups from the name service. The value is specified as an integer to indicate the number of seconds for which to cache the successful lookup. The default value of this property is -1, which indicates that the successful DNS lookup value is cached indefinitely in the JVM. If you set this property to 0 (zero), the successful DNS lookup is not cached.

- **Solution:** To pick up DNS entry changes without the need to stop and restart the integration node and JVM, disable DNS caching.

  Edit file `$JAVA_HOME/jre/lib/security/java.security`, and set the value of the **`networkaddress.cache.ttl`** property to `0` (zero).

  Then, run the following command:

```
mqsichangeproperties <INodeName> -e <IntegrationServer> -o ComIbmJVMManager -n
 jvmSystemProperty -v "-Dsun.net.inetaddr.ttl=0"
```

The TimeoutControl node issues error message BIP4606 or BIP4607 when the timeout request start time that it receives is in the past

Procedure

- **Scenario:** When a TimeoutControl node receives a timeout request message that contains a start time in the past, it issues error message BIP4606 or BIP4607: `The Timeout Control Node '&2' received a timeout request that did not contain a valid timeout start date/time value`.
- **Explanation:** The start time in the message can be calculated by adding an interval to the current time. If a delay occurs between the node that calculates the start time and the TimeoutControl node, the start time in the message will have passed by the time it reaches the TimeoutControl node. If the start time is more than approximately five minutes in the past, a warning is issued and the TimeoutControl node rejects the timeout request. If the start time is less than five minutes in the past, the node processes the request as if it were immediate.
- **Solution:** Ensure that the start time in the timeout request message is a time in the future.

You are using a TimeoutControl node with a TimeoutNotification node, with multiple clients running concurrently, and messages appear to be being dropped

Procedure

- **Scenario:** You are using a TimeoutControl node with a TimeoutNotification node, with multiple clients running concurrently, and messages appear to be being dropped. In the timeout request message, allowOverwrite is set to TRUE.
- **Explanation:** If multiple clients are running concurrently, and allowOverwrite is set to TRUE in the timeout request message, messages can overwrite each other.
- **Solution:** Ensure that different TimeoutNotification nodes that are deployed on the same integration node do not share the same unique identifier.

Error message BIP5347 is issued on AIX when you run a message flow that uses a message set

About this task

Procedure

- **Scenario:** Error message BIP5347 (`MtilmbParser2: RM has thrown an unknown exception`) is issued on AIX in either of these circumstances:
  - When you are deploying a message set
  - When you are running a message flow that uses a message set

- **Explanation:** BIP5347 is typically caused by a database exception, and it is issued when an integration server tries to load an MRM dictionary for use by a message flow. This process involves two steps:

  1. The integration server retrieves the dictionary and wire format descriptors from the integration node data store.
  2. The integration server stores the dictionary in the memory that a message flow would use to process an MRM message.

  BIP5347 is typically issued during step 1. This problem can appear to be intermittent; if you restart the integration server, the message is sometimes processed correctly.

  BIP5347 might also be caused by the presence of a datetime value constraint in the message set, which causes the error each time the message set is deployed.
- **Solution:** To identify the cause of the error, capture a service level debug trace to confirm that the database exception is occurring.
  - If the error is caused by the presence of a datetime value constraint, a message similar to the following message appears in the service level debug trace (the exact message depends on the datetime constraint in the message set):

    ```
    Unable to parse datetime internally, 9, 2001-12-17T09:30:47.0Z,
    yyyy-MM-dd'T'HH:mm:ss.SZZZ
    ```

    This error occurs because the MRM element in question has a datetime value that is not compatible with the datetime format string, so the dictionary is rejected. To solve this problem, ensure that the datetime value is compatible with the datetime format string.

Error message BIP2130 is issued with code page value of -1 or -2

Procedure

- **Scenario:** The following error message is issued:

```
BIP2130: Error converting a character string to or from codepage [code page value]
```

  where `[code page value]` is either -1 or -2. You have not, however, specified a code page of either -1 or -2 in your message tree. You have, however, used one of the IBM MQ constants MQCCSI_EMBEDDED or MQCCSI_INHERIT.
- **Explanation:** The IBM MQ constants MQCCSI_EMBEDDED and MQCCSI_INHERIT are resolved when the whole of the message tree is serialized to produce the IBM MQ bit stream. This happens when the message is put on the IBM MQ transport. Until that time, these values exist in the message tree as either -1 (for MQCCSI_EMBEDDED) or -2 (for MQCCSI_INHERIT). If one or more parts of the message tree are serialized independently, such as with a ResetContentDescriptor node or ESQL ASBITSTREAM function, this error occurs.
- **Solution:** You do not have to set MQCCSI_EMBEDDED or MQCCSI_INHERIT in the message tree's CodedCharSetId field. You can achieve the same result by explicitly setting the required CodedCharSetId to the previous header's CodedCharSetId value. For example, you would need to replace:

```
SET OutputRoot.MQRFH2.(MQRFH2.Field)CodedCharSetId = MQCCSI_INHERIT;
```

  with

```
SET OutputRoot.MQRFH2.(MQRFH2.Field)CodedCharSetId = InputRoot.MQMD.CodedCharSetId;
```

  where the MQMD folder is the header preceding the MQRFH2 header.

The integration server restarts before an MQGet node has retrieved all messages

Procedure

- **Scenario:** You have created a message flow that contains an MQGet node. Not all of the messages are retrieved from the queue because the integration server restarts before the node has retrieved all the messages. No abend files are generated.
- **Explanation:** In IBM App Connect Enterprise, processing that involves nested or recursive processing can cause extensive use of the stack. Message flow processing occurs in a loop until the MQGet node has retrieved all the messages from the queue. Each time that processing returns to the MQGet node, the stack size increases.
- **Solution:** Use a PROPAGATE statement. The statement propagates each message through the message flow in a loop, but each time that processing returns to the PROPAGATE statement, the stack is cleared.

  Use an ESQL variable (for example, set Environment.Complete to true) in the environment tree to terminate the ESQL loop, stop the propagations, and wait for the next trigger message. If you need to store content from the messages, store it in the environment tree because other trees are deleted when message flow processing returns to the PROPAGATE statement. For more information about how to use this statement, see PROPAGATE statement.

Resolving problems when you use IMS nodes

Advice for dealing with common problems that can arise when you develop message flows that contain IMS nodes.

Before you begin

- Read about IMS in "IBM Information Management System (IMS)" on page 1146.
- Ensure that you have set up the IBM App Connect Enterprise runtime environment correctly, as described in "Preparing the environment for IMS nodes" on page 215.

About this task

If you experience problems when you use IMS nodes in message flows, follow the instructions for the following scenarios to diagnose and solve the problem.

How can I tell if my integration node is connected to IMS Connect?

Procedure

- **Scenario:** You need to check if your integration node is connected to IMS Connect.
- **Explanation:** You can use SDSF on z/OS to issue a command to see which ports have clients connected to them.

- **Solution:** Using SDSF, enter the following **QUERY MEMBER** command, where *IM0ACONN* is the name of your IMS Connect job:

```
/F IM0ACONN,QRY MEMBER TYPE(IMSCON)
```

The output is in the following format:

```
/F IM0ACONN,QRY MEMBER TYPE(IMSCON)
HWSC0001I   HWS ID=IM0ACONN RACF=Y  PSWDMC=N
HWSC0001I      MAXSOC=50  TIMEOUT=0
HWSC0001I      RRS=N   STATUS=REGISTERED
HWSC0001I      VERSION=V10 IP-ADDRESS=009.017.252.024
HWSC0001I      SUPER MEMBER NAME=
HWSC0001I    ADAPTER=N
HWSC0001I    DATASTORE=IM0A     STATUS=ACTIVE
HWSC0001I      GROUP=IM0AGRNM MEMBER=IM0ACONN
HWSC0001I      TARGET MEMBER=IM0A
HWSC0001I      DEFAULT REROUTE NAME=HWS£DEF
HWSC0001I      RACF APPL NAME=
HWSC0001I      OTMA ACEE AGING VALUE=2147483647
HWSC0001I      OTMA ACK TIMEOUT VALUE=120
HWSC0001I      OTMA MAX INPUT MESSAGE=5000
HWSC0001I    NO ACTIVE IMSPLEX
HWSC0001I    PORT=1080     STATUS=ACTIVE
HWSC0001I      CLIENTID USERID   TRANCODE STATUS       SECOND  CLNTPORT  IP-ADDRESS

HWSC0001I      HWSEHYMO JDOE   IVTNO    RECV             21      1109  009.017.137.11

HWSC0001I      TOTAL CLIENTS=1  RECV=1 CONN=0 XMIT=0 OTHER=0
```

This example shows that one client is connected on TCP port 1109, and that the client is connecting from the IP address 9.17.137.11.

You can run netstat on that system to find out in which process that client is running.

Use the following IMS command to view the TPIPEs that are created for those connections:

```
/DISPLAY TMEMBER IMSConnect_Name TPIPE ALL
```

- For transactions that have a commit mode of 1, the TPIPE name is the port number that is used for that interaction (for example, 1080 in the previous example).
- For transactions that have a commit mode of 0, the TPIPE name is the same as the client ID (for example, HWSEHYMO in the previous example). The client ID is generated automatically in the IMSRequest node.

How can I discover the correct settings for `Hostname`, `Portnumber`, and `DataStoreName`?

Procedure

- **Scenario:** Your integration node fails to connect to IMS and you want to verify your settings.
- **Explanation:** You can use SDSF on z/OS to issue a command to see members of the XCF group to which your IMS control region belongs. One of these members should be IMS Connect. You can then run a command against IMS Connect to discover these properties.
- **Solution:** Use SDSF to enter the following command:

```
/xx/display OTMA
```

where *xx* is the reply ID for your IMS control region job.

For example, if you see `....... *26 DFS996I *IMS READY* IM0A` in `S.log`, run the command `/26/DISPLAY OTMA`.

The output from that command shows the name of the IMS Connect that is in the same XCF group as this IMS control region:

```
DFS000I     GROUP/MEMBER      XCF-STATUS   USER-STATUS    SECURITY  TIBINPT SMEM   IM0A
```

```
DFS000I                          DRUEXIT  T/O                                          IM0A
DFS000I     IM0AGRNM                                                                  IM0A
DFS000I     -IM0A             ACTIVE       SERVER         CHECK                      IM0A
DFS000I     -IM0A               N/A        0                                         IM0A
DFS000I     -IM0ACONN         ACTIVE       ACCEPT TRAFFIC CHECK       05000          IM0A
DFS000I     *08350/175112*   IM0A
```

Use SDSF to enter the following **QUERY MEMBER** command, where *IM0ACONN* is the name of your IMS Connect job that was reported by the previous command:

```
/F IM0ACONN,QRY MEMBER TYPE(IMSCON)
```

The output is in the following format:

```
/F IM0ACONN,QRY MEMBER TYPE(IMSCON)
HWSC0001I   HWS ID=IM0ACONN RACF=Y  PSWDMC=N
HWSC0001I      MAXSOC=50  TIMEOUT=0
HWSC0001I      RRS=N   STATUS=REGISTERED
HWSC0001I      VERSION=V10 IP-ADDRESS=009.017.252.024
HWSC0001I      SUPER MEMBER NAME=
HWSC0001I    ADAPTER=N

```

What should I do when my transaction times out?

Procedure

- **Scenario:** The transaction times out and the message is sent to the Timeout terminal, or an exception is issued.
- **Explanation:** Your transaction is taking longer than the values that are set for the execution or socket timeouts, therefore the node stops waiting for a response, and issues an exception or sends the message to the Timeout terminal.

  If the transaction subsequently completes successfully, the result depends on the commit mode that is set on the IMSRequest node:

  – If the `Commit mode` property is set to `0: COMMIT_THEN_SEND`, the unit of work is committed and the response is discarded.

  – If the `Commit mode` property is set to `1: SEND_THEN_COMMIT`, the response is not sent and the unit of work is rolled back.
- **Solution:** Increase the execution or socket timeout values to give enough time for the transaction to complete.

  – Configure the execution timeout by using the `Timeout waiting for a transaction to be executed` property on the IMSRequest node.

How many physical connections should I expect in IMS Connect?

Procedure

- **Scenario:** You need to set the values for the number of connections that are required by clients that are connecting to IMS Connect.

- **Explanation:** The number of physical connections that can be opened in IMS Connect is limited. The limit depends on the MAXSOC and MAXFEILEPROC settings.
  - The MAXSOC setting in IMS Connect determines the number of sockets that can be opened in IMS, which is the number of ports on which IMS listens for connections, plus the number of physical connections.
  - MAXFILEPROC is a UNIX System Services (USS) setting, which must be greater than or equal to MAXSOC, otherwise IMS reaches this limit before it reaches its own MAXSOC limit.

  If the IMS Connect process is granted superuser authority in USS, it sets MAXFILEPROC automatically.

  If the MAXSOC value is reached, IMS Connect issues warning message HWSS0771W, and refuses new requests for connections from clients. This behavior continues until the number of open sockets is below the limit (for example, after some clients have disconnected).

  If the MAXFILEPROC value is reached, USS issues information message BPXI040I.
- **Solution:** When you set values for MAXSOC and MAXFILEPROC, consider how many clients are likely to connect concurrently to IMS Connect, and how many connections those clients will require.

  IBM App Connect Enterprise acts as a client to IMS Connect, and opens connections to IMS Connect. Therefore, find out how many connections are required by IBM App Connect Enterprise by gathering the following information:
  - The number of message flows with IMS nodes that are deployed
  - For those message flows, the values of the `Additional instances` property

  The maximum number of connections required for each integration node is determined by the number of threads that can be running concurrently in the IMS nodes. In the following example, three message flows with IMS nodes exist:
  - Message flow A has 0 additional instances, therefore one thread is running.
  - Message flow B has 3 additional instances, therefore four threads can be running concurrently.
  - Message flow C has 4 additional instances, therefore five threads can be running concurrently.

  In this example, the maximum number of connections required by the integration node is 10 (1+4+5). If you have four other similar integration nodes, all connecting to the same instance of IMS Connect, which has five ports configured, you would set the maximum number of sockets (MAXSOC) to at least 55 (the maximum number of connections for five integration nodes plus the number of ports: 10x5+5).

Resolving problems when you use Salesforce nodes

Use the advice given here to help you to avoid or resolve problems that might arise when you are using SalesforceRequest nodes.

Connecting to Salesforce

Procedure

- When you set the Salesforce password by using the mqsisetdbparms command, ensure that the password is suffixed with the Salesforce security token for the Salesforce ID. You can get the security token from the email that was sent to the email address associated with the credentials when the security token was last reset.

  For more information, see "Configuring a secure connection to Salesforce.com" on page 1196.
- After creating a new IBM App Connect Enterprise Connected App in Salesforce.com, click **Manage** and ensure that the OAuth policy **Permitted Users** is set to `All users may self-authorize`. If this option is not selected, connections might fail even if the correct credentials are supplied.
- Ensure that the Salesforce user ID that you use allows for the number of operations that you want to perform. Some types of account apply quotas to the number of operations that can be performed in a given time period using the Force.com REST API.

Working with Salesforce records

Procedure

- If you want to use a SalesforceRequest node for production purposes, you must purchase a separate license entitlement for IBM Application Integration Suite. You must then change the operation mode of the integration node to `applicationIntegrationSuite` mode.

  For more information, see "License requirements" on page 5 and "Changing the operation mode" on page 86.
- You can reduce the amount of data returned from Salesforce through a `retrieve` operation, by using a **`field`** filter to specify the particular fields that you want to retrieve. Performance is improved as a result because, if no fields are specified, an extra call is made by the Salesforce client code to retrieve the full list of fields.
- After a `retrieve` operation, the output message body will be a JSON array, unless a Salesforce ID is specified to retrieve a single record.
- If you are using the JSON schema for Salesforce objects in a Mapping node, the schema and the message map must reside in the same shared library or REST API. For more information, see "Using Salesforce models" on page 1212.
- Several fields in Salesforce objects are read-only, and an attempt to create or update a read-only field will return an error from Salesforce. Fields that are read-only are typically system properties (such as '`CreatedDate`') or derived fields (such as '`BillingAddress`').

Handling errors returned from the SalesforceRequest node

About this task

When you are using the SalesforceRequest node, several different types of failure can be propagated to the failure terminal of the node, including the following:

- **Missing or badly formed data is supplied to the SalesforceRequest node**.

  If the validation of the input data in the message body or the local environment fails, error `bip3859` or `bip3862` will be propagated to the Failure terminal, which contains details of the incorrectly formed or missing data. For example, if a request is made to retrieve a set of records but the filter property in the LocalEnvironment specifies the limit clause as a negative value, error `bip3859` will be sent to the Failure terminal with details of the field that caused the validation error:

  ```
  Feb 22 11:32:02 localhost IIB[25130]: IBM Integration Bus v10004 (Server1.default) [Thread
   26660] (Msg 3/3) BIP3859E: The property 'filter.limit'='-1' supplied to the SalesforceRequest
   node is invalid.
  ```

- **A communications failure with Salesforce**.

  If there is a communications failure with Salesforce, for example if an invalid URL was supplied or an authorization failure occurs, error `bip3858` will be sent to the Failure terminal of the SalesforceRequest node, with the message inserts containing details of the failure. For example, if a request is made to retrieve a set of records but the URL provided on the SalesforceRequest node is incorrect, error `bip3858` will be sent to the Failure terminal with details of the error:

  ```
  Feb 22 11:37:01 localhost IIB[25130]: IBM Integration Bus v10004 (Server1.default) [Thread
   27379] (Msg 3/3) BIP3858E: The SalesforceRequest node received error code 'Error' while
   executing 'Retrieve' operation. Error 'getaddrinfo ENOTFOUND badlogin.salesforce.com'.
  ```

- **The Salesforce operation returned a failure**.

  If the Salesforce operation executed but returned a failure, error `bip3858` will be sent to the Failure terminal of the SalesforceRequest node, with the message inserts containing details of the failure. For example, if a request is made to retrieve a set of records but the filter property in the LocalEnvironment

specifies an invalid name in the field clause, error `bip3858` will be sent to the Failure terminal with details of the error:

```
Feb 22 12:05:36 localhost IIB[25130]: IBM Integration Bus v10004 (Server1.default) [Thread
 31343] (Msg 3/3) BIP3858E: The SalesforceRequest node received error code 'INVALID_FIELD'
 while executing 'Retrieve' operation. Error ' SELECT Id, Name, RemoteAddress FROM Account
 ^ ERROR at Row:1:Column:18 No such column 'RemoteAddress' on entity 'Account'. If you are
 attempting to use a custom field, be sure to append the '__c' after the custom field name.
 Please reference your WSDL or the describe call for the appropriate names.'.
```

- **An update or delete request was made specifying a Salesforce identifier, but no record exists with that Salesforce ID**.

  This error code is returned only for the `update` and `delete` requests; if no record exists for a `retrieve` request, no error is returned, but an empty result is returned through the Out terminal to the SalesforceRequest node. For example, if a request is made to delete a record, but no record exists with the specified Salesforce Id, error `bip3863` is sent to the failure terminal:

```
Feb 22 12:16:47 localhost IIB[25130]: IBM Integration Bus v10004 (Server1.default) [Thread
 414] (Msg 3/3) BIP3863E: A request was sent to Salesforce specifying an ID with value
 '000000000000000000' while processing the 'delete' operation, but no Salesforce record could
 be found with that ID.
```

  This is not a complete list of the errors code which may be returned from the SalesforceRequest node.

Resolving problems when using Kafka nodes

Use the advice given here to help you to avoid or resolve problems that might arise when you are using KafkaConsumer or KafkaProducer nodes.

Connecting to a Kafka cluster

Procedure

- When you set the Kafka user ID and password by using the **mqsisetdbparms** command, ensure that you used the form `kafka::KAFKA::`*integrationServerName*.

  For more information, see “Configuring security credentials for connecting to Kafka” on page 904.
- If you are connecting to IBM Event Streams in IBM Cloud, ensure that the **Security protocol** property on the Kafka node is set to SASL_SSL. For more information about configuring the security credentials for connecting to Event Streams, see “Using Kafka nodes with IBM Event Streams” on page 909.

Using log4j to investigate connection and configuration problems

About this task

If you have a problem when you connect to Kafka, and the problem persists after you validate that the configuration of the nodes is correct, you might find more information by enabling tracing from the Kafka client.

The Kafka client uses the log4j component to capture trace information. The `lib` subdirectory of the IBM App Connect Enterprise installation directory contains a `log4j.properties` file, which contains an example of how tracing can be enabled for the Kafka client:

```
################################################################################
 ## Kafka logger, un-comment the following section to write Kafka log messages
 ## to a file.
 ## The logging level, currently 'DEBUG' is the most detailed level of
 ## logging available. The log4j.appender.kafkaAppender.Threshold value may
 ## be changed to one of
 ##     DEBUG, TRACE, INFO, WARN, ERROR, FATAL
 ## to reduce the information written to the log file.
 ################################################################################
 log4j.logger.org.apache.kafka=DEBUG, kafkaAppender
 log4j.appender.kafkaAppender=org.apache.log4j.FileAppender
```

```
log4j.appender.kafkaAppender.File=/tmp/kafkadebug.log
log4j.appender.kafkaAppender.Threshold=DEBUG
log4j.appender.kafkaAppender.Append=true
log4j.appender.kafkaAppender.layout=org.apache.log4j.PatternLayout
log4j.appender.kafkaAppender.layout.ConversionPattern=[%d] %p %m (%c)%n
```

Procedure

Complete the following steps to enable tracing from the Kafka client:

1. Copy the `log4j.properties` file from the `lib` subdirectory of the IBM App Connect Enterprise installation directory to the **workpath** of the integration server:

   For an independent integration server, the target directory is shown in the following example:

   ```
   - cp <install dir>/server/lib/log4j.properties <work-dir>/log4j.properties
   ```

   For a managed integration server, the target directory is shown in the following example:

   ```
   - cp <install dir>/server/lib/log4j.properties <workpath>/components/<integrationNodeName>/
   servers/<serverName>/log4j.properties
   ```

   For all integration servers that are managed by the same integration node, the target directory is shown in the following example:

   ```
   - cp <install dir>/server/lib/log4j.properties <workpath>/components/<integrationNodeName>/
   log4j.properties
   ```

2. In the file that you copied, uncomment the `kafkaAppender` configuration, and modify the level of logging and the destination for the captured trace, as required.
3. Restart the integration server to start capturing logging information from the Kafka client.

Enabling JSSE trace to troubleshoot issues

About this task

If you have a problem when you connect to Kafka, and the problem persists after you validate that the configuration of the nodes is correct, you might find more information by enabling JSSE tracing.

At the time of writing, the following instructions work only for HTTP listeners. If you want to troubleshoot an application that uses secure connection (HTTPS) you can gather agent service trace if you are using the integration node listener, or DataFlowEngine service trace if you are using the embedded listener. In some cases, you might need to collect both types of traces concurrently. For more information, see “Using trace” on page 3026.

Procedure

You can enable JSSE trace by setting the environment variable *IBM_JAVA_OPTIONS* as follows:

```
export IBM_JAVA_OPTIONS=-Djavax.net.debug=all
```

Alternatively, enable JSSE trace by completing the following steps:

1. Stop the integration node or integration server as described in “Starting and stopping an integration node” on page 247 and “Stopping an integration server” on page 254.
2. In the `server.conf.yaml` file for the integration server, update the parameter **jvmSystemProperty** as follows:

   ```
   jvmSystemProperty: '-Djavax.net.debug=true'
   ```

   For more information about updating the `server.conf.yaml` file, see “Configuring an integration server by modifying the server.conf.yaml file” on page 172.

3. Restart the integration node or integration server as described in “Starting and stopping an integration node” on page 247 and “Starting an integration server” on page 250.
4. Re-create the issue.

   If you set the parameter correctly, the text "IBMJSSE2 will not allow protocol SSLv3 per com.ibm.jsse2.disableSSLv3 set to TRUE or default" appears in standard output (STDOUT). If you do not see this text, review your steps and try again. For more information about standard output (STDOUT), see Standard system logs.

Resolving mapping and message reference problems when developing message flows

Advice for dealing with some common mapping and message reference problems that can arise when developing message flows:

Resources that are referenced by the mapping file cannot be resolved

Procedure

- **Scenario:** You have imported some message flows into the IBM App Connect Enterprise Toolkit that contain mappings. An error is issued, indicating that the resources that are referenced by the mapping file cannot be resolved.
- **Explanation:** Mappings can use resources that exist in other projects. For example, a mapping reference to a message set might exist in a different project. If the reference cannot be resolved, it probably means that the reference to the other project has been lost.
- **Solution:** Create a new project reference.

  For more information, see “Referencing resources in other libraries” on page 1976.

Warnings or errors are issued for message references

Procedure

- **Scenario:** Warnings or errors are issued for message references, yet you are certain that your references are correct.
- **Explanation:** This is never the case with messages that are using the XML parser. For these message references, direct validation is not performed because the references could be used for generic XML.

  There is an ESQL editor preference that allows you to choose to ignore message reference mismatches, or to have them be reported as a warning or an error. By default, this type of problem is reported as a warning, so that you can still deploy the message flow.
- **Solution:** To use the validation feature, ensure that you have set up a project reference from the project that contains the ESQL to the project that contains the message set.

  For more information, see “Referencing resources in other libraries” on page 1976.

  If you are using reference in a subroutine, take the following steps:

  a) Create a reference to the tree and the parser in the module's main procedure.

  b) Associate the reference to the correlation name, for example InputRoot or Root. Alternatively, create the OutputRoot.*parser* node, where *parser* is the name of the parser that you want to use.

  c) Pass the reference as a parameter to an ESQL subroutine that identifies the XSD type of the reference.

Results

This practice is beneficial because the passed reference supports content assistance and validation for ESQL. The message type content properties `open`, or `open defined` are not used in validation, and the assumption is that this property is `closed`.

Target is not referencing a valid variable warning when you set the value of a target

Procedure

- **Scenario:** You have set the value for a target to a variable, such as an IBM MQ constant, and when you save the map file the warning `The target "$target" is not referencing a valid variable` is generated.
- **Explanation:** The variable that you have referenced is not recognized. For example, you might have entered an expression of the form `$mq:` followed by an IBM MQ constant, but the constant is not recognized. This might be because the variable has been entered incorrectly or it is not supported. Alternatively, you might be referencing a new variable or constant that can be resolved only at run time. If this is the case you can ignore the warning.
- **Solution:** Try one of the following to solve the problem:
  - Check that the variable has been entered correctly.
  - If you are using IBM MQ constants, use **Edit** > **Content Assist** to select from the list of available IBM MQ constants.

There are missing or unexpected targets in a message map

Procedure

- **Scenario:** In your message map, warning messages are displayed that indicate a target element is missing, or a target element is at an unexpected location. As a result the output message generated by the message map might be incorrect.
- **Explanation:** If target elements are missing from the Spreadsheet pane when you edit and save the message map, a warning is displayed that a target is missing. This situation can occur if you use the **Insert Children** wizard and do not select all the required elements, or if you create mappings using the drag-and-drop method and do not create mappings for all the required fields. If target elements in the Spreadsheet pane are in an unexpected order, a warning that the element is unexpected at that location is displayed. This situation can occur if you drag elements to new locations in the Spreadsheet pane.
- **Solution:** To solve the problem:
  - Use **Insert Children** on the parent element to add any missing target elements to the Spreadsheet pane.
  - Drag any target elements that are in an unexpected location to the correct location. Use the message tree in the Target pane as a guide to the expected structure of the output message.

Resolving trace problems when developing message flows

Follow this advice to deal with some common trace problems that can arise when you develop message flows.

About this task

- "You cannot determine which node is being referenced in your trace file" on page 2944
- "You cannot see any alerts when you change user trace " on page 2945
- "Data that the Trace node sends to the syslog on Linux is truncated" on page 2945

You cannot determine which node is being referenced in your trace file

Procedure

- **Scenario:** You have generated a service trace file for your message flow, to trace the path of a message. However, you cannot determine which node is being referenced in the trace file.

- **Explanation:** In the trace file you might see text such as:

  ```
  Video_Test#FCMComposite_1_1 ComIbmMQInputNode , Video_Test.VIDEO_XML_IN
  ```

  The elements in the text have the following meanings:

  Video_Test
  is the name of the message flow

  FCMComposite_1_1
  is the internal name for the node

  ComIbmMQInputNode
  is the type of node

  VIDEO_XML_IN
  is the node label, and is the name you see in your flow

  The number at the end of the internal name is incremented; for example, FCMComposite_1_4 would be the fourth node you added to your flow. In the example, this section of the trace is referring to the first node in the message flow.

You cannot see any alerts when you change user trace

Procedure

- **Scenario:** You cannot see any alerts for an integration server or message flow in the Alerts viewer when you use the **mqsichangetrace** command to change the user trace setting.
- **Explanation:** No alert is generated when an integration server runs user trace at normal or debug level. Alerts are generated only for message flow trace. For message flow trace, the IBM App Connect Enterprise Toolkit is not notified of trace changes that are initiated by the **mqsichangetrace** command.
- **Solution:** To see the alert, refresh the message flow, or disconnect, then reconnect to the domain.

Data that the Trace node sends to the syslog on Linux is truncated

Procedure

- **Scenario:** You are using a Trace node on Linux and have set the `Destination` property to `Local Error Log`. You send a message to the Trace node that consists of multiple lines, but the message that appears in the syslog is truncated at the end of the first line.
- **Explanation:** On Linux, syslog entries are restricted in length and messages that are sent to the syslog are truncated by the new line character.
- **Solution:** To record a large amount of data in a log on Linux, set the `Destination` property on the Trace node to `File` or `User Trace` instead of `Local Error Log`.

Resolving problems when developing message flows with WebSphere Adapters nodes

Advice for dealing with common problems that can arise when you develop message flows that contain WebSphere Adapters nodes.

About this task

WebSphere Adapters nodes

- "Error messages BIP3414 and BIP3450 are issued when you deploy a WebSphere Adapters input node" on page 2946
- "Error messages are issued when classes cannot be found, or when problems occur with Java initialization " on page 2946

- "The WebSphere Adapters are not visible when you run ITLM" on page 2947
- "A message flow with an SAPRequest, SiebelRequest, or PeopleSoftRequest node has deployed successfully, but message BIP3540 is issued indicating that connection failed" on page 2947

SAP nodes

- "You have deployed an SAP inbound adapter but do not receive expected messages" on page 2948
- "You have imported an existing project into your workspace, but messages are issued when you try to build SAP message sets" on page 2948
- "An error is issued when you use the message set that is generated by the Adapter Connection wizard" on page 2948
- "When you run the SAP samples on Linux or UNIX, IBM App Connect Enterprise does not connect to the SAP gateway" on page 2949
- "SAP inbound messages (ALE and BAPI) appear to be missing" on page 2949
- "When two ALE inbound modules use the same RFC program ID with SAP JCo version 3.0.2, NullPointer exceptions are logged in the JCo trace and the Adapter does not receive IDocs" on page 2949

Siebel nodes

- "You are using a SiebelInput node with the delivery type set to unordered, and error message BIP3450 is issued with a NullPointer exception" on page 2950

JD Edwards nodes

- "Error message BIP3450 is issued when you include a JDEdwardsRequest node in a message flow and try to connect to a JD Edwards EnterpriseOne server" on page 2950

Error messages BIP3414 and BIP3450 are issued when you deploy a WebSphere Adapters input node

Procedure

- **Scenario:** When you deploy a message flow that contains a SiebelInput node, error message BIP3414 is issued.
- **Explanation:** The error messages explain that the SiebelInput node could not register with the adapter component to receive events.

  This problem can be caused when the integration node does not know where to find the client libraries for the Siebel Enterprise Information Service (EIS). You might also encounter this problem if you are using the WebSphere Adapter for Siebel on an unsupported operating system.
- **Solution:** Use the **mqsireportproperties** and **mqsichangeproperties** commands to configure the integration node with the location of the Siebel client libraries, as described in "Preparing the environment for WebSphere Adapters nodes" on page 209.

Error messages are issued when classes cannot be found, or when problems occur with Java initialization

Procedure

- **Scenario:** You are deploying WebSphere Adapters, and error messages are issued that indicate that classes cannot be found, or problems are occurring with Java initialization. BIP3521 and BIP3522 error messages might also be issued.
- **Explanation:** The SAP, Siebel, and PeopleSoft adapters need client libraries from the manufacturer of the Enterprise Information System (EIS). If these libraries are missing, not installed correctly, or at an incorrect level, errors are issued.

- **Solution:** To solve this problem, complete the following steps.
  a) Ensure that the adapter policy correctly identifies the location of the Java and native libraries (see Policy properties).
  b) Ensure that the libraries are installed correctly, are valid for your operating system, and have the correct permission so that the integration node can access them.
  c) Ensure that your operating system is supported by IBM App Connect Enterprise and the EIS provider. For details about supported operating systems, visit the IBM App Connect Enterprise system requirements Web site.

The WebSphere Adapters are not visible when you run ITLM

Procedure

- **Scenario:** The adapter is not visible when you run the IBM Tivoli License Manager (ITLM).
- **Explanation:** If you want to use ITLM with the WebSphere Adapters, you must activate the ITLM file for each adapter.
- **Solution:** Follow the instructions in "Activating IBM License Metric Tool for WebSphere Adapters" on page 1108.

A message flow with an SAPRequest, SiebelRequest, or PeopleSoftRequest node has deployed successfully, but message BIP3540 is issued indicating that connection failed

Procedure

- **Scenario:** From an SAPRequest, SiebelRequest, or PeopleSoftRequest node, an exception is thrown to indicate that the node is unable to make a connection even though the message flow has deployed successfully. The exception contains message BIP3540 with inserted text that indicates that connection failed.
  For example, for SAP, the inserted text is:

```
Exception in connecting to SAP:Connect to SAP gateway failed
Connect_PM GWHOST= invalidhost.test.co, GWSERV=sapgw00, ASHOST= invalidhost.test.co,
  SYSNR=00
LOCATION CPIC (TCP/IP) on local host ERROR partner not reached (host
  invalidhost.test.co, service 3300) TIME Mon Dec 01 16:43:52 2008 RELEASE 640
COMPONENT NI (network interface) VERSION 37 RC -10 MODULE nixxi_r.cpp LINE 8719
DETAIL NiPConnect2 SYSTEM CALL SiPeekPendConn ERRNO 10061 ERRNO TE
```

  For PeopleSoft, the inserted text is:

```
001DOWNbea.jolt.ServiceException: Invalid Session
```

- **Explanation:** The connection details are not verified when the message flow is deployed. For request nodes, the connection is made at first use.
- **Solution:** If you have configured a policy for this adapter, review the connection properties on that policy and review the text in the BIP3540 message to determine if the connection properties are incorrect.

  If no policy exists for this adapter, review the connection properties on the adapter. If the properties are incorrect, correct them and redeploy the adapter. Alternatively, create a new policy with the correct properties to override the properties that are set on the adapter.

You have deployed an SAP inbound adapter but do not receive expected messages

Procedure

- **Scenario:** You have deployed an SAP inbound adapter but do not receive the IDoc messages that you expected to receive.
- **Explanation:** If you have not received IDoc messages from SAP, it is possible that deployment was unsuccessful or the SAP server has not started.
- **Solution:** Check user trace for message BIP3484 occurring at the time of deployment. The adapter component writes diagnostic information to this message, in an insert that begins "CWYAP...". If this message is issued, it explains the cause of the problem.

You have imported an existing project into your workspace, but messages are issued when you try to build SAP message sets

Procedure

- **Scenario:** You have imported an existing project into your workspace, but when you try to build an SAP message set, you see the message set compile error message BIP0182.
- **Explanation:** This error occurs when you choose the option to "Import existing projects into your workspace" from the Import dialog box. By choosing this option when you import, a link is created from the workspace to the existing projects in an external location and a required file is not available to the workspace. To copy the entire project into your workspace, use the option to import the Project Interchange (PI) file.
- **Solution:** When you import an exiting SAP project into your workspace, click **File** > **Import**, expand the **Other** folder, and click **Project Interchange**.

  For more information, see “Migrating development resources to IBM App Connect Enterprise 12.0” on page 62.

An error is issued when you use the message set that is generated by the Adapter Connection wizard

Procedure

- **Scenario:** You run the Adapter Connection wizard and select an inbound SAP IDoc. You run the wizard again, but this time you select an outbound SAP IDoc. When you use the message set that is generated, the following error is issued:

```
'Selector exception caught from generateEISFunctionname', 'commonj.connector.runtime.SelectorException:
commonj.connector.runtime.SelectorException: For the IDoc type SapYwmspgi01, operation key=YWMSPGIWMS
 not
found using the application-specific information {Create={MsgType=, MsgCode=, MsgFunction=}} verify
 appropriate
combination of MsgType, MsgCode, MsgFunction is set in SapYwmspgi01, application-specific information.
```

  - **Explanation:** If you run the Adapter Connection wizard for an inbound SAP IDoc, then you run the wizard again for an outbound SAP IDoc, the outbound IDoc definition replaces the inbound IDoc definition. Information that is stored in the inbound definition is used to map MsgType, MsgCode, and MsgFunction to a method binding. The outbound definition does not contain these mappings, so processing of the inbound IDoc fails.
  - **Solution:** To avoid this error, ensure that inbound and outbound SAP IDocs have different names if they are stored in the same message set.

When you run the SAP samples on Linux or UNIX, IBM App Connect Enterprise does not connect to the SAP gateway

Procedure

- **Scenario:** When you run the SAP samples on Linux or UNIX, the message flow deploys successfully, but a connection is not established between IBM App Connect Enterprise and the SAP system.

  You might see the following error message:

  ```
  message: Connect to SAP gateway failed
  Connect parameters: TPNAME=SAMPRFC GWHOST=sapdev10 GWSERV=sapgw00
  ERROR service 'sapgw00' unknown
  ```

- **Explanation:** For the SAP Java Connector (SAP JCo) to communicate across the network, you need to configure the TCP/IP service. If you have installed a working SAP GUI on your workstation, the TCP/IP service is configured as part of the installation. If you have not installed an SAP GUI, you must configure the TCP/IP service manually so that the SAP samples run successfully.
- **Solution:** Locate the services file in `/etc/services` and edit it so that it includes the appropriate gateway service IDs and the port numbers for the TCP/IP service in the format `sapgw`*`SID`* *`portnumber`*`/tcp`, where *SID* is the SAP system ID.

  For example:

  ```
  sapgw00  3300/tcp
  sapgw01  3301/tcp
  sapgw02  3302/tcp
  ```

  and so on.

  For more information about TCP/IP configuration, see the Network Integration section of the SAP Support Portal.

SAP inbound messages (ALE and BAPI) appear to be missing

Procedure

- **Scenario:** SAP inbound messages (ALE and BAPI) appear to be missing. You might find that every other message does not reach the integration node but no errors are issued.
- **Explanation:** This problem is typically caused when two integration nodes share the same program ID (SAP RFC Destination). For example, a developer has deployed a message flow, but someone else has used the same BAR file without having changed the program ID.
- **Solution:** Ensure that no other integration nodes are running with the same program ID. Use SAP transaction SMGW to determine whether other integration nodes are connected to the SAP system.

When two ALE inbound modules use the same RFC program ID with SAP JCo version 3.0.2, NullPointer exceptions are logged in the JCo trace and the Adapter does not receive IDocs

Procedure

- **Scenario:** When two ALE inbound modules use the same RFC program ID with SAP JCo version 3.0.2, NullPointer exceptions are logged in the JCo trace and the Adapter does not receive IDocs.

  The following example shows a typical exception in the JCo trace.

  ```
  JCoDispatcherWorkerThread [16:44:42:140]: [JCoApi] Dispatcher.getNextListener() returns
   dispatch next call rfc handle(1) for null
  JCoDispatcherWorkerThread [16:44:42:140]: [JCoApi] caught Throwable in DispatcherWorker.run()
   while trying to dispatch a request java.lang.NullPointerException
   at java.util.Hashtable.get(Hashtable.java:518)
   at com.sap.conn.jco.rt.DefaultServerManager
  $DispatcherWorker.run(DefaultServerManager.java:268)
  ```

```
  at java.lang.Thread.run(Thread.java:735)

JCoDispatcherWorkerThread [16:44:42:140]: [JCoApi] Dispatcher.getNextListener() returns no
 calls
```

- **Explanation:** SAP JCo version 3.0.2 does not support the use of two ALE inbound modules with the same RFC program ID.
- **Solution:** To solve this problem, download a hotfix from SAP; the SAP ticket reference number is 584247/2009.

You are using a SiebelInput node with the delivery type set to unordered, and error message BIP3450 is issued with a NullPointer exception

Procedure

- **Scenario:** You are using a SiebelInput node, you have set the delivery type to unordered in the Adapter Connection wizard, and the minimum number of connections is 1 or less. The following exception is shown in user trace: `RecoverableException BIP3450E: An adapter error occurred during the processing of a message. The adapter error message is java.lang.NullPointerException`.
- **Explanation:** When using unordered events, the minimum connections (`MinimumConnections`) and maximum connections (`MaximumConnections`) properties must be greater than 1 for event delivery to be successful.
- **Solution:** Set the `MinimumConnections` and `MaximumConnections` properties on the Adapter Connection wizard to values greater than 1. For example, set the minimum number of connections to 2 and the maximum number of connections to 4.

Error message BIP3450 is issued when you include a JDEdwardsRequest node in a message flow and try to connect to a JD Edwards EnterpriseOne server

Procedure

- **Scenario:** You have created a message flow that contains a JDEdwardsRequest node, but error message BIP3450 is issued, indicating that the node is unable to connect to the JD Edwards EnterpriseOne server.
- **Explanation:** This error message indicates that the JDEdwardsRequest node is trying to connect to the JD Edwards EnterpriseOne server but is unable to do so. This error can be caused by the following situations.
  - The JD Edwards EnterpriseOne server is not running.
  - The JD Edwards adapter has been configured with incorrect connection details; for example, the name of the JD Edwards EnterpriseOne Environment to which to connect.
  - The JDBC drivers that are required to connect to the JD Edwards EnterpriseOne server are missing from the class path. The following table lists the required JDBC driver files for each database.

Database	JDBC driver files	Implementation class
Oracle	tsnames.ora classes12.zip	oracle.jdbc.driver.OracleDriver
SQLServer	sqljdbc.jar	com.ibm.microsoft.sqlserver.jdbc.SQLServerD
AS/400	jt400.jar	com.ibm.as400.access.AS400JDBCDriver
DB2 Type-2 (JDK 1.4/1.5)	db2java.zip	com.ibm.db2.jdbc.app.DB2Driver

Database	JDBC driver files	Implementation class
DB2 Type-4 (JDK 1.4/1.5)	db2jcc.jar db2jcc_license_cu.jar	com.ibm.db2.jcc.DB2Driver
DB2 Type-4 (JDK 1.6)	db2jcc4.jar	com.ibm.db2.jcc.DB2Driver

- **Solution:** Ensure that the following conditions have been met.
  - The JD Edwards EnterpriseOne server is running.
  - The JD Edwards adapter has been configured with the correct connection details.
  - The drivers that are required to connect to the JD Edwards EnterpriseOne server are in the class path.

Resolving other problems when developing message flows

Use the advice given here to deal with problems that can arise when developing message flows, and that are not covered in the specific categories listed in "Resolving problems when developing message flows"

About this task

- "The values of your promoted properties are lost after editing" on page 2951
- "The Message Flow editor experiences problems when opening a message flow, and opens in error mode" on page 2951
- "A message flow has subflows with the same user-defined property set to different values, but only one value is set at run time" on page 2952
- "You want to move resources to a new broker schema that you have created but it is not visible in the Application Development view" on page 2952
- "A selector exception is raised when you use WebSphere Adapters" on page 2952

The values of your promoted properties are lost after editing

Procedure

- **Scenario:** You edited a message flow using the Message Flow editor, and the values of your promoted properties are lost.
- **Explanation:** The values of promoted properties for nodes with more than a single subflow definition (that is, two identically named subflows in the same project reference path) are lost if the flow is edited and saved.
- **Solution:** To avoid this problem, ensure that each subflow in your project has a different name.

The Message Flow editor experiences problems when opening a message flow, and opens in error mode

Procedure

- **Scenario:** You attempt to open an existing message flow in the Message Flow editor and it opens in read-only error mode, displaying a list of parsing or loading errors. The message flow is not open and a message is displayed indicating that the message flow file is not valid.
- **Explanation:** The message flow file is unreadable or is corrupted, and the Message Flow editor cannot render the model graphically.
- **Solution:** Contact IBM Customer Support for assistance with the corrupted file.

A message flow has subflows with the same user-defined property set to different values, but only one value is set at run time

Procedure

- **Scenario:** You have a message flow that contains identical subflows. Each subflow has the same user-defined property (UDP), but with different values. At run time, only one of the values is set.
- **Explanation:** A UDP has global scope and is not specific to a particular subflow. If you reuse a subflow in a message flow, and those subflows have identical UDPs, you cannot set the UDPs to different values.
- **Solution:** If you need to set a different value for each subflow, use a different UDP for each subflow.

You want to move resources to a new broker schema that you have created but it is not visible in the Application Development view

Procedure

- **Scenario:** You have created a new broker schema and you want to move a resource to it, but the schema is not visible in the Application Development view.
- **Explanation:** If category mode is selected, you cannot see the broker schema in the Application Development view.
- **Solution:** To move resources to a broker schema that you have created, take one of the following steps.
  - Click **Hide Categories** () on the Application Development view toolbar. The new broker schema appears in the Application Development view and you can drag resources onto it.
  - Right-click a resource, click **Move**, then select the schema that you have created. When you click **OK**, the resource is moved to the selected schema.

A selector exception is raised when you use WebSphere Adapters

Procedure

- **Scenario:** You run the Adapter Connection wizard for an inbound IDOC, then you run the wizard again for an outbound IDOC. When the message set is generated, you see the following error message:

```
'Selector exception caught from generateEISFunctionname' ,
'commonj.connector.runtime.SelectorException:
commonj.connector.runtime.SelectorException: For the IDoc type
SapYwmspgi01, operation key=YWMSPGIWMS not found using the
application-specific information {Create={MsgType=, MsgCode=, MsgFunction=}}
verify apropriate combination of MsgType,MsgCode, MsgFunction is set in
SapYwmspgi01, application-specific information.
--
```

- **Explanation:** When you run the Adapter Connection wizard for an inbound IDOC, then you run the wizard again for an outbound IDOC, the outbound IDOC definition replaces the inbound IDOC definition. Information that is stored in the inbound definition is used to map MsgType, MsgCode, and MsgFunction to a method binding. The outbound definition does not contain these mappings, so processing of the inbound IDOC fails.
- **Solution:** To avoid this error, ensure that inbound and outbound IDOCs have different names if they are stored in the same message set.

Resolving problems when deploying message flows or message sets

Use the advice given here to help you to resolve common problems that can arise when you deploy message flows or message sets.

Initial checks

Procedure

1. To debug problems when deploying, check the following logs:
   - The administration log
   - The local error log (the Windows Event log or the syslog)
   - The IBM MQ logs

   These logs might be on separate computers, and must be used with the IBM App Connect Enterprise Toolkit output to ensure that the deployment was successful.

   Use the **mqsilist** command to check that the deployment was successful, or look in the Windows Event or Administration Log view.
2. Use this checklist when you have deployment problems:
   - Make sure that the mode that your integration node is working in is appropriate for your requirements. See “Operation modes” on page 3.
   - Make sure that the client connection to a remote queue manager is running.
   - Make sure that channels are running.
   - Display the channel status to see if the number of system messages sent increases.
   - Check the channel from the remote end.
   - Check the queue manager name.
   - Determine whether the channel is a cluster channel.

Common problems

About this task

- "You receive exception ('MQCC_FAILED') reason '2042' ('MQRC_OBJECT_IN_USE')" on page 2961

Resolving problems that occur when preparing to deploy message flows

Use the advice given here to help you to resolve common problems that can occur during preparations to deploy message flows or message sets.

An error is issued when you add a message set to a BAR file

Procedure

- **Scenario:** An error is issued when you add a message set to a BAR file.
- **Explanation:** After you create a BAR file and add a message set project to it, two files are created in the BAR file: `messageset.user.txt` and `messageset.service.txt`. The `user.txt` file contains user log information, such as warning message BIP0177W, which states that the dictionary that you have created is not compatible with earlier versions.
- **Solution:** Use the information in the `user.txt` file to diagnose the error. The `service.txt` file contains detailed information that is used by the integration node, and can be used by the IBM Support Center to diagnose problems.

You cannot drag a BAR file to an integration node

Procedure

- **Scenario:** You cannot drag a BAR file to an integration node.
- **Explanation:** BAR files can be deployed only on an integration server.
- **Solution:** Select an integration server in the deploy dialog.

You cannot deploy a message flow that uses a user-defined message flow

Procedure

- **Scenario:** You have created a message flow that contains an input node in a user-defined node project. However, you cannot deploy a message flow that uses this node.
- **Explanation:** Validation, compilation, and deployment do not recognize that a user-defined message flow contains an input node.
- **Solution:** To work around the problem, add a dummy input node to the flow that you intend to deploy.

The compiled message flow file (`.cmf`) has not been generated

Procedure

- **Scenario:** The compiled message flow file (`.cmf`) has not been generated.

  Therefore, it is not added to the BAR file, and cannot be deployed.
- **Explanation:** When you create files that define message flow resources in the IBM App Connect Enterprise Toolkit, the overall file path length of those files must not exceed 256 characters, because of a Windows file system limitation.

  If you have a message flow that includes resource files that have a path length that exceeds 256 characters, the message flow cannot be compiled when you try to add it to a BAR file, and therefore cannot be deployed.

  You might also be affected by this restriction when you use the Adapters Connection wizard; names discovered and returned by the EIS can be very long. The Adapters Connection wizard attempts to write these files to the message set on the local file system, but their path exceeds the operating system limit, and the files appear corrupted.

- **Solution:** To ensure that the path length does not exceed 256 characters, use names that are as short as possible for all resources; for example:
  - The installation path
  - Project names and broker schema names
  - ESQL and mapping file names
  - Inbound and outbound adapter files

You cannot deploy a message flow that contains restricted resources

Procedure

- **Scenario:** An error is issued when you deploy a BAR file containing resources that are not valid for your runtime operation mode.
- **Explanation:** In express mode and scale mode, the integration node operates with a limited set of nodes. If a BAR file contains nodes that are restricted in the runtime operation mode, you cannot deploy the BAR file.
- **Solution:** Rework your message flow to use resources that are valid for your runtime operation mode; see "Restrictions that apply in each operation mode" on page 5. Alternatively, contact your IBM representative to upgrade your license.

Resolving problems that occur during deployment of message flows

Use the advice given here to help you to resolve problems that can arise during deployment of message flows or message sets.

Procedure

You receive a warning message about the mode of your integration node

About this task

Message BIP1806

- **Scenario:** Warning message BIP1806 is displayed.
- **Explanation:** Your integration node has not been started.
- **Solution:** Check that the integration node is started: if it is not started, start it by using the **`mqsistart`** command.

Message BIP1821

- **Scenario:** Warning message BIP1821 is displayed.

- **Explanation:** Your integration node is running in a mode that restricts the number of integration servers that you can use; see "Restrictions that apply in each operation mode" on page 5.
- **Solution:** Contact your IBM representative to upgrade your license, or remove the required number of integration servers; see "Deleting an integration server" on page 175.

The message flow deploys on the test system, but not elsewhere

Procedure

- **Scenario:** The message flow that you have developed deploys on the test system, but not elsewhere.
- **Solution:** Carry out the following checks:
  - Ensure that you have verified the installation on the target system by creating and starting an integration node, and deploying a single integration server. These actions confirm that the integration node is correctly defined.
  - Ensure that the BAR file's `broker.xml` file contains references to the correct resources for the new system.
  - Ensure that any referenced message sets are deployed.
  - If database resources or user-defined nodes are not accessible or authorized from the target system, the deploy fails. On distributed systems, ensure that you have defined either ODBC or JDBC connections to your databases so that they can be accessed from the integration node. Also, set the integration node environment to allow access to the databases. On Linux or UNIX systems, you might have to run a database profile.
  - Any user-defined extensions that you are using in your message flow might not load if they cannot be found, or are not linked correctly. Consult the documentation for your operating system for details of tools that can help you to check the binary files of your user-defined extension.

Error messages about your integration node mode are issued when you create an integration server

About this task

Message BIP1825

- **Scenario:** Error message BIP1825 is displayed.
- **Explanation:** The integration server cannot be created because the maximum number of integration servers for the mode of the target integration node has been reached, and creating the integration server causes this limit to be exceeded; see "Restrictions that apply in each operation mode" on page 5. The integration server was not created.
- **Solution:** Reuse an existing integration server, or delete an existing integration server and try the command again; see "Deleting an integration server" on page 175. Alternatively, contact your IBM representative to upgrade your license.

Error messages about your integration node mode are issued when you deploy

About this task

Message BIP1829

- **Scenario:** Error message BIP1829 is displayed.
- **Explanation:** The BAR file cannot be deployed because the maximum number of integration servers for the mode of the target integration node has been reached; see "Restrictions that apply in each operation mode" on page 5. The BAR file was not deployed.
- **Solution:** Delete an existing integration server and try the command again; see "Deleting an integration server" on page 175. Alternatively, contact your IBM representative to upgrade your license.

You create a policy, then deploy a message flow and inbound adapter, but the deployment fails

Procedure

- **Scenario:** You create a policy, then deploy a message flow and inbound adapter, but the deployment fails.
- **Explanation:** When you create a policy for an adapter that has not yet been deployed, the connection properties are not fully validated until you deploy the adapter and the message flow that uses that adapter. Therefore, the properties that you set on the policy might be invalid.
- **Solution:** Inspect the error message that is returned from the deployment and determine whether the deployment failed because of invalid connection properties on the policy. If so, update the values in the policy, then redeploy the policy project.

You have created a WebSphere Adapters message flow that uses secondary adapters, and a naming clash has occurred in the secondary adapters or message sets

Procedure

- **Scenario:** You have created a WebSphere Adapters message flow that uses secondary adapters, and a naming clash has occurred. You need to know which adapters and message sets the WebSphere Adapters node is using, and if the method names in the adapters or the message type names in the message sets are clashing.
- **Explanation:** Method names must be unique across all primary and secondary adapters, and the message set that is created must not contain any types that share the same name and namespace of existing message sets. Information about secondary adapters and message sets is written to user trace at the following stages.
  - When the node is first deployed, information about the current set of secondary adapters and message sets is reported.
  - When adapters and message sets are deployed subsequently, information about them is reported at the time of deployment.
  - When the message flow, integration node, or integration server is stopped then restarted, information about the entire set of secondary adapters and message sets is written to user trace, including those secondary adapters and message sets that are deployed after the message flow was first deployed.

  This information is reported by the following messages.

  - BIP3432 and BIP3434 list the adapters and message sets that are available when the node is deployed or when the integration node, integration server, or message flow are restarted.
  - BIP3433 reports that a secondary adapter is being deployed and added to the set.
  - BIP3435 reports that a secondary message set is being deployed.
  - BIP3436 identifies the message set in which each type is being defined.
  - BIP3437 identifies message sets that attempt to redefine a type that is already defined.
  - BIP3438 identifies the adapter in which each method is being defined.
  - BIP3439 identifies adapters that attempt to redefine a method that is already defined.

  Messages BIP3436, BIP3437, BIP3438, and BIP3439 are issued when a message is processed to report whether definitions are used for that message.

- **Solution:** The following steps describe how to use user trace when working with secondary adapters.
  - **When you deploy the flow for the first time**
    1. Start user trace.
    2. Deploy your message flow, primary adapter, primary message set, and any secondary adapters or message sets that are ready.
    3. Read user trace, looking out for the messages described.
    4. Optional: Reset user trace, stop and restart the message flow, then read user trace again, looking out for the messages described.
  - **When you add new adapters and message sets**
    1. Start user trace.
    2. Deploy the secondary adapters and message sets.
    3. Read user trace, looking out for the messages described.
    4. Optional: Reset user trace, stop and restart the message flow, then read user trace again, looking out for the messages described.

  When you have identified where the naming clash has occurred, you can ensure that names are unique by editing them in the following ways:

  - Edit method names by clicking **Edit Operations** on the **Service Generation and Deployment Configuration** panel of the **Adapter Connection** wizard.
  - Edit the namespaces of the types in the message set by using the Business Object Namespace control on the **Adapter Connection** wizard.

Deployment fails when you have circular project dependencies

Procedure

- **Scenario:** Circular project dependencies exist in the projects that you are deploying and deployment fails.
- **Explanation:** A circular project dependency occurs when two or more projects depend on each other.

  For example, File A in Project X depends on File B in Project Y, and File C in Project Y depends on File D in Project X. For Project X to build successfully, Project Y must be built first so that Project X can resolve the dependency on File B. However, for Project Y to build successfully, Project X must be built first so that Project Y can resolve the dependency on File D. The IBM App Connect Enterprise Toolkit is based on the Eclipse platform, which does not support circular project dependencies.
- **Solution:** To deploy successfully, avoid circular project dependencies.

  For example, if Project X depends on File B in Project Y, and Project Y depends on File D in Project X, move File B to Project Z. The projects must be built in the order Project Z, Project X, then Project Y so that the dependencies can be resolved.

Error messages are issued when you deploy

About this task

Additional error messages that might be generated during a deployment are explained in this section.

Message BIP1106 with IBM MQ reason code 2030

- **Scenario:** Error message BIP1106 is issued with reason code 2030 when you are deploying a large message set.
- **Explanation:** The size of the message exceeds the maximum message length of the transmission queue to the integration node queue manager.

- **Solution:** Increase the maximum message length for the transmission queue using the IBM MQ **alter qlocal** command, where the maximum message length (maxmsgl) is in bytes:

```
alter ql(transmit_queue_name) maxmsgl(104857600)
```

For more information about this command, see the *System Administration Guide* section of the IBM MQ product documentation online.

Message BIP2066

- **Scenario:** You have initiated a deployment request; for example, you have deployed a BAR file to an integration server. Error message BIP2066 is returned one or more times.
- **Explanation:** The deployment request was not acknowledged by the integration server before the sum of the values for the integration node timeout parameters **ConfigurationChangeTimeout** and **InternalConfigurationTimeout** expired.
- **Solution:** Increase these timeout values by specifying the **-g** and **-k** parameters of the **mqsicreatebroker** command (command).

Message BIP2080

- **Scenario:** The integration node has started an integration server; for example, if you have issued **mqsistart** for the integration node, or an error has occurred and the integration server is being recovered. Error message BIP2080 is displayed one or more times.
- **Explanation:** The internal configuration request was not acknowledged by the integration server before the value of the **InternalConfigurationTimeout** (default 60 seconds) expired.
- **Solution:** Change the configuration timeout by specifying the **-k** parameter of the **mqsicreatebroker** command (command).

Message BIP2241

- **Scenario:** Error message BIP2241 is displayed.
- **Explanation:** You are attempting to deploy a message flow containing a node that is not available on the target integration node.
- **Solution:** Ensure that the version of the IBM App Connect Enterprise Toolkit in which the message flow has been developed matches the version of the integration node to which the message flow is being deployed. If the message flow is using a user-defined node, or a node supplied in a SupportPac, ensure that the runtime node implementation has been correctly installed on the computer on which the integration node is running. If your message flow includes a user-defined node, see “Installing user-defined extension runtime files on an integration node” on page 2455. If your message flow includes a node provided in a SupportPac, see the installation information, if supplied, for the SupportPac.

Message BIP2242

- **Scenario:** Error message BIP2242 is displayed.
- **Explanation:** The deployment request (configuration change) was not accepted before the timeout value set by the integration node parameter **ConfigurationChangeTimeout** expired. This configuration timeout value must be long enough for the message flow to complete processing its current message, then accept the deploy request; the default is 300 seconds.
- **Solution:** Set the configuration timeout values by specifying the **-g** and **-k** parameters of the **mqsicreatebroker** command.

Message BIP3226

- **Scenario:** Error message BIP3226 is displayed; for example:

```
(Semipersistent_Compute1.Main, 27.89) : Array index evaluated to '0' but must
evaluate to a positive, nonzero integer value.
```

The first insert in BIP3226 (in this example, `Semipersistent_Compute1.Main`) identifies the node and routine in which the statement occurs. The second insert (in this example, `27.89`) identifies the approximate line and column of the index value shown in the third insert (in this example, '0').

- **Explanation:** The validity of using a field reference index of zero was corrected in WebSphere Message Broker Version 7.0. If you have statements in your ESQL modules that include an index of zero, error BIP3226E is generated.

  For example, your ESQL module might contain the following statement:

```
SET OutputRoot.XMLNSC.Top.A[0].B = 42;
```

- **Solution:**

  You must correct all ESQL statements that use an index of zero to use an index of 1. Statements might use a variable as well as a literal value for the index; check for both possible situations. For example, your changed code might read:

```
SET OutputRoot.XMLNSC.Top.A[1].B = 42;
```

Tagged/Delimited String (TDS) Validator error

- **Scenario:** You try to deploy a message set with a TDS wire format that has an error.
- **Explanation:** The following extract from an error log illustrates what you might see for a TDS Validator error. In this case, the cause of the problem is that the element Town does not have a tag defined.

```

- **Solution:** Use the information in the error log to correct the problem.

Resolving problems that occur after deployment of message flows

Use the advice given here to help you to resolve common problems that can arise after deploying message flows or message sets.

You receive exception ('MQCC_FAILED') reason '2042' ('MQRC_OBJECT_IN_USE')

Procedure

- **Scenario:** This exception message occurs when the following conditions are met:
  a) You have a message flow containing a SOAPRequest node that is using the JMS Transport.
  b) The message flow has additional instances defined, and is running under load.
  c) You are using the IBM MQ JMS provider.
  d) You have not specified a reply-to destination, and so are using JMS temporary dynamic queues.
- **Explanation:** If you do not specify a reply-to destination, and you are using the IBM MQ JMS provider in a message flow with additional instances, you must configure JMS temporary dynamic queues before deploying your message flow.
- **Solution:** Complete the steps in the topic Configuring JMS temporary dynamic queues for the JMS provider.

Your XSLTransform node does not work after deployment

About this task

Two scenarios explain why your XSLTransform node might not work after deployment:

Error messages are displayed indicating that the style sheets were not found

Procedure

- **Scenario:** Error messages are displayed indicating that the style sheets were not found.
- **Explanation:** This error message is displayed if the integration node cannot find the style sheets or XML files required, or if the content of a style sheet or XML file is damaged and therefore no longer usable. This error message can happen if a file system failure occurs during a deployment.
- **Solution:** If the style sheets or XML files are damaged, redeploy the damaged style sheets or XML files.

What to do next

You get unexpected transformation results

- **Scenario:** You get unexpected transformation results.
- **Explanation:** For complex message flows, incompatibility might arise among style sheets and XML files after a deployment. The two typical reasons for this error are:
  - Only part of the cooperating style sheets or XML files are deployed and updated (a file system failure could cause this failure).
  - Multiple XSLTransform nodes that are running inside the same integration server are supposed to use compatible style sheets, but are using different versions to process the same incoming message.
- **Solution:** If only part of the cooperating style sheets or XML files are deployed and updated, resolve all incompatibility by redeploying the compatible versions. To avoid multiple XSLTransform nodes using different versions of the style sheet, pause relevant message flows in the target integration server before performing the deployment, then restart the flows.

Resolving problems that occur when debugging message flows

Advice on dealing with some of the common problems that you see when debugging message flows.

About this task

Resolving problems that occur when starting and stopping the debugger

Use the advice given here to help you to resolve common problems that can arise when you debug message flows.

An endless "waiting for communication" progress bar is displayed when you start the debugger

Procedure

- **Scenario:** After you click **Start Debugging**, you get an endlessly cycling progress bar entitled "waiting for communication". The "debug session started" message is not displayed in the information pane.
- **Explanation:** If the message flow has nodes with ESQL statements, the flow might not deploy even if the statements are correct syntactically.
  This situation can occur, for example, because of multiple declarations or uninitialized variables (that is, semantic problems that the syntax parser does not pick up).

  Always check the IBM App Connect Enterprise Toolkit Administration log to confirm that the debugged version of your message flow has deployed successfully; it has the same name as the original message flow, with the suffix _debug_.

  If the message flow does not deploy properly, the debugger cannot establish communication with the flow, and you see the endless progress bar.
- **Solution:** Click **Cancel** to clean up and return to a good state, then fix your errors and try again.

  As a check, see if your flow can deploy without the debugger.

The debugger seems to stop

Procedure

- **Scenario:** You are debugging a message flow and continue after encountering a breakpoint. However, nothing seems to happen and after about a minute, a progress bar appears, indicating that the debugger is waiting for communication.
- **Explanation:** This situation can occur for the following reasons:
  - The message flow might have encountered a time-intensive operation, such as a huge database query, and you must wait for the flow to complete the action.
  - The integration node ended, or some other extraordinary condition occurred, and communication was lost. In this case, click **Cancel** to stop the debug session.

The session ends abnormally while debugging

Procedure

- **Scenario:** After debugging a message flow, the session ends abnormally and you still have the debug instance of the message flow (mf_debug_) deployed to the integration node's integration server. You are concerned that this is going to affect the operation of the flow, and want to put the integration server back to its original state.
- **Explanation:** The orphaned message flow should behave as the flow would have done normally, and the Debug nodes have no effect on message processing.

  If you have a small number of nodes in the message flow, corrective action makes no noticeable difference to the flow, apart from its name. However, if you have a large message flow (that is, more than 15 nodes or several subflows), take the corrective action described later in this section, because the performance of message processing might be affected.
- **Solution:** Redeploy the integration node.

  A full redeploy of the integration node should replace the orphaned flow with the original message flow. If this action has no effect, remove the orphaned flow from the integration server, deploy, then add the flow and deploy to restore the original state of the integration node as it was before the debugging session.

An error message is displayed indicating that the debug session cannot be launched

Procedure

- **Scenario:** You try to relaunch or invoke a new debug session but when you click the green **Debug** icon  , an error message is displayed stating: `Cannot launch this debug session`.
- **Explanation:** When you click **Debug** , it relaunches the last debug session. It fails if you have not created a debug session previously. It also fails if the integration node and integration server that were attached previously in a debug session are no longer running, or have been restarted; the session cannot be reattached without re-selection of the integration node and integration server process instance.
- **Solution:**
  a) Close the error message and click the arrow immediately to the right of the **Debug** icon.
  b) Re-select or modify the integration node and integration server information from the previous debug launch configuration by clicking **Debug** in the menu and selecting the previous debug launch configuration. See “Attaching the flow debugger to an integration server for debugging” on page 665 for more information.

Errors are generated when you copy a message map into an application, library, or integration project

Procedure

- **Scenario:** You are copying a message map into an application, library, or integration project and errors have appeared in the task list.
- **Explanation:** The application, library, or integration project did not have the correct references set before you copied the message mapping.
- **Solution:** These errors remain in the task list, even if you reset the project references immediately after copying. Therefore, you must perform a clean build of the application, library, or integration project.

Resolving problems when debugging message flows

This topic contains advice for dealing with some of the common problems that can arise when debugging message flows.

The debugger does not pause at the next breakpoint

Procedure

- **Scenario:** The message flow debugger does not pause at the next breakpoint in your message flow.
- **Solution:** Perform the following checks:
  a) Check whether your DataFlowEngine is running; if it is not, restart it.
  b) Check the input queue. If your input queue has the leftover messages from the previous time that you used the debugger, clear them before you send a new message.

The message does not stop executing at any breakpoint

Procedure

- **Scenario:** The message does not stop executing at any breakpoint after you attach to the debugger.
- **Explanation:** This error could be caused by a timing problem, or if you have set the wrong parameters for the debug session.
- **Solution:** Perform the following steps.
  a) Check your launch configuration settings, ensuring that you have specified the correct Flow Project, HostName and Flow Engine for the debug session.
  b) Restart the debug session.

Editing problems occur in the Message Flow editor

Procedure

- **Scenario:** While debugging a message flow, editing problems occur when you are using the Message Flow editor.
- **Solution:** Do not attempt to edit the message while the flow debugger is attached. To edit a message flow, detach the debugger, edit the message flow, then redeploy the message flow.

Editing the MQ message descriptor (MQMD) causes unexpected behavior in the debugger

Procedure

- **Scenario:** You edit properties of the message MQMD descriptor in the Message Set editor, but this causes unexpected behavior in the debugger.
- **Explanation:** If you edit the content of the MQMD descriptor, these fields take a certain range of values.

  You need to know these ranges before editing the properties. Unless you explicitly specify the value of these fields, they take default values, and certain fields might not have been specified in the message. The values in the fields that are not set explicitly in the message are default values; do not change these unless you are aware of their importance or the possible range of values.

You cannot see the message content when debugging your message flow

Procedure

- **Scenario:** You are using the message flow debugger, and you can see the message passing through the message flow, but you cannot see the content of the message.
- **Solution:** Open the Flow Debug Message view by clicking **Window** > **Show View** > **Other** > **Message Flow** > **Flow Debug Message**, then **OK**.

An exclamation mark appears above a node during debugging

Procedure

- **Scenario:** In the Message Flow editor, an exclamation mark (!) is displayed above a node during debugging.
- **Explanation:** An exception has occurred in the node during debugging.
- **Solution:** Look under the ExceptionList in the **Variables** view of the Debug perspective to find out what error has occurred.

The message does not stop processing at breakpoints

Procedure

- **Scenario:** Message processing continues when a breakpoint is encountered.
- **Explanation:** This error could be caused by a timing problem, or if you have set the wrong parameters for the debug session.
- **Solution:** Check your launch configuration setting. Ensure you have specified the correct Flow Project, HostName and Flow Engine for the debug session. Restart the debug session.

You cannot see where the debugger is in the Graphical Data Mapping editor

Procedure

- **Scenario:** The Graphical Data Mapping editor has opened in the IBM App Connect Enterprise Toolkit, but it is unclear where the debugger is in the map.
- **Explanation:** The source lookup path for the message map file is not configured correctly.
- **Solution:** Check your debug launch configuration settings and ensure you have configured the source lookup path for the message map file correctly.

When debugging a message map, the debugger does not move to the next field

Procedure

- **Scenario:** You are debugging a message map, and the debugger does not move to the next field. You have to click the **Step over** button multiple times.
- **Explanation:** The source lookup path for the message map file is not configured correctly.
- **Solution:** Check your debug launch configuration settings and ensure you have configured the source lookup path for the message map file correctly.

When debugging a message map, the debugger does not move out of the mapping node

Procedure

- **Scenario:** You are debugging a message map, and the debugger does not move out of the message map.
- **Explanation:** The source lookup path for the message map file is not configured correctly.
- **Solution:** Check your debug launch configuration settings and ensure you have configured the source lookup path for the message map file correctly.

The message flow stops at a collector node

Procedure

- **Scenario:** Message processing stops after selecting the Step into Source Code icon on a Collector node.
- **Explanation:** The collector node is a multithreaded node and the thread is ended by selecting Step into Source Code.
- **Solution:** Set a breakpoint manually after the collector node.

Resolving problems that occur after debugging:

This topic contains advice for dealing with some of the common problems that can arise after debugging message flows.

You cannot change a message flow after debugging

Procedure

- **Scenario:** You were debugging, but now your message flow seems to be stuck. When you put a new message in, nothing happens.
- **Explanation:** This might be because a message was backed out, but you have not set the **`Backout requeue name`** property of your input queue.
- **Solution:** Set the **`Backout requeue name`** property to a valid queue name (such as the name of the input queue itself) and your flow will become unstuck.

You redeployed a debugged message flow but deployment hangs

Procedure

- **Scenario:** You found problems in your message flow by using the debugger. You changed your message flow and then redeployed it, but now the deployment hangs.
- **Solution:** Make sure that when you redeploy the flow to an integration server, the integration server is not still attached to the debugger.

Resolving diagnostic data collection errors

About this task

Procedure

- **Scenario:** When you collect data by using the **aceDataCollector** command, you receive the following error:

```
Access is denied.
The directory or file cannot be created.
The directory or file cannot be created.
The directory or file cannot be created.
The directory or file cannot be created.
The directory or file cannot be created.
The directory or file cannot be created.
 - Capturing environment and version data

The system cannot find the path specified.
The system cannot find the path specified.
```

- **Explanation:** The user who is running the **aceDataCollector** command does not have either read or write access to the current working directory.
- **Solution:** Ensure that the user who is running the **aceDataCollector** command had the necessary permissions for the directory from which the command is run.

Resolving problems when developing message models

This topic contains advice for dealing with some common problems that can arise when working with message sets.

About this task

Message definition files:

Other:

Your message definition file does not open

Procedure

- **Scenario:** You have created a complex type with a base type that causes the types to be recursive, and now your message definition file does not open.
- **Solution:** Recover the last saved version of your message definition file from the local history or from your repository.

A message definition file error is written to the task list

Procedure

- **Scenario:** An error is written to the task list indicating that the message definition file has been corrupted.
- **Explanation:** This error message appears when the base type of the complex type is itself, or a circular definition of two or more simple types. This type of recursion is not supported.
- **Solution:** Examine your code and ensure that the type of recursion described above does not occur.

Your physical format property values have reverted to defaults

Procedure

- **Scenario:** Someone has sent you a message definition file. You have added it to a message set project, but all the physical format property values have reverted to defaults.
- **Explanation:** You cannot transfer message definition files on their own in this way because these files are not entirely independent.

  It is the `messageSet.mset` file that lists all the physical formats that are applicable to a message set.

  For example, if you have a message set *A* with CWF format *Binary1*, and a message set *B* without any physical formats, a message definition file copied from *A* to *B* does not show *Binary1* as a known physical format (although the properties are still in the message definition file).
- **Solution:** If possible, request the entire message set project.

  Alternatively, add physical formats to the receiving message set so that they match the originating message set. Then any dormant properties become visible. However, make sure that the message set level physical format properties match, or those object properties that inherit defaults from the message set level will be incorrect.

You are unable to enter text in the Message Definition editors

Procedure

- **Scenario:** You are unable to enter text in the Message Definition Overview editor, or change the text of an enumeration or pattern facet in the Message Definition Properties editor.

- **Solution:** The Message Definition editors are cell editors, and to enable them you have to double-click the cell.

  The first click selects the cell; the second click puts the cell into active state, allowing you to edit it.

Objects in your message definition file are not listed in alphabetic order

Procedure

- **Scenario:** The objects in your message definition file (`.mxsd`) are listed in the order that you created them, but you want them to be in alphabetic order.
- **Solution:**

  a) In the Integration Development perspective, double-click the message definition file to open it in the Outline view.

  b) Click **az** (at the top of the Outline view).

  This action changes the order of objects within each of the message definition file's folders (the Messages, Types, Groups, Elements, and Attributes folders) to be alphabetic.

Error messages are written to the task list after you have imported related XML Schema files

Procedure

- **Scenario:** When you have finished importing a collection of related XML Schema files, you find that the IBM App Connect Enterprise Toolkit task list contains error messages for the message set project, indicating that referenced types or other objects cannot be found.
- **Explanation:** These errors are typically an indication that one message definition file includes or imports another message definition file, but that the Message Definition editor is unable to resolve the specified link.
- **Solution:**

  – Check that a message definition file exists in the IBM App Connect Enterprise Toolkit for each of the related XML Schema files that you are importing. If the new message definition files have been created, they appear in the Application Development view.

  – Using the Properties Hierarchy in the Message Definition editor, check that any message definition files that include or import other message definition files are correctly locating the target files.

  One common scenario is where you have two XML Schema files *X* and *Y*, which both exist in the same directory in the file system but where *X*, which includes *Y*, is defined with a real target namespace, while *Y* is defined in the notarget namespace. After you import the two files, *X* is placed into the location that is determined by its namespace, but *Y* is placed into the default namespace location used for files defined in the notarget namespace. This situation causes the link between the two files to break, and you must modify *X* so that it correctly includes *Y* in its new relative location.

A group contains two different elements with the same XML name in the same namespace

Procedure

- **Scenario:** A warning is written to the task list because a group contains two different elements that have the same XML element name, in the same namespace.

- **Explanation:** When a message that has an XML physical format is validated, the validation includes a test to identify any part of a message definition where the parser might not be able to uniquely determine which element is represented by the XML name.

  This test generates a warning when a group contains two different XML elements with the same element name in the same namespace, even in cases where the duplication is legitimate.
- **Solution:** Determine whether the duplication that is identified in the warning message is in fact a problem that needs to be corrected, or whether it has arisen because of two elements on opposite sides of a choice sharing the same XML name, in which case the duplication is legitimate because no ambiguity can occur.

You are unable to set up a message definition file to include a message definition file within another message definition file

Procedure

- **Scenario:** You are unable to set up the include property of a message definition file to include a second message definition file that is included within another message definition file.
- **Explanation:** A message definition file can reference objects in another message definition file only if the first file references the second file directly.
  For example, if three message definition files exist, *A*, *B* and *C*, where *A* includes *B* and *B* includes *C*, *A* can reference objects in *B*, and *B* can reference objects in *C*, but *A* cannot reference objects in *C*.

  You might also encounter this problem after importing XML Schema files that have nested includes.
- **Solution:** You can work around this problem by including the message definition file directly, which, in the above example, would mean including *C* directly in *A*.

  Alternatively, you can define all the message set definitions that are in *C* directly in *B*, then delete *C* so that *A* needs to include only *B*.

You want to make the Properties tab the default tab in the Message Definition editor

Procedure

- **Scenario**: When using the Message Definition editor to edit your message definition files, you prefer to use the **Properties** tab rather than the **Overview** tab, but the **Overview** tab is always selected as the default.
- **Solution:** Use the IBM App Connect Enterprise Toolkit preferences to choose the **Properties** tab as the default tab:
  a) From the menu, click **Windows** > **Preferences**.
  b) Expand Integration Development, then **Message Set**.
  c) Expand **Editors** and select **Tab Extensions**.
  d) In the **Message Definition Editor** section, select the **Properties** and the **Overview** check boxes.
  e) Click **OK**.

Error message BIP5410 is issued because a union type cannot be resolved

Procedure

- **Scenario:** Error message BIP5410 is raised indicating that an element or attribute is based on a union type and that the element or attribute could not be cast to any member of the union.

- **Explanation:** When parsing an element or attribute that is based on a union type, the MRM XML parser uses an xsi:type attribute, where present, to resolve the union.

  If an xsi:type attribute is not present, or an attribute is being parsed, the parser tries each union member type in turn, attempting to cast to the associated simple type, until the cast succeeds. The order of precedence for the attempted cast is the order in which the member types are listed in the message model, under the union type, in the Outline view.

  If the data cannot be cast to any of the simple types within the union, the union cannot be resolved and a parser error is reported.
- **Solution:** Perform the following checks:
  - Check that the message contains a valid value for the element or attribute that is identified in the error message.
  - Check that the member types of the union that are identified in the error message contain the correct list of simple types.
  - If possible, use an xsi:type attribute to resolve the union explicitly.

Error message BIP5395 is issued because an xsi:type attribute value does not correspond to a valid member type of the union

Procedure

- **Scenario:** Error message BIP5395 is issued, indicating that an element is based on a union type that has an xsi:type attribute with a value that should resolve the union explicitly to one of its modeled member types and that the xsi:type attribute value does not correspond to a valid member type of the union.
- **Explanation:** When parsing or writing an element or attribute that is based on a union type, the MRM XML parser or writer uses an xsi:type attribute, where present, to resolve the union.

  The parser resolves the value of the xsi:type attribute to a simple type in the dictionary and checks that the simple type is a valid member type of the union.

  If the xsi:type attribute identifies a type that is not a member type of the union, it reports an error.
- **Solution:** Perform one of the following steps:
  - Modify the message so that the xsi:type attribute identifies a valid member type of the union.
  - Check that the member types of the union identified in the error message contain the correct list of simple types.

Error message BIP5396 is issued because a data type does not correspond to any of the valid data types of the union

Procedure

- **Scenario:** Error message BIP5396 is issued, indicating that an element or attribute is based on a union type but the data type does not correspond to any of the valid data types in the union.
- **Explanation:** When writing an element or attribute that is based on a union type, the MRM XML writer uses an xsi:type attribute, where present, to resolve the union.

  If an xsi:type attribute is not present, the writer tries to match the data type of the literal value in the tree to a simple type in the union. If the literal value cannot be matched to any of the simple types in the union, it reports a writing error.

- **Solution:** Perform one of the following steps:
  - Check that the message or ESQL contains a valid value for the element or attribute.
  - Check that the union type on which the element is based contains the correct list of simple types.
  - Consider using an xsi:type attribute to resolve the union explicitly.
  - Consider changing the type of the element in the tree to correspond with one of the union member types.

A union type contains two or more simple types that are derived from the same fundamental type

Procedure

- **Scenario:** A warning is issued during logical validation indicating that a union type contains two or more simple types that are derived from the same fundamental type.
- **Explanation:** The integration node does not apply value constraints until the data is in the logical tree. Therefore, it is not possible to choose between two simple types that are derived from the same fundamental type but with different constraints. For example, the integration node cannot differentiate between a member type of integer with a range of 1-10 and another member type of integer with a range of 11-20, therefore it resolves the union to the first member type of integer.
- **Solution:** Ensure that the union type that is identified in the warning does not contain more than one simple type that is derived from the same fundamental type or ensure that the ordering of such member types is as desired.

A list type is based on a union that also contains a list type

Procedure

- **Scenario:** An error message is issued during logical validation, indicating that a list type is based on a union type that includes a list type as one of its member types.
- **Explanation:** Lists of lists are not legal. An item type of a list type cannot be a list type itself nor can it be derived at any level from another list type. Therefore, a list type cannot have an item type of a union type that includes a list type as one of its member types.
- **Solution:** Ensure that any union type specified as an item type for a list type does not include a list type as one of its member types.

A union type contains an enumeration or pattern facet

Procedure

- **Scenario:** An error message is raised during logical validation, indicating that a union type contains an enumeration or pattern facet that is not supported because enumeration and pattern facets must be specified directly on the member type.
- **Explanation:** The integration node cannot support the union type facets of pattern and enumeration applied directly to a restriction of a union type. It can support facets directly on the chosen member type only. The Message Definition editor provides support for these facets to enable the import of schemas using direct facets on a restriction of a union type but it issues a warning notifying that they will be ignored by the integration node.
- **Solution:** If you want to use the enumeration or pattern facets, specify them directly on the member type and not on the union type itself.

Error message BIP5505 is issued because input data is not valid for the data type

Procedure

- **Scenario:** A data conversion fails while a message is being read or written. Error message BIP5505 is issued, indicating that the input data was not valid for the data type.
- **Solution:**

  Perform the following checks:

  – Ensure that the bit stream is correctly aligned to the model. If the incoming message is not consistent with the model, the wrong bytes are allocated to fields, and the data presented to a field is unlikely to contain valid data for the logical type.

  – Ensure that the correct encoding and CodedCharSetId are applied to the body of the input message. If the wrong encoding is used, the input message bit stream is subject to byte swapping and changes to the byte order. This change can affect the nature of data that applies to a field and make it unusable.

  – Ensure that an appropriate IBM MQ format is applied to the body of the input message. For example, if MQSTR is applied to a bit stream that contains numeric data, character conversions, rather than encodings, are used to translate the bytes. This use can change the meaning of bytes and make them not valid for the logical data type. If character conversions are used with negative external decimals, consider using the EBCDIC custom option.

  – If the error is on a numeric field, ensure that the input data is compatible with the physical format settings. For example, if the field is signed, ensure that a valid sign byte has been passed in, that it corresponds to the orientation of the sign, and that it is included or excluded as appropriate.

  – If the input message is found not to be compatible with the MRM message definitions, check the message at the source. If it is sent over channels, check that the conversion settings on the channels are correct.

A deprecation error is issued on an imported `.mrp` file

Procedure

- **Scenario:** You have imported an `.mrp` file, and get an error message indicating that complex elements or embedded simple types are deprecated.
- **Explanation:** Complex elements and embedded simple types have no exact equivalent in XML Schema. The closest equivalent to a complex type in XML Schema is to derive a complex type from a simple type. However, such a type is not allowed to contain elements; only attributes are allowed.
- **Solution:** If your complex type contains elements that cannot be modeled as attributes, set the **`Mixed content`** flag on the complex type. If you need to parse messages that contain mixed content, set the **`Mixed content`** flag on the parent complex type. The anonymous data that used to be modeled by the complex type or the embedded simple type, then appears as a self-defining node in the parsed message tree.

User trace detects an element length error

Procedure

- **Scenario:** You have defined an MRM message and when you execute the message flow, an error message is written to the user trace indicating that the length of an element is invalid.
- **Explanation:** You have added an element of type string to the complex type making up the message, but you have not defined the length of the string in the instance of the element in its type.

- **Solution:**
  a) Open the message definition file in the Message Definition editor.
  b) In the Outline view, expand the appropriate complex type, then click the element to display its properties in the editor area.
  c) In the Properties Hierarchy, make sure that the element is selected within the CWF physical format under **Physical Properties**.
  d) Specify the properties that this element will have when it is part of the complex type; for example, in the above case, make sure that the **Length Count** value is set.
  e) Save any changes in the Message Definition editor and redeploy the message.

MRM dateTime value has changed after it has been parsed

Procedure

- **Scenario:** You have defined an MRM dateTime element but the value created in the message tree is different from the value that you defined.
- **Explanation:** The parser uses lenient dateTime checking, converting out-of-band data values to the appropriate in-band value.
- **Solution:** See the information about lenient dateTime checking in Message Sets: DateTime as string data with particular reference to how years and fractional seconds are represented.

Resolving problems when using messages

Use the advice given here to help you to resolve common problems that can arise when you use messages.

About this task

Procedure

A communication error is issued when you use the enqueue facility

Procedure

- **Scenario:** You use the enqueue or dequeue tools to put a message on a queue, but an error message is issued indicating that a communication error has occurred with the queue manager name.
- **Explanation:** The IBM MQ queue manager has not started.
- **Solution:** Restart the IBM MQ queue manager.

The enqueue facility is not picking up changes made to a message

Procedure

- **Scenario:** You are using the IBM App Connect Enterprise Toolkit message enqueue facility to put messages to IBM MQ queues. You have updated a message and want to put the message to the queue, but your changes do not seem to have been picked up.
- **Solution:**
  a) Close, then reopen your enqueue file.
  b) Select the message that you want to put to the queue.
  c) Save and close the enqueue file.
  d) Select the menu next to the **Put a message to a queue** icon.
  e) Click **Put message**.
  f) Click the enqueue file in the menu.
  g) Click **Finish**.

  This action puts your updated message to the queue.

You do not know which header elements affect enqueue

Procedure

- **Scenario:** When using the Enqueue editor, the accounting token, correlation ID, group ID, and message ID in the message header do not seem to affect behavior.
- **Explanation:** These fields do not affect behavior because they are not serialized properly.

Enqueue message files are still listed after they have been deleted

Procedure

- **Scenario:** Enqueue message files are still listed in the menu after they have been deleted.
- **Explanation:** Deleted enqueue files are not removed from the menu. Nothing happens if you selecting these files.

The ESQL transform of an XML message gives unexpected results

Procedure

- **Scenario:** You have created an XML message that looks like the following content:

  ```
  <?xml version ="1.0" standalone="no"?><!DOCTYPE doc
  [<!ELEMENT doc (#PCDATA)*>]><doc><I1>100</I1></doc>
  ```

  You apply the ESQL transform:

  ```
  SET OutputRoot.XMLNS.doc.I1 = 112233;
  ```

  This transform generates the XML message (after serialization):

  ```
  <?xml version ="1.0" standalone="no"?><!DOCTYPE doc
  [<!ELEMENT doc (#PCDATA)*>]<I1>112233<I1>><doc><I1>100</I1></doc>
  ```

  The new value for *I1* has been put inside the DOCTYPE, and has not replaced the value of *100*, as you expected.
- **Explanation:** The XML in your message contains two doc elements:
  - The doctype element
  - The xmlElement that represents the body of the message

  The parser has found the first instance of an element called doc and has created a child *I1* with the value *112233*.
- **Solution:** To assign a new value to the element *I1* within the message body element doc, explicitly identify the second doc element, in the following way:

  ```
  SET OutputRoot.XMLNS.(XML.tag)doc.I1 = 112233;
  ```

An XML message loses carriage return characters

Procedure

- **Scenario:** You are parsing an input XML message that contains carriage return or line feed characters, or you are writing an output XML message that contains carriage return line feed characters in an XML element. However, some or all the carriage return characters are not present in the output message.
- **Explanation:** This behavior is correct, as described by the XML specification, and occurs in the XML, XMLNS, or XMLNSC domains.

  In XML, the main line separator characters is a line feed character. Carriage return characters are accepted in an XML document, but an XML parser normalizes any carriage return line feed characters into a single-line feed character. For more information, see the latest XML specification at Extensible Markup Language (XML), in particular, Section 2.11 *End of Line Handling*.

  You cannot work around this problem by embedding your data into a CDATA section; the XML specification states that a CDATA section is intended only to escape blocks of text that contain

characters that could be interpreted as markup. In addition, CDATA sections are not protected from the parser.

You cannot use the `xml:space` attribute to preserve carriage return line feed characters; the XML specification states that normalization of carriage return and line feed characters is done before any other processing is performed.

- **Solution:** XML-compliant data must not rely on the presence of carriage return line feed characters because in XML, the line feed character is only a line feed character and XML-compliant applications or data must be aware that the parser normalizes any carriage return line feed characters.

The integration node is unable to parse an XML message

Procedure

- **Scenario:** You receive a large XML file and wrap it in a SOAP envelope to be passed to a .NET web service. The integration node is unable to parse the XML message
- **Explanation:** The message that you receive is defined as UTF-8 but it contains UTF-16 characters, such as £. The presence of these characters causes a problem with the parser: the integration node is unable to parse the XML message because it contains an invalid character.
- **Solution:** Force the coded character set ID (CCSID) to 1208 instead of the default 437.

Error message BIP5004 is issued by the XMLNS parser

Procedure

- **Scenario:** Error message BIP5004 is issued, indicating that the XMLNS parser has encountered a problem with an input XML message.
- **Explanation:** This message is issued for a number of reasons. Some of the more commonly occurring scenarios when this message is issued are:
  - You have specified an invalid XML character in the input XML message.
  - You have included binary data in your XML message that, when treated as character data, is invalid.
  - The message has arrived as part of an IBM MQ message and the MQMD.CodedCharSetId does not correctly represent the XML text bit stream.
  - You have used characters that are recognized as markup.
- **Solution:**
  - Check that your sending application is sending only valid data. If, however, it is not possible to prevent invalid characters from being included in the XML message, represent it in BLOB domain and use the ESQL REPLACE function to replace or remove the invalid characters. You can then assign the modified bit stream to the required XML parser.

    In accordance with XML specification, a CDATA section can be used only to protect characters that would be interpreted as markup. It cannot be used to protect invalid characters or binary data from the XML parser.
  - If the input XML message contains binary data, ensure that the sending application is changed to represent this data as base encoded binary encoded data. If the application cannot be changed, represent the message in the BLOB domain, and extract and replace the binary data before the bit stream is assigned to the required XML parser.
  - Check that the incoming XML message is being represented by the correct MQMD.CodedCharSetId.

Error message BIP5378 is issued by the MRM parser

Procedure

- **Scenario:** Error message BIP5378 is issued, which reports a problem with a missing mandatory repeating element in an MRM message.
- **Explanation:** This message indicates that a mandatory repeating element is not present in the message.

  In previous releases, this condition was reported by error message BIP5374 which now reports only when a mandatory repeating element exists in the message but has the incorrect number of instances.

  If you have programmed automated error checking routines, review and change these routines if appropriate.
- **Solution:**

  Check your message definition to ensure that the element must be mandatory, and repeating. The error message tells you the elements that occur before and after the expected location of the missing element. If the definition is correct, the message has not been created correctly by the sending application, which must be amended.

Error message BIP5005 is issued by the Compute node

Procedure

- **Scenario:** You send a simple XML message into a simple message flow. The message is:

  ```
  <doc><I1>100</I1></doc>
  ```

  The Compute node in the message flow contains the following ESQL:

  ```
  SET OutputRoot.XMLNS.abc = InputBody;
  ```

  You expect the following output message to be created:

  ```
  <abc><doc><I1>100</I1></doc></abc>
  ```

  The Compute node generates error message BIP5005 and does not implement the ESQL.
- **Explanation:** You are assigning an element of one type (`root`) to an element of another type (`xmlElement`). The parser does not do this implicit cast for you.
- **Solution:** You can do the cast yourself in the ESQL to achieve the result that you want, using either of the following two casts:

  ```
  SET OutputRoot.XMLNS.(XML.Element)abc = InputBody;
  ```

  or:

  ```
  SET OutputRoot.XMLNS.(XML.tag)abc = InputBody;
  ```

A message is propagated to the Failure terminal of a TimeoutControl node

Procedure

- **Scenario:** The TimeoutControl node receives a message with invalid, corrupt, or missing timeout information. The message is propagated to the Failure terminal of the TimeoutControl node and an exception list is generated.

- **Explanation:** The following error conditions can cause propagation to the Failure terminal:
  - A timeout request has no Action or no Identifier.
  - A SET request has an Identifier that matches an existing stored SET request for this TimeoutControl node (identified by the Unique Identifier property) and AllowOverwrite of the original request is set to FALSE.
  - A CANCEL request has an Identifier that does not match an existing stored SET request for this TimeoutControl node (identified by the Unique Identifier property).
  - A SET request has a Count of 0 or is less than -1.
  - The StartDate or StartTime are not in the correct format (or one of the understood keywords).
  - The calculated timeout is in the past.
  - The Interval is less than 0, or 0 with a Count of -1.
- **Solution:** Check for one or more of the error conditions listed here, and correct them.

Message processing fails within a TimeoutNotification node

Procedure

- **Scenario:** A message is propagated to the Failure or Catch terminal of a TimeoutNotification node.
- **Explanation:** If the processing of a timeout generates an error within the TimeoutNotification node, an exception list is generated and a message is propagated to the Failure terminal. This action is done under the same transaction, if one is being used. If the Failure terminal is not connected, propagation does not occur.

  If an error happens downstream of the TimeoutNotification node after a successful propagation (either to the Out or Failure terminal), the message is propagated to the Catch terminal (all under the same transaction). If the Catch terminal is not connected, or the propagation along the Catch flow fails, the processing of that timeout is rolled back.
- **Solution:** Ensure that the Failure and Catch terminals of your TimeoutNotification node have been connected correctly.

An MRM CWF message is propagated to the Failure terminal

Procedure

- **Scenario:** Your MRM CWF message is propagated to a Failure terminal, and generates error messages BIP5285, BIP5125, and BIP5181 or messages BIP5285, BIP5125, and BIP5288.
- **Explanation:** These errors report an inconsistency between the length of the message being processed, and the length of the message that is defined in the message model.
- **Solution:** Ensure that the length of the message as defined in the CWF layer is accurate. Check and correct the definition.

Problems with XML attributes

About this task

XML tags are written where XML attributes are expected, and vice versa.

Procedure

- **Explanation:** The XML domains and the XML Wire Format in the MRM domain have their own representation of XML attributes.
  - XML domains rely on setting a field type of XML.Attribute in the message tree, because they have no model to parse against.
  - For the XML Wire Format in the MRM domain, the message model indicates whether an element is an attribute or a tag, therefore the message tree does not need to reflect whether a field is an attribute or a tag.

  Therefore, if fields are copied out of the XMLNS or MRM domains, the fact that fields are attributes is lost. This loss happens if they are copied out to each other, or to another message tree, such as the environment tree.

  This problem typically appears in the following situations:
- **Scenario 1:** You are writing an XML message in the MRM domain, and XML tags are being written instead of XML attributes.
- **Solution 1:** Check that your message tree has the same structure and sequence as the message model. If the message tree does not match the message model, the field is written as self-defining, and consequently the XML Render property is not used.
  - Switch on message validation. Validation shows where the message tree and message definition do not match.
  - Alternatively, take a user debug trace of the message flow; BIP5493W messages indicate which fields are being written as self-defining. Use this information to ensure that the message tree matches the model. When you have corrected any discrepancies, attributes are correctly written.
- **Scenario 2:** An MRM message has been copied to an XMLNS domain, and the XML attributes are now written as tags.
- **Solution 2:** Take one of these actions:
  - Serialize the XML message in the MRM domain, for example using the ESQL ASBITSTREAM function, then use the ESQL CREATE PARSE clause to reparse the message using the required XML domain.
  - When copying fields between the MRM domain and XMLNS, copy attribute fields individually, and specifically specify XML.Attribute on the target XML field.
- **Scenario 3:** An XML message has been copied to another message tree, such as Environment. When the message is copied back to the XML message tree, XML attributes are now seen as XML tags.
- **Solution 3:** Serialize the XML message, for example using the ESQL ASBITSTREAM function, then use the ESQL CREATE PARSE clause to reparse the XML message into the required target message tree. See CREATE statement for an example.
- **Scenario 4:** A portion of a non-XML message tree has been detached and attached to an XML tree, and XML tags are now written as XML attributes.
- **Solution 4:** Do not detach and attach portions of message trees that are owned by different parsers. Instead, use a tree copy.
- **Scenario 5:** An XML tag is copied to an XML attribute and the XML attribute is not written in the output message.
- **Solution 5:** When referencing the source XML tag, use the ESQL FIELDVALUE function to copy the specific field value to the target XML attribute field.

An MRM XML message exhibits unexpected behavior

Procedure

- **Scenario:** Your message flow is processing a message that you have modeled in the MRM. The message tree has not been created as you expected, the output XML message does not have the

expected contents, or the message contents are not being validated. No error message has been issued.

- **Explanation:** Two reasons might cause this problem:
  - **Explanation 1:** The XML physical format settings for a message set contain a property called Root Tag Name. This property defaults to MRM, in order to remain compatible with previous releases of the product. If you have not deleted the contents of this field, the MRM XMLNS parser expects the root tag for all XML messages to be MRM.

    Solution 1: Clear this field, or set it to the root tag used by all your XML messages. If you provide a value in this field, the root tag does not need to be modeled in all your message definitions.
  - **Explanation 2:** In order to remain backwards compatible, the integration node recognizes the format XML and invokes the XMLNS parser with specific default values. If you have created an XML physical layer for this message with the name XML, the integration node uses your definition. However, if you have not created an XML physical layer with this name, but have specified XMLNS as the format, either in the input node or the MQRFH2 header (when the input bit stream is parsed to a message tree), the integration node accepts the value specified and passes default values to the parser to create the message tree.

    Similarly, if you set XML in the Properties folder for the output message in the Compute node, this value is passed to the parser when it creates the message bit stream from the message tree, typically in the output node.

    The use of these default values by the parser might result in different content, structure, or both, for either message tree or output message. You can find further information about the action taken by the integration node in the user trace log where the following information might be written:

```
XMLWorker::initializeParse file:C:\s000\src\cpi\pwf\xml\xmlworker.cpp
line:126 message:5409.BIPmsgs
No dictionary present have you specified Wire Format 'XML' in error? ,
UserTrace   BIP5409E: XML Worker: Wire Format 'XML' specified.
                      Default MRM XML settings are being used because wire format
                      identifier 'XML' was specified and not found.
                      This can be due to an incorrect setting of the wire format
                      identifier in a message.
```

    Solution 2: If you have incorrectly entered the identifier of the format that you have defined, correct your code and try again. If you do not want the default action to be taken, define a physical layer that produces the required results.

The MRM parser has failed to parse a message because two attributes have the same name

Procedure

- **Scenario:** Two attributes in different name spaces have identical names. Error message BIP5117 is issued.
- **Explanation:** The MRM parser has failed to parse the message.
- **Solution:** Modify the attribute names so that they are not identical. This problem is a known limitation with the parser.

You encounter problems when messages contain EBCDIC newline characters

Procedure

- **Scenario:** If your bit stream input message contains EBCDIC newline (NL) characters, problems might arise if your message flow changes the target CCSID to an ASCII CCSID. For example, during conversion from CCSID 1047 to CCSID 437 (US PC ASCII), an NL character is translated from hex '15' to hex '7F', which is an undefined character. The error occurs because no corresponding code point for the newline character exists in the ASCII code page.

- **Solution:** You can overcome the problem in these cases:
  - On a system where the queue manager uses an ASCII code set, make sure that incoming messages do not contain any EBCDIC NL characters by:
    - Specifying that IBM MQ performs the conversion at the input node
    - Setting the queue manager attribute to convert NL to Line Feed (LF)
  - Where the input bit stream is character data, you can use MRM Tagged/Delimited message sets in a Compute node to replace the NL character with the required output.

The MIME parser produces a runtime error while parsing a message

Procedure

- **Scenario:** A MIME message is received by a message flow and produces a runtime error when the message is parsed.
- **Explanation:** The following errors can cause the MIME parser to reject a message:
  - The MIME header is not correctly formatted.
  - Either the top-level MIME header block, or a MIME header block for a nested multipart part, does not have a valid Content-Type header.
  - The top-level Content-Type has a media type of `message`.
  - The top-level Content-Type has a media type of `multipart` and no boundary definition.
  - A MIME header block is not correctly terminated by a blank line.
  - The constituent MIME parts are not correctly separated by boundary lines.
  - A boundary parameter value occurs in the content of a MIME part.
- **Solution:** Check the MIME message for one or more of the error conditions listed here, and correct them.

Runtime errors are issued when you write a MIME message from the logical message tree

Procedure

- **Scenario:** You are writing a MIME logical message tree as a bit stream and the parser generates a runtime error.
- **Explanation:** The following errors can cause the MIME parser to reject a logical message tree:
  - The root of the tree is not called MIME.
  - The last child of MIME is not called Parts or Data.
  - The Parts element has a value-only element, and this element is not the first or last child of Parts.
  - The Parts element has children that are not value-only elements or Part children.
  - The Parts element does not have any children called Part.
  - The last child of a Data element is not a BLOB.
- **Solution:** Check the MIME logical message tree for one or more of the error conditions listed here, and correct them.

Output message has an empty message body

Procedure

- **Scenario:** You have unexpectedly encountered an empty message body, or the ASBITSTREAM function has produced a zero length BLOB.

- **Explanation:** This error can happen for the following reasons:
  - You have created a message tree folder in a user-defined node but have not associated it with an owning parser. An owning parser is not associated with the message tree if you have created standard elements by using code similar or equivalent to:

    ```
    MbElement createElementAfter(int)
    MbElement createElementAfter(int, String, Object)
    MbElement createElementAsFirstChild(int)
    MbElement createElementAsFirstChild(int, String, Object)
    MbElement createElementAsLastChild(int)
    MbElement createElementAsLastChild(int, String, Object)
    MbElement createElementBefore(int)
    MbElement createElementBefore(int, String, Object)
    ```

  - You have used ESQL to create a message tree folder by using ESQL CREATE but without setting an owning parser for it. You might have used code similar or equivalent to:

    ```
    CALL CopyMessageHeaders();
       DECLARE outRef REFERENCE TO OutputRoot;
       CREATE LASTCHILD OF outRef AS outRef NAME 'BLOB';
       CREATE LASTCHILD OF outRef NAME 'BLOB' VALUE X'01';
    ```

    or the `outRef` reference variable was passed to an ESQL function or procedure that contained similar CREATE statements. You have not specified an owning parser by using the DOMAIN clause on the CREATE statement.
  - An MRM message tree has been constructed, then only part of it has been passed, by specifying a subfolder or field, to the ASBITSTREAM function with the parser mode option set to RootBitStream. This combination is not valid, and results in a zero length BLOB.
  - You have copied a message tree, or part of a message tree, to a folder and the owning parser association is not maintained.
- **Solution:** Depending on the reason for the empty message body or zero length BLOB, ensure that:
  - When you create a message tree folder in a user-defined node, associate an owning parser with it. Use code similar or equivalent to:

    ```
    createElementAfter(String parserName)
       createElementAsFirstChild(String parserName)
       createElementAsLastChild(String parserName)
       createElementBefore(String parserName)
    ```

  - When you use ESQL CREATE to create a message tree folder, use the DOMAIN clause to associate an owning parser with the message tree, for example:

    ```
    CALL CopyMessageHeaders();
       DECLARE outRef REFERENCE TO OutputRoot;
       CREATE LASTCHILD OF outRef AS outRef DOMAIN 'BLOB' NAME 'BLOB';
       CREATE LASTCHILD OF outRef NAME 'BLOB' VALUE X'01';
    ```

    This code creates a BLOB folder that has the BLOB parser associated with it.
  - When copying a message tree, or part of a message tree, ensure that the owning parser association is maintained, by first serializing, then reparsing the message into the appropriate message tree. An example scenario is where you have created a field:

    ```
    SET Environment.Variables.myMsg = InputRoot.XMLNS;
    ```

    Now you must pass it to the ASBITSTREAM function. Unless you use ESQL similar or equivalent to:

```
DECLARE xmlMsgBlob BLOB
          ASBITSTREAM(InputRoot.XMLNS, InputRoot.MQMD.Encoding, InputRoot.MQMD.CodedCharSetId);
  CREATE LASTCHILD OF Environment.Variables.myMsg DOMAIN('XMLNS')
         PARSE(xmlMsgBlob,
               InputRoot.MQMD.Encoding,
               InputRoot.MQMD.CodedCharSetId);
```

    the result is a zero length bit stream.

Output message has an invalid message body indicated by error message BIP5005, BIP5016, or BIP5017

Procedure

- **Scenario:** You have unexpectedly encountered a multi-root message body or a message without any root.
- **Explanation:** This error can occur when you have created an XML message tree folder with multiple roots or no root at all by:
  - Using a user-defined node
  - Using an MQGet node
  - Using ESQL
- **Solution:** Ensure that the final output message tree has one, and only one, XML root node.

Error message BIP5651 is issued when receiving a SOAP with Attachments message from a WebSphere Application Server client

Procedure

- **Scenario:** When a WebSphere Application Server client sends a SOAP with Attachments message to the integration node over JMS, error message BIP5651 is issued stating that no valid Content-Type header has been found.
- **Explanation:** When a WebSphere Application Server client sends a SOAP with Attachments message to the integration node over JMS, the MIME Content-Type value appears in the MQRFH2 header and not in the MIME message body.
- **Solution:** To solve this problem, the Content-Type value needs to be copied from the MQRFH2 header to the beginning of the message as a MIME header before the message is parsed. The following ESQL adds the Content-Type value to the beginning of the WebSphere Application Server message, then invokes the MIME parser on the result.

```
create procedure parseWAS_JMS(IN InputMessage reference,IN OutputMessage reference)
/**********************************************************************
* convert a WAS/JMS message to the correct format for the MIME parser
**********************************************************************/
begin
  -- get the data as a BLOB
  declare body BLOB InputMessage.BLOB.BLOB;

  -- get the Content-Type value from the RFH2 header. Content-Type is the only
  -- header which is critical for the MIME parser, but the same approach can be
  -- used for any MIME headers which have been stored under the RFH2 header.
  declare contentType char InputMessage.MQRFH2.usr.contentType;

  -- add the contentType to the bit stream as part of an RFC822 header block
  set body = cast(('Content-Type: '||contentType) as blob ccsid 819)||x'0d0a0d0a'||body;

  -- invoke MIME parser on the modified bit stream
  CREATE LASTCHILD OF OutputMessage DOMAIN('MIME') PARSE(body);
end;
```

A message flow can take in the JMS message in the BLOB domain, and call the procedure shown here from a Compute node. The procedure can be called by using the following ESQL from a Compute node:

```
CALL CopyMessageHeaders();                -- standard procedure to copy headers
CALL parseWAS_JMS(InputRoot, OutputRoot);  -- parse the ‘body' as MIME
```

WebSphere Application Server produces an error when receiving a SOAP with Attachments message

Procedure

- **Scenario:** When sending a SOAP with Attachments message to a WebSphere Application Server client using JMS, an error is generated stating that the bit stream contains unexpected characters.
- **Solution:** When the integration node sends a SOAP with Attachments message to WebSphere Application Server over JMS, the MIME Content-Type value must appear in the MQRFH2 header and not in the body of the message. The following procedure removes any MIME style headers from the front of the message bit stream and adds the Content-Type value to the MQRFH2 header. The supplied boundary value allows you to locate the start of the multipart MIME content.

```
create procedure writeWAS_JMS(IN OutputTree reference,IN boundary char)
/*****************************************************************************
* Serialise a MIME tree as normal, but then strip off any initial headers
* and save the Content-Type value in the RFH2 header as expected by WAS/JMS.
* Note: boundary - must be supplied with the leading hyphen pair
*****************************************************************************/
begin
  -- convert MIME subtree to BLOB
  declare body BLOB asbitstream(OutputTree.MIME);

  -- locate first occurrence of boundary and discard any data before this
  declare firstBoundary integer;
  set firstBoundary = position (cast(boundary as blob ccsid 819) in body);
  set body = substring(body from firstBoundary);

  -- save the MIME Content-Type value in the RFH2 header. Any other MIME
  -- headers which need to be preserved in the RFH2 header can be handled
  -- in the same way
  set OutputTree.MQRFH2.usr."contentType" = OutputTree.MIME."Content-Type";

  -- clear the MIME tree and create a new BLOB child for the modified body
  set OutputTree.MIME = null;
  CREATE LASTCHILD OF OutputTree DOMAIN('BLOB')PARSE(body);
end
```

Before calling this procedure, the message flow needs to be able to obtain the value of the boundary. This value might be available only within a Content-type header. The following procedure allows you to extract the Boundary value:

```
create procedure getBoundary(IN ct reference,OUT boundary char)
/*****************************************************************
* return value of the boundary parameter from a Content-Type value
*****************************************************************/
begin
  declare boundaryStart  integer;
  declare boundaryEnd    integer;

  set boundaryStart  = position('boundary=' in ct) + 9;
  set boundaryEnd    = position(';' in ct from boundaryStart);
  if (boundaryStart <> 0) then
    if (boundaryEnd <> 0) then
     set boundary  = substring(ct from boundaryStart for boundaryEnd-boundaryStart);
    else
      set boundary  = substring(ct from boundaryStart);
    end if;
  end if;
end;
```

A Compute node can invoke these procedures for sending a MIME message using the following ESQL:

```
SET OutputRoot = InputRoot;

declare boundary char;
CALL getBoundary(OutputRoot.Properties.ContentType, boundary);

CALL writeWAS_JMS(OutputRoot,boundary);
```

java_lang_StackOverflowError on AIX when processing a message flow that contains Java nodes and uses Java 5

Procedure

- **Scenario:** You get an abend on AIX when processing a message flow that contains Java nodes and uses Java 5.

  The abend file shows that there was an abend which indicates a segmentation fault, but a check of the `stderr` file shows a stack overflow in the JVM:

```
Exception in thread "Thread-15" java/lang/StackOverflowError: operating system stack overflow
        at com/ibm/broker/plugin/MbOutputTerminal._propagate    (Native Method)
        at com/ibm/broker/plugin/MbOutputTerminal.propagate    (MbOutputTerminal.java:103)
        at com/ibm/xsl/mqsi/XMLTransformNode.evaluate    (XMLTransformNode.java:1002)
        at com/ibm/broker/plugin/MbNode.evaluate (MbNode.java:1434)
        at com/ibm/broker/plugin/MbOutputTerminal._propagate   (Native Method)
        at com/ibm/broker/plugin/MbOutputTerminal.propagate   (MbOutputTerminal.java:103)
        at com/ibm/xsl/mqsi/XMLTransformNode.evaluate   (XMLTransformNode.java:1002)
        at com/ibm/broker/plugin/MbNode.evaluate   (MbNode.java:1434)
        at com/ibm/broker/plugin/MbOutputTerminal._propagate   (Native Method)
        at com/ibm/broker/plugin/MbOutputTerminal.propagate   (MbOutputTerminal.java:103)
        at com/ibm/xsl/mqsi/XMLTransformNode.evaluate   (XMLTransformNode.java:1002)
        at com/ibm/broker/plugin/MbNode.evaluate (MbNode.java:1434)
```

- **Explanation:**Java 5 has a parameter to adjust the stack size for Java threads. The default operating system stack size for Java 5 is only 256 KB. In certain message flows (for example, flows that contain Java user-defined nodes or XMLT nodes) this size might not be sufficient, and so you see a stack overflow error in the `stderr` file. Use the JVM option `-Xmso` to adjust the operating system stack for Java.

  You can display information about the stack by using the following command:

```
export MQSIJVERBOSE=-verbose:stack,sizes
```

  This command creates in the `stderr` file on startup an entry that has the folllowing content, or similar:

```
   -Xmca32K        RAM class segment increment
   -Xmco128K       ROM class segment increment
   -Xmns0K         initial new space size
   -Xmnx0K         maximum new space size
   -Xms125000K     initial memory size
   -Xmos125000K    initial old space size
   -Xmox250000K    maximum old space size
   -Xmx250000K     memory maximum
   -Xmr16K         remembered set size
   -Xlp0K          large page size
                   available large page sizes: 4K 16M
   -Xmso256K       OS thread stack size
   -Xiss2K         java thread stack initial size
   -Xssi16K        java thread stack increment
   -Xss256K        java thread stack maximum size
   -Xscmx16M       shared class cache size

Note: The stack size defaults to 256K.
```

- **Solution:**

  1. Issue the following command to set the operating system stack size for Java to 2 MB:

```
export IBM_JAVA_OPTIONS=-Xmso2m
```

  2. Restart the integration node.

Unable to access messages on a remote IBM MQ queue

Procedure

- **Scenario:** Error message BIP2677 occurs when an MQInput node is attempting to access messages on a remote queue.

- **Explanation:** This error can occur when an MQInput node is using the IBM MQ callback mechanism to receive messages from a queue.
- **Solution:** Check the IBM MQ completion and reason codes in the IBM MQ product documentation to determine the cause of the error. If the error is MQ_ENVIRONMENT_ERROR (2012), a likely cause is that the SHARECNV (shared conversations) parameter for the connected channel is set to `0`. To resolve the problem, ensure that the SHARECNV parameter for the channel is set to the default value of `10`.

An IBM MQ message does not complete backout processing, and `BackoutCount` increments continuously

Procedure

- **Scenario:** In a running message flow, an input message on an MQInput node is continuously backed out, and the `BackoutCount` increments indefinitely, even if the backout threshold was reached. BIP2630 appears in the local error log.
- **Explanation:** This error occurs when the message was backed out, and the queue manager for the integration node does not have a backout requeue queue or a dead letter queue defined, or there was an MQPUT error in connecting to either queue. The message cannot be put to a queue, and so is continuously backed out.
- **Solution:** If this situation occurs because neither a backout requeue queue or dead letter queue exists, define one (or both) of the queues to resolve the problem. If the condition that prevented the message from being processed is resolved, you can temporarily increase the value of the BOTHRESH attribute, which forces the message through normal processing.

Resolving problems when you are writing business rules

Use the advice that is given here to help you to resolve problems that can arise when you are writing business rules.

Resolving problems when you are writing business rules

Procedure

- **Scenario:** You are retrieving rules at run time from an IBM Operational Decision Manager repository but rules are not being updated automatically.
- **Explanation:** This problem can be caused when the TCP/IP port that you configure for IBM App Connect Enterprise to communicate with IBM Operational Decision Manager is used by another application.
  For example, the default IBM Operational Decision Manager TCP/IP port is 1883, which is also the default TCP/IP port for IBM MQ Telemetry.
- **Solution:** Check that the TCP/IP port that is configured for IBM Operational Decision Manager is not used by another application. If a conflict exists, change the port number for the JDBC Providers policy that defines the connection to the IBM Operational Decision Manager repository.

Resolving problems when you use the IBM App Connect Enterprise Toolkit

Use the advice given here to help you to resolve common problems that might occur you use the IBM App Connect Enterprise Toolkit.

About this task

Resolving problems that occur when connecting:

- "Your integration node is not recognized by the IBM App Connect Enterprise Toolkit" on page 2988
- "You cannot connect to the integration node from the IBM App Connect Enterprise Toolkit or command line" on page 2989

- “You cannot connect to a migrated integration node” on page 2989
- “Connection to the integration node is slow” on page 2990

Resolving error messages that occur when using the IBM App Connect Enterprise Toolkit:

- “IBM App Connect Enterprise Toolkit on Red Hat 7.n crashes with "JVM terminated. Exit code=160" error” on page 2991
- “After you start the IBM App Connect Enterprise Toolkit, runtime functions do not work” on page 2993
- “Errors occur while you are using the IBM App Connect Enterprise Toolkit” on page 2994
- “An error message is displayed when you start the Flow Exerciser” on page 2994
- “The plug-in repository cannot be found when you are installing a plug-in into the IBM App Connect Enterprise Toolkit” on page 2994
- “MSVCP120.dll missing message is issued ” on page 2995
- “An error is issued when you access the help system ” on page 2995
- “The IBM App Connect Enterprise Toolkit displays an error message after the error has been fixed” on page 2995
- “The message Unable to create part: filename.extension is issued” on page 2995

Resolving problems relating to the appearance of the workbench:

- “A view is missing from the workbench” on page 2996
- “You cannot close a message dialog box” on page 2996
- “You want to filter entries in the Problems view” on page 2996
- “Your message flow and message set projects have changed their appearance” on page 2996

Resolving non-specific problems when using the workbench:

- “Main menu entries missing on Linux” on page 2996
- “Editors do not update automatically when the same file is open in multiple windows” on page 2997
- “Deleting or closing a project takes a long time” on page 2997
- “You are experiencing poor performance when working with large or complex projects” on page 2997
- “You do not know how to return to the welcome page ” on page 2997

Resolving problems that occur when connecting the IBM App Connect Enterprise Toolkit and an integration node

Use the advice given here to help you to resolve common problems that can arise when you connect to an integration node.

Your integration node is not recognized by the IBM App Connect Enterprise Toolkit

Procedure

- **Scenario:** Your integration node is not recognized by the IBM App Connect Enterprise Toolkit.
- **Explanation:** Integration node names in the workbench are case sensitive.
- **Solution:** When you identify an integration node in the IBM App Connect Enterprise Toolkit, make sure that you use the same case that was used when it was created. On some operating systems, the name of the integration node might be folded to uppercase when it was created, even though you entered its name in lowercase.

You cannot connect to the integration node from the IBM App Connect Enterprise Toolkit or command line

Procedure

- **Scenario:** Error messages are issued when you try to connect to the integration node from the IBM App Connect Enterprise Toolkit or the command line.
- **Solution:** The following table shows the checks to carry out when an error message is issued in the IBM App Connect Enterprise Toolkit, or returned to the command line, when you try to connect to the integration node:

Error message		Actions
IBM App Connect Enterprise Toolkit	**Command line**	
BIP0914E	BIP1921E	Check that the integration node and its HTTP listener are running, and that the correct port is specified for the web user interface connection.
BIP0889E	BIP1920E	Check that the integration node is running. Check the system event log to ensure that the integration node is available for use, and correct all errors that are shown.
BIP0915E	BIP1923E	Check that the IBM App Connect Enterprise Toolkit local user ID is created on the integration node system. If it is not, create it. Check if the IBM App Connect Enterprise Toolkit local user ID that is created on the integration node system is authorized to connect to the web user interface.
	BIP1291E	Remove the **-q** parameter, and use the **-i** or **-p** parameters instead.

You cannot connect to a migrated integration node

Procedure

- **Scenario:** You cannot connect from the IBM App Connect Enterprise Toolkit, the IBM App Connect Enterprise Toolkit, or an IBM App Connect Enterprise Toolkit application to an integration node that you have migrated to Version 12.0.
- **Explanation:** The connection is failing because the IBM MQ channel does not exist.

  When you migrate an integration node to Version 12.0, the default server connection channel SYSTEM.BKR.CONFIG is created if it does not exist. However, if the integration node shared a queue manager with a Configuration Manager, this channel is deleted when you delete the Configuration Manager.
- **Solution:** Re-create the server connection channel SYSTEM.BKR.CONFIG on the queue manager.

You cannot connect to a remote integration node

Procedure

- **Scenario:** You have correctly configured your IBM App Connect Enterprise Toolkit to connect to a remote integration node, but attempting to connect to the remote integration node by using the

IBM App Connect Enterprise Toolkit results in error MQRC 2059. You can connect to your remote integration node from the same computer without error by completing the following steps:

a) Set the following environment variable:

- On Windows: `set MQSERVER=ChannelName/TCP/server-address(port)`
- On Linux: `export MQSERVER=ChannelName/TCP/'server-address(port)'`

b) Open an IBM App Connect Enterprise command prompt, and enter the following test command:

```
amqsputc queueName qmgrName
```

- **Explanation:** The network configuration of your IBM App Connect Enterprise Toolkit installation is incorrect.
- **Solution:**

a) In the IBM App Connect Enterprise Toolkit, click **Window** > **Preferences** > **General** > **Network Connection**.

The Preferences window opens, and the Network Connections preferences are displayed.

b) From the Active Provider list, select **Direct**.

For more information about the Active Provider setting, see the "Network Connections" topic in the Eclipse product documentation.

You can now connect to your remote integration node by using the IBM App Connect Enterprise Toolkit.

Connection to the integration node is slow

Procedure

- **Scenario:** Connection to the integration node is slow and you cannot complete other actions in the IBM App Connect Enterprise Toolkit when you request the following operations:
  - Creating an integration node
  - Creating an integration server
  - Deploying a BAR file, using the **Deploy a BAR File** wizard
  - Opening the Administration log editor
- **Solution:** Click **Cancel** on the progress monitor dialog box to cancel the in-progress connection.

  Connection to the integration node is canceled, so that you can perform other actions in the IBM App Connect Enterprise Toolkit. You can then resubmit the canceled operation.

Resolving errors that occur when using the IBM App Connect Enterprise Toolkit

Use the advice given here to help you to resolve common problems that can occur when you use the IBM App Connect Enterprise Toolkit.

About this task

- “Timeout issues and an inability to acquire a lock when you start the IBM App Connect Enterprise Toolkit” on page 2991
- “IBM App Connect Enterprise Toolkit on Red Hat 7.n crashes with "JVM terminated. Exit code=160" error” on page 2991
- “IBM App Connect Enterprise Toolkit on Linux becomes unresponsive after opening a DFDL or XSD file” on page 2992
- “Internal web browser in IBM App Connect Enterprise Toolkit does not work on Red Hat 7.n ” on page 2993

Timeout issues and an inability to acquire a lock when you start the IBM App Connect Enterprise Toolkit

Procedure

- **Scenario:** You try to start the IBM App Connect Enterprise Toolkit but it fails to start, or hangs on the splash screen. The log reports a timeout issue and an inability to acquire a lock.
- **Explanation:** The failure of the toolkit to start can be an issue with Windows defender on Windows 10. The Windows anti-malware takes away the CPU from the toolkit, making it impossible for the toolkit to start. You can look in the Windows task manager and observe that the *Antimalware Service executable* is using a similar amount of CPU as the toolkit.
- **Solution:** Add the IBM App Connect Enterprise installation directory to the exclusion list in Windows defender.

  1. Open **Windows Security**.
  2. Click **Virus and Threat Protection**.
  3. Click the **Manage Settings**.
  4. Click **Add or Remove Exclusions**.
  5. Click the "+" sign next to **Add an Exclusion**. The **Certificate** window is displayed.
  6. Select **Folder** from the menu to open **Windows Explorer**.
  7. Go to the installation directory for IBM App Connect Enterprise. For example, `C:\Program Files \IBM\ACE`.
  8. Click **Select Folder**. The **User Account Control** prompt is displayed.
  9. Select **Yes** in **User Account Control** to confirm your changes. The list of exclusions is updated to include your selection.

IBM App Connect Enterprise Toolkit on Red Hat 7.n crashes with "JVM terminated. Exit code=160" error

Procedure

- **Scenario:** When the IBM App Connect Enterprise Toolkit runs on Red Hat Linux 7.n, and you click the Patterns Explorer view or you use the Tutorials Gallery, the IBM App Connect Enterprise Toolkit can crash with the following error:

  ```
  JVM terminated. Exit code=160
  ```
- **Explanation:** Red Hat Linux 7.n ships with WebKitGTK version webkitgtk.x86_64 1.2.6-5.el6, which can have problems with the Eclipse SWT browser.

- **Solution:** To work around this problem, complete one of the following steps:
  - Update the IBM App Connect Enterprise Toolkit `eclipse.ini` file to use XULRunner instead of WebKitGTK for browser support by completing the following steps:
    1. Download XULRunner 10.0.4 ESR 64-bit from http://ftp.mozilla.org/pub/mozilla.org/xulrunner/releases/10.0.4esr/runtimes/xulrunner-10.0.4esr.en-US.linux-x86_64.tar.bz2.
    2. Expand the compressed file into a convenient directory. For example, `/usr/lib/xulrunner_new`.
    3. Add the following lines to the end of the `eclipse.ini` file in the `tools` directory under the IBM App Connect Enterprise installation directory:

       ```
       -Dorg.eclipse.swt.browser.XULRunnerPath=filepath/xulrunner
       -Dorg.eclipse.swt.browser.DefaultType=mozilla
       ```

       For example:

       ```
       -Dorg.eclipse.swt.browser.XULRunnerPath=/usr/lib/xulrunner_new/xulrunner
       -Dorg.eclipse.swt.browser.DefaultType=mozilla
       ```

    4. Restart the IBM App Connect Enterprise Toolkit.

IBM App Connect Enterprise Toolkit on Linux becomes unresponsive after opening a DFDL or XSD file

Procedure

- **Scenario:** When the IBM App Connect Enterprise Toolkit runs on Linux (for example, Red Hat Linux 7.n) and you open a DFDL or XSD file in the DFDL editor or XML Schema Editor, the IBM App Connect Enterprise Toolkit can become unresponsive and might not shut down correctly. Killing the `javaw` process manually closes the IBM App Connect Enterprise Toolkit, and might result in a `javacore` file with the main thread in the following method:

  ```
  org/eclipse/swt/internal/gtk/OS._gtk_enumerate_printers(Native Method)
  ```

- **Solution:** This issue is caused by Eclipse Bug 153936 (Eclipse freezes when opening an editor). Complete one of the following steps to resolve the problem:
  - Add the following line to the end of the `eclipse.ini` file in the tools directory under the IBM App Connect Enterprise installation directory:

    ```
    -Dorg.eclipse.swt.internal.gtk.disablePrinting
    ```

  - Install the GTK2 32-bit drivers by running the following command from the command line:

    ```
    sudo yum install gtk2.i686
    ```

Internal web browser in IBM App Connect Enterprise Toolkit does not work on Red Hat 7.n

Procedure

- **Scenario:** When the IBM App Connect Enterprise Toolkit runs on Red Hat Linux 7.n and you use any of the views that require an internal web browser, you might see one or more of the following error messages:
  - In the Pattern Specification editor:

    ```
    No internal web browser can be resolved. Pattern specifications is opened in default
     system web browser.
    ```

  - In the Tutorials Gallery view:

    ```
    No more handles [Unknown Mozilla path (MOZILLA_FIVE_HOME not set)]
    ```

  - In the XML View tab in the DFDL Test - Logical Instance view:

    ```
    The default browser installed on your system is not compatible or environment variables
     need to be specified.
    Consult the Welcome screen (Help and Welcome in the menu) for information about
     configuring your system.
    ```

- **Solution:** To work around this problem, update the IBM App Connect Enterprise Toolkit eclipse.ini file to use XULRunner instead of WebKitGTK for browser support, by completing the following steps:
  a) Download XULRunner 10.0.4 ESR 64-bit from http://ftp.mozilla.org/pub/mozilla.org/xulrunner/releases/10.0.4esr/runtimes/xulrunner-10.0.4esr.en-US.linux-x86_64.tar.bz2
  b) Expand the compressed file into a convenient directory (such as /usr/lib/xulrunner_new).
  c) Add the following lines to the end of the eclipse.ini file in the tools directory under the IBM App Connect Enterprise installation directory:

     ```
     -Dorg.eclipse.swt.browser.XULRunnerPath=<location of unzipped download file>/xulrunner
     -Dorg.eclipse.swt.browser.DefaultType=mozilla
     ```

     For example:

     ```
     -Dorg.eclipse.swt.browser.XULRunnerPath=/usr/lib/xulrunner_new/xulrunner
     -Dorg.eclipse.swt.browser.DefaultType=mozilla
     ```

  d) Restart the IBM App Connect Enterprise Toolkit.
  e) If the IBM App Connect Enterprise Toolkit fails with an error saying `JVM terminated. Exit code=160`, run the following command before launching the toolkit in the same terminal window:

     ```
     export LD_LIBRARY_PATH=<location of unzipped download file>/xulrunner:$LD_LIBRARY_PATH
     ```

     For example:

     ```
     export LD_LIBRARY_PATH=/usr/lib/xulrunner_new/xulrunner:$LD_LIBRARY_PATH
     ```

After you start the IBM App Connect Enterprise Toolkit, runtime functions do not work

Procedure

- **Scenario:** After you start the IBM App Connect Enterprise Toolkit, runtime functions including tutorials, patterns, the Flow Exerciser, and integration node administration do not work correctly.

- **Explanation:** This error occurs if you start the IBM App Connect Enterprise Toolkit by using one of the following commands to start Eclipse:
  - On Windows: `eclipse.exe`
  - On Linux: `./eclipse`
- **Solution:** Always start the IBM App Connect Enterprise Toolkit by using one of the following methods:
  - On Windows:
    - Use the Windows menu option.
    - From the IBM Integration Console, type `ace toolkit`.
  - On Linux:
    - From the command environment, type `./ace toolkit`.

Errors occur while you are using the IBM App Connect Enterprise Toolkit

Procedure

- **Scenario:** An error has occurred while you are using the IBM App Connect Enterprise Toolkit, and you want information to help you to diagnose the problem.
- **Solution:** Some errors that occur in the IBM App Connect Enterprise Toolkit are logged in the `.log` file in your `workspace\.metadata` directory.

  You can view this log by switching to the Plug-in Development perspective, and clicking the Error Log tab in the lower-right pane. The log shows in which plug-in the error occurred, and gives further information.

  You can also use trace to try and determine the cause of your problem. See "Using trace" on page 3026 for more information about tracing.

An error message is displayed when you start the Flow Exerciser

Procedure

- **Scenario:** Either your IBM App Connect Enterprise Toolkit is Version 10.0.0.1 (or later) and your integration node is Version 10.0.0.0, or your IBM App Connect Enterprise Toolkit is Version 10.0.0.0 and your integration node is Version 10.0.0.1 (or later). You open a message flow in the message flow editor and start the Flow Exerciser. The flow deploys correctly, but the progress window displays a failure message. The error contains the following text:

  ```
  BIP2210E: Invalid configuration message: attribute name 'testRecordMode' not valid for target
   object 'object_name'
  ```

- **Solution:** If the IBM App Connect Enterprise Toolkit is Version 10.0.0.0, you can use the Flow Exerciser only with an integration node that is Version 10.0.0.0. If the IBM App Connect Enterprise Toolkit is Version 10.0.0.1 (or later), you can use the Flow Exerciser only with an integration node that is Version 10.0.0.1 (or later).

  To check the version of an integration node within the IBM App Connect Enterprise Toolkit, click on the integration node in the **Integration Nodes** view, and then look in the **Properties** view.

Windows *The plug-in repository cannot be found when you are installing a plug-in into the IBM App Connect Enterprise Toolkit*

Procedure

- **Scenario:** You are installing a plug-in into the IBM App Connect Enterprise Toolkit and an error message is issued stating that no repository that contains the plug-in can be found.

- **Solution:** Ensure that you start the IBM App Connect Enterprise Toolkit by right clicking it in the **Start** menu and selecting **Run as administrator**.

Windows *MSVCP120.dll missing message is issued*

Procedure

- **Scenario:** You are using the IBM App Connect Enterprise Toolkit and a pop-up window is seen that states `mqsisetsecurity.exe has stopped working`. Clicking the details in the pop-up window shows that the MSVCP120.dll file is missing.
- **Solution:** Download and install the Microsoft Visual C++ 2010 Redistributable Package.

An error is issued when you access the help system

Procedure

- **Scenario:** You are accessing the help system through the IBM App Connect Enterprise Toolkit, and an error message is issued stating that the Web page that you requested is not available offline.
- **Explanation:** This error might occur if you previously had a connection to a Web-based version of the help system and lost it, or if you have **`Work Offline`** selected in your Internet Explorer options.
- **Solution:** Click **Connect** to load the help system.

The IBM App Connect Enterprise Toolkit displays an error message after the error has been fixed

Procedure

- **Scenario:** The IBM App Connect Enterprise Toolkit is in an inconsistent state, or displays an error message after the error has been fixed
- **Solution:** Clean the workspace:
  1. From the IBM App Connect Enterprise Toolkit, click **Project** > **Clean**.
  2. Click **Clean all projects** and **Finish**.

     This action cleans the whole workspace of any internal files, which are then re-created so that none of your data is lost.

The message `Unable to create part: filename.extension` is issued

Procedure

- **Scenario:** You open an editor in the IBM App Connect Enterprise Toolkit, and an error message is raised stating that a file cannot be created.

  This problem is caused by one of following situations:
- **Explanation 1:** The given file is not associated with a recognized editor.
  - **Solution 1:** Right-click the file and choose the default editor to open it, or choose another editor if the default editor cannot open it.
- **Explanation 2:** The given file contains syntax errors and cannot be loaded into the chosen editor. However, if you then try to open a valid file, you get the same error message repeatedly.
  - **Solution 2:** Restart the IBM App Connect Enterprise Toolkit; do not load the file into an editor again until you have fixed the syntax errors.

Resolving problems relating to the appearance of IBM App Connect Enterprise Toolkit

Use the advice given here to help you to resolve common problems that relate to the appearance of the IBM App Connect Enterprise Toolkit.

A view is missing from the workbench

Procedure

- **Scenario:** A view you are expecting to be displayed in IBM App Connect Enterprise Toolkit is not visible, or you have closed a view.
- **Explanation:** The perspective has changed since it was first created, and the default views are no longer visible.
- **Solution:** To restore the default views in a perspective you can reset the perspective. Click **Window** > **Reset perspective**.

You cannot close a message dialog box

Procedure

- **Scenario:** You have opened a menu, and a message dialog box tells you that previous changes made have been processed successfully by the integration node. You cannot close the dialog.
- **Solution:** If you cannot close the dialog box by clicking **OK**, press Esc.

You want to filter entries in the Problems view

Procedure

- **Scenario:** The Problems view has many entries, and it is difficult to find the entry that you want.
- **Solution:** At the top of the Problems View, click the icon with the arrows pointing to the right. This action opens a dialog box, in which you can tailor your selections to display only a subset of the entries in the view. For example, you can select only those entries for the project that you have selected.

Your message flow and message set projects have changed their appearance

Procedure

- **Scenario:** You have created a new simple project in the IBM App Connect Enterprise Toolkit and now all your message flow and message set projects look different.
- **Explanation:** When you create a new simple project, the IBM App Connect Enterprise Toolkit switches automatically to the Integration Development perspective.
- **Solution:** To return to the previous view, switch to the perspective with which you were working..

Resolving non-specific problems when using the IBM App Connect Enterprise Toolkit

Use the advice given here to help you to resolve some common problems that can occur when you use the IBM App Connect Enterprise Toolkit that are not dealt with in previous categories.

Main menu entries missing on Linux

Procedure

- **Scenario:** The main menu on Linux no longer contains items that relate to the IBM App Connect Enterprise Toolkit.

- **Explanation:** If you have installed the IBM App Connect Enterprise Toolkit in more than one package group, and have now removed one of those installations, a known restriction causes the main menu items to be removed when the component is uninstalled.
- **Solution:** Invoke the IBM App Connect Enterprise Toolkit from the command line.

  Navigate to the installation directory for the package group in which you have installed the IBM App Connect Enterprise Toolkit, and enter the following command:

  ```
  ./eclipse -product com.ibm.etools.msgbroker.tooling.ide
  ```

Editors do not update automatically when the same file is open in multiple windows

Procedure

- **Scenario:** You are working in the Integration Development perspective, and are using the associated editor to work with one or more resources; for example, you are editing a message flow in the message flow editor or an ESQL module in the ESQL editor.

  You have clicked **Window** > **New Window** to create a second Eclipse view, and have opened the same resource in the second window. Changes that you make to the resource in the first editor window are not reflected in the second editor window.
- **Explanation:** The IBM App Connect Enterprise Toolkit editors do not automatically update multiple windows in which you have opened the same resource.
- **Solution:** Save the contents of the resource file in the first editor window, then close and reopen additional windows.

  The reopened windows reflect the updated content.

Deleting or closing a project takes a long time

Procedure

- **Scenario:** Deleting or closing a project to save memory takes a long time.
- **Explanation:** If a project is referenced by other projects, removing that project requires all the other projects, and the projects that refer to them recursively, to be built fully. This process occurs to keep the content-assist and validation models current.
- **Solution:** To keep a project open in the workspace requires very little memory, therefore you do not need to close or delete projects.

You are experiencing poor performance when working with large or complex projects

Procedure

- **Scenario:** You are experiencing poor performance in the IBM App Connect Enterprise Toolkit when working with large or complex projects.
- **Explanation:** Frequent project changes, such as adding and removing projects, or using **Project** > **Clean**, use large amounts of memory because of the size and number of files and the connections between them.
- **Solution:** Increase your system memory.

You do not know how to return to the welcome page

Procedure

- **Scenario:** You do not know how to return to the welcome page that was displayed in the IBM App Connect Enterprise Toolkit when you first started using it.

- **Solution:** To open the welcome page:
  a) From the **Help** menu, select **Welcome**.
     If only one welcome page is available, it is displayed. If more than one is available, a list is displayed.
  b) Select the welcome page that you want, for example, IBM App Connect Enterprise IBM App Connect Enterprise Toolkit.
  c) Click **OK**.

Resolving problems when using Data Analysis

Use the following advice to help you to resolve problems that can arise when you use Data Analysis.

About this task

- "'DOCID' and 'ID' columns are inserted into my database" on page 2998

'DOCID' and 'ID' columns are inserted into my database

Procedure

- **Scenario:** You map your database to Data Analysis and the columns 'DOCID' and 'ID' are inserted into your database.
- **Explanation:** The 'DOCID' and 'ID' columns are added to provide a unique key string for database operations. The 'DOCID' column is set to a unique string that you can use to identify the insertion of each entry into the database and remove if necessary. The 'ID' is the foreign key that links related tables together.
- **Solution:** Works as designed.

Resolving problems when using databases

Use the advice given here to help you to resolve problems that can arise when using databases.

Before you begin

- Read "Is there a problem with a database?" on page 2885

Procedure

- "DB2 error message SQL0443N is issued" on page 2999
- "DB2 error message SQL0805N is issued" on page 2999
- "DB2 error message SQL0998N is issued on Linux" on page 3000
- "DB2 error message SQL0998N or SQL1248N is issued" on page 3000
- "DB2 error message SQL1040N is issued" on page 3000
- "DB2 error message SQL1224N is issued when you connect to DB2" on page 3000
- "You do not know how many database connections an integration node requires" on page 3002
- "You want to use XA with DB2 databases" on page 3002
- "The db2swit file that is needed for XA with DB2 databases cannot be loaded" on page 3002
- "XA coordination fails if the database restarts while the integration node is running" on page 3003
- "Error message BIP2322 IM004 is issued when you connect to an Informix database" on page 3003
- "On Oracle, a database operation fails to return any rows, even though the rows exist" on page 3004
- "Integration node commands fail when the Oracle 10g Release 2 client runs on Linux on POWER with Red Hat Enterprise Linux Advanced Server V4.0" on page 3004

DB2 error message SQL0443N is issued

Procedure

- **Scenario:** After you upgrade your DB2 server to a new fix pack level, a DB2 error message SQL0443N is issued if you invoke a DB2 Call Level Interface (CLI) catalog function, such as `SQLTables()`, `SQLColumns()`, or `SQLStatistics()`.
  An example of the error message is:

  ```
  SQL0443N Routine "SYSIBM.SQLTABLES" (specific name "TABLES") has returned an error SQLSTATE with diagnostic text SYSIBM:CLI:-805". SQLSTATE=38553.
  ```

- **Solution:** Bind the `db2schema.bnd` file against each database by entering the following commands at a command prompt:

  ```
  db2 terminate
  db2 connect to database-name
  db2 bind path\db2schema.bnd blocking all grant public sqlerror continue
  db2 terminate
  ```

  where *database-name* is the name of the database to which the utilities must be bound, and *path* is the full path name of the directory where the bind files are located. For example, the default location on Windows is `C:\Program Files\IBM\SQLLIB\bnd\`.

  To list all the names of databases for a particular DB2 instance, run the DB2 CLI command **`db2 list database directory`**. For further information, see the DB2 documentation.

DB2 error message SQL0805N is issued

Procedure

- **Scenario:** When a message flow that includes a Database node runs, SQL error `SQL0805N NULLID.SQLLF000` is issued.
- **Solution:** Open a DB2 Command Line Processor window and issue a bind command to the database.

  Linux UNIX On Linux and UNIX systems, enter the commands:

  ```
  connect to db
  bind ~/sqllib/bnd/@db2cli.lst grant public CLIPKG 5
  connect reset
  ```

  where *db* is the database name.

  Windows On Windows systems, enter the commands:

  ```
  connect to db
  bind x:\sqllib\bnd\@db2cli.lst blocking all grant public
  ```

```
connect reset
```

where *x:* identifies the drive onto which you installed DB2, and *db* is the database name.

DB2 error message SQL0998N is issued on Linux

Procedure

- **Scenario:** You are trying to use a globally coordinated message flow with DB2 on Linux and error message SQL0998N is issued with Reason Code 09 and Subcode " ".
- **Solution:** Check that the LD_ASSUME_KERNEL environment variable is not set.

  If it is set, use the **unset** command to remove it from your environment and ensure that you modify your profile scripts so that it remains unset.

DB2 error message SQL0998N or SQL1248N is issued

Procedure

- **Scenario:** When you try to use a globally coordinated message flow with a DB2 database, you get one of the following error messages:
  - SQL0998N with Reason Code 09 and Subcode ""
  - SQL1248N with a message indicating that the database is not defined with the transaction manager
- **Solution:** Use the instructions in “Configuring global coordination with DB2” on page 709 to configure the database and XAResourceManager stanza.

DB2 error message SQL1040N is issued

Procedure

- **Scenario:** You are using a DB2 database, and error message BIP2322 is issued with error SQL1040N.
- **Explanation:** The following DB2 message indicates that the value of the DB2 database configuration parameter **maxappls** has been reached:

```
"SQL1040N The maximum number of applications is already connected to the database.
SQLSTATE=57030"
```

  DB2 has rejected the attempt to connect.
- **Solution:**
  a) Stop all integration nodes that connect to the affected database.
  b) Increase the value of the **maxappls** configuration parameter.

     Also, check the value of the associated parameter **maxagents**, and increase it in line with **maxappls**.
  c) Restart the DB2 database.
  d) Restart the integration nodes.

DB2 error message SQL1224N is issued when you connect to DB2

Procedure

- **Scenario:** DB2 error message SQL1224N is issued when you connect to a DB2 database. This error indicates that a database agent could not be started, or was ended because of a database shutdown or force command.

- **Solution:** On AIX, use TCP/IP to connect to DB2 databases, to avoid the shared memory limit of 10 connections.

  To set up AIX and DB2 loop-back to use a TCP/IP connection:

  a) Configure DB2 to use TCP/IP, and to start the TCP/IP listener.

     On the database server machine, log in as the DB2 instance owner, typically `db2inst1`, and issue the following commands:

     ```
     db2set DB2COMM=tcpip
     db2stop
     db2start
     ```

  b) If the DB2 connection port is not defined in `/etc/services`, edit the services file to add the DB2 connection and interrupt ports. You must use unique names, and port numbers that are not already defined in the services file; for example:

     ```
     db2svc1     3700/tcp          # DB2 Connection Service
     db2isvc1    3701/tcp          # DB2 Interrupt Service
     ```

  c) Update the DB2 configuration; for example:

     ```
     db2 update dbm cfg using svcename db2svc1
     ```

     where *db2svc1* is the name of the DB2 Connection port service in `/etc/services`.

     Alternatively, you can specify a port number directly.

  d) Stop and restart the database by using the following commands:

     ```
     db2stop
     db2start
     ```

  e) Catalog a new TCP/IP connection node:

     ```
     db2 catalog tcpip node NODENAME remote HOSTNAME server db2svc1
     ```

     where:

     NODENAME
     is the name of the new TCP/IP connection node. You can use `local` as your node name, if it is a unique identifier.

     HOSTNAME
     is the name of your computer.

     db2svc1
     is the name of the DB2 connection port service in `/etc/services`.

     Message DB20000I is displayed when the command completes successfully.

  f) Catalog the database with a new alias name; for example:

     ```
     db2 catalog database DATABASE as DBALIAS at node NODENAME
     ```

     where:

     DATABASE
     is the physical name of the database.

     DBALIAS
     is the database alias name that you want to use.

     Specify the new alias name in all subsequent references to the local database.

  g) Stop and start DB2:

     ```
     db2 terminate
     db2stop
     ```

```
db2start
```

h) Log on with the user ID under which the integration node is running.

i) Update the ODBC configuration file for each integration node to add definitions for the database:

a. At the top of the file, add a definition for the database alias name:

```
DBALIAS=IBM DB2 ODBC Driver
```

b. Add a new stanza for the database alias:

```
 [DBALIAS]
Driver=INSTHOME/sqllib/lib/db2o.o
Description=Database Alias
Database=DBALIAS
```

where *INSTHOME* is the path to your DB2 Instance directory.

j) Update your message flows to specify the alias database name, redeploy the BAR file to the integration node, and test the flows.

You do not know how many database connections an integration node requires

Procedure

- **Scenario:** You do not know how many database connections to set up for your integration node.
- **Solution:** Determine the number of database connections required by an integration node for capacity and resource planning. On DB2, the default action taken is to limit the number of concurrent connections to a database to the value of the **maxappls** configuration parameter; the default value for **maxappls** is 40. The associated parameter **maxagents** also affects the current connections.

  The connection requirements for a single integration node are:

  – Five are required by internal integration node threads.

  – One is required for each database access node to separate ODBC data source names for each message flow thread (that is, if the same DSN is used by a different node, the same connection is used).

You want to use XA with DB2 databases

Procedure

- **Scenario:** You want to use XA with one or more DB2 databases.
- **Solution:** Ensure that your queue manager is configured to use **ThreadOfControl=THREAD**.

  – Linux UNIX On Linux and UNIX systems, configure this parameter in the XAResourceManager stanza in the file `qm.ini` for the integration node queue manager.

  – Windows On Windows systems, configure this parameter in IBM MQ Explorer.

The `db2swit` file that is needed for XA with DB2 databases cannot be loaded

Procedure

- **Scenario:** Error messages are present in the IBM MQ queue manager error logs indicating that the `db2swit` file cannot be loaded.
- **Explanation:** IBM App Connect Enterprise provides a prebuilt switch load file that is used for XA with DB2. If this file cannot be loaded, XA transactions cannot take place.

- **Solution:** There are 2 reasons why this situation might arise:
  1. IBM App Connect Enterprise and IBM MQ might not have been correctly configured. To establish correct configuration, refer to the instructions in "Configuring global coordination with DB2" on page 709.
  2. The switch load file, `db2swit`, that is provided with IBM App Connect Enterprise might not be compatible with the version of DB2 that you are running. If this is the case, you must build your own version of the `db2swit` file. For instructions on building your own `db2swit` file, refer to the `sample/xatm/readme.db2` file in your IBM App Connect Enterprise installation.

XA coordination fails if the database restarts while the integration node is running

Procedure

- **Scenario:** XA global coordination fails, and you get an error like the following example, which is from a DB2 database:

```
Database error: SQL State '40003'; Native Error Code '-900';  Error Text '[IBM]
[CLI Driver] SQL0900N  The application state  is in error. A database connection
does not exist.SQLSTATE=08003'.
```

- **Explanation:** A globally coordinated message flow cannot automatically reconnect to a database if the database is restarted while the integration node is still running.
- **Solution:** Stop and restart the integration node if the database goes down, or is brought down for a scheduled maintenance.

Error message BIP2322 IM004 is issued when you connect to an Informix database

Procedure

- **Scenario:** You are using the **mqsicvp** command to connect to an Informix database, and you see the following error message.

```
BIP2322E: Database error: SQL State 'IM004'; Native Error Code '0'; Error Text '[DataDirect]
[ODBC lib]
Driver's SQLAllocHandle on SQL_HANDLE_ENV failed'. The error has the following diagnostic
 information:
SQL State 'IM004' SQL Native Error Code '0' SQL Error Text '[DataDirect][ODBC lib] Driver's
 SQLAllocHandle
on SQL_HANDLE_ENV failed'.
```

- **Explanation:** This error can be caused when the environment for the database has not been initialized.
- **Solution:** Check the documentation for the client on your integration node system for details of the actions that you must take. For example, you might have to specify the following environment variables:

```
export INFORMIXDIR=/installation_directory_of_informix_client_software
export PATH=${INFORMIXDIR}/bin:${PATH}
export INFORMIXSERVER=server_name
export INFORMIXSQLHOSTS=${INFORMIXDIR}/etc/sqlhosts
export TERMCAP=${INFORMIXDIR}/etc/termcap
export TERM=vt100
export LIBPATH=${INFORMIXDIR}/lib:${INFORMIXDIR}/lib/esql:
```

```
                ${INFORMIXDIR}/lib/cli:$LIBPATH
```

where *server_name* is defined in the file `sqlhosts` (the required value is typically the machine name), and the location of the file `sqlhosts` is set up as part of the installation process.

To configure your system to run this setup at the start of every session, add these statements to the login profile of the user that is going to run the integration node.

For more information, see "Running database setup scripts before starting an integration node" on page 83.

On Oracle, a database operation fails to return any rows, even though the rows exist

Procedure

- **Scenario:** You are using Oracle databases in your message flows, and ESQL binds against columns that are declared as data type CHAR, and those parameter markers are referenced in a WHERE clause. The database operation fails to return any rows, even though the rows exist.
- **Explanation:** Fixed-length character strings must be padded with blank characters on Oracle for this type of comparison to succeed.
- **Solution:** Define the CHAR columns as VARCHAR2 columns, or pad the ESQL variable with blank characters to the required column length, so that the comparison locates the required rows from the table.

Integration node commands fail when the Oracle 10g Release 2 client runs on Linux on POWER with Red Hat Enterprise Linux Advanced Server V4.0

Procedure

- **Scenario:** Integration node commands fail in an environment where an Oracle 10g Release 2 client runs on Linux on POWER with Red Hat Enterprise Linux Advanced Server V4.0.

  Abend files might be created, with contents like the following data:

  ```
  /opt/mqsi/lib/libCommonServices.so(.ImbAbendSignalHandler+0x10)[0x800017d3c0]
  [0x80022b33f0]
  /lib64/tls/libpthread.so.0[0x80cc2339d8]
  /lib64/tls/libpthread.so.0[0x80cc230e4c]
  /lib64/tls/libpthread.so.0[0x80cc22af54]
  bipservice[0x10005e38]
  /lib64/tls/libpthread.so.0[0x80cc22a1d8]
  /lib64/tls/libc.so.6[0x80cc0dd3e4]
  ```

  or

  ```
  /opt/mqsi/lib/libImbCmdLib.so(._ZN15ImbCreateTables15createAllTablesEv+0x38)
  [0x800014c9bc]mqsicreatebroker[0x10023324]mqsicreatebroker[0x1002c0c4]
  /opt/mqsi/lib/libImbCmdLib.so(._ZN10ImbCmdBase20processCommandStringEv+0x6c)
  [0x80001dcad4]mqsicreatebroker[0x1000d728]/lib64/tls/libc.so.6[0x80cc02423c]
  /lib64/tls/libc.so.6[0x80cc0243c4]
  ```

- **Explanation:** The Oracle installation library contains copies of `libgcc` library files. The Oracle user profile adds the directory containing these files to the environment variable LD_LIBRARY_PATH. This action causes the `libgcc` library files to be found before the system libraries, and leads to the failure of integration node commands and the production of abend files.
- **Solution:** Ensure that you add `/lib64` to the environment variable LD_LIBRARY_PATH before the Oracle library path. Before you run **`mqsiprofile`**, include a string like:

  ```
  /lib64::/usr/lib:/oracle/app/oracle/product/10.2.0/db_1/lib
  ```

  which shows `/lib64` preceding the Oracle library directory.

Error message BIP2322 `Driver not capable` is issued when you use an Informix database

Procedure

- **Scenario:** When you try to access an Informix database from a node in a message flow, the following error message is issued:

```
BIP2322E: Database error: SQL State 'HYC00'; Native Error Code '-11092';
Error Text '[Informix][Informix ODBC Driver]Driver not capable.'.
```

- **Explanation:** The integration node uses transaction statements, therefore the database must be created, and configured to enable logging.
- **Solution:** Consult your database administrator to ensure that transaction logging has been enabled on the Informix database that the integration node is trying to access.

  For example, create the database with a buffered log:

```
create database with [buffered] log;
```

Database updates are not committed as expected

Procedure

- **Scenario:** You have included a Database node, Compute node, or Filter node in a message flow, and you have set the **`Transaction`** property to Commit. The message flow has raised an exception and has rolled back, but the database updates have not been committed.
- **Explanation:** When you set **`Transaction`** to Commit, the database updates performed by the node are committed when the node completes successfully. If an exception is raised before the node has completed, and causes the message flow to be rolled back, the commit is not issued and the database updates are also rolled back. The conditions under which this situation can occur are:
  - The node itself causes an exception to be raised. The commit is never performed.
  - The ESQL contains a PROPAGATE statement. This statement does not complete until all processing along the path taken by the propagated message has completed, and control returns to the node. Only then can the commit be performed. If an exception is raised along this path, control is not returned and the database updates are rolled back as part of the message flow.
- **Solution:** Review the operation of the node that performs the database updates.
  For example, you might be able to split the work between two nodes, with the first updating the database, and the second propagating the output message. Consider changing the ESQL code to process the message in a different way.

You want to list the database connections that the integration node holds

Procedure

- **Scenario:** You want to list the database connections that the integration node holds.
- **Solution:** The integration node does not have any functionality to list the connections that it has to a database. Use the facilities that your database supplies to list connections. Refer to the documentation for your database to find out how to perform this task.

You want to know whether the password that is set for a database is as expected

Procedure

- **Scenario:** You want to check the password that is set for a database that is associated with an integration node is the password that you expect.
- **Solution:** Use the **mqsireportdbparms** command with the integration node name, user ID, and password. The command reports whether the entered password was correct or not. For more information, see "Checking the password for a resource that is used by an integration server" on page 2630.

The queue manager finds the XA resource manager is unavailable when configured for XA with DB2 on Windows

Procedure

- **Scenario:** You have configured a queue manager for XA coordination with DB2 on your Windows computer.

  When you restart the queue manager, it reports error AMQ7604 in the queue manager error log. All subsequent attempts at XA coordination between IBM MQ and DB2 fail.

  The error message has the following content, or similar:

```
23/09/2008 15:43:54 - Process(5508.1) User(MUSR_MQADMIN) Program(amqzxma0.exe)
AMQ7604: The XA resource manager 'DB2 MQBankDB database' was not available
when called for xa_open.
The queue manager is continuing without this resource manager.
```

- **Explanation:** The user ID that runs the IBM MQ Services process `amqmsrvn.exe`, which has a default value of MUSR_MQADMIN, is running with an access token that does not contain group membership information for the group DB2USERS.
- **Solution:** Check that the IBM MQ Services user ID is a member of the group DB2USERS, stop the IBM MQ service (for example, by issuing the command **net stop "IBM MQSeries"**), and all other processes that are running under the same user ID, and then restart these processes.

  You can restart your computer to stop and restart these processes after you have checked the user ID status, but this action is typically not required.

Error messages are received when you are trying to remove a DB2 database on Windows when you are using a sample

Procedure

- **Scenario:** You are running a sample, and you are trying to remove a DB2 database on your Windows computer, and you receive a BIP9835E error message with the error code SQLSTATE=57019.

  The error message has content like the following data:

```
BIP9830I: Deleting the DB2 Database <Your database name>.
BIP9835E: The DB2 batch command failed with the error code SQLSTATE=57019.
The database <Your database name> could not be created/deleted.
The error code SQLSTATE=57019 was returned from the DB2 batch command.
```

- **Explanation:** If you use the DB2 Control Center to perform a query, a connection is opened against the database. This connection stays open until the DB2 Control Center is closed, at which point the connection is ended.
- **Solution:** Close the DB2 Control Center application, and try to run the sample again.

DB2 error message SQL7008N is issued

Procedure

- **Scenario:** You are using DB2 and encounter error SQL7008N when updating or inserting into tables on iSeries.
- **Explanation:** SQL7008N is a common error when the tables being accessed on an iSeries server are not being journaled.
- **Solution:** To correct the error, take one of the following steps:
  - Journal your tables.
  - Change the isolation level to `No Commit`. You can change the isolation level of the database alias referenced by your ODBC data source to `No Commit` by using the following DB2 command:

    ```
    db2 update cli cfg for section <db_alias> using TxnIsolation 32
    ```

Resolving problems when using publish/subscribe

Use the advice given here to help you to resolve common problems that can occur when you run publish/subscribe applications.

About this task

Procedure

- "Application responses are not received" on page 3007
- "Your application is not receiving publications" on page 3008
- "Publishing a message causes a filter error" on page 3008
- "Symbols in subscription filters cause problems" on page 3009
- "There are performance problems on AIX when the JIT compiler is not loaded" on page 3009
- "The Publication node fails with MQRC 2035" on page 3009

Application responses are not received

Procedure

- **Scenario:** Application responses are not received.
- **Explanation:** Depending on the application code, a publisher or subscriber might request confirmation that its message was processed successfully. Responses can make debugging client problems much easier, because a response code is given if a problem occurs.

  Typically, a response is always returned to a subscriber. However, for the publishing side, a message might be published without the knowledge of the originating application (for example, by using the default topic property on the input node, or by using a Compute node to modify this property in a message flow). The results of processing that message are still logged in user trace, which might give clues as to what is happening.

  If a response is not received, it is typically due to one of the following causes:

  - The system is busy. Messages might build up on the input queue, and the client might not be waiting long enough for its response.
  - IBM MQ expiry is being used. There are cases where this option is what is required, but the expiry of the input message is copied to the response. As a result, the message might expire on the input

queue, or it might expire on the way back to the client. This situation is not an error, even with a persistent message.

  - The input message or response might have been put to the dead-letter queue, if one is configured. Look on this queue to see if any new messages are there. This situation is typically accompanied by error messages in the log written by the integration node that describe the problem. For example, the reply-to queue might have been specified incorrectly in the input message, therefore the reply message has been put to the dead-letter queue.

- **Solution:** If your application is not asking for responses (that is, not using messages of type MQMT_REQUEST) consider doing so, particularly when developing applications.

Your application is not receiving publications

Procedure

- **Scenario:** Your application is not receiving publications through the MQ pub/sub broker.
- **Explanation:** If an application has subscribed successfully, it receives publications that match its subscription.

  Subscribers are sent messages only if they match the topic, the subscription point, *and* the filter. Because the subscription point is specified in the message flow, not in the publication message, an incorrect message flow setting can cause unexpected failures.

  A user trace of the flow that contains the Publication node shows you whether publications are matching anything.

- **Solution:** If a filter is being used, a user trace shows you whether this message is being evaluated as expected.

  The case with multiple integration servers, or multiple integration nodes, is more complex. A response is sent to a subscriber after the message has been processed by the target integration server. Other integration servers (and integration nodes) are updated asynchronously. As a result, there might be a delay before publications made elsewhere are received. If the integration node is busy, there can be a delay before messages are processed fully. In a multi-integration node setup, if communications have been suspended, subscription changes are propagated through the network of integration nodes. Check the channels.

  With multiple integration servers or integration nodes, it might be possible to fill intermediate IBM MQ queues if the load is high. This situation might be reported in the syslog (if an integration node cannot put to a queue because it is full) or in the IBM MQ log (if a message coming across a channel cannot be put to the target queue because it is full). If you see messages of this type, display the queue depths on all your queue managers to see if any are almost full.

Publishing a message causes a filter error

Procedure

- **Scenario:** When you publish a message, you receive an error response message with reason text MQRCCF_FILTER_ERROR.
- **Explanation:** An integration node returns this message to a publication when subscriptions have been registered that specify filter expressions (for Content Based Routing) and an error has been encountered when the integration node attempts to filter the published message.
  This situation can occur, for example, if a message is published that includes unsupported data types, or if the message body is corrupted.

Symbols in subscription filters cause problems

Procedure

- **Scenario:** If you specify certain symbols when you use filters in a subscription, the filter does not work.

  Sometimes your subscription messages are put to the dead-letter queue, and a number of error messages are written to the local error log indicating MQRFH2 parsing errors.
- **Explanation:** The MQRFH2 header employs standard XML encoding, so that its parser interprets some symbols in a special way.
- **Solution:** If you want to include these symbols in your filters, use the appropriate escape character to ensure that they are parsed correctly:

Symbol	Escape character
<	&lt;
>	&gt;
"	&quot;
'	&apos;
&	&amp;

  For example, if you want to use:

```
<Filter>Body.e_ALERT_BODY.eqnum<6</Filter>
```

  specify:

```
<Filter>Body.e_ALERT_BODY.eqnum&amp;lt;6</Filter>
```

The Publication node fails with MQRC 2035

Procedure

- **Scenario:** The Publication node fails with MQRC 2035.
- **Explanation:** IBM App Connect Enterprise publishes messages with the user ID in the original message, not the integration node service ID.
- **Solution:** You can force IBM App Connect Enterprise to use the integration node service ID in all circumstances by setting the environment variable *MQSI_PUBSUB_USE_BROKER_USERID* to any value. If there is no MQMD header, or if there is an MQMD header but its `UserIdentifier` field is blank, IBM App Connect Enterprise continues to use the integration node's user ID.

There are performance problems on AIX when the JIT compiler is not loaded

Procedure

- **Scenario:** There are performance problems on AIX when the JIT compiler is not loaded.
- **Explanation:** The environment variable LIBPATH can affect the loading of the Java JIT (just-in-time) compiler on AIX.

  IBM App Connect Enterprise for AIX runs correctly without the JIT compiler, but publish/subscribe performance is adversely affected.

- **Solution:** Ensure that the JIT compiler runs.

  The JIT compiler loads and runs correctly if LIBPATH is not set, therefore do not set LIBPATH. You can make libraries available by linking them into `/var/wmqi/lib` (for all IBM App Connect Enterprise for AIX processes) or `/usr/lib` (for all processes on the system). AIX IBM App Connect Enterprise for AIX configuration does this action for DB2 libraries.

  If it is necessary to set LIBPATH, update it to include the directory `/usr/java130/bin`.

  For example, you can use the following command to start the integration node:

  ```
  LIBPATH=/usr/local/lib:/usr/java130/bin mqsistart mybroker
  ```

Resolving problems with performance

Use the advice given here to help you to resolve common problems with performance.

About this task

- **Scenario:** You are experiencing problems with performance, such as:
  - Poor response times in the IBM App Connect Enterprise Toolkit when developing message flows
  - Poor response time at deployment
  - Individual messages taking a long time to process
  - Poor overall performance, or performance that does not scale well
- **Solution:** Possible solutions are:
  - Tune the integration node
  - Speed up IBM MQ persistent messaging by optimizing the I/O (input/output)
  - Speed up database access by optimizing I/O
  - Increase system memory
  - Use additional instances or multiple integration servers
  - Optimize ESQL statements for best performance

A good source of information about performance is the set of reports in IBM MQ Family Category 2 (freeware) SupportPacs, available for download from the IBM MQ SupportPacs web page.

For more information, read "Do you have a component that is running slowly?" on page 2887.

This topic contains advice for dealing with some common performance problems that can arise:

A WHILE loop in a large XML array takes a long time to process

Procedure

- **Scenario:** A WHILE loop in a large XML array takes a long time to process.

- **Explanation:** This problem arises when you use the CARDINALITY() function to determine the size of the array in the WHILE statement. With large arrays, the cost of determining the number of elements is proportional to the size of the array.

  The CARDINALITY function is invoked each time the WHILE statement is executed. The message has many elements, therefore takes a long time to process when running the loop in this way.
- **Solution:** Unless you have a message in which the number of elements of the array grows dynamically, determine the size of the array before entering the WHILE loop. Use code like the following example:

```
DECLARE i,c INTEGER;
SET i = 1;
SET c=CARDINALITY(OutputRoot.XMLNS.MyMessage.Array[ ]);
WHILE i <= c DO
      . . .
      . . .  loop processing
      . . .
END WHILE;
```

Message flow performance is reduced when you access message trees with many repeating records

Procedure

- **Scenario:** Message flow performance is reduced when the following conditions are true:
  - You are using ESQL processing to manipulate a large message tree.
  - The message tree consists of repeating records or many fields.
  - You have used explicit SET statements with field reference paths to access or create the fields.
  - You have observed a gradual slowing of message flow processing as the ESQL processes more fields or repetitions.
- **Explanation:** This problem occurs when you use field references, rather than reference variables, to access or create consecutive fields or records.

  Consider the following example, in which independent SET statements use field reference paths to manipulate the message tree. The SET statement takes a source and target parameter, where either or both parameters are field references:

```
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field = '1';
```

  The problem arises when the SET statement is used to create many more fields, as shown in the following example:

```
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field1 = '1';
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field2 = '2';
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field3 = '3';
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field4 = '4';
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field5 = '5';
```

  In this example, the five fields that are created are all children of ParentA. Before the specified field can be created or modified, the integration node must navigate the named message tree to locate the point in the message tree that is to be altered. For example:

  - To access field 1, the SET statement navigates to ParentA, then to the first field, therefore involving two navigations.
  - To access field 5, the SET statement navigates to ParentA, then traverses each of the previous fields until it reaches field 5, therefore involving six navigations.

  Navigating over all the fields that precede the specified field causes the loss in performance.

  Now consider a scenario that accesses repeating fields in an input message tree; for example:

```
DECLARE myChar CHAR;
DECLARE thisRecord INT 0;
```

```
WHILE thisRecord < 10000 DO
 SET thisRecord = thisRecord + 1;
 SET myChar = InputRoot.MRM.myParent.myRepeatingRecord[thisRecord];
END WHILE;
```

When index notation is used, as the count increases, the processing needs to navigate over all the preceding fields to get the one it wants; that is, it has to count over the previous records to get to the one that is represented by the current indexed reference.

- When accessing InputRoot.MRM.myParent.myRepeatingRecord[1], one navigation takes place to get to the first record.
- When accessing InputRoot.MRM.myParent.myRepeatingRecord[2], two navigations take place to get to the second record.
- When accessing InputRoot.MRM.myParent.myRepeatingRecord[N], *N* navigations take place to get to the N-th record.

Therefore, the total number of navigations for this WHILE loop is: 1 + 2 + 3 + ... + *N*, which is not linear.

- **Solution:** If you are accessing or creating consecutive fields or records, use reference variables. When you use reference variables, the statement navigates to the main parent, which maintains a pointer to the field in the message tree. The following example shows the ESQL that can be used to reduce the number of navigations when creating new output message tree fields:

```
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field1 = '1';
DECLARE outRef REFERENCE TO OutputRoot.XMLNS.TestCase.StructureA.ParentA;
SET outRef.field2 = '2';
SET outRef.field3 = '3';
SET outRef.field4 = '4';
SET outRef.field5 = '5';
```

When referencing repeating input message tree fields, you could use the following ESQL:

```
DECLARE myChar CHAR;
DECLARE inputRef REFERENCE TO InputRoot.MRM.myParent.myRepeatingRecord[1];
WHILE LASTMOVE(inputRef) DO
 SET myChar = inputRef;
 MOVE inputRef NEXTSIBLING NAME 'myRepeatingRecord';
END WHILE;
```

For further information, see “Creating dynamic field references” on page 1639.

You are experiencing poor performance in the IBM App Connect Enterprise Toolkit when working with large projects

Procedure

- **Scenario:** You are experiencing poor performance in the IBM App Connect Enterprise Toolkit when working with large or complex projects.
- **Explanation:** Performance is reduced because of frequent project changes, such as adding and removing projects, or using **Project** > **Clean**. Complete project updates use large amounts of memory due to the size, number, and connections between files.
- **Solution:** Increase your system memory.

Performance is reduced when you run web services with small message sizes

Procedure

- **Scenario:** You see poor response times and throughput rates when you run web services using HTTP, and send smaller messages sizes (typically less than 32 KB). Throughput rates can fluctuate with message size. IBM App Connect Enterprise running on the AIX platform might be affected.
- **Explanation:** The default configuration of HTTP enables the Nagle algorithm, which seeks to improve the efficiency of Internet Protocol networks by reducing the number of packets sent. It works

by buffering small packets together, creating a smaller number of large packets. By default, the **tcpnodelay** setting on the sockets of the HTTPRequest is `true`. You can disable the Nagle algorithm at either the operating system level (system wide) or through IBM App Connect Enterprise (affecting only the IBM App Connect Enterprise HTTP sockets).

- **Solution:** Stop the integration node and use the following commands to disable the Nagle algorithm:

  HTTPRequest, SOAPRequest, and SCARequest nodes

  ```
  mqsichangeproperties integrationNodeName -e integrationServerName
        -o ComIbmSocketConnectionManager -n tcpNoDelay -v true|false -f
  mqsichangeproperties integrationNodeName -e integrationServerName
        -o ComIbmSocketConnectionManager -n tcpNoDelaySSL -v true|false -f
  ```

  To determine the value set, take the following steps:

  Report property values

  Start the integration node and use the following commands:

  ```
  mqsireportproperties integrationNodeName -e integrationServerName
        -o ComIbmSocketConnectionManager -r
  mqsireportproperties integrationNodeName -e integrationServerName
        -o HTTPConnector -r
  mqsireportproperties integrationNodeName -e integrationServerName
        -o HTTPSConnector -r
  mqsireportproperties integrationNodeName -b NodeHttpListener
        -o HTTPConnector -r
  mqsireportproperties integrationNodeName -b NodeHttpListener
        -o HTTPSConnector -r
  ```

Resolving problems when you monitor message flows

Follow the advice for dealing with common problems that can arise when you are monitoring IBM App Connect Enterprise flows.

Procedure

- "You are not receiving monitoring events from IBM App Connect Enterprise" on page 3013
- "Statistics options are not visible in the web user interface" on page 3014

You are not receiving monitoring events from IBM App Connect Enterprise

Procedure

- **Scenario:** You are not receiving monitoring events from IBM App Connect Enterprise.
- **Explanation:** You can configure IBM App Connect Enterprise flows to emit event messages. These messages can be used to support transaction monitoring and business monitoring. The events that are published by IBM App Connect Enterprise can be written to a transaction repository, creating an audit trail of the transactions that are processed by an integration node. You can also use IBM Business Monitor to monitor events. To receive monitoring events, you must configure and enable event sources, activate monitoring, and subscribe to the topic for the flow.

- **Solution:** If you are not receiving monitoring events, check that the following resources are configured correctly.
  a) Check that event sources are configured on the flow by using monitoring properties or a monitoring profile. For more information, see "Monitoring properties and monitoring profiles" on page 2786.
  b) Check that event sources are enabled by setting the **-i** parameter on the **mqsichangeflowmonitoring** command. For more information, see "Enabling and disabling event sources" on page 2801.
  c) Check that monitoring is activated for the flow by setting the **-c** parameter on the **mqsichangeflowmonitoring** command. For more information, see "Activating monitoring" on page 2804.
  d) Check that publication of monitoring events is enabled, and the corresponding pub/sub broker is configured and running.
  Monitoring events are in the `BusinessEvents` group. For more information about configuring the pub/sub broker, and reporting if publication is enabled, see "Configuring and subscribing to performance and monitoring events" on page 2807.
  e) Check that you have subscribed to the topic for the flow.
  For example, on an MQ pub/sub broker:
  ```
  $SYS/Broker/integrationNodeName/Monitoring/integrationServerName/flowName
  ```
  and on an MQTT pub/sub broker:
  ```
  IBM/IntegrationBus/integrationNodeName/Monitoring/integrationServerName/flowName
  ```
  f) If you are writing events to a transaction repository, complete the following extra checks.
  – Check that events are configured for your transactions.
  – Check that you have subscribed to the event topic and written events to a repository.
  g) If you are using IBM Business Monitor to monitor events, complete the following extra checks.
  – Check that IBM Business Monitor is installed, and that a monitor server is created and started. For more information, see IBM Business Process Manager product documentation online.
  – Check that the monitoring model application and message-driven bean (MDB) are installed and configured.
- To report monitoring settings, use the **mqsireportflowmonitoring** command.
  For more information, see command.

Statistics options are not visible in the web user interface

Procedure

- **Scenario:** Your integration node is configured for statistics, but you cannot view or use statistics in the web user interface.
- **Explanation:** The pubsub component was configured, and one of the requirements for statistics is unavailable or disabled. By default, the built-in MQTT broker is used for `OperationalEvents`, which includes statistics.
  For example, if the built-in MQTT broker is disabled and an alternative broker is not specified, statistics will be unavailable.

- **Solution:** Check for one of the following scenarios by using the **mqsireportproperties** command with the **-b** parameter set to pubsub, and take the corrective action:
  a) MQTT is disabled for `OperationalEvents`. Enable `OperationalEvents` over MQTT on the pubsub component.
     For more information, see "Configuring the publication of event messages" on page 2807.
  b) MQTT is enabled for `OperationalEvents` and uses the default policy. However, the built-in MQTT broker is not currently running. Start the MQTT broker.
     For more information, see "Configuring the built-in MQTT pub/sub broker" on page 2811.
  c) MQTT is enabled for `OperationalEvents`, but was configured with an invalid policy URL. Either the syntax is invalid, or the specified policy document does not exist. Check that the URL is valid.
  d) MQTT is enabled for `OperationalEvents` and a valid policy URL was specified. The policy document is valid and refers to an MQTT server. However, the MQTT server is not running. Start the MQTT server.

Resolving problems when developing custom integration applications

Use the advice given here to help you to resolve problems that can arise when developing IBM Integration API applications.

About this task

- "Your custom integration application hangs if the integration node is not available" on page 3015
- "You set a property of an object and query its value, but the value has not changed" on page 3015
- "You cannot connect to an integration node when using a .broker file" on page 3016

Your custom integration application hangs if the integration node is not available

Procedure

- **Scenario:** When the integration node is unavailable, the custom integration application hangs.
- **Explanation:** Communication between the IBM Integration API and the integration node is asynchronous, therefore the custom integration application hangs because it is waiting for a message from the integration node.
- **Solution:** Configure the maximum amount of time that the custom integration application waits by using the following method:

```
// Wait for a maximum of 10 seconds
BrokerProxy.setRetryCharacteristics(10000);
```

  The value specified represents the time in milliseconds that the custom integration application will wait for information before throwing the `BrokerProxyPropertyNotInitializedException` exception.

  If you set this timeout value too low, an exception is thrown, even if the integration node is available.

You set a property of an object and query its value, but the value has not changed

Procedure

- **Scenario:** You have set a property of an object, then queried its value; the value has not changed.
- **Explanation:** Methods that change properties of integration node objects are not processed immediately. If you call a property change method on a custom integration application

object, the IBM Integration API sends a message that requests the specified change to the integration node. The integration node processes the request asynchronously, and notifies all `AdministeredObjectListeners` of the affected object when the change has been attempted.

- **Solution:** Methods that change state typically return to the calling program as soon as the request has been put to the queue manager of the integration node, or, following a call to `BrokerProxy.beginUpdates()`, as soon as the request has been added to the current batch. If the property has still not been updated after the action's response to the request has been returned to the application, consult the response message for more details.

You cannot connect to an integration node when using a `.broker` file

Procedure

- **Scenario:** You cannot connect to an integration node when you use a `.broker` file.
- **Explanation:** If your custom integration applications use the `MQPropertyFileBrokerConnectionParameters` class, they can connect to an integration node by using a connection file that has a `.broker` extension. However, this file can be parsed only if an XML parser is available.
- **Solution:** Ensure that a supported parser is available on the CLASSPATH. A supported parser is shipped with IBM App Connect Enterprise.

  Alternatively, your application can use the `IntegrationNodeConnectionParameters` class instead of the `MQPropertyFileBrokerConnectionParameters` class. This class connects to an integration node by specifying the host name, queue manager name, and web administration port of the target integration node directly. This method does not require an XML parser.

Resolving problems when using an MQ Service

Use the following advice to help you to resolve problems that can arise when you use an MQ Service.

About this task

- "SOAP bindings error when you drag a WSDL file onto Message Flow editor" on page 3016
- "SOAP bindings warning in Problems view when an MQ Service generates a WSDL" on page 3016

SOAP bindings error when you drag a WSDL file onto Message Flow editor

Procedure

- **Scenario:** You drag a WSDL file, that was generated when you created an MQ Service, onto the Message Flow editor. A window opens that contains the error, 'There are no imported SOAP bindings in the WSDL file'.
- **Explanation:** IBM App Connect Enterprise Toolkit expects WSDL files to contain SOAP bindings, but the WSDLs that an MQ Service generates do not contain SOAP bindings.
- **Solution:** The WSDL files that the MQ Service generates are valid. Creating a node by using an MQ Service WSDL file is not supported. To create an MQ node, drag the MQ Service, rather than the WSDL file, onto the Message Flow editor.

SOAP bindings warning in Problems view when an MQ Service generates a WSDL

Procedure

- **Scenario:** You create an MQ Service, and that generates a WSDL file. The Problems view displays the warning, 'The Service does not contain any binding that uses a SOAP 1.1 binding'.

- **Explanation:** The validator expects WSDL files to contain SOAP bindings, and deems a WSDL file invalid if it does not contain them. However, not all WSDL files require SOAP bindings. The WSDL files that an MQ Service generates do not contain SOAP bindings, and are valid.
- **Solution:**
  a) Click **Window** > **Preferences**.
  b) In the Preferences window, open **Integration Development** > **WSDL** > **Validation**.
  c) Check the Allow Services that contain non-SOAP bindings check box and click **Apply**.

Resolving problems with user-defined extensions

Advice for dealing with some common problems that can arise when you work with user-defined extensions

About this task

Procedure

You cannot deploy one of your user-defined nodes, despite having a plug-in LIL in the correct directory.

Procedure

- **Scenario:** You cannot deploy one of your user-defined nodes, despite having a plug-in LIL in the correct directory.
- **Explanation:** You have `memset()` the data area to zero and have not initialized the CNI_VFT structure with the initialization constant `{CNI_VFT_DEFAULT}`.
- **Solution:** Initialize by copying a predefined initialization structure over the function table area, as follows:

  ```
  static CNI_VFT virtualFunctionTable = {CNI_VFT_DEFAULT};
  ```

  In addition, implement logging from your user-defined node so that you can see if the plug-in API is producing error codes; the integration node does not log these to its own log, unless you take a service trace.

You cannot deploy a flow with one of your user-defined nodes in it.

Procedure

- **Scenario:** You cannot deploy a flow with one of your user-defined nodes in it.
- **Explanation:** Your LIL file has failed to load.
- **Solution:** Check system log (syslog or Eventviewer) of integration node startup; did you see a BIP2308 message saying a LIL file failed to load? If there are any problems loading a LIL file, a BIP2308 message appears in the system log.

You get problems when nodes try to use the ESQL path interface in the plug-in API

Procedure

- **Scenario:** When you attempt to use the ESQL path interface in the plug-in API, the return value is CCI_PATH_NOT_NAVIGABLE.
- **Explanation:** The plug-in API allows you to specify a path in the form of an ESQL path expression and navigate to that element, returning a handle to it if it exists. It also allows you to create elements along the path to the requested element.

  The navigate path utility function (`cniSqlNavigatePath`) executes the SQLPathExpression created with the `cniSqlCreateReadOnlyPathExpression` or `cniSqlCreateModifiablePathExpression` utility functions, as defined by the `sqlPathExpression` argument.

  If the path is not navigable, the return code is set to CCI_PATH_NOT_NAVIGABLE. This might be returned when embedding a path expression in another path expression. The input `cciMessage*` functions must not be NULL; however, any of the output `cciMessage*` functions can be NULL. If you embed a path expression that can be NULL inside a path expression that cannot be NULL, CCI_PATH_NOT_NAVIGABLE is returned.
- **Solution:** If the return code is set to CCI_PATH_NOT_NAVIGABLE, ensure that if a correlation name is specified in a path, the respective parameter is not NULL.

After migration your custom property editor does not work

Procedure

- **Scenario:** You have migrated to a new version of IBM App Connect Enterprise and your custom property editor no longer works.
- **Explanation:** Custom property editors can use Eclipse or RAD APIs. If any of those APIs are changed in a new version of IBM App Connect Enterprise, your property editor might not work.
- **Solution:** Update your property editor code to comply with the changed API.

Interpreting problems in user-defined extensions

Procedure

- **Scenario:** You want to debug problems in user-defined nodes and parsers.

- **Solution:** Start user trace at debug level. In order to see BIP4142, BIP4144, BIP4145, and BIP4146 messages, this must be done at the integration server level. For example, use the **mqsichangetrace** command without the **-f** parameter.

  The following debug messages are available to help you to understand the execution of your user-defined nodes and parsers:

  – BIP2233 and BIP2234: a pair of messages that are traced before and after a user-defined extension implementation function is invoked. These messages report the input parameters and returned value. For example:

    BIP2233 `Invoking user-defined extension function [function name] ([function call parameters])`

    BIP2234 `Returned from user-defined extension function [function name] with result: [result of call]`

    Note: In these messages, an *implementation function* can be interpreted as either a C implementation function or a Java implementation method.

  – BIP2308: a message that is logged when the integration node fails to load a LIL file.

    BIP2308 `File [name of LIL file] could not be loaded; operating system return code [error code return from operating system]`

  – BIP3904: a message that is traced before invoking the Java `evaluate()` method of a user-defined node. For example:

    BIP3904 `(for Java): Invoking the evaluate() method of node (class=[node class name], name=[label of node in flow])` where *node class name* is the name of the Java user-defined extension class.

  – BIP3905: a message that is traced before invoking the C `cniEvaluate` implementation function (iFpEvaluate member of CNI_VFT) of a user-defined node. For example:

    BIP3905 `(for C): Invoking the cniEvaluate() implementation function of node (class=[node class name], name=[label of node in flow])` where *node class name* is the name of the user-defined extension class that is provided by the user-defined extension while calling C cniDefineNodeClass.

  – BIP4142: a debug message that is traced when invoking a user-defined node utility function, where the utility function alters the state of a syntax element. This includes all utility functions that start with `cniSetElement*`, where * represents all nodes with that stem. For example:

    BIP4142 `Evaluating cniSetElement [element identifier type]. Changing value from [value before user's change] to [value after user's change]"`

  – BIP4144 and BIP4145: a pair of messages that are traced by certain implementation functions that, when invoked by a user-defined extension, can modify the internal state of an integration node object. Possible integration node objects include syntax element, node, and parser. These messages report the input parameter provided to the invoked method and the returned value. For example:

    BIP4144 `Entered function [function name] ([function call parameters])`

    BIP4145 `Exiting function [function name] with result: [result to be returned]`

    In these messages, an *implementation function* can be interpreted as either a C implementation function or a Java implementation method.

    The C implementation functions that invoke messages BIP4144 and BIP4145 include:

For user-defined parsers	For user-defined nodes
cpiCreateParserFactory	cniCreateElement*
cpiDefineParserClass	cniDeleteMessage
cpiAppendToBuffer	cniAdd*

For user-defined parsers	For user-defined nodes
cpiCreateElement	cniDetach
cpiCreateAndInitializeElement	cniCopyElementTree
cpiAddBefore	cniFinalize
cpiAddAfter	cniWriteBuffer
cpiAddAsFirstChild	cniSql*
cpiAddAsLastChild	cniSetInputBuffer
cpiSetNameFromBuffer	cniDispatchThread

(* represents all nodes with that stem; for example, cniAdd* includes cniAddAfter, cniAddasFirstChild, cniAddasLastChild, and cniAddBefore.)

The Java methods that invoke messages BIP4144 and BIP4145 are:

For user-defined nodes
com.ibm.broker.plugin.MbElement.CreateElement*
com.ibm.broker.plugin.MbElement.add*
com.ibm.broker.plugin.MbElement.detach

For user-defined nodes
com.ibm.broker.plugin.MbElement.copyElementTree

- BIP4146: a debug message that is traced when invoking a user-defined parser utility function, where the utility function alters the state of a syntax element. This includes all utility functions that start with `cpiSetElement*`, where * represents all nodes with that stem. For example:

  ```
  BIP4146 Evaluating cpiSetElement [element identifier type]. Changing value
  from [value before user's change] to [value after user's change]
  ```

  For information on the C user-defined API, see the C language user-defined parser API and the C language user-defined node API.
- BIP4147: an error message that is traced when a user-defined extension passes an invalid input object to a user-defined extension utility API function. For Example:

  ```
  BIP4147 User-defined extension input parameter failed debug validation
  check. Input parameter [parameter name] passed into function [function
  name] is not a valid object.
  ```
- BIP4148: an error message that is traced when a user-defined extension damages an integration node object. For Example:

  ```
  BIP4148 User-defined extension damaged an integration node object. Function
  [function name] has damaged integration node object passed as parameter
  [parameter name].
  ```
- BIP4149: an error message that is traced when a user-defined extension passes an invalid input data pointer to a user-defined extension utility API function. For Example:

  ```
  BIP4149 User-defined extension input parameter failed debug validation
  check. Input parameter [parameter name] passed into function [function
  name] is a NULL pointer.
  ```
- BIP4150: an error message that is traced when a user-defined extension passes invalid input data to a user-defined extension utility API function. For example:

  ```
  BIP4150 User-defined extension input parameter failed debug validation
  check. Input parameter [parameter name] passed into function [function
  name] does not have a valid value.
  ```
- BIP4151: a debug message that is traced when `cniGetAttribute2` or `cniGetAttributeName2` sets the return code to an unexpected value. Expected values are CCI_SUCCESS, CCI_ATTRIBUTE_UNKNOWN, and CCI_BUFFER_TOO_SMALL. Any other value is an unexpected value. For example:

  ```
  BIP4151 An unexpected value was returned from User-defined extension
  implementation function [function name].
  ```
- BIP4152: a debug message that is traced when `cniGetAttribute2` or `cniGetAttributeName2` sets the return code to CCI_BUFFER_TOO_SMALL, and then `cniGetAttribute2` or `cniGetAttributeName2` is called again, this time with the correct size buffer, however the return code is still set to CCI_BUFFER_TOO_SMALL. For example:

  ```
  BIP4152 User-defined extension Implementation function [function name]
  returned CCI_BUFFER_TOO_SMALL on 2nd attempt.
  ```

You want to debug classloading

Procedure

- **Scenario:** You want to debug classloading.
- **Solution:** Classes and the location from which they are loaded are written to user trace. Use this information to check that the correct classes are being loaded.

An error is issued when you deploy a user-defined extension on Linux

Procedure

- **Scenario:** When you deploy a user-defined extension on Linux , an error is displayed in the log of each integration server, stating that there is insufficient authority to open the LIL file.
- **Explanation:** On Linux , the user-defined extension must have group read permission.
- **Solution:**

  On Linux , set the file permissions of the user-defined extension to group read by issuing the command **chmod a+r**

You cannot determine which user-defined extensions have been loaded by the integration node on startup

Procedure

- **Scenario:** You cannot determine which user-defined extensions have been loaded by the integration node on startup.
- **Solution:** Use the **mqsireportproperties** command for each type of user-defined extension.
  - For a Java user-defined extension, issue the command:

```
mqsireportproperties INODE -e default -o ComIbmJavaPluginNodeFactory -r
```

    You see a report similar to this example:

```
ComIbmJavaPluginNodeFactory
 uuid='ComIbmJavaPluginNodeFactory'
 userTraceLevel='none'
 traceLevel='none'
 userTraceFilter='none'
 traceFilter='none'
 NodeClassName='ComIbmJMSClientInputNode'
 NodeClassName='ComIbmJMSClientOutputNode'
 NodeClassName='ComIbmJavaComputeNode'
 NodeClassName='ComIbmXslMqsiNode'
 NodeClassName='SearchFilterNode'

BIP8071I: Successful command completion.
```

    The user-defined extension called SearchFilter has a NodeClassName of SearchFilterNode.
  - For a C user-defined extension (assuming that CONST_PLUGIN_NODE_FACTORY was set to ComIbmSamplePluginNodeFactory in the `NodeFactory.h` file, as in the sample NumComputeNode), issue the command:

```
mqsireportproperties INODE -e default -o ComIbmSamplePluginNodeFactory -r
```

    You see a report similar to this example:

```
ComIbmSamplePluginNodeFactory
 uuid='ComIbmSamplePluginNodeFactory'
 userTraceLevel='none'
 traceLevel='none'
 userTraceFilter='none'
 traceFilter='none'
 NodeClassName='NumComputeNode'

BIP8071I: Successful command completion.
```

    The user-defined extension called NumCompute has a NodeClassName of NumComputeNode.

You are migrating a C user-defined node and cniDefineNodeClass returns CCI_INV_IMPL_FUNCTION.

Procedure

- **Scenario:** When you attempt to migrate a C user-defined node, `cniDefineNodeClass` returns CCI_INV_IMPL_FUNCTION.
- **Explanation:** New fields have been added to the CNI_VFT struct. CNI_VFT_DEFAULT has been updated to initialize these new fields in the header file BipCci.h. If you initialize your CNI_VFT with CNI_VFT_DEFAULT, you should not need to make any code changes. However, if you do not initialize CNI_VFT with CNI_VFT_DEFAULT, these new fields are initialized with random values.
- **Solution:** Initialize your CNI_VFT with CNI_VFT_DEFAULT.

Using logs

There are a variety of logs that you can use to help with problem determination and troubleshooting.

About this task

This section describes how to view the various logs available to you with IBM App Connect Enterprise, and how to interpret the information in those logs. It contains the following topic areas:

Local error log

- "Windows: Viewing the local error log" on page 3023
- "Linux and UNIX systems: Configuring the syslog daemon" on page 3024

Eclipse log

- "Viewing the Eclipse error log" on page 3025

Exception log

- "Viewing the exception log" on page 3026

Activity log

- "Viewing Activity Logs for message flows in the web user interface" on page 2856

Admin log

- "Viewing administration activity in the admin log" on page 330

There is also a section of reference topics about the various types of log.

Windows: Viewing the local error log

The Windows Event Viewer is where IBM App Connect Enterprise writes records to the local system. Use Windows system facilities to view this log.

Viewing the system log

About this task

The system log contains events logged by the Windows system components. For example, the failure of a driver or other system component to load during startup is recorded in the system log. To view the system log:

Procedure

1. Open a command prompt.

2. At the prompt, type **eventvwr**. This opens the Windows Event Viewer.

Viewing the application log

About this task

The application log contains events that are logged by applications or programs. For example, a database program might record a file error in the application log. To view the application log:

Procedure

1. Open a command prompt.
2. At the prompt, type **eventvwr**. This opens the Windows Event Viewer.

Interpreting log information

About this task

In both logs, each event is displayed on a separate row, in date and time order (most recent first), with the following information:

- **Type:** The event type, which can be information, a warning, or an error.
- **Date and time:** The date and time when the event was written to the log.
- **Source:** What action has caused the event.
- **Category:** The category of the event. The default category is none.
- **Event:** The event number.
- **User:** The name of the user at the time of the event.
- **Computer:** The name of the local machine.

To view an individual log entry:

Procedure

1. Within the system or application log, find the log entry.
2. Right-click the entry.
   - On Windows, click **Events** to open the Event Properties window.

     The window shows a description of the event. Select the Details tab to view bytes or words that were parsed when the record was written to the log.
3. Use the up and down arrows to move through the events of the log.
4. To close the window, click **OK** to return to the system or application log.

Linux and UNIX systems: Configuring the syslog daemon

On Linux and UNIX systems, all IBM App Connect Enterprise messages (other than messages that are generated by the command-line utilities) are sent to the syslog subsystem.

About this task

UNIX You must configure this subsystem so that all diagnostic messages that enable you to monitor the performance and behavior of your integration node environment are displayed.

The configuration steps you make to ensure that all relevant messages are displayed depend on the version of Linux and UNIX that you are using. Refer to your operating system documentation relating

to syslog (or syslog-ng for some versions of Linux) for information about how to configure the syslog subsystem.

IBM App Connect Enterprise processes call the syslog commands on the operating system but only those messages that correspond to the filter defined for the output destination are displayed. IBM App Connect Enterprise messages have:

- A facility of `user`.
- A level of `err`, `warn`, or `info`, depending on the severity of the situation causing the message to be issued.

To record all IBM App Connect Enterprise messages, create a filter on the `user` facility for messages of level `info` or greater. It is good practice to write these messages to a separate file; there might be a high number of them and they are more likely to be of interest to broker administrators rather than to system administrators.

The following line in a `syslog.conf` file causes all IBM App Connect Enterprise events to be written to a file `/var/log/user.log`

```
user.info /var/log/user.log
```

Note: Ensure that your log file permissions are set to `-rw-rw-rw`. For example:

```
chmod 666 /var/log/user.log
```

Many UNIX systems provide a command-line utility, known as logger, to help you test and refine your configuration of the syslog subsystem.

On UNIX, syslog entries are restricted in length and messages that are sent to the syslog are truncated by the new line character. To record a large amount of data in a log on UNIX, set the `Destination` property on the Trace node to `File` or `User Trace` instead of `Local Error Log`.

What to do next

See the documentation for your operating system.

Viewing the Eclipse error log

The Eclipse error log captures internal errors that are caused by the operating system or your code.

About this task

To view the Eclipse error log:

Procedure

1. Switch to the Plug-in Development perspective.
2. From the main menu, select **Window** > **Show view** > **Other**. Then select **General** > **Error Log**.

   The error log is displayed, showing the following information for each error:

   - The status of the error (for example, error or warning)
   - A brief description of the error
   - From which plug-in the error derived
   - The date and time that the error was produced
3. If an error has a plus sign (+) at the start of it, it is a complex problem, and there are a number of errors contributing to it. Click the plus sign to view the individual errors.
4. To see the details of a particular problem, double-click the entry in the Problems view.

   A separate window is displayed, showing more details of the error.

Viewing the exception log

The exception log enables the diagnosis of exceptions that occur at any time during processing on an integration server.

About this task

The exception log is controlled by three properties in the `ExceptionLog` subsection of the `ResourceManagers` section of the `server.conf.yaml` configuration file.

The exception log is written to one of the following locations depending on whether the integration server is independent or is managed by an integration node:

- `WorkDirectory/config/common/log/integration_server.`*`IntegrationServerName`*`.exceptionLog.txt` when the integration server is independent.
- `MQSI-REGISTRY/common/log/`*`IntegrationNodeName`*`.`*`IntegrationServerName`*`.exceptionLog.txt` when the integration server is managed by an integration node.

The exception log is a rolling collection of 4 files; when a file is full, data is added to the next file. When the last file has been filled, data starts to be added to the first file, overwriting the previous data there. This cycle of writing continues, ensuring that the newest data is retained. Restarting the integration server causes the previous log to be moved and a numeric suffix added to it.

The exception log includes:

- A summary or short description of the exception
- A list of the exception's inserts
- Message numbers of any nested exceptions
- Optionally, details recorded by the Flow Thread Reporter. If the exception occurs in a message flow, the Flow Thread Reporter provides data to enable you to identify the location in the message flow at which the exception occurred.

Exceptions are listed in the order of their creation.

Procedure

Access the exception log by navigating to the appropriate location:

- `WorkDirectory/config/common/log/integration_server.`*`IntegrationServerName`*`.exceptionLog.txt` if the integration server is independent.
- `MQSI-REGISTRY/common/log/`*`IntegrationNodeName`*`.`*`IntegrationServerName`*`.exceptionLog.txt` if the integration server is managed by an integration node.

Using trace

You can use different types of trace to help you with problem determination and troubleshooting.

About this task

If you cannot get enough information about a particular problem from the entries that are available in the various logs, the next troubleshooting method to consider is using trace. Trace provides more details about what is happening while code runs. The information that is produced from trace is sent to a specified trace record so that you or IBM support personnel can analyze it to discover the cause of your problem.

Trace is inactive by default, and must be explicitly activated by using a command, the IBM App Connect Enterprise web user interface, or the REST API.

There are two main types of trace available in IBM App Connect Enterprise: user trace and service trace. Typically, you run user trace for debugging your applications; you can trace integration nodes, integration servers, and deployed message flows. With service trace, you can activate more comprehensive integration node tracing, and trace the execution of all the commands that are described in commands.

When you start user tracing, you cause extra processing for every activity in the component that you are tracing. Large quantities of data are generated by the components, so you can expect performance to be affected while trace is active. You can limit this extra processing by being selective about what you trace, and by restricting the time during which trace is active.

You can use the following types of trace in IBM App Connect Enterprise:

User trace
You can start, stop, and reset user trace from the IBM App Connect Enterprise web user interface or by using commands. Users of the product in its current form can also investigate the administrative REST API provided by IBM App Connect Enterprise.

For more information, see:

- “User trace” on page 3027
- “Starting user trace” on page 3028
- “Changing user trace options” on page 3029
- “Stopping user trace” on page 3030
- “User trace example” on page 3030

Service trace
Service trace is a type of optional trace that provides more information than that provided by the Event Log or user trace. For more information, see:

- “Service trace” on page 3032
- “Starting service trace” on page 3033
- “Changing service trace options” on page 3035
- “Stopping service trace” on page 3035

For user trace and service trace:

- “Interpreting trace” on page 3036
- “Clearing old information from trace files” on page 3037

ODBC trace
For more information, see “ODBC trace” on page 3037

Integration API trace
For more information, see “IBM Integration API trace” on page 3038

For more information about starting and stopping Trace nodes, see “Switching Trace nodes on and off” on page 3038.

You can also trace a specific command, without modifying trace settings on the integration server, by specifying the trace flag when you run the command. For more information, see the explanation of the **`--trace`** parameter in the relevant command topic.

For more help with data collection, you can use the command command.

User trace

User trace is one of two main types of optional trace that are available in IBM App Connect Enterprise and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, the IBM App Connect Enterprise web user interface, or a REST API command.

For information about logs, see Logs. For information about controlling user trace, see "User trace example" on page 3030.

Typically, you use user trace for debugging your applications, as it can trace integration nodes, integration servers, and deployed message flows.

When you activate user trace, you cause additional processing for every activity in the component that you are tracing. Large quantities of data are generated by the components. Expect to see some effect on performance while user trace is active. You can limit this additional processing by restricting the time during which trace is active.

The user trace log files

When trace is active, information is recorded in the user trace log files in plain text format.

For independent integration servers, the location of the trace logs is *workpath*`/config/common/log`, where *workpath* is the work directory of the integration server as specified on the **IntegrationServer** command.

For integration servers that are managed by an integration node, the trace logs are written to `MQSI_WORKPATH/Common/log/`*`integration_node_name`*`.`*`integration_server_name`*`.userTrace.0.txt`

Note: For information about checking and changing the location of the work path; see "Changing the location of the IBM App Connect Enterprise working directory " on page 474.

Trace data is written to files with the format `integration_server.`*`name`*`.userTrace.`*`number`*`.txt` where:

name
The name of your integration server as specified on the **--name** of the **IntegrationServer** command.

number
An integer in the range 0 through 4. There are 5 user trace log files and IBM App Connect Enterprise writes to these files in a rotational manner. When user trace is started, trace data is written to the `integration_server.`*`name`*`.userTrace.0.txt` file. When the `integration_server.`*`name`*`.userTrace.0.txt` file becomes full, user trace data is then written to the `integration_server.`*`name`*`.userTrace.1.txt` file. The process continues until the `integration_server.`*`name`*`.userTrace.4.txt` file is full, at which point user trace data is written to the `integration_server.`*`name`*`.userTrace.0.txt` file and the existing data there is overwritten. The process continues in this rotational manner until user trace is stopped.

Using a Trace node

If you include a Trace node in your message flows when you are developing and testing them, this option not only gives you the ability to trace messages and activity in the flow, but also allows you to specify an alternative target file for the trace contents to isolate the detail in which you are interested. For details of how to use and configure a Trace node, see node and "Switching Trace nodes on and off" on page 3038.

Starting user trace

Use user trace for debugging your applications; you can trace integration nodes, integration servers, and deployed message flows. Start user trace facilities by using the **mqsichangetrace** command, the web user interface, or the REST API.

Before you begin

Before you start to trace an integration node, an integration server, or a deployed message flow, the integration node or server must be running. For more information, follow the instructions in the Chapter 7, "Deploying integration solutions," on page 2463 topic.

About this task

To start a user trace, complete the following steps.

Procedure

1. Start IBM App Connect Enterprise user trace facilities by using the **mqsichangetrace** command, the web user interface, or the REST API:
   - Specify the **-u** parameter on the command.
   - In the IBM App Connect Enterprise web user interface, select **Start user trace** from the options list.
   - Use the REST API provided by IBM App Connect Enterprise.

   You can select only one integration node or server on each invocation of the command, but you can activate concurrent traces for more than one integration node or server, by invoking the command more than once.
2. Specify an individual integration server or message flow within the specified integration node to limit the scope of a trace.

   The events that are recorded when you select the message flow option include:
   - Sending a message from one Message Processing node to the next
   - Evaluating expressions in a Compute or Filter node
3. Start your trace.

   You can start trace at two levels:

   normal
   This tracks events that affect objects that you create and delete, such as nodes.

   debug
   This tracks the beginning and end of a process, as well as monitoring objects that are affected by that process.

Example: starting user trace for an integration server

About this task

To start normal level user trace for integration server `integrationServer1` on integration node `INODE`, enter the command

```
mqsichangetrace INODE -u -e integrationServer1 -l normal
```

where:

-u specifies user trace
-e specifies the integration server (in this case, `integrationServer1`)
-l specifies the level of trace (in this case, normal)

Changing user trace options

Use the **mqsichangetrace** command to change the trace options that you have set.

Procedure

•

Example: changing user trace from normal to debug

About this task

To change from a normal level of user trace to a debug level on the default integration server of an integration node called INODE, on distributed systems, enter the command

```
mqsichangetrace INODE -u -e default -l debug
```

where:

-u specifies user trace
-e specifies the integration server (in this case, the default integration server)
-l specifies the level of trace (in this case, changing it to debug)

Stopping user trace

Use user trace for debugging your applications; you can trace the integration server . Stop user trace facilities by using the **mqsichangetrace** command.

About this task

Use the **mqsichangetrace** command with a trace level of none to stop an active trace. This action stops the trace activity for the component that you specify on the command. It does not affect active traces on other components. For example, if you stop tracing on the integration server `test`, an active trace on another integration server continues.

User trace example

You can start, stop, and reset user trace to control tracing of an integration node or server. Use the **mqsichangetrace** command, the IBM App Connect Enterprise web user interface, or the administrative REST API to control user trace.

Before you begin

Before you start to trace an integration server, the integration server must be running.

About this task

User trace enables you to trace activity in the integration server. User trace is written in plain text format; there is no need to format it before reading it.

To **start** user tracing of the integration server, use one of the following methods:

- In the IBM App Connect Enterprise web user interface, navigate to the top level of the integration server, then select **Start user trace** from the menu at the top-right corner of the page.
- Use the command.
- Use the REST API provided by IBM App Connect Enterprise.

To **stop** user tracing of the integration server, use one of the following methods:

- In the IBM App Connect Enterprise web user interface, navigate to the top level of the integration server, then select **Stop user trace** from the menu at the top-right corner of the page.
- Use the command.
- Use the REST API provided by IBM App Connect Enterprise.

To **reset** user tracing of the integration server, which results in any user trace data that has already been written to the user trace log files being erased, use one of the following methods:

- In the IBM App Connect Enterprise web user interface, navigate to the top level of the integration server, then select **Reset user trace** from the menu at the top-right corner of the page.

- Use the command.
- Use the REST API provided by IBM App Connect Enterprise.

Trace logs:

For independent integration servers, the trace logs are written to *workpath*/config/common/log, where *workpath* is the work directory of the integration server as specified on the **IntegrationServer** command.

For integration servers that are managed by an integration node, the trace logs are written to MQSI_WORKPATH/Common/log/*integration_node_name*.*integration_server_name*.userTrace.0.txt

Example

The following example user trace shows a message that was received by an HTTPInput node being passed to a Mapping node and theMapping node starting to process the data:

```
2018-04-27 09:55:37.845248    12276  UserTrace   BIP3122I: Message received and propagated to
 'out'
terminal of HTTP input node 'Transformation_Map.HTTP Input'.
2018-04-27 09:55:37.845608    12276  UserTrace   BIP3904I: Invoking the evaluate() method of
 node
(class=ComIbmMSLMappingNode, name=FCMComposite_1_3, label=Map).  About to pass a message to the
evaluate() method of  the specified node.  No user action required.
2018-04-27 09:55:37.850016    12276  UserTrace   BIP3964I: The Mapping node 'Map' in message
 flow
'Transformation_Map' is about to process the mapping routine '{default}:Transformation_Map'.
 The Mapping
node is about to process the named mapping routine.  Check the following messages to see the
 progression of
the mapping process.
2018-04-27 09:55:37.851412    12276  UserTrace   BIP11306I: A Parser of type 'WSPROPERTYPARSER'
 has
been created at address '0x248db510'.
2018-04-27 09:55:37.851752    12276  UserTrace   BIP6060I: Node 'Transformation_Map.HTTP Input'
 used
parser type 'Properties' to process a portion of the incoming message of length '0' bytes
 beginning at offset '0'.
2018-04-27 09:55:37.958100    12276  UserTrace   BIP4142I: Evaluating cniElementSetName.
 Changing value
from 'Root' to 'LocalEnvironment'.  Element 'Name' has been changed to 'LocalEnvironment'.  No
 user action
required.
2018-04-27 09:55:37.980888    12276  UserTrace   BIP3963I: The Mapping node is performing a deep
 copy of
the input tree element 'MbElement( type: 1000000 name: Properties )' into the output tree.  The
 Mapping node
is copying the named input tree element, and all its descendents, into the output tree.  Check
 the following
messages to see the progression of the mapping process.
2018-04-27 09:55:37.981508    12276  UserTrace   BIP4145I: Exiting function cniAddBefore with
 result:
CCI_SUCCESS(0).  About to exit the specified the function with the specified result.  No user
 action required.
2018-04-27 09:55:37.984728    12276  UserTrace   BIP3960I: The Mapping node is adding a new
 element with
name 'SaleEnvelopeA' into the output tree.  The Mapping node is adding a new element to the
 output tree, as
defined in the transform that is being processed.  If this element is assigned a value, then
 this assignment will be
reported in an additional message.  Check the following messages to see the progression of the
 mapping process.
2018-04-27 09:55:37.984864    12276  UserTrace   BIP11306I: A Parser of type 'XMLNSC' has been
 created at
address '0x32c2490'.
2018-04-27 09:55:37.984932    12276  UserTrace   BIP4144I: Entered function
cniCreateElementAsLastChild(TRUE, TRUE, N/A, N/A, N/A, N/A, N/A, N/A, N/A, N/A, N/A).  Entered
 the
specified function with the specified parameters.  No user action required.
2018-04-27 09:55:37.984972    12276  UserTrace   BIP4145I: Exiting function
 cniCreateElementAsLastChild
with result: CCI_SUCCESS(0).  About to exit the specified the function with the specified
 result.  No user action
required.
```

Service trace

Service trace is a type of optional trace that is available in IBM App Connect Enterprise, and it provides more information than that provided by the entries that are written to the Event Log or to user trace. Service trace is inactive by default; you must activate it explicitly by using a command.

With service trace, you can activate more comprehensive tracing of an integration node or server. You can also trace the execution of all the commands described in commands, including the trace commands themselves.

Activate service trace only when you receive an error message that instructs you to, or when you are directed to do so by your IBM Support Center. You use the **mqsichangetrace** command to start service trace; you cannot start it through the IBM App Connect Enterprise Toolkit. For more information about how to use service trace, see "Starting service trace" on page 3033.

When you activate service trace, you cause additional processing for every activity in the component that you are tracing. Large quantities of data are generated by the components, so you can expect performance to be affected while service trace is active. You can limit this additional processing by being selective about what you trace, and by restricting the time during which trace is active.

The location of the trace log depends on whether it is the trace for a command, an integration node (or integration server managed by an integration node), or an independent integration server:

- **Command trace**:

  The location of the trace log for a command is determined by the file name and path that you specify on the **--trace** parameter of the command. When you run a command with trace turned on, you specify the file in which the trace output will be written, as shown in the following example:

  ```
  mqsilist myIntegrationNode --trace c:\tmp\listtrace.txt
  ```

  The trace data is written to the specified file in plain text format (in this example, `c:\tmp\listtrace.txt`). The output is appended to the end of the file; if the file does not exist, it is created automatically.

- **Integration node trace:**

  The location of the trace logs for an integration node (or for an integration server that is managed by an integration node) depends on your environment:

  Windows

  If you have set the work path by using the **-w** parameter of the **mqsicreatebroker** command, the location is `workpath\log`.

  If you have not specified the integration node work path, the default location is `%PROGRAMDATA%\IBM\MQSI\Common\log` where `%PROGRAMDATA%` is the environment variable that defines the system working directory. The default directory depends on the operating system.

  Linux

  `/var/mqsi/common/log`

  When the log file is created, its file name is based on the integration node and integration server to which it relates; for example:

  ```
  myIntegrationNodeName.myIntegrationServerName.trace.n.txt
  ```

  where *n* is a number between 0-3, indicating this specific file in the series of four equally-sized files into which the trace log is divided.

- **Integration server trace:**

  For an independent integration server (which is not managed by an integration node), the trace logs are written to the following location:

  ```
  <workdir>/config/common/log
  ```

  The name of the log file takes the following form:

  ```
  integration_server.myIntegrationServerName.trace.n.txt
  ```

  where *n* is a number between 0-3, indicating this specific file in the series of four equally-sized files into which the trace log is divided.

The directory to which the service trace logs are written must be able to hold all the logs for that computer. You might want to place it on a separate file system, if that is allowed by your system operator.

Starting service trace

Use service trace to get detailed information about your environment for use by your IBM Support Center.

About this task

Activate service trace only when you receive an error message that instructs you to start service trace, or when directed to do so by your IBM Support Center.

Use the **mqsichangetrace** command to start IBM App Connect Enterprise service trace facilities.

You can select only one integration node or server on each invocation of the command, but you can activate concurrent traces for more than one by invoking the command more than once.

To limit the scope of a trace, you must specify the individual integration node or server that you want to trace.

You can trace any IBM App Connect Enterprise command by using the **--trace** parameter. This parameter takes an argument that is the name of the file to which trace records are written. For example, the following command outputs trace of the **mqsistartmsgflow** command to the specified file:

```
mqsistartmsgflow INODE -e eg1 -f simpleflow --trace C:\tracefiles\trace.txt
```

Starting service trace for a command

About this task

To trace an IBM App Connect Enterprise command, use the **--trace** parameter on the command to specify the file to which trace records will be written. For example, the following command outputs a trace of the **mqsilist** command to the specified file:

```
mqsilist myIntegrationNode --trace c:\tmp\listtrace.txt
```

If you want to trace the command executable files themselves, set the environment variables MQSI_UTILITY_TRACE and MQSI_UTILITY_TRACESIZE before you run the command.

MQSI_UTILITY_TRACE
Set this variable to `normal` for a basic level of trace, or `debug` for a fuller trace.

MQSI_UTILITY_TRACESIZE
The size, in kilobytes, of the binary trace file. See the **-c** parameter of the **mqsichangetrace** command.

Ensure that you reset these variables when the command that you are tracing has completed. If you do not do so, all subsequent commands are also traced, and their performance will be degraded.

Starting service trace for an integration node

About this task

To start a debug-level service trace for the integration node INODE, enter the following command:

```
mqsichangetrace INODE -t -b -l debug
```

where:

-t specifies service trace
-b specifies that trace for the `agent` subcomponent of the specified component is to be started
-l specifies the level of trace (in this case, debug)

Starting service trace for an integration server that is managed by an integration node

About this task

To start a debug-level service trace for an integration server IS1 on INODE, enter the following command:

```
mqsichangetrace INODE  -t -e IS1 -l debug -m fast -c 200000 -r
```

where:

-t specifies service trace
-l specifies the level of trace (in this case, debug)
-m specifies the way trace information is to be buffered (in this case, fast)
-c specifies the size of the trace file in KB (in this case, 200000)
-r specifies that the trace file is reset

Starting service trace for an independent integration server

About this task

You can start service trace for an independent integration server, either by setting the **trace** property in the integration server's `server.conf.yaml` file, or by running the **IntegrationServer** command with the **--service-trace** parameter:

- Start service trace for an independent integration server by setting the **trace** property in the integration server's `server.conf.yaml` file, as shown in the following example:

  ```
  trace: 'service'
  ```

  The settings in the `server.conf.yaml` file take effect when the integration server is restarted. For more information about configuring an integration server, see “Configuring an integration server by modifying the server.conf.yaml file” on page 172.
- Start an independent integration server with service trace enabled, by running the following command:

  ```
  IntegrationServer --name myIntegrationServer1 --work-dir c:\mywrk\myaceworkdir --service-trace
  ```

  For more information about starting an integration server, see command.

Changing service trace options

Use the **mqsichangetrace** command to change the service trace options that you have set.

Example: changing service trace from debug to normal

About this task

To change from a debug level of trace to a normal level on the integration node, on distributed systems, enter the following command:

```
mqsichangetrace BrokerA -t -b -l normal
```

where:

-t specifies service trace
-b specifies that tracing for the `agent` subcomponent of the specified component is to be changed
-l specifies the level of trace (in this case, changing it to normal)

z/OS On z/OS, enter the following command:

```
F MQP1BRK,ct t=yes, b=yes, l=normal
```

Stopping service trace

Use the **mqsichangetrace** command to stop an active service trace.

Procedure

- Use the **mqsichangetrace** command with a trace level of `none` to stop an active trace.

  This action stops the trace activity for the component that you specify on the command. It does not affect active traces on other components. For example, if you stop tracing on the integration server `test`, an active trace on another integration server continues.

Results

If you redeploy a component from the IBM App Connect Enterprise Toolkit, trace for that component is returned to its default setting of `none`.

Example: stopping service trace on an integration server, using the `mqsichangetrace` command

About this task

To stop debug level service tracing for an integration server `IS1` on integration node A on distributed systems, enter the command

mqsichangetrace `BrokerA -t -e IS1 -l none`

where:

-t specifies service trace
-l specifies the level of trace (in this case, none)

z/OS On z/OS, enter the command

```
F MQPIBRK,ct t=yes, b=yes, l=none
```

Example: stopping service trace on the integration node

About this task

To stop the trace started by the command shown in "Starting service trace" on page 3033, on distributed systems, enter the following command:

```
mqsichangetrace BrokerA -t -b -l none
```

where:

-t specifies service trace
-b specifies that trace for the `agent` subcomponent of the specified component is to be stopped
-l specifies the level of trace (in this case, none)

z/OS On z/OS, enter the following command:

```
F MQP1BRK,ct t=yes, b=yes, l=none
```

Interpreting trace

Use the information in a formatted trace file to identify unexpected behavior.

About this task

A formatted log file contains a sequence of IBM App Connect Enterprise messages. These messages record the activity in a specific part of the system (the part that you identify when you start the trace). You can use this sequence to understand what is happening, and to check that the behavior that is recorded is what you are expecting.

For example, message flow trace records the path that a message takes through the message flow. You can see why decisions result in this path (where a choice is available).

Procedure

1. Verify that the trace file is complete.

   If the size of the trace log is too small to contain all events, trace output continues at the start of the trace log, overwriting existing entries. This is known as *wrapping*.

   An indication that a trace has wrapped is the relationship between the first and last timestamp in it, and the time that trace was enabled. For example, assume that you start tracing at 10:15, and collect the trace at 10:30. If the trace timestamps run from 10:20 to 10:30, it is probable that trace wrapped. Of course it could mean that nothing happened between 10:15 and 10:20.

   Examine the trace and decide whether the beginning of it makes sense, and whether it looks complete. For example, if you want to trace the passage of three messages through a flow, and trace starts half way through the second message, it could have wrapped, or trace might not have been enabled early enough.
2. If trace has wrapped, increase the size of the trace file, and rerun trace.

   For information on trace settings, see command.
3. If you see unexpected behavior in a message flow or integration server, use this trace information to check the actions that have been taken and identify the source of an error or other discrepancy.

Results

The messages contain identifiers for the resources that are being traced, for example the integration servers and message flows. The identifier that is given is typically the label (the name) that you gave to the resource when you defined it.

Here is an extract from a user trace file. In the example, each column has been labeled:

```
Timestamp                 Thread ID Trace type  Message
2005-07-12 16:17:18.242605   5344   UserTrace   BIP2537I: Node 'Reply.MapToRequestor':
                                                Executing statement   ''SET I = I + 1;''
                                                at ('.MapToRequestor.CopyMessageHeaders',
                                                '6.4').
2005-07-12 16:17:18.242605   5344   UserTrace   BIP2539I: Node 'Reply.MapToRequestor':
                                                Evaluating expression ''I'' at
                                                ('.MapToRequestor.CopyMessageHeaders',
                                                '6.12'). This resolved to ''I''. The
                                                result was ''1''.
2005-07-12 16:17:18.242605   5344   UserTrace   BIP2539I: Node 'Reply.MapToRequestor':
                                                Evaluating expression ''I + 1'' at
                                                ('.MapToRequestor.CopyMessageHeaders',
                                                '6.14'). This resolved to ''1 + 1''.
                                                The result was ''2''.
2005-07-12 16:17:18.242605   5344   UserTrace   BIP2566I: Node 'Reply.MapToRequestor':
                                                Assigning value ''2'' to field / variable
                                                ''I''.
```

References such as `'6.12'` apply to the row and column number within a function that specify the location of the command that is being executed; in this case, row 6, column 12.

Clearing old information from trace files

If the component that you are tracing has stopped, you can delete its trace files from the log subdirectory of the IBM App Connect Enterprise home directory.

About this task

If you are tracing an integration server, you can use the **-r** parameter of the **mqsichangetrace** command to reset (clear) the trace log (the **-r** parameter can be specified only if you specify the **-e** parameter). You might clear the log when you start a new trace, to ensure that all the records on the log are unique to the new trace.

Example: clearing the user trace log for the default integration server

About this task

To clear the user trace log for the default integration server, on distributed systems, enter the command: **mqsichangetrace WBRK_BROKER -u -e default -r** where:

WBRK_BROKER specifies the name of the integration node
-u specifies user trace
-e specifies the integration server (in this case the default integration server)
-r clears the trace log

ODBC trace

You can use various methods to trace for ODBC activity, depending on the operating system that you are using.

About this task

Windows For Windows, use the **Tracing** tab of the ODBC function:

1. Click **Start** > **Settings** > **Control Panel** > **Administrative Tools**.
2. Double-click **Data Sources**.
3. Click the **Tracing** tab.
4. Click **Start Tracing Now**.
5. Click **OK**.

To stop ODBC tracing, on the **Tracing** tab, click **Stop Tracing Now**, then **OK**.

Linux UNIX For Linux and UNIX operating systems using IBM Integration ODBC Database Extender drivers:

- To initiate trace for ODBC activity, edit the [ODBC] stanza in the `odbcinst.ini` file in the directory pointed to by your ODBCSYSINI environment variable as follows:
  1. Change `Trace=no` to `Trace=yes`.
  2. Specify a path and file name for `TraceFile`
  3. Ensure that the `TraceFile` entry points to a file system that has enough space to receive the trace output

IBM Integration API trace

Enable or disable service trace for the IBM Integration API.

Enabling IBM Integration API trace

About this task

To enable tracing for the IBM Integration API for your application, set the environment variable MQSI_IAPI_TRACE, where *<filename>* is the name of the file to which the trace is sent:

```
export MQSI_IAPI_TRACE=<filename>
```

Or you can enable tracing by using the following API call in your code:

```
// Enable Administration service trace
     IntegrationAPI.enableAdministrationAPITracing("outputfile.txt");
```

This request logs all calls to the IBM Integration API to the `outputfile.txt` file in the current directory. All IBM Integration API activity in the entire Java virtual machine is logged.

You can also enable IBM Integration API service trace from the **File** menu of the IBM Integration API Exerciser. Alternatively, you can enable IBM Integration API tracing in the IBM App Connect Enterprise Toolkit by clicking **Window** > **Preferences** > **Unit Test Settings** > **Integraton API**.

Disabling IBM Integration API trace

About this task

To disable tracing for the IBM Integration API for your application, use the following API call in your code:

```
// Disable Administration service trace
   IntegrationAPI.disableIntegrationAPITracing()
```

You can also disable IBM Integration API service trace from the **File** menu of the IBM Integration API Exerciser.

Switching Trace nodes on and off

You can enable and disable Trace nodes by setting properties in the `server.conf.yaml` configuration file.

About this task

When an integration server is created, or a message flow is deployed, its Trace node switch is set to on by default. The message flow level Trace node switch setting is not changed on redeployment. You can significantly improve the performance of a flow that includes Trace nodes by switching Trace nodes off.

If the Trace node setting for an integration server is off, all Trace nodes in its flows are disabled. You can change the settings for Trace nodes in individual message flows; the settings are applied when you turn on Trace nodes for the integration server. If the Trace node setting for an integration server is on, the Trace node switch setting of each message flow determines the effective settings.

Example: switching off Trace nodes for an integration server, by using the server.conf.yaml file

Procedure

1. Open the `server.conf.yaml` configuration file for your integration server, by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, which are invalid in YAML and would cause your integration server configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
2. Set the **`traceNodeLevel`** property to `false`.

   For more information about configuring an integration server by using the `server.conf.yaml` file, see “Configuring an integration server by modifying the server.conf.yaml file” on page 172.
3. Restart the integration server for the changes to take effect.

   For information about how to start an integration server, see “Starting an integration server” on page 250.

Using dumps and abend files

A dump or an abend file might be produced when a problem occurs. Dumps and abend files can be used by IBM to resolve the problem.

About this task

Refer to the topics in the Procedure section:

Procedure

- “Checking for dumps” on page 3039
- “Checking for abend files” on page 3040

What to do next

You can also use the command command to help with data collection.

Checking for dumps

If a dump occurs on your system, an error message is produced.

Procedure

- **On Windows**

  BIP2111 error message (IBM App Connect Enterprise internal error). The error message contains the path to the MiniDump file in your errors directory.
- **On UNIX**

  BIP2060 error message (integration server terminated unexpectedly). Look in the directory where the integration node was started, or in the service user ID's home directory, to find the core dump file.

Checking for abend files

Abend files are produced when a process ends abnormally. The information contained in an abend file helps the IBM Support Center to diagnose and fix the problem.

About this task

The following list contains examples of what might cause the integration node to produce an abend file:

Procedure

- The integration node runs out of memory.
- A user-defined extension causes an instruction in the integration node process that is not valid.
- An unrecoverable error occurs in the integration node.

Results

Abend files are never produced during normal operation. If an abend file is produced, contact the IBM Support Center for assistance.

Contacting your IBM Support Center

If you cannot resolve problems that you find when you use IBM App Connect Enterprise, or if you are directed to do so by an error message generated by IBM App Connect Enterprise, you can contact your IBM Support Center.

About this task

Before you contact your Support Center, use the checklist that is shown here to gather important information. Some items might not be relevant in every situation, but provide as much information as you can to enable the IBM Support Center to re-create your problem. You can also use the command to collect diagnostics.

For IBM App Connect Enterprise:

- The product version.
- Any fix packs applied.
- Any interim fixes applied.
- All current trace and error logs, including relevant Windows Event log or LinuxUNIX operating system syslog entries, and any abend or dump files from the *install_dir*\errors directory on Windows, or the /var/mqsi/errors directory on Linux UNIX. Obtain user trace log files at debug level for all relevant message flows and preferably format them. Also, include any requested service trace files.

  To send files from distributed systems, create a compressed file by using any compression utility.

  To send a file from the file system to IBM, use **tar** to compress the file. For example, `tar -cx -f coredump.0002009E coredump.toibm`. To send MVS data sets to IBM, terse them using TRSMAIN, which you can download from z/OS tools download.
- A list of the components installed. Include details of the number of computers and their operating systems, the number of integration nodes and the computers on which they are running.
- The compressed file that is obtained by exporting your workspace and appropriate message flows and message sets. This task is done in the IBM App Connect Enterprise Toolkit.
- Details of the operation that you were running, the results that occurred, and the results that you were expecting.
- A sample of the messages that were being used when the problem arose.

- If relevant, the report file from the C or COBOL importer. This file is located in the directory from which the file import was attempted.
- If you are using tagged delimited wire format on message sets, include the Tivoli Directory Server log files.

For IBM MQ:

- The product version.
- Any fix packs applied.
- Any interim fixes applied.
- All current trace and error logs, including relevant Windows Event log or Linux and UNIX operating system syslog entries and First Failure Support Technology (FFST) output files. You can find these files, which have the extension `.fdc`, in the errors subdirectory in the IBM MQ home directory.
- Details of IBM MQ client software, if appropriate.

For each database that you are using:

- The product and release level (for example, DB2 9.1).
- Any fix packs applied.
- Any interim fixes applied.
- All current trace and error logs, including relevant Windows Event log or Linux and UNIX operating system syslog entries, for example the `db2dialog.log` file on DB2. Check the database product documentation for details of where to find these files.
- Definitions of any database tables.
- Any ODBC traces.

Windows For Windows:

- The version.
- The Service Pack level.
- The environment settings.

UNIX For Linux and UNIX operating systems:

- The product version. You can find the version that is installed by using the **`uname -a`** command.
- Any service level and patches that are applied.
- The environment settings.

Collecting diagnostics

You can collect diagnostic documents by using the **`aceDataCollector`** command.

About this task

You can run the command that is provided in the following topic to collect the appropriate information for IBM App Connect Enterprise.

Procedure

- command

Searching knowledge bases

If you have a problem with your IBM software, you want it resolved quickly. Begin by searching the available knowledge bases to determine whether the resolution to your problem is already documented.

Procedure

1. **Search the product documentation**

   IBM provides extensive documentation. Product documentation can be installed on your local computer or on a local intranet. Product documentation can also be viewed on the IBM website. You can use the powerful search function of the product documentation to query conceptual and reference information as well as detailed instructions for completing tasks.

2. **Search the Internet**

   If you cannot find an answer to your question in the product documentation, search the Internet for the latest, most complete information that might help you resolve your problem, including:

   - IBM technotes
   - IBM downloads
   - IBM Redbooks publications
   - IBM developerWorks
   - Forums and newsgroups
   - Internet search engines

Getting product fixes

A product fix might be available to resolve your problem. You can determine what fixes are available from the IBM support site.

About this task

To determine what fixes are available from the IBM support site:

1. Open the IBM App Connect Enterprise support web page.
2. Click **Downloads**, then **Recommended fixes**. This web page provides links to the latest available maintenance for the in service IBM App Connect Enterprise family of products.

To receive weekly email notifications about fixes and other news about IBM products, follow these steps.

Procedure

1. From the support site (IBM App Connect Enterprise support web page), locate the **Notifications** box in the center of the page.
2. If you are not signed in, click **Sign in to create, manage or view your subscriptions**. If you have not registered, click **register now** on the sign-in page and follow the on-screen instructions.
3. Click **Manage my subscriptions**.
4. Click the **Subscribe** tab. A list of products families is shown.
5. In the Software column, click **WebSphere**. A list of products is shown.
6. Select the product for which you want to receive notifications (for example, **IBM Integration Bus**), then click **Continue**.
7. Set options to determine what notifications you receive, how often you receive them, and to which folder they are saved, then click **Submit**.

Contacting IBM Software Support

IBM Software Support assists with product defects.

About this task

Before you contact IBM Software Support, you must ensure that your company has an active IBM software subscription and support contract, and that you are authorized to submit problems to IBM. The type of software subscription and support contract that you need depends on the type of product that you have:

- For IBM distributed software products (including, but not limited to, Tivoli, Lotus®, and Rational products, DB2 and WebSphere products that run on Windows or UNIX operating systems). Enroll in Passport Advantage in one of the following ways:
  - Online: Go to the Passport Advantage website and click **How to Enroll**.
  - By telephone: For the telephone number to call in your country, go to the Software Support Handbook, click **Contacts**, then **Worldwide contacts**.
- For customers with Subscription and Support (S & S) contracts, go to the Open service request web page.
- For customers with IBMLink, CATIA, Linux, S/390®, iSeries, pSeries, zSeries, and other support agreements, go to the IBM Support Line web page.
- For IBM eServer™ software products (including, but not limited to, DB2 and WebSphere products that run in zSeries, pSeries, and iSeries environments), you can purchase a software subscription and support agreement by working directly with an IBM marketing representative or an IBM Business Partner. For more information about support for eServer software products, go to the Support for IBM Systems web page.

If you are not sure what type of software subscription and support contract you need, call 1-800-IBMSERV (1-800-426-7378) in the United States. From other countries, go to the contacts page of the Software Support Handbook and click the name of your geographic region for telephone numbers of people who support your location.

Complete the following steps to contact IBM Software Support:

Procedure

1. “Determine the effect of the problem on your business” on page 3043
2. “Describe your problem and gather background information” on page 3044
3. “Submit your problem to IBM Software Support” on page 3044

Determine the effect of the problem on your business

About this task

When you report a problem to IBM, you are asked to supply a severity level. Therefore, you need to understand and assess the effect on your business of the problem that you are reporting. Use the following criteria:

Severity 1
: **Critical** effect on business: You are unable to use the program, resulting in a critical effect on operations. This condition requires an immediate solution.

Severity 2
: **Significant** effect on business: The program is usable but is severely limited.

Severity 3
: **Some** effect on business: The program is usable with less significant features (not critical to operations) unavailable.

Severity 4

Minimal effect on business: The problem has little effect on operations, or a reasonable workaround to the problem was implemented.

Describe your problem and gather background information

About this task

When you are explaining a problem to IBM, be as specific as possible. Include all relevant background information so that IBM Software Support specialists can help you to solve the problem efficiently. To save time, know the answers to these questions:

- What software versions were you running when the problem occurred?
- Do you have logs, traces, and messages that are related to the problem symptoms? IBM Software Support is likely to ask for this information.
- Can the problem be re-created? If so, what steps led to the failure?
- Have you changed the system? (For example, changes to hardware, operating system, networking software.)
- Are you currently using a workaround for this problem? If so, be prepared to explain it when you report the problem.
- The **aceDataCollector** command can be used to collect diagnostic information. For more information, see command.

Submit your problem to IBM Software Support

About this task

You can submit your problem in the following ways:

- Online: Go to the Software Support Handbook and enter your information into the appropriate problem submission tool.
- By telephone: For the telephone number to call in your country, go to the contacts page of the Software Support Handbook. Click the name of your geographic region for telephone numbers of people who support your location.

If the problem that you submit is for a software defect or for missing or inaccurate documentation, IBM Software Support might create an Authorized Program Analysis Report (APAR). The APAR describes the problem in detail. Whenever possible, IBM Software Support provides a workaround for you to implement until the APAR is resolved and a fix is delivered.

IBM publishes resolved APARs on the IBM product support web pages daily so that other users who experience the same problem can benefit from the same resolutions.

Chapter 11. IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX)

IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) enables z/OS customers to run and manage IBM App Connect Enterprise in zCX by using JCL or z/OS console commands.

About this task

You can configure IBM App Connect Enterprise to run on IBM z/OS Container Extensions (zCX) as described in "Configuring App Connect Enterprise to run in Docker" on page 111.

If you prefer to use JCL or IBM z/OS console commands to administer integration servers, and run IBM App Connect Enterprise commands, you can install and configure IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX). IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) provides the following resources:

- JCL. You can use the supplied JCL to build or load Docker images and administer the integration server Docker containers.
- Shell scripts. Shell scripts are used to interact with the zCX instance and issue commands. You run the shell scripts by editing and submitting the supplied JCL or by running the supplied console listener program.
- Console listener program. You can use the console listener program if you want to administer integration server Docker containers by using IBM z/OS console commands.

Procedure

Install and configure IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) by completing the steps in the following topics:

- "Provisioning an IBM z/OS Container Extensions (zCX) instance" on page 3046
- "Installing and configuring IBM App Connect Enterprise on zCX" on page 3046
- "Customizing the JCL" on page 3048

You can then create an IBM App Connect Enterprise Integration Server Docker image on IBM z/OS Container Extensions (zCX) by completing the following task:

- "Creating an IBM App Connect Enterprise Integration Server Docker image on IBM z/OS Container Extensions (zCX) by using the supplied JCL" on page 3049

You can then use either JCL or z/OS console commands to manage your integration servers and to run IBM App Connect Enterprise commands. Complete the steps described in one of the following topics, according to your chosen method:

- "Administering IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) by using JCL" on page 3053
- "Administering IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3056

The following topics contain additional reference information, which you can use to help you complete the relevant tasks:

- "Planning and customization tasks on z/OS" on page 3061
- "Environment variables in STDENV and BIPENVS" on page 3062
- "Configuring access to Integration Servers running in IBM z/OS Container Extensions (zCX) " on page 3071
- Troubleshooting on IBM z/OS Container Extensions (zCX)
- Applying maintenance toIBM z/OS Container Extensions (zCX)

Provisioning an IBM z/OS Container Extensions (zCX) instance

Provision an IBM z/OS Container Extensions (zCX) instance.

Procedure

1. If you do not have an available instance of IBM z/OS Container Extensions (zCX), provision an instance as described in z/OS Container Extensions (zCX) content solution.
2. If they do not exist, create one or more Docker users in zCX to run the integration server processing as described in Local user management.
3. For each user in IBM z/OS Container Extensions (zCX), create an ssh private/public key pair to be used to run the integration server processing.
   a. Create the keys by using the `ssh-keygen` command, or create them according to your installation standards. Do not set a passphrase. For example, you can use the following command to generate a private/public key pair:

      ```
      ssh-keygen -t rsa -b 4096 -C "your_email@domain.com"
      ```

      The private key is named *id_rsa*, and the public key is named *id_rsa.pub*, or the keys are named as you specified when you generated them. You can run the command from the z/OS UNIX System Services file system, but you are not obliged to do so. If you run the command from the z/OS UNIX System Services file system, the keys are created by default in the `.ssh` subdirectory of your home directory. For example, `/u/aceadmin/.ssh`. For more information, see Steps for setting up user authentication when using UNIX files to store keys, and Local user management in the IBM z/OS documentation online.
   b. Copy the public ssh key into the IBM z/OS Container Extensions (zCX) instance. For example, if you created the key for the Docker user *zcxuser* in your home directory of the z/OS UNIX System Services file system, run the following command:

      ```
      cat ~/.ssh/id_rsa.pub | ssh -p 8022 zcxuser@9.20.11.10 'cat >> .ssh/authorized_keys &&
       echo "Key copied"'
      ```

   c. Store the private key on the z/OS UNIX System Services file system for use when you run the integration server processing. The private key must be set as the *ZCX_SSH_KEY* environment variable, and the associated Docker user must be set as the *ZCX_USER* environment variable.

   For more information about access options, see Configuring SSH access for IBM z/OS Container Extensions (zCX).

What to do next

Install and configure IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX), as described in “Installing and configuring IBM App Connect Enterprise on zCX” on page 3046.

Installing and configuring IBM App Connect Enterprise on zCX

Install and configure IBM App Connect Enterprise on zCX.

About this task

You can install and configure IBM App Connect Enterprise on zCX by completing the following steps:

Procedure

1. Go to IBM Passport Advantage (https://www.ibm.com/software/passportadvantage/pao_customer.html) and download the appropriate IBM App Connect Enterprise Linux on Z for IBM zCX Multilingual portable software instance image.

2. Transfer the image to your z/OS UNIX file system. If you are using FTP to transfer the file, ensure that the mode is set to `binary`.
3. Extract the files from the downloaded image, by using the `pax -rvf image.pax.Z` command. This command extracts the files into the current directory.
4. Log on to the IBM z/OS Management Facility for your z/OS system.
5. In the main navigation, expand **Software** and select **Software Management**.
6. In the **Software Management table**, click **Portable Software Instances**.
7. In the table header, click the **Actions** drop-down menu and select **Add from z/OSMF system**.
8. Select the following details for where your image is stored:
   - **System**. The logical partition (LPAR) where your image is located. Select this value by using the drop-down list or the **Select** button.
   - **File location**. The file system location for the image; for example `/u/jo/ace`.
9. Click **Retrieve**, check that the IBM App Connect Enterprise PSI is shown in the table, then click **OK**.
10. In the table, select **IBM App Connect Enterprise**. In the **Switch To** drop-down menu, select **Deployments**.
11. Initially, no deployments are displayed. In the table header, click the **Actions** drop-down menu and select **New** to create a new one.
12. In the **Deployment Checklist**, click **Specify the properties for this deployment**.
13. Enter a name for the deployment; for example, *ACE*. Click **OK**.
14. In the **Deployment Checklist**, click **Select the software to deploy**.
15. Set the software type by clicking **Portable Software Instance**.
16. Select the PSI that you created previously, then click **OK**.
17. In the **Deployment Checklist**, click **Select the objective for this deployment**.
18. In the **Select Deployment Objective** tab, select the following parameters:
    - Set **Objective** to **Create a new software instance and connect to the following global CSI**, then select **A new global zone CSI**.
    - Set **Target system** to be the LPAR to install on.
19. Click **OK**.
20. In the **Deployment Checklist**, click **Check for missing SYSMODs**.
21. Click **Next**, then clear the following reports, which are not required for a new installation:
    - Requisite SYSMODs and Fix Categories reports.
    - Regressed SYSMODs and HOLDDAATA Delta reports.
22. Click **Finish** and ignore the warning that is issued when no reports are selected.
23. In the **Deployment Checklist**, click **Configure this deployment**.
24. Work through the configuration wizard. To use the existing values, click **Next**, or to change the values, click **Modify**.
25. When the wizard is complete, in the **Deployment Checklist**, click **Define the job settings. z/OSMF creates the deployment summary and jobs.**
26. Make updates to the **JOB statement** as required. When the changes are complete, click **OK**.
27. In the **Deployment Checklist**, click **Submit deployment jobs**.
28. The jobs in the **Submit Deployment Jobs** tab must be submitted one at a time in the specified sequence. When a job completes successfully, submit the next job. To submit a job, select the checkbox next to the job, then open the **Actions** drop-down menu and click **Submit**.
29. When all the jobs are completed, the file system is ready, but is not mounted. Update the SYS1.PARMILIB BPXPRMxx configuration file to mount the file system. The standard mount point for IBM App Connect Enterprise is `/usr/lpp/ace/v12/`.
30. In the **Deployment Checklist**, click **Specify the properties for the target software instance**.

31. By default, the software instance name and description are copied from the source software instance, but you can edit them. When the name and description are appropriate, click **OK**. Software deployment is complete.
32. Ensure that the environmental requirements for IBM z/OS Container Extensions (zCX) are met, as described in "Planning and customization tasks on z/OS" on page 3061.

Results

The IBM z/OS Management Facility installation process on zCX provides the following libraries and file systems:

Table 103. Libraries and file systems that are provided by the IBM z/OS Management Facility installation process:

Name	Description
`<hlq>.SACECNTL`	Contains sample JCL
`<hlq>.SACELOAD`	Contains the load module for the console listener task.
Mounted file system	Contains the shell scripts and sample Dockerfile to build the docker image.

What to do next

Customize the JCL as described in "Customizing the JCL" on page 3048.

Customizing the JCL

Customize the JCL, as part of creating an integration server on IBM z/OS Container Extensions (zCX).

About this task

All JCL has a standard header, which includes the following items:

- A brief description of its function.
- A description where further information can be found.
- Instructions about how to customize the JCL.
- A section that lists the JCL itself.

The following sample JCL is supplied by the IBM z/OS Management Facility installation process:

- `BIPXBLD` - Sample job to build a Docker image to run an integration server.
- `BIPXCLIS` - Sample job to run the console listener program.
- `BIPXDBG` - Sample job to debug the integration server Docker container.
- `BIPXDLI` - Sample job to load a Docker image from a `.tar` archive on z/OS UNIX System Services.
- `BIPXDSP` - Sample job to run a Docker system purge to clear space on the zCX instance.
- `BIPXGET` - Sample job to copy or move a file from a running integration server Docker container to UNIX System Services.
- `BIPXIS` - Sample job to run an integration server in zCX and display its logs.
- `BIPXISCM` - Sample job to run an integration server runtime command.
- `BIPXISTP` - Sample job to stop the integration server or to stop and remove its container, or to remove the container that is already stopped.
- `BIPXPUT` - Sample job to copy a file from UNIX System Services to a running integration server Docker container.

Procedure

1. Customize the JCL files by following the instructions in the files. You can customize the files by using an ISPF edit macro that you must tailor, or you can edit each of the PDSE members manually. Most of the customizations are standard for all of the JCL files.
2. Create environment files and set the environment variables that you need for each task.

   You need a different set of environment variables for each task such as building an image, starting an integration server, or running commands. Therefore, you can choose to create a different environment file for each task and or integration server. For each task, you might need more than one environment file if different users have different levels of access. You can specify multiple environment files in the *STDENV* concatenation. For more information, see "Environment variables in STDENV and BIPENVS" on page 3062.

What to do next

Create an IBM App Connect Enterprise Integration Server Docker image on IBM z/OS Container Extensions (zCX), as described in "Creating an IBM App Connect Enterprise Integration Server Docker image on IBM z/OS Container Extensions (zCX) by using the supplied JCL" on page 3049.

Creating an IBM App Connect Enterprise Integration Server Docker image on IBM z/OS Container Extensions (zCX) by using the supplied JCL

Create an IBM App Connect Enterprise integration server Docker image on IBM z/OS Container Extensions (zCX) by using the supplied JCL.

About this task

You can build your own integration server Docker image by using the supplied JCL. The image must be made available to the zCX instance. If you choose not to build your own image by using the supplied JCL, you can use any image that is built for the s390x architecture. The following alternatives are available:

- You can use an existing image in any Docker registry to which your zCX instance is connected. For more information, see Docker registries in the IBM z/OS documentation online.
- You can load a docker image from a `.tar` archive in the z/OS UNIX System Services file system. For more information, see "Loading a Docker image from a .tar file on the z/OS UNIX System Services file system" on page 3051.
- You can build your own Docker image by using your own processing methods as described in "Building your own Docker image" on page 3052.

Procedure

To build your own integration server Docker image by using the supplied JCL, complete the following steps:

1. Download an IBM App Connect Enterprise Linux on IBM Z package from Passport Advantage / PassportAdvantage Express Overview and place it in the UNIX System Services file system on z/OS.

   Do not to use Secure Copy Protocol (SCP) to transfer the package. SCP assumes that files are text, so binary files that are copied between EBCDIC and ASCII operating systems are corrupted during the copying process.

2. Set the environment variables in the environment file, ENVFILE, as described in "Environment variables in STDENV and BIPENVS" on page 3062.

   You must set the zCX access environment variables and the environment variables that are specific to creating an IBM App Connect Enterprise Integration Server Docker image on IBM z/OS Container Extensions (zCX).

   For more information about access options, see Configuring SSH access for IBM z/OS Container Extensions (zCX).

   - Specify the location of the downloaded Linux on IBM Z package. For example:

     ```
     ACE_DOWNLOAD_PACKAGE_DIR=/u/aceadmin
     ```

   - Specify the name of the downloaded Linux on IBM Z package. For example:

     ```
     ACE_DOWNLOAD_PACKAGE_NAME=ace-12.0.1.0.tar.gz
     ```

   - If you want to include a BAR file, place it in the UNIX System Services file system on z/OS and set the environment variables *ACE_DOCKER_IMAGE_BAR_DIR*, and *ACE_DOCKER_IMAGE_BAR_NAME*. For example:

     ```
     ACE_DOCKER_IMAGE_BAR_DIR=/u/aceadmin/bars
     ```

     ```
     ACE_DOCKER_IMAGE_BAR_NAME=zcx.bar
     ```

   - If you want to include a `server.conf.yaml` file, place it in the UNIX System Services file system on z/OS and set the environment variables *ACE_DOCKER_IMAGE_YAML_DIR*, and *ACE_DOCKER_IMAGE_YAML_NAME*. For example:

     ```
     ACE_DOCKER_IMAGE_YAML_DIR=/u/aceadmin
     ```

     ```
     ACE_DOCKER_IMAGE_YAML_NAME=server.conf.yaml
     ```

   - If you want to include an MQClient, download IBM MQ v9.2 or later Client deb install packages for IBM MQ on Ubuntu on z Systems from Fix Central. Place the downloaded image in the UNIX System Services file system on z/OS. Set the environment variables *ACE_DOCKER_IMAGE_MQCLIENT_TAR_DIR*, and *ACE_DOCKER_IMAGE_MQCLIENT_TAR_NAME*. For example:

     ```
     ACE_DOCKER_IMAGE_MQCLIENT_TAR_DIR=/u/aceadmin/tars
     ```

     ```
     ACE_DOCKER_IMAGE_MQCLIENT_TAR_NAME=9.2.0.0-IBM-MQC-UbuntuLinuxS390X.tar.gz
     ```

   - Specify the name of the image to build and specify a tag by setting the environment variables *ACE_IMAGE*, and *ACE_TAG*. For example:

     ```
     ACE_IMAGE=ace_jenkins_2020-06-15_09:59:01.957539
     ```

     ```
     ACE_TAG=testing
     ```

3. Choose from two methods to provide access to the running integration server. Which method you choose, depends on the level of access that you want to give to users who run IBM App Connect Enterprise commands.

   For more information, see "Configuring access to Integration Servers running in IBM z/OS Container Extensions (zCX) " on page 3071.

4. Customize the JCL job *BIPXBLD* as described in "Customizing the JCL" on page 3048.
5. Submit the JCL job *BIPXBLD* to build the image.

What to do next

You can then use either JCL or z/OS console commands to manage your integration servers and to run IBM App Connect Enterprise commands, as described in "Administering IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) by using JCL" on page 3053 and "Administering IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3056.

Loading a Docker image from a .tar file on the z/OS UNIX System Services file system

Load a Docker image from a `.tar` file on the z/OSUNIX System Services file system by running the JCL job BIPXDLI.

About this task

You can load a Docker image from a `.tar` file on the z/OS UNIX System Services file system by running the JCL job BIPXDLI.

For more information about building your own image, see "Building your own Docker image" on page 3052.

Procedure

To load a Docker image from a `.tar` archive in the z/OS UNIX System Services file system, complete the following steps:

1. Set the environment variables in the environment file, STDENV. For more information, see "Environment variables in STDENV and BIPENVS" on page 3062. You must set the zCX access environment variables and the environment variables that are specific to Loading a Docker image from a `.tar` file on the z/OS UNIX System Services file system. Specify the name and location of the .tar file that you want to load, by setting the environment variables *ACE_DOCKER_IMAGE_TAR_DIR*, and *ACE_DOCKER_IMAGE_TAR_NAME*.
   For example:

   ```
   ACE_DOCKER_IMAGE_TAR_DIR=/u/aceadmin
   ```

   ```
   ACE_DOCKER_IMAGE_TAR_NAME=ace-s390x.tar
   ```

2. Customize the JCL job `BIPXDLI` as advised in the job comments. For more information, see "Customizing the JCL" on page 3048.
3. Submit the job `BIPXDLI`.

Results

The job `BIPXDLI` runs and the Docker image is loaded from the z/OS UNIX System Services file system into zCX, and is ready to use.

What to do next

You can then use either JCL or z/OS console commands to manage your integration servers and to run IBM App Connect Enterprise commands (with the naming convention *mqsi** or *ibmint**), as described in "Administering IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) by using JCL" on page 3053 and "Administering IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3056.

Building your own Docker image

Build your own Docker image by using your own processing methods.

About this task

If you choose not to build an image by using the JCL that is supplied with IBM App Connect Enterprise on z/OS, or to use the ot4i image, you can build your own image. The image must be made available to the zCX instance, and it must be built for the s390x architecture. The following options are available:

- You can build a custom version of the ot4i image by following the instructions in the section entitled "Building a container image" in /ot4i/ace-docker.
- You can use your own image that is built without using the supplied JCL or by customizing the ot4i image. You might need to specify your own parameters to use on the docker run command that is issued when you submit the JCL jobs `BIPXIS` or `BIPXCLIS`.

Procedure

To build your own image without using the supplied JCL or by customizing the ot4i image, complete the following steps:

1. Build the image by using your own processing methods, and make the image available to the zCX instance.
   For example, place it in any Docker registry to which your zCX instance is connected. For more information, see Docker registries in the IBM z/OS documentation online, and "Loading a Docker image from a .tar file on the z/OS UNIX System Services file system" on page 3051.
2. Ensure that when you docker exec onto the container, you docker exec into an IBM App Connect Enterprise command environment. For more information, see "Setting up a command environment" on page 64.
3. Optional: If you want to administer your integration server Docker container by using JCL, complete the following steps:
   a) Set the environment variables in the environment file, STDENV. You must set the zCX access environment variables and all of the following environment variables:
      - *SERVER_NAME*. The zCX processing assumes that the Docker container is called *SERVER_NAME* and it sets *SERVER_NAME* as the container name when it starts the container.
      - *SERVER_RUN_OVERRIDE*. Specify the parameters, including port mappings to use when you submit the JCL job `BIPXIS`, which issues the docker run command.
      - *ACE_IMAGE*. You must set this environment variable for the framework to work.
      - *ACE_TAG*. You must set this environment variable for the framework to work.
   b) Submit the JCL job `BIPXIS`.
      The JCL job `BIPXIS` starts the integration server docker container by running the following command:

      ```
      docker run --name $SERVER_NAME $SERVER_RUN_OVERRIDE $ACE_IMAGE:$ACE_TAG
      ```
4. Optional: If you want to administer your integration server Docker container by using IBM z/OS console commands, you must set your integration server to write console log messages in *ibmjson* format. One way that you can set the format is to complete the following steps:
   a. **Set** *consoleLog* to **`true`**, and set *outputFormat* to **`ibmjson`** in the `server.conf.yaml` configuration file:

      ```
      Log:
                  consoleLog: true             # Control writing BIP messages to standard out.
       Set to true or false, default is true.
      ```

```
              outputFormat: 'ibmjson'      # Control the format of BIP messages written to
 standard out and file.
```

b. Set the environment variables in the environment file, BIPENVS. You must set the zCX access environment variables and all of the following environment variables:

- *SERVER_NAME*. The zCX processing assumes that the Docker container is called *SERVER_NAME* and it sets *SERVER_NAME* as the container name when it starts the container.
- *SERVER_RUN_OVERRIDE*. Specify the parameters, including port mappings to use when you submit the JCL job BIPXCLIS, which issues the docker run command.
- *ACE_IMAGE*. You must set this environment variable for the framework to work.
- *ACE_TAG*. You must set this environment variable for the framework to work.

c. Start the console listener task.

The console listener task starts the integration server Docker container by running the following command:

```
docker run --name $SERVER_NAME $SERVER_RUN_OVERRIDE $ACE_IMAGE:$ACE_TAG
```

Results

Your own image is built.

What to do next

You can then use either JCL or z/OS console commands to manage your integration servers and to run IBM App Connect Enterprise commands (with the naming convention *mqsi** or *ibmint**), as described in the following topics:

- “Administering IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) by using JCL” on page 3053
- “Administering IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands” on page 3056

Administering IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) by using JCL

IBM App Connect Enterprise IBM z/OS Container Extensions (zCX) enable z/OS customers to run IBM App Connect Enterprise in a docker container.

About this task

When the docker image is available to zCX, you can use JCL to administer IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX).

Procedure

Complete the steps in the following tasks to manage integration servers and run IBM App Connect Enterprise commands on IBM z/OS Container Extensions (zCX) by using JCL:

- “Starting an integration server on IBM z/OS Container Extensions (zCX) by using JCL” on page 3054
- “Stopping an integration server on IBM z/OS Container Extensions (zCX) by using JCL” on page 3054
- “Deleting an integration server on IBM z/OS Container Extensions (zCX) by using JCL” on page 3055
- “Running IBM App Connect Enterprise commands on IBM z/OS Container Extensions (zCX) by using JCL” on page 3055

Starting an integration server on IBM z/OS Container Extensions (zCX) by using JCL

Start an integration server on IBM z/OS Container Extensions (zCX) by running the JCL job BIPXIS.

About this task

You can use your own JCL files, or the JCL files that are supplied with IBM App Connect Enterprise on z/OS.

Procedure

1. Set the environment variables in `ENVFILE`, as described in "Environment variables in STDENV and BIPENVS" on page 3062. For more information about access options, see Configuring SSH access for IBM z/OS Container Extensions (zCX).
2. Customize the JCL job `BIPXIS` as advised in the job comments. For more information, see "Customizing the JCL" on page 3048.
3. Submit the job `BIPXIS`.

Results

The job `BIPXIS` runs, and the integration server is started. The integration server log messages are written to the job log in the format that you requested; `text`, `ibmjson`, or `idText`. The log messages continue to be written when the integration server runs.

What to do next

You can deploy resources to your integration server, and run IBM App Connect Enterprise commands against it. For more information, see Chapter 7, "Deploying integration solutions," on page 2463, and "Running IBM App Connect Enterprise commands on IBM z/OS Container Extensions (zCX) by using JCL" on page 3055.

Stopping an integration server on IBM z/OS Container Extensions (zCX) by using JCL

Stop an integration server on IBM z/OS Container Extensions (zCX) by running the JCL job BIPXISTP.

About this task

You can use your own JCL files, or the JCL files that are supplied with IBM App Connect Enterprise on z/OS.

Procedure

1. Set the environment variables in `ENVFILE`.

   For more information, see "Environment variables in STDENV and BIPENVS" on page 3062.
2. Customize the JCL job `BIPXISTP` as advised in the job comments. By default, the integration server stops by quiescing. If it fails to stop, you can customize `BIPXISTP` to use the **`force`** option. If you want to remove the integration server Docker container, you must append the parameter **`rm`** to the `stopace.sh` command in the JCL. For more information, see "Deleting an integration server on IBM z/OS Container Extensions (zCX) by using JCL" on page 3055, and "Customizing the JCL" on page 3048.
3. Submit the JCL job, BIPXISTP.

Results

The job `BIPXISTP` runs, and the integration server is stopped.

Deleting an integration server on IBM z/OS Container Extensions (zCX) by using JCL

Delete an integration server by running the JCL job BIPXISTP with the **rm** parameter.

About this task

You can use your own JCL files, or the JCL files that are supplied with IBM App Connect Enterprise on z/OS.

Procedure

1. Set the environment variables in ENVFILE.

   For more information, see "Environment variables in STDENV and BIPENVS" on page 3062.
2. Customize the JCL job BIPXISTP as advised in the job comments. To delete the integration server Docker container, use the `rm` command in docker by appending the parameter **rm** to the `stopace.sh` command in the JCL. If the integration server Docker container is running, it is stopped before it is deleted. For more information, see "Customizing the JCL" on page 3048.
3. Submit the JCL job, BIPXISTP.

Results

The JCL job BIPXISTP runs. The integration server is deleted.

Running IBM App Connect Enterprise commands on IBM z/OS Container Extensions (zCX) by using JCL

Run IBM App Connect Enterprise commands (with the naming convention *mqsi** or *ibmint**) on IBM z/OS Container Extensions (zCX) by using the JCL job, BIPXISCM.

Procedure

1. Set the environment variables in ENVFILE, as described in "Environment variables in STDENV and BIPENVS" on page 3062. For more information about access options, see "Configuring access to Integration Servers running in IBM z/OS Container Extensions (zCX) " on page 3071.
2. Customize the JCL job BIPXISCM as advised in the job comments. For more information, see "Customizing the JCL" on page 3048.

   For more information about the commands that are available on IBM App Connect Enterprise, see Runtime commands.

Some commands require parameters to specify the work directory of an independent integration server. For example, command - , , and systems requires you to specify **-w** *workDir*, or **--working-directory** *workDir*, depending on whether you decide to use the short names or the alternative long names for the parameters. For these commands, you must specify `/home/aceuser/ace-server` for *workDir*.

Some commands require parameters to specify the hostname or IP address of the computer on which the integration server is running, and the port on which the web user interface HTTP connection listener is listening. For example, command requires you to specify **-i** *ipAddress*, or **--admin-host** *ipAddress*, and **-p** *port*, or **--admin-port** *port*, depending on whether you decide to use the short names or the alternative long names for the parameters. For these commands, you must specify `0.0.0.0` for

ipAddress. For **-p** or **--admin-port**, you must specify the value that you set for *REST_PORT* in your environment file ENVFILE.

Some commands, for example `mqsideploy`, require one or more input files to first be made available on the docker container that runs the integration server. If the files are not available on the integration server docker container, you must use the BIPXPUT sample JCL to transfer them.

Some commands produce output. You can copy or move files from the integration server docker container by using the BIPXGET sample JCL.

BIPXPUT and BIPXGET always overwrite a file that is already there and always transfer in BINARY mode. IBM z/OS Container Extensions (zCX) run in *ASCII* mode. You can convert a file from *ASCII* to *EBCDIC* in UNIX System Services by using `iconv`. For example:

```
iconv -f ISO8859-1 -t IBM-1047 props.txt > props.ebcdic.txt
```

3. Optional: Customize the JCL job BIPXPUT as advised in the job comments. For more information, see "Customizing the JCL" on page 3048.
4. Optional: Customize the JCL job BIPXGET as advised in the job comments. For more information, see "Customizing the JCL" on page 3048.
5. Optional: Submit the JCL job BIPXPUT.
6. Submit the job BIPXISCM.
7. Optional: Submit the JCL job BIPXGET.

Results

1. If you submit the JCL job BIPXPUT, the job runs, and the input files are transferred.
2. When you submit the JCL job BIPXISCM, the job runs. The output from the IBM App Connect Enterprise command is displayed in the job log.
3. If you submit the JCL job BIPXGET, the job runs, and the output files are copied or moved.

What to do next

When you finish working with the IBM App Connect Enterprise commands, you can stop or delete the integration server. For more information, see "Stopping an integration server on IBM z/OS Container Extensions (zCX) by using JCL" on page 3054 and "Deleting an integration server on IBM z/OS Container Extensions (zCX) by using JCL" on page 3055.

Administering IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands

IBM App Connect Enterprise IBM z/OS Container Extensions (zCX) enable z/OS customers to run IBM App Connect Enterprise in a Docker container.

About this task

You can use IBM z/OS console commands to administer IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX).

Procedure

- "Copying the started task to the procedures library" on page 3057

Complete the steps in the following tasks to manage integration servers and run IBM App Connect Enterprise commands on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands:

- "Starting an integration server on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3058

- "Stopping an integration server on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3058
- "Deleting an integration server on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3059
- "Running IBM App Connect Enterprise commands on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3059

Copying the started task to the procedures library

Copy the started task to the procedures library and set the environment variables for the IBM z/OS console listener.

About this task

You can administer IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) by using console commands. You must set the necessary environment variables in your environment file. You must also run a supplied console listener program as a started task (one console listener program for each IBM App Connect Enterprise integration server). The console listener program is provided by the IBM z/OS Management Facility installation process, as described in "Installing and configuring IBM App Connect Enterprise on zCX" on page 3046.

Procedure

1. Optional: If you supply your own docker image, you must configure the integration server to output logs to the IBM App Connect Enterprise command line in *ibmjson* format.

   For more information, see "Building your own Docker image" on page 3052.
2. Set the environment variables that are specific to the console listener in your environment file:
   - `ACE_SCRIPTS_DIR` - set this variable to the UNIX System Services directory where the scripts are installed.
   - `SERVER_REUSE` - if you want the integration server to persist after it is stopped or if you want to reconnect to a stopped or running integration server, then set this variable to `yes`. By default, the integration server is deleted when the started task is stopped.

   For more information, see "Environment variables in STDENV and BIPENVS" on page 3062.
3. Copy the Started Task JCL into an appropriate procedures library, with the name that you agreed with the systems programmer.
   For example, copy `BIPXCLIS` into `USER.PROCLIB`. For more information, see "Planning and customization tasks on z/OS" on page 3061.
4. Customize the Started Task JCL according to the instructions in the job. For more information, see "Customizing the JCL" on page 3048.

What to do next

You can start and stop the integration server and run IBM App Connect Enterprise commands (with the naming convention *mqsi**) from the console. For more information, see the following topics:

- "Starting an integration server on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3058
- "Stopping an integration server on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3058
- "Deleting an integration server on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3059
- "Running IBM App Connect Enterprise commands on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3059

Starting an integration server on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands

Start an integration server on IBM z/OS Container Extensions (zCX) by using the IBM z/OS console listener.

Before you begin

- Set the necessary environment variables. For more information, see "Environment variables in STDENV and BIPENVS" on page 3062.
- Copy the started task JCL into an appropriate procedures library, with a name that you agreed with the systems programmer. For more information, see "Copying the started task to the procedures library" on page 3057.

Procedure

Run the console command to start the started task, which starts the integration server.
For example, if your started task is called `BIPXCLIS`, then run the following command:

```
/S BIPXCLIS
```

If the environment variable *SERVER_REUSE* is set to **yes**, the command reconnects to a running integration server Docker container or restarts a stopped one.

Results

The integration server is started. The integration server messages are written as BIP messages to ACELOG in the job log, and to the system log.

What to do next

You can deploy resources to your integration server, and run IBM App Connect Enterprise commands against it. For more information, see Chapter 7, "Deploying integration solutions," on page 2463 and "Running IBM App Connect Enterprise commands on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3059.

Stopping an integration server on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands

Stop an integration server on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands.

Before you begin

- Ensure that you set the necessary environment variables. Unless *SERVER_REUSE* is set to **yes**, the console command deletes the integration server Docker container. For more information, see "Environment variables in STDENV and BIPENVS" on page 3062.
- Copy the started task into the procedures library, as described in "Copying the started task to the procedures library" on page 3057.

Procedure

Run the console command to stop the started task, which stops the integration server.

For example:

```
/P BIPXCLIS
```

Results

The integration server is stopped. Unless *SERVER_REUSE* is set to **yes**, the console command deletes the integration server Docker container, and the Integration Server, as described in "Deleting an integration server on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3059.

What to do next

You can restart or delete the integration server by using IBM z/OS console commands. For more information, see "Starting an integration server on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3058, and "Deleting an integration server on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3059.

Deleting an integration server on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands

Delete an integration server docker container by using IBM z/OS console commands.

Before you begin

- Check the environment variables. Unless *SERVER_REUSE* is set to **yes**, the IBM z/OS console command deletes the integration server Docker container. For more information, see "Environment variables in STDENV and BIPENVS" on page 3062.
- Copy the started task into the procedures library, as described in "Copying the started task to the procedures library" on page 3057.

Procedure

Run the IBM z/OS console command to stop the started task, which stops the integration server docker container.

For example:

```
/P BIPXCLIS
```

Results

- The integration server docker container is stopped.
- Unless *SERVER_REUSE* was set to **yes**, the integration server docker container is deleted.

What to do next

If you stopped the integration server docker container with *SERVER_REUSE* set to **yes**, you can delete it by using JCL. For more information, see "Deleting an integration server on IBM z/OS Container Extensions (zCX) by using JCL" on page 3055.

Running IBM App Connect Enterprise commands on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands

Run IBM App Connect Enterprise commands on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands.

Before you begin

- Set the necessary environment variables. For more information, see "Environment variables in STDENV and BIPENVS" on page 3062.
- For more information about access options, see "Configuring access to Integration Servers running in IBM z/OS Container Extensions (zCX) " on page 3071.

- Copy the started task into the procedures library, as described in "Copying the started task to the procedures library" on page 3057.

About this task

You can run IBM App Connect Enterprise commands (with the naming conventions *mqsi** or *ibmint**) on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands. The IBM App Connect Enterprise command names are case-sensitive. The commands `mqsiAssemblyInstall`, `mqsicommandconsole`, `mqsicredentials`, and `mqsivault` are not supported on IBM z/OS Container Extensions (zCX).

Some commands, for example `mqsideploy`, require one or more input files to first be made available on the docker container that runs the integration server. If the files are not available on the integration server docker container, you must use the BIPXPUT sample JCL to transfer them.

Some commands produce output. You can copy or move files from the integration server docker container by using the BIPXGET sample JCL.

BIPXPUT and BIPXGET always overwrite a file that is already there and always transfer in BINARY mode. IBM z/OS Container Extensions (zCX) run in *ASCII* mode. You can convert a file from *ASCII* to *EBCDIC* in UNIX System Services by using `iconv`. For example, if you want to convert the *ASCII* file `props.txt` to *EBCDIC*, run the following command:

```
iconv -f ISO8859-1 -t IBM-1047 props.txt > props.ebcdic.txt
```

Procedure

1. Optional: If your command requires one or more input files to be available on the docker container that runs the integration server, customize the JCL job BIPXPUT as advised in the job comments. For more information, see "Customizing the JCL" on page 3048.
2. Optional: If your command produces output, customize the JCL job BIPXGET as advised in the job comments. For more information, see "Customizing the JCL" on page 3048.
3. Optional: Submit the JCL job BIPXPUT.
4. Run the IBM z/OS console command to run an IBM App Connect Enterprise command. Specify the name of your started task JCL, the name of the IBM App Connect Enterprise command that you want to run, and any parameters that are required.
   For example, if your started task is called BIPXCLIS, and you want to run the IBM App Connect Enterprise command `mqsiexplain`, with the parameter **3750**, run the following command:

   ```
   /F BIPXCLIS,APPL='mqsiexplain 3750'
   ```

   Some commands require parameters to specify the work directory of an independent integration server. For example, command - , , and systems requires you to specify **-w** *workDir*, or **--working-directory** *workDir*, depending on whether you decide to use the short names or the alternative long names for the parameters. For these commands, you must specify `/home/aceuser/ace-server` for *workDir*.

   Some commands require parameters to specify the hostname or IP address of the computer on which the integration server is running, and the port on which the web user interface HTTP connection listener is listening. For example, command requires you to specify **-i** *ipAddress*, or **--admin-host** *ipAddress*, and **-p** *port*, or **--admin-port** *port*, depending on whether you decide to use the short names or the alternative long names for the parameters. For these commands, you must specify `0.0.0.0` for *ipAddress*. For **-p** or **--admin-port**, you must specify the value that you set for *REST_PORT* in your environment file ENVFILE.

   For more information about the commands that are available on IBM App Connect Enterprise, see Runtime commands.
5. Submit the JCL job BIPXGET.

Results

The output of the command is written to *ACECMDS* in the job log.

What to do next

When you finish running commands, you can stop the integration server by using IBM z/OS console commands. For more information, see "Stopping an integration server on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3058.

Planning and customization tasks on z/OS

You must ensure that the planning and customization tasks on z/OS are completed.

Naming conventions

Decide upon a naming convention for your IBM z/OS Container Extensions (zCX) integration servers.

Each integration server must have a unique name. The Docker container in which the integration server runs, automatically uses the integration server's name as its container name. Therefore, each integration server must have a unique name for the zCX instance in which it runs.

Port allocation

Each integration server must have its own unique set of IBM App Connect Enterprise ports defined. The ports must be unique for the zCX instance on which the integration server runs:

- *REST*
- *HTTP*
- *HTTPS*
- *SSH*. For more information, see "Configuring access to Integration Servers running in IBM z/OS Container Extensions (zCX) " on page 3071.

Environment variable definition data sets

Define data sets to hold the environment variable definitions. For more information, see "Environment variables in STDENV and BIPENVS" on page 3062.

Authorizations

Ensure that the Authorization requirements are met. The z/OS users under which the JCL or the console listener run require access to the following items:

JCL

The user ID under which the JCL runs needs:

- An OMVS segment
- A home directory
- Access to `<hlq>.SACECNTL` JCL library (read)
- Access to the UNIX System Services directory that contains the installed scripts (read + execute)
- Access to environment variable definition data sets (read)
- Access to the ssh key ZCX_SSH_KEY (read), unless you use direct access to the integration server docker container. For more information, see "Configuring access to Integration Servers running in IBM z/OS Container Extensions (zCX) " on page 3071.

Console listener

If you want to administer IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands, you must set up the following environment for each integration server:

- Decide on the started task name for the integration server console listeners task. This name is used to set up started task authorizations, and to manage your system performance.
- Copy <hlq>.SACECNTL(BIPXCLIS) to the appropriate procedures library, for example USER.PROCLIB with the agreed name.
- Associate the started task procedure with the user ID to be used. For example, you can use the STARTED class in RACF.
- The started task user ID requires:
  - An OMVS segment
  - A home directory
  - Access to <hlq>.SACELOAD load library (read + execute)
  - Access to scripts (read + execute)
  - Access to environment variable definition data sets (read)
  - Access to the ssh key *ZCX_SSH_KEY* (read)
  - The started task writes integration server messages as BIP messages to the system log. To avoid BIP messages that have a prefix of BPXM023I (*userid*), the started task user ID also needs READ access to BPX.CONSOLE in the FACILITY class or equivalent.

Environment variables in STDENV and BIPENVS

You must set environment variables according to the task that you want to run. The values in the following sections are examples only.

The JCL and the console listener program drive shell scripts. When you submit the JCL jobs, the shell scripts are run under BPXBATCH, and the JCL job passes in an environment file that sets the environment variables. For JCL, the environment file is referred to as STDENV, and for the console listener program, the environment file is referred to as BIPENVS. For more information, see Passing environment variables to BPXBATCH.

You can put all the environment variables in one ENVFILE member or split them up into separate environment files. For example, you can have one member to specify the connection parameters, one member for build details, and one member for each integration server Docker instance for server port allocation.

The resources that you need to run IBM z/OS Container Extensions (zCX) need to be available on the z/OS UNIX System Services file system. The resources must be readable by the user ID under which the JCL or started task runs.

The values in the following sections are examples only.

Values for each zCX instance

Set the following values from the IBM z/OS Container Extensions (zCX) instance that you provision, as described in “Provisioning an IBM z/OS Container Extensions (zCX) instance” on page 3046.

- ZCX_IPADDR=9.20.2.2 - The IP address of the zCX instance to use
- ZCX_PORT=8022 - The SSH port of the zCX instance to use. Defaults to 8022 if unset. Not required for BIPXISCM, BIPXPUT, or BIPXGET if you use server ssh access. For more information, see “Configuring access to Integration Servers running in IBM z/OS Container Extensions (zCX) ” on page 3071.
- ZCX_USER=zcxuser - The user ID under which to access the zCX instance. Not required for BIPXISCM, BIPXPUT, or BIPXGET if you use server ssh access. For more information, see “Configuring access to Integration Servers running in IBM z/OS Container Extensions (zCX) ” on page 3071.
- ZCX_SSH_KEY=/u/aceadmin/.ssh/id_rsa - The SSH key to be used to access the zCX instance as ZCX_USER. Not required for BIPXISCM, BIPXPUT, or BIPXGET if you use server ssh access. For more

information, see “Configuring access to Integration Servers running in IBM z/OS Container Extensions (zCX) ” on page 3071.

Values for building the Docker image

Set the following values before you submit the JCL job BIPXBLD.

- ACE_DOWNLOAD_PACKAGE_DIR=/u/aceadmin. The directory that holds the downloaded IBM App Connect Enterprise Linux on IBM Z package.
- ACE_DOWNLOAD_PACKAGE_NAME=ace-aceserver1-s390x.tar.Z. The name of the downloaded IBM App Connect Enterprise Linux on IBM Z package.
- ACE_DOCKER_IMAGE_BAR_DIR=/u/aceadmin/bars. This environment variable is optional. If it is set along with ACE_DOCKER_IMAGE_BAR_NAME, build processing includes the BAR file in the built Docker image to be made available when the integration server Docker container is run.
- ACE_DOCKER_IMAGE_BAR_NAME=*zcx.bar* . This environment variable is optional. If it is set along with ACE_DOCKER_IMAGE_BAR_DIR, build processing includes the BAR file in the built Docker image to be made available when the integration server Docker container is run.
- ACE_DOCKER_IMAGE_YAML_DIR=/u/aceadmin. This environment variable is optional. If it is set along with ACE_DOCKER_IMAGE_YAML_NAME, the integration server Docker container that uses this image uses this directory to find its server.conf.yaml configuration file.
- ACE_DOCKER_IMAGE_YAML_NAME=server.conf.yaml. This environment variable is optional. If it is set along with ACE_DOCKER_IMAGE_YAML_DIR, the integration server Docker container that uses this image uses this file as its server.conf.yaml configuration file.
- ACE_IMAGE=ace_jenkins_2020-06-15_09:59:01.957539. The name of the Docker image to be built.
- ACE_TAG=testing. The tag of the Docker image to be built. The default value is *latest*.
- SERVER_ACCESS_SSH_PUBLIC_KEY=/u/aceadmin/.ssh/aceserver1_rsa.pub. This environment variable is optional. The public key of the private/public key pair used to provide direct access to the integration server Docker container. For more information about ssh access, see “Configuring access to Integration Servers running in IBM z/OS Container Extensions (zCX) ” on page 3071.
- If you want to include the IBM MQ Client in the Docker image to be made available when the integration server Docker container is run, you must set the environment variables *ACE_DOCKER_IMAGE_MQCLIENT_TAR_DIR*, and *ACE_DOCKER_IMAGE_MQCLIENT_TAR_NAME*:
- ACE_DOCKER_IMAGE_MQCLIENT_TAR_DIR=/u/aceadmin/tars. This environment variable is optional. If you set it, you must also set ACE_DOCKER_IMAGE_MQCLIENT_TAR_NAME.
- ACE_DOCKER_IMAGE_MQCLIENT_TAR_NAME=9.2.0.0-IBM-MQC-UbuntuLinuxS390X.tar.gz. This environment variable is optional. If you set it, you must also set ACE_DOCKER_IMAGE_MQCLIENT_TAR_DIR.

Values for loading a Docker image from a .tar archive by submitting the JCL job BIPXDLI

- ACE_DOCKER_IMAGE_TAR_DIR=/u/aceadmin. The directory that contains the .tar archive file to be loaded as a Docker image. Ensure that the image to be loaded was saved by *repository*/*tag*, so that when the image is loaded, it has a repository and tag to set as *ACE_IMAGE/ACE_TAG*.
- ACE_DOCKER_IMAGE_TAR_NAME=ace-s390x.tar. The name of the .tar archive file to be loaded as a Docker image. Ensure that the image to be loaded was saved by *repository*/*tag*, so that when the image is loaded, it has a repository and tag to set as *ACE_IMAGE/ACE_TAG*.

Values for starting an integration server

- ACE_IMAGE=*ali.zcx*. The name of the Docker image to be used to run the integration server Docker container.

- ACE_TAG=*latest*. The tag of the Docker image to be used to run the integration server Docker container. The default value is *latest*.
- SERVER_NAME=*ace1*. The name of the integration server. The default value is *ace1*.
- REST_PORT=*port*. The number of the port to be used as the integration server's REST administration port. The default value is 7600. If you do not want to expose a REST administration port, set this value to 0. The value must be unique for everything that runs in the zCX instance.
- HTTP_PORT=*port*. The port number for the integration server's HTTP listener. The default value is 7800. If you do not want to expose an HTTP port, set this value to 0. The value must be unique for everything that runs in the zCX instance.
- HTTPS_PORT=*port* . The port number for the integration server's HTTPS listener. The default value is 7843. If you do not want to expose an HTTPS port, set this value to 0. The value must be unique for everything that runs in the zCX instance. Default is 7843.
- SERVER_REUSE=*yes/no*. Valid values are yes and no. The default value is no. You can set SERVER_REUSE to yes to allow processing to restart or reattach to an existing integration server container or start a new one. If you restart an integration server, the original input settings are used even if they were changed. If SERVER_REUSE is set to yes, the console listener does not attempt to remove the stopped integration server Docker container when the started task ends.

  SERVER_REUSE=yes

  When you run BIPXIS or the console listener, it checks whether an instance of the integration server container exists. One of the following events takes place:

  – If the integration server exists and is running, its logs are reattached to the new task.
  – If the integration server exists and is stopped, it is started and attached to the new task.
  – If the integration server does not exist, an attempt is made to start a new integration server container.

  When the console listener ends, it stops the integration server container but does not delete it.

  If you run BIPXIS or the console listener again, the integration server is restarted.

  SERVER_REUSE=no

  When you run BIPXIS or the console listener, an attempt is made to start a new integration server container.

  When the console listener ends, it stops the integration server container and deletes it.

  The integration server is not restarted if you run BIPXIS or the console listener.
- SERVER_ACCESS_SSH_PORT=*port*. The number of the port to be used as the integration server docker container's SSH port. The value must be unique for every docker container that runs on the zCX instance. For more information, see “Configuring access to Integration Servers running in IBM z/OS Container Extensions (zCX) ” on page 3071.
- SERVER_RUN_OVERRIDE= -p 7604:7604 -p 7804:7804 -p 7844:7843 -e LICENSE=accept. If you build your own image by using your own processing methods, specify the parameters, including port mappings to use when you issue the docker run. For more information, see “Building your own Docker image” on page 3052.

Integration server ports

If you do not want to expose a port for HTTP_PORT, HTTPS_PORT, or REST_PORT, set the value to 0.

These port numbers are for the ports that are made available outside of the integration server Docker container. For the HTTP and admin ports, to ensure that the internal port numbers that are reported in messages and statistics match these external port numbers, their internal port settings are overridden when you start the integration server. Do not set these port settings in server.conf.yaml because they are overridden. You cannot override the HTTPS port in this way. If you need to match internal and external port numbers for HTTPS, use the default value.

- SERVER_NAME. The name of the integration server. The default value is *ace1*.
- SERVER_ACCESS_SSH_PORT=*port*. This environment variable is optional. The number of the port to be used as the integration server docker container's SSH port. The value must be unique for every docker container that runs on the zCX instance.
- SERVER_ACCESS_SSH_KEY=/u/aceadmin/.ssh/aceserver1_rsa. This environment variable is optional. The private key of the private/public key pair used to provide direct access to the integration server Docker container.

For more information about ssh access, see "Configuring access to Integration Servers running in IBM z/OS Container Extensions (zCX) " on page 3071.

ACE_DEBUG

Specify this option only if you are directed to do so by your IBM service representative.

Environment variables that are addressed by STDENV and BIPENVS:

Environment variable name	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	BIPXPUT	BIPXGET	BIPXDBG	Console listener

ACE_DEBUG				

Configuring access to Integration Servers running in IBM z/OS Container Extensions (zCX)

If you use the supplied processing to build a docker image, you can choose from two methods to provide access to the running integration server. Which method you choose, depends on the level of access that you want to give to users who run IBM App Connect Enterprise commands by using the supplied JCL.

About this task

Users need to access the zCX instance to interact with the integration server Docker container. Users who want to start, stop and delete integration servers, or maintain images, need to access the zCX instance by using the *ZCX_SSH_KEY*. You might prefer not to give this access to users who need only to access running integration servers and run IBM App Connect Enterprise commands. Instead, you can give those users ssh access directly into the integration server docker container without using the *ZCX_SSH_KEY*.

Procedure

Configure SSH access for IBM z/OS Container Extensions (zCX) by completing one of the following steps:

1. Optional: You can provide full access to the zCX instance by using the *ZCX_SSH_KEY*. Users who have this level of access can complete the following tasks:
   - Access a running integration server
   - Create, start, stop, and delete an integration server.
   - Maintain images.
   - Run IBM App Connect Enterprise commands.
   - Submit the JCL jobs BIPXPUT and BIPXGET

   To provide full access to the zCX instance by using the *ZCX_SSH_KEY*, complete the following steps:
   - Create an environment file ENVFILE.
   - Set the following environment variables in the environment file ENVFILE that you created:
   - – ZCX_SSH_KEY
     – ZCX_SSH_PORT
     – ZCX_SSH_USER

2. Optional: You can provide access directly into the integration server docker container without using the *ZCX_SSH_KEY*. Users who have this level of access can complete the following tasks:
   - Access a running integration server
   - Run IBM App Connect Enterprise commands.
   - Submit the JCL jobs BIPXPUT and BIPXGET

   To provide access directly into the integration server docker container without using the *ZCX_SSH_KEY*, complete the following steps:

   a. Before you create the integration server Docker image by running the JCL job BIPXBLD as described in "Creating an IBM App Connect Enterprise Integration Server Docker image on IBM z/OS Container Extensions (zCX) by using the supplied JCL" on page 3049, you must create an SSH key pair as described in "Provisioning an IBM z/OS Container Extensions (zCX) instance" on page 3046 but with different name. For example, run the following command:

   ```
   ssh-keygen -t rsa -b 4096 -C "your_email@domain.com" -f aceserver1_rsa
   ```

   In this example, the private key is named *aceserver1_rsa*, and the public key is named *aceserver1_rsa.pub*.

   You can create separate keys for each integration server or share keys over multiple or all integration servers, depending on your access security needs. Each key pair needs its own integration server Docker image that contains the appropriate public key.

   b. Before you create the integration server Docker image by running the JCL job BIPXBLD as described in "Creating an IBM App Connect Enterprise Integration Server Docker image on IBM z/OS Container Extensions (zCX) by using the supplied JCL" on page 3049, you must set the *SERVER_ACCESS_SSH_PUBLIC_KEY* environment variable. Set *SERVER_ACCESS_SSH_PUBLIC_KEY* to the name of the file that contains the public key. For example, `/u/aceadmin/.ssh/aceserver1_rsa.pub`.

   c. Before you use the image that you built in the previous step to start an integration server, as described in "Starting an integration server on IBM z/OS Container Extensions (zCX) by using JCL" on page 3054, and "Starting an integration server on IBM z/OS Container Extensions (zCX) by using IBM z/OS console commands" on page 3058, you must set the environment variable *SERVER_ACCESS_SSH_PORT*. Set *SERVER_ACCESS_SSH_PORT* to specify a port number to use for ssh access to the integration server Docker container. The port number must be unique over everything that runs in that zCX instance. When the integration server Docker container starts, it also starts an ssh server that listens on the port that you specified.

   d. When you run IBM App Connect Enterprise commands by submitting the JCL job BIPXISCM, BIPXPUT, or BIPXGET, as described in "Running IBM App Connect Enterprise commands on IBM z/OS Container Extensions (zCX) by using JCL" on page 3055, do not specify *ZCX_USER* or *ZCX_SSH_KEY* in the environment variables file that is referenced by the JCL jobs.

   Set the *SERVER_ACCESS_SSH_PORT* environment variable to the port that you set when you started the integration server Docker container.

   Set the *SERVER_ACCESS_SSH_KEY* environment variable to the file that contains the private key that is associated with the public key that is built into the image. For example, `/u/aceadmin/.ssh/aceserver1_rsa`.

   If you set *SERVER_ACCESS_SSH_PORT*, only server SSH access is attempted, even if the zCX credentials are also specified. If neither are specified, the IBM App Connect Enterprise command fails.

What to do next

You can then use the supplied JCL to manage your integration servers and to run IBM App Connect Enterprise commands. For more information, see "Administering IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) by using JCL" on page 3053.

Troubleshooting on IBM z/OS Container Extensions (zCX)

Investigate and resolve errors on IBM z/OS Container Extensions (zCX).

About this task

You can use various techniques to diagnose and fix errors that occur when you run IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX).

Procedure

Environment variables

- Check the *STDOUT* and *STDERR* in the job log for errors that report missing or incorrect environment variables.

  Edit the ENVFILE to address these errors. For more information, see "Environment variables in STDENV and BIPENVS" on page 3062.

Space

- Check the *STDOUT* and *STDERR* in the job log for error messages about lack of disk space.

  Customize and run the JCL job BIPXDSP. The job BIPXDSP removes all unused containers, unused networks, and used images (both dangling and unreferenced). For more information, see "Customizing the JCL" on page 3048.

BIPXBLD

BIPXBLD fails to unzip or untar the IBM App Connect Enterprise or MQClient packages.

- Check the *STDOUT* and *STDERR* in the job log for error messages that are related to unzipping or untarring the IBM App Connect Enterprise or MQClient packages.

  Do not to use Secure Copy Protocol (SCP) to transfer the package. SCP assumes that files are text, so binary files that are copied between EBCDIC and ASCII operating systems are corrupted during the copying process.

BIPXBLD fails to install the IBM App Connect Enterprise or the MQClient packages.

- Check the *STDOUT* and *STDERR* in the job log for error messages that are related to installing the IBM App Connect Enterprise or MQClient packages.

  Ensure that the tar file is for the *Client deb install packages for IBM MQ on Ubuntu on z Systems*, and not the *Client rpm install packages for IBM MQ on Linux for z Systems*.

Docker container issues

- Submit the JCL job BIPXDBG to obtain more information on the docker container in which the integration server is expected to run.

Console listener issues

The console listener task does not work.

- Check whether the integration server is running, by submitting the JCL job BIPXDBG, and checking the output.
  - If the integration server is stopped, cancel the console listener task.
  - If the integration is running, submit the JCL job BIPXSTP to stop it, or delete it.

The console listener fails with RC=3584.

- Check whether the user ID under which the console listener runs has execute access to the supplied scripts specified in the *ACE_SCRIPTS_DIR* environment variable.

  For more information, see "Environment variables in STDENV and BIPENVS" on page 3062.

Applying maintenance to IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX)

Apply maintenance to and install fix packs on IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX) to obtain service updates and fixes.

About this task

Service updates and other fixes are delivered occasionally in the form of APARS or fix packs. You can find information about available fix packs on the IBM App Connect Enterprise support web page.

Procedure

To apply maintenance to the IBM App Connect Enterprise package in the integration server Docker image, complete one of the following steps, depending on how you built your integration server Docker image.

- Optional: If you built your integration server Docker image by using the supplied JCL, you must complete the following steps. Run the steps on the new image that you download:
  a) Find details of the appropriate APAR or fix pack from the IBM App Connect Enterprise support web page and download it.
  b) Place the downloaded APAR or fix pack in the UNIX System Services file system on z/OS.
  c) Create a new integration server Docker image from the downloaded APAR or fix pack by using the supplied JCL, as described in “Creating an IBM App Connect Enterprise Integration Server Docker image on IBM z/OS Container Extensions (zCX) by using the supplied JCL” on page 3049.
  d) Start an integration server on IBM z/OS Container Extensions (zCX) to use the newly created image by running the JCL job BIPXIS, as described in “Starting an integration server on IBM z/OS Container Extensions (zCX) by using JCL” on page 3054.
- Optional: If you built your integration server Docker image by using your own processing methods, you must complete the following steps:
  a) Build your own Docker image by using your own processing methods, as described in “Building your own Docker image” on page 3052.
  b) Start an integration server on IBM z/OS Container Extensions (zCX) to use the newly created image by running the JCL job BIPXIS, as described in “Starting an integration server on IBM z/OS Container Extensions (zCX) by using JCL” on page 3054.

To apply maintenance to the MQClient libraries in the integration server Docker image, complete one of the following steps, depending on how you built your integration server Docker image:

- Optional: If you built your integration server Docker image by using the supplied JCL, you must complete the following steps. Run the steps on the new image that you download:
  a) Download IBM MQ v9.2 or later Client deb install packages for IBM MQ on Ubuntu on z Systems from Fix Central.
  b) Place the downloaded IBM MQ Client installation package in the UNIX System Services file system on z/OS.
  c) Set the environment variables *ACE_DOCKER_IMAGE_MQCLIENT_TAR_DIR*, and *ACE_DOCKER_IMAGE_MQCLIENT_TAR_NAME* to point to the newly downloaded version of the MQClient.
  For example:

```
ACE_DOCKER_IMAGE_MQCLIENT_TAR_DIR=/u/aceadmin/tars
```

```
ACE_DOCKER_IMAGE_MQCLIENT_TAR_NAME=9.2.0.0-IBM-MQC-UbuntuLinuxS390X.tar.gz
```

  d) Create a new integration server Docker image to include the new IBM MQ Client by using the supplied JCL, as described in "Creating an IBM App Connect Enterprise Integration Server Docker image on IBM z/OS Container Extensions (zCX) by using the supplied JCL" on page 3049.
  e) Start an integration server on IBM z/OS Container Extensions (zCX) to use the newly created image by running the JCL job BIPXIS, as described in "Starting an integration server on IBM z/OS Container Extensions (zCX) by using JCL" on page 3054.
- Optional: If you built your integration server Docker image by using your own processing methods, you must complete the following steps.
  a) Build your own Docker image by using your own processing methods, as described in "Building your own Docker image" on page 3052.
  b) Start an integration server on IBM z/OS Container Extensions (zCX) to use the newly created image by running the JCL job BIPXIS, as described in "Starting an integration server on IBM z/OS Container Extensions (zCX) by using JCL" on page 3054.

To apply maintenance to IBM App Connect Enterprise on IBM z/OS Container Extensions (zCX), complete the following steps:

- Download the required maintenance from Fix Central and make it available on your z/OS system.
- Log on to the IBM z/OS Management Facility for your z/OS system.
- Install the maintenance by following the IBM z/OS Management Facility Software Update process described in Software Update task.

What to do next

Migration of runtime changes is not supported. For example, if you deployed a bar file to the integration server before you applied maintenance, you must redeploy it.

Notices

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing
IBM Corporation
North Castle Drive
Armonk, NY 10504-1785
U.S.A.

For license inquiries regarding double-byte (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

IBM World Trade Asia Corporation
Licensing 2-31 Roppongi 3-chome, Minato-ku
Tokyo 106-0032, Japan

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law: INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some states do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM Web sites are provided for convenience only and do not in any manner serve as an endorsement of those Web sites. The materials at those Web sites are not part of the materials for this IBM product and use of those Web sites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

IBM Corporation
Software Interoperability Coordinator, Department 49XA
3605 Highway 52 N
Rochester, MN 55901
U.S.A.

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this information and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement, or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs.

If you are viewing this information softcopy, the photographs and color illustrations may not appear.

Programming interface information

Programming interface information, if provided, is intended to help you create application software for use with this program.

However, this information may also contain diagnosis, modification, and tuning information. Diagnosis, modification and tuning information is provided to help you debug your application software.

Important: Do not use this diagnosis, modification, and tuning information as a programming interface because it is subject to change.
