IBM App Connect Enterprise
12.0

IBM App Connect Enterprise 12.0; User Guide

Note

Before using this information and the product it supports, read the information in “Notices” on page 3077.

Contents

Chapter 1. Planning your IBM App Connect Enterprise solution

Use the topics in this section to help you plan your implementation of IBM® App Connect Enterprise.

Finding the latest information

Access the latest information for IBM App Connect Enterprise, including system requirements and product documentation.

About this task

The following information is provided:

System requirements web page
For the latest details of hardware requirements, operating systems, and software requirements on all supported platforms, visit the IBM App Connect Enterprise system requirements web page.

`readme.html` file
The product `readme.html` file is frequently updated and includes information about last-minute changes and known problems and work-arounds. You can find the current readme file at https://www.ibm.com/support/pages/node/318359.

Supporting programs for web page
For a list of supporting program versions for IBM App Connect Enterprise 12.0, IBM App Connect Enterprise for Developers 12.0, and IBM App Connect Standard 12.0, see Supporting programs for IBM App Connect.

Online documentation
The main source of product documentation is online at https://www.ibm.com/docs/app-connect/12.0, which is also accessible from the IBM App Connect Enterprise Toolkit with an internet connection.

Understanding your data and message processing requirements

It is important to be clear about your processing requirements, and to understand what you want IBM App Connect Enterprise to do for your business.

About this task

In a typical IT environment there are many interacting components, each with a role to play, and it is important that you are able to clearly define the role of IBM App Connect Enterprise in the broader environment. A key design decision is how much business logic to implement within your message flows. IBM App Connect Enterprise enables you to implement large amounts of processing within a message flow, and implementations can vary significantly from the simple routing of messages to complex validation and transformation. Some implementations also read data from a database and use that data to populate messages. Regardless of the amount of function that you decide to implement in a message flow, it is important to have clear boundaries between pieces of application processing.

Several different processing styles are commonly used with IBM App Connect Enterprise, and it is important to understand the ones that are most relevant to you, such as:

Request Reply
This is the most common type of processing, and enables two applications to communicate, even if they use different data formats. For example, a message flow transforms a request message from Application 1 into a format that Application 2 can understand. The output of the first message flow is then sent to Application 2, which processes the request and issues a reply. The reply is processed in a second message flow, which converts the response message into a format that Application 1 can understand.

Aggregation
This type of processing is often used to invoke one or more back-end systems and coordinate replies. It is a more complex form of a Request Reply case, in which all the replies from the intermediate applications must be collected together before the reply message for the original request can be sent. For example, this type of processing could be used to book a holiday, in which a flight, hotel, and a car are required, and all must be successfully processed before the holiday confirmation can be sent.

Routing
Routing is used to redirect messages, and one or more copies of a message can be sent to one or more destinations.

Transformation
This type of processing involves the use of one or more transformation technologies such as Compute, JavaCompute, XMLT, or Mapping node. In this type of processing the input message is processed according to some business rules, and there might also be a change of message format or protocol.

File processing
The use of files is one of the most common methods of storing data. You can create message flows to process data in files, accepting data in files as input message data, and producing output message data for file-based destinations.

Database handling
You can configure your message flows to access and manipulate business data in databases.

Web services
IBM App Connect Enterprise can be used as both a consumer and provider of web services.

Transport switching
You can use this type of processing to switch between transports such as HTTP and JMS.

For information about how to choose the appropriate edition of IBM App Connect Enterprise to suit your requirements, see "Choosing your IBM App Connect Enterprise edition and operation mode" on page 2. For more information about the capabilities provided by IBM App Connect Enterprise, see features.

Choosing your IBM App Connect Enterprise edition and operation mode

The capability and capacity provided by IBM App Connect Enterprise vary according to the operation mode in which your integration servers are running, and your entitlement to run in a particular mode depends on the edition of the product that you have purchased.

About this task

You can choose the mode of operation based on the functionality and capacity that you require. You must ensure that your use and configuration of the product conforms to the license agreement that you have purchased. Some features of IBM App Connect Enterprise have specific requirements, such as the availability of an additional product, such as a database.

The following topics describe the features that are available, together with additional requirements and restrictions:

- features
- "Operation modes" on page 3
- "Restrictions that apply in each operation mode" on page 5

For more information about the license requirements for each operation mode, see "License requirements" on page 5.

Operation modes

The operation mode that you can use for your integration servers is determined by the license that you purchase.

The following modes are supported:

- "Advanced mode" on page 3. All features are enabled and no restrictions or limits are imposed. This mode is the default mode, unless you have the Developer Edition.
- "Nonproduction mode" on page 3. All features are enabled and no functional limits are imposed, but you can use the product for evaluation, development, and test purposes only.
- "Nonproductionfree mode" on page 4. All features are enabled and no functional limits are imposed, but you can use the product for development and functional testing purposes only (not for performance, scalability, or security testing).
- "Developer mode" on page 4. All features are enabled, but you can use the product for evaluation, development, and test purposes only. Developer Edition is limited to one message (transaction) per second at the message flow level.
- "Standard mode" on page 4. All features are enabled. If you are using an integration node, you can associate only one integration server with it, but the number of message flows that you can deploy to it is unlimited.

Operation modes typically restrict the number of message flow nodes that are available, and integration server capacity, but many features are available across all modes of operation. For an overview of the main IBM App Connect Enterprise capabilities, see features.

You must ensure that your integration servers are running in the operation mode for which you have purchased a license.

If you have purchased a license for the full package or the Standard Edition, your integration servers are automatically created in `advanced` mode unless you specify the correct mode for your license.

Change the mode of your integration node to conform to your license if necessary; see "Changing the operation mode" on page 86. You can also report the current mode of your integration node; see "Checking the operation mode" on page 87.

The IBM App Connect Enterprise Toolkit remains the same in all modes. All the capabilities of the IBM App Connect Enterprise Toolkit are available in all modes. If you try to deploy too many message flows or integration servers for the mode, or try to use a message flow node that is not valid in the mode, the operation is rejected, and an error message is displayed indicating the reason for the failure; see "Restrictions that apply in each operation mode" on page 5. Restrictions for a given mode also apply to the use of message flows generated by IBM App Connect Enterprise patterns.

If you intend to use the IBM App Connect Enterprise features that require MQ functionality, you can install and use IBM MQ within the terms of your IBM App Connect Enterprise license. For more information about using IBM MQ with IBM App Connect Enterprise, see "Installing IBM MQ" on page 96.

Advanced mode

In `advanced` mode, all features are enabled, and there are no operational limits on the creation of integration servers or on the number of flows that are deployed to an individual integration server. If you want to use all or most of the features available, your integration servers must operate in this mode, and you therefore require the full license. If you do not specify another mode, your integration servers have the mode set to the default value, which is `advanced`.

Nonproduction mode

In `nonproduction` mode, all features are enabled. You can use all available function, and no limits are imposed on the number of resources that you can create or the rate at which messages can be processed. The functions that are available in `nonproduction` mode are the same as in `advanced` mode, but `nonproduction` mode can be used for evaluation, development, and test purposes only. When you are

ready to move to a production environment, you will need to obtain the full IBM App Connect Enterprise license and change your integration servers to `advanced` mode.

Nonproductionfree mode

In `nonproductionfree` mode, all features are enabled. You can use all available function, and no limits are imposed on the number of resources that you can create or the rate at which messages can be processed. The functions that are available in `nonproductionfree` mode are the same as in `advanced` mode, but `nonproductionfree` mode can be used for development and functional testing purposes only. For non-functional testing (including performance, scalability, and security testing), you must use `nonproduction` mode and obtain a license for that mode. When you are ready to move to a production environment, you will need to obtain the full IBM App Connect Enterprise license and change your integration servers to `advanced` mode. For more information about license agreements, contact your IBM representative.

Developer mode

In `developer` mode, all features are enabled. You can use all available function, and you are not limited in the number of resources that you can create and maintain. IBM App Connect Enterprise for Developers (Developer Edition) is provided for evaluation, development, and test purposes only.

Developer Edition is limited to one message (transaction) per second at the message flow level. Each message flow is able to process one message per second, irrespective of the number of input nodes that are attached to the message flow, or the number of additional instances. When using Developer Edition, if a policy is deployed to increase the message rate throughput above one message per second, a message is reported in the syslog and event log stating that the message rate cannot be changed in Developer Edition. The policy that is deployed has no effect on the message rate.

You can download Developer Edition at no charge from https://www.ibm.com/marketing/iwm/iwm/web/dispatcher.do?source=swg-wmbfd, and you are free to use it for as long as you require, within the terms of the license. There is no expiry period for the Developer Edition license.

When you have installed Developer Edition, if you subsequently purchase a license and install the full version of IBM App Connect Enterprise, any Developer mode integration servers that are started with the full version are treated as Advanced mode integration servers. In this case, you must also modify the operation mode of these integration servers by using the **`mqsimode`** command to reflect the license that you have purchased. For more information, see “Changing the operation mode” on page 86.

Standard mode

In `standard` mode, all features are enabled. Use this edition if you expect to use all or most of the features that are available, but intend to configure a limited environment because of low capacity requirements.

You can use all the available functions, but are limited in the number of resources that you can create and maintain. You can associate only one integration server with an integration node; for more information, see “Restrictions that apply in each operation mode” on page 5. If you attempt to exceed the limits of this mode, the deployment is rejected.

Development and unit test

Your license also covers use of the product for development and unit test purposes, but check the license to ensure that you conform to any restrictions for development and unit test. You can view the license for IBM App Connect Enterprise by visiting the Software license agreements search website. Search for "IBM App Connect Enterprise" and choose the license that applies to the version you are using.

Contact your IBM representative if you want further details about license agreements, or if you want to purchase additional licenses or change the type of license that you have purchased.

Integration with Tivoli License Manager

If you use IBM Tivoli® License Manager to control and manage your licensed software products, you must ensure that you choose the correct license for the IBM App Connect Enterprise edition that you have purchased. For more information, see “Installing IBM License Metric Tool” on page 100.

Restrictions that apply in each operation mode

The operation mode in which you are running your installation of IBM App Connect Enterprise determines how many integration servers you can use, and the purposes for which you can use the product.

Advanced mode

All features are enabled, and there is no limit to the number of integration servers or the number of message flows that can be deployed to each integration server.

For more information about the features that are available in IBM App Connect Enterprise, see features.

Nonproduction mode

All features are enabled, and no limits are imposed on the number of resources that you can create or the rate at which messages can be processed. The functions that are available in `nonproduction` mode are the same as in `advanced` mode, but `nonproduction` mode can be used for evaluation, development, and test purposes only.

Nonproductionfree mode

All features are enabled, and no limits are imposed on the number of resources that you can create or the rate at which messages can be processed. The functions that are available in `nonproductionfree` mode are the same as in `advanced` mode, but `nonproductionfree` mode can be used for development and functional testing purposes only. For non-functional testing (including performance, scalability, and security testing), you must use `nonproduction` mode and obtain a license for that mode.

Developer mode

All features are enabled for an unlimited time, but you can use the product for evaluation purposes only (within the terms of the license). IBM App Connect Enterprise for Developers, which is also known as Developer Edition, is restricted to processing one message (transaction) per second. For more information, see “Operation modes” on page 3.

Standard mode

All features are enabled. If you are using an integration node, you can associate only one integration server with it, but the number of message flows that you can deploy to it is unlimited.

License requirements

You must ensure that your use and configuration of the product conforms to the license agreement that you have purchased.

The following list shows the IBM App Connect Enterprise operation modes that can be used with each of the IBM App Connect Enterprise license agreements:

IBM App Connect Enterprise for Developers (Developer Edition)
`developer` mode

IBM App Connect Enterprise Standard Edition
`standard` mode

IBM App Connect Enterprise (unrestricted license)
`advanced` mode

`developer` mode

`standard` mode

For more information, see “Operation modes” on page 3.

If you choose to change your license agreement from a full license to one of the specialized licenses, you might find that your current configuration is no longer supported. For further details about what features are available for each license, and how to configure your environment, see technical overview.

You can upgrade to the full license from another edition, if appropriate, by purchasing another license.

When you purchase a license for IBM App Connect Enterprise, your license entitles you to install and use IBM MQ, which enables you to use the IBM App Connect Enterprise features that require MQ functionality. For more information about using IBM MQ with IBM App Connect Enterprise, see “Installing IBM MQ” on page 96.

You can view the full license for IBM App Connect Enterprise by visiting the Software license agreements search website. Search for "IBM App Connect Enterprise" and choose the license that applies to the version you are using.

You can view licenses after installation in your chosen language in directory *install_dir*`/server/license/`. Terms and conditions are also supplied for third-party products that are used by IBM App Connect Enterprise. The file containing these details is stored in the same license subdirectory when you install one or more runtime components.

Contact your IBM representative if you want further details about license agreements, or if you want to purchase additional licenses or change the type of license that you have purchased.

Installing IBM License Service and adding annotations for IBM App Connect Enterprise containers

If you create your own container with IBM App Connect Enterprise, you must install an IBM License Service operator and add annotations to your container to ensure that you comply with the IBM licensing requirements.

License Service is required for monitoring and measuring license usage of IBM App Connect Enterprise in accordance with the pricing rule for containerized environments. You must deploy License Service on all clusters where IBM App Connect Enterprise is installed. Manual license measurements are not allowed. License annotations let you track usage based on the limits defined on the container, rather than on the underlying machine. You configure your clients to deploy the container with specific annotations that the IBM License Service then uses to track usage.

The integrated licensing solution collects and stores the license usage information, which can be used for audit purposes and for tracking license consumption in cloud environments. The solution works in the background and does not require any configuration. Only one instance of the License Service is deployed per cluster regardless of the number of Cloud Paks and containerized products that you have installed on the cluster.

You must deploy License Service on each cluster where IBM App Connect Enterprise is installed. License Service can be deployed on any Kubernetes cluster. For more information about License Service, including how to install and use it, see the License Service documentation.

To ensure license reporting continuity for license compliance purposes, ensure that License Service is successfully deployed and periodically verify whether it is active. For example, to validate whether License Service is deployed and running on the cluster, you can log in to the cluster and run the following command:

```
`kubectl get pods --all-namespaces | grep ibm-licensing | grep -v operator`
```

The following response is a confirmation of successful deployment:

```
1/1     Running
```

For more information about the supported environments and installation instructions, see the ibm-licensing-operator page on GitHub. For further information about IBM container licenses, see the IBM Container Licenses page on Passport Advantage.

IBM License Service is installed on the Kubernetes cluster where the IBM App Connect Enterprise container is deployed, and pod annotations are used to track usage. Clients must be configured to deploy the pod with specific annotations that the IBM License Service uses. Based on your entitlement and capabilities deployed within the container, use one or more of the following annotations:

- "IBM App Connect Enterprise" on page 7
- "IBM App Connect Enterprise for non-production" on page 7
- "IBM App Connect Enterprise for Developers" on page 8

Each of your annotations must contain a single product metric.

IBM App Connect Enterprise

Use one of the following annotations for IBM App Connect Enterprise to specify your chosen product metric, which can be either VIRTUAL_PROCESSOR_CORE or PROCESSOR_VALUE_UNIT, but not both:

VPC:

```
productName: "IBM App Connect Enterprise"
productID: "b8b6252aa88b4cd996c4b7aca350d2fe"
productMetric: "VIRTUAL_PROCESSOR_CORE"
productChargedContainers : "All"
```

PVU:

```
productName: "IBM App Connect Enterprise"
productID: "b8b6252aa88b4cd996c4b7aca350d2fe"
productMetric: "PROCESSOR_VALUE_UNIT"
productChargedContainers : "All"
```

IBM App Connect Enterprise for non-production

Use one of the following annotations for IBM App Connect Enterprise for non-production to specify your chosen product metric, which can be VIRTUAL_PROCESSOR_CORE, PROCESSOR_VALUE_UNIT, or FREE:

VPC:

```
productName: "IBM App Connect Enterprise for non-production"
productID: "eb5b5e73f62b4dcf8c434c6274a158a7"
productMetric: "VIRTUAL_PROCESSOR_CORE"
productChargedContainers : "All"
```

PVU:

```
productName: "IBM App Connect Enterprise for non-production"
productID: "eb5b5e73f62b4dcf8c434c6274a158a7"
productMetric: "PROCESSOR_VALUE_UNIT"
productChargedContainers : "All"
```

FREE:

```
productName: "IBM App Connect Enterprise for non-production"
productID: "eb5b5e73f62b4dcf8c434c6274a158a7"
productMetric: "FREE"
```

You cannot specify multiple product metrics in the same annotation.

IBM App Connect Enterprise for Developers

Use the following annotation for IBM App Connect Enterprise for Developers:

```
productName: "IBM App Connect Enterprise for Developers - FREE"
productID: "53ec37b661cb40e693639822785f02f2"
productMetric: "FREE"
```

Planning an IBM App Connect Enterprise environment

When you start to plan your IBM App Connect Enterprise environment, you must first consider the design of your system infrastructure. A major consideration when you are planning to use IBM App Connect Enterprise is how it will fit into your overall system architecture, and it is important to understand the movement of data around your whole system.

About this task

It is also important to understand the high-level goals of the system that you are building, and to be clear about the functional requirements. For example, IBM App Connect Enterprise has extremely powerful routing and transformation capabilities, but it is not designed to function as an application server whose primary function is data processing that involves a high number of complex calculations.

Another important consideration is whether you require a highly available (HA) system that can withstand the failure of an individual integration server or integration node. For more information about high availability, see “Configuring integration nodes for high availability” on page 120.

The capability and capacity of your integration nodes is partly determined by the operation mode in which the integration nodes are running, and this is determined by the IBM App Connect Enterprise license that you have purchased. For more information, see features and “Operation modes” on page 3.

The following topics describe these factors.

Planning the high-level infrastructure

When you are planning to use IBM App Connect Enterprise, consider your complete system of products as a whole and ensure that the flow of data throughout the system is carefully planned.

About this task

It is important to understand how IBM App Connect Enterprise will fit into the overall system of products in your business, and to be clear about the movement of data around the whole system. It is also important to understand the high-level goals of the system and your functional requirements, so that you can ensure that you are planning to use IBM App Connect Enterprise in a way that will gain the maximum benefit. For example, IBM App Connect Enterprise has powerful routing and transformation capabilities, but it is not designed to function as an application server whose primary function is data processing with a high number of complex calculations. Therefore, it is important to fully understand the role of the product within your overall IT system, in order to use it to its full advantage.

Some common considerations are listed here to assist with your planning.

- Consider whether you need to install IBM MQ to access more IBM App Connect Enterprise functions. For example, if you want global transaction management in your solution. For more information about what functions require access to IBM MQ, see “IBM App Connect Enterprise features requiring supplementary products” on page 9.
- If you are planning to use databases, check the database documentation for information about connections, and the limits or restrictions that might apply. For example, there might be a limit to the maximum number of connections that are allowed at any one time.

The following topics describe some additional factors to consider when you plan your implementation of IBM App Connect Enterprise:

IBM App Connect Enterprise features requiring supplementary products

IBM App Connect Enterprise has no mandatory prerequisites; however, a subset of capabilities require access to other products.

These features affect the main IBM App Connect Enterprise product operations, not your applications. For information about how these products integrate with IBM App Connect Enterprise, see technical overview. For more information about IBM App Connect Enterprise features that have specific requirements, such as a particular mode of operation, product licenses, or access to additional products, see features.

The following table shows the products and systems that are required for specific capabilities in IBM App Connect Enterprise:

Capabilities	Required system
IBM MQ capabilities: • MQ nodes • MQ FTE nodes • CD nodes • Sequence nodes • Timeout nodes • Aggregate nodes • Collector nodes • SAP nodes (if transactional support is required in the flow) • Record-Replay capability • Global transaction support • HTTP proxy servlet • Multi-instance integration nodes	IBM MQ
Database capabilities: Database nodes	For a full list of compatible databases, review the *Detailed System Requirements* in the IBM App Connect Enterprise system requirements for your operating system.
Security profiles	Any of the following systems or protocols: Lightweight Directory Access Protocol (LDAP) Tivoli Federated Identity Manager (TFIM) Microsoft Active Directory (MSAD)

Review the following sections to learn what is required to use these capabilities.

IBM MQ

On distributed systems, IBM MQ is not provided as part of the IBM App Connect Enterprise installation package; however, when you purchase a license for IBM App Connect Enterprise, your license entitles you to install and use IBM MQ. If you choose to use the IBM App Connect Enterprise features that require MQ functionality, you can install and use IBM MQ within the terms of the license. You can install IBM MQ at any time.

The following functions require access to system queues on a queue manager that is specified on the integration node:

- Sequence nodes
- Timeout nodes
- Aggregate nodes
- Collector nodes
- Record-Replay capability
- CD nodes
- HTTP proxy

If you want to use these functions, you must specify a queue manager for the integration node, and then explicitly define a set of MQ objects for that queue manager. For more information, see command.

For information about the supported versions of IBM MQ, see the *Detailed System Requirements* in the IBM App Connect Enterprise system requirements for your operating system.

Database capabilities

You can connect a number of databases with IBM App Connect Enterprise. To learn more about databases, see "Databases overview" on page 1131.

Security profiles

Security profiles form part of optional message flow security. To learn more about security profiles, see "Security profiles" on page 2552.

Naming conventions for integration nodes and associated resources

Establish a naming convention for all the IBM App Connect Enterprise resources in your integration node environment to ensure that names are unique, and that users that create new resources can be confident of not introducing duplication or confusion.

Consider the names that you use for your integration nodes and resources:

Integration nodes

When you create an integration node, give it a name that is unique within your integration node environment. You must use the same name for that integration node when you create it on the system in which it is installed, by using the command **`mqsicreatebroker`**. Integration node names are case-sensitive, except on Windows platforms.

Databases

Ensure that the databases that you use for application data, which are accessed through your deployed message flows, are uniquely named throughout your network, so that confusion and errors are avoided by all your users.

Integration servers

Each integration server name must be unique within an integration node.

Message flows and message processing nodes

Each message processing node must be unique within the message flow it is assigned to. Nodes within the same message flow must not share the same name, even if they are of different types. For example, if you include two MQOutput nodes in a single message flow, provide a unique name for each one.

Message flow names must be unique within the integration node. All references to that name are always to the same message flow. If you assign the same message flow to more than one integration node, you must ensure that you maintain unique message flow names across those integration nodes.

Message sets and messages

Each message name must be unique within the message set to which it belongs.

Message set names must be unique within the integration node. All references to that name are always to the same message set. If you assign the same message set to more than one integration node, you must ensure that you maintain unique message set names across those integration nodes.

IBM MQ objects

If you are using IBM MQ services and objects with your IBM App Connect Enterprise resources, you must consider what conventions to adopt for IBM MQ object names. If you already have an IBM MQ naming convention, use a compatible extension of this convention for IBM App Connect Enterprise resources.

Ensure that every queue manager name is unique within your network of interconnected queue managers, even if some queue managers are not in your IBM App Connect Enterprise network. Unique naming ensures that each queue manager can unambiguously identify the target queue manager that a message must be sent to, and that IBM App Connect Enterprise applications can also interact with IBM MQ applications.

IBM MQ supports a number of objects that are defined to queue managers. These objects (queues, channels, and processes) also have naming conventions and restrictions. For more information about IBM MQ naming conventions, see the topic *Naming IBM MQ objects* in the IBM MQ product documentation.

Business planning

Consider the role of IBM App Connect Enterprise in your overall business solution, and understand the potential benefits and limitations based on your functional and business requirements.

About this task

It is important to understand the capability and capacity that you require from your system. The capability and capacity of your integration nodes are partly determined by the operation mode in which they are running, and this is determined by the IBM App Connect Enterprise license that you have purchased. For information about the features and modes of operation provided in each edition, see “Choosing your IBM App Connect Enterprise edition and operation mode” on page 2.

It is also important to consider the most suitable technology for your business; this varies between projects and organizations, and there are various factors to consider when assessing your requirements:

- The pool of development skills available. For example, if your developers are already skilled in the use of ESQL, you might want to continue using this transformation technology. However, if you have strong Java™ skills, the JavaCompute node might be the better choice, rather than having to teach your Java developers ESQL.
- The ease with which you can teach developers a new development language. For example, if you have many developers it might be not be viable to teach all of them ESQL, and you might choose instead to educate only a few people who can then develop common functions or procedures.
- The skills of individual people. If your developers have relatively little experience with IBM App Connect Enterprise, you might find that the graphical interface provided by the Mapping node is more suitable than other transformation technologies.
- Asset reuse. If you are an existing user of IBM App Connect Enterprise, you might already have large amounts of ESQL code that you would like to reuse. You might also have other resources that you want to reuse, such as Java classes for key business processing, style sheets, or mappings. You might want to use these as the core of message flow processing and extend the processing with one of the other technologies.
- Performance. If message throughput is a prime consideration, you might choose to use ESQL or Java. For more information about designing your system for optimum performance, see “Message flow design and performance” on page 2689 and “Code design and performance” on page 2690.

- Solution scalability, cost and flexibility. You might have an existing network infrastructure that you want to use, or you might want to take advantage of IBM App Connect Enterprise cloud capabilities. For more information on choosing a solution for your installation, see “Cloud overview” on page 12.

For more information about factors to consider when planning your IBM App Connect Enterprise solution, see the following topics:

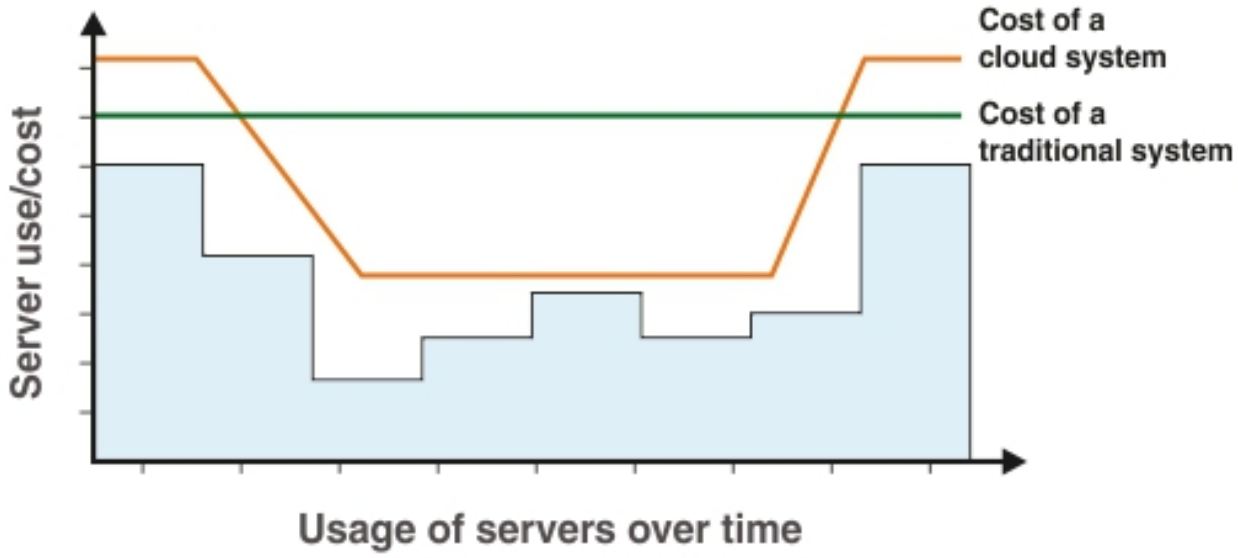
- “Planning an IBM App Connect Enterprise environment” on page 8
- “Planning the high-level infrastructure” on page 8
- “Understanding your data and message processing requirements” on page 1
- “Performance planning” on page 16
- “Planning for security” on page 17

Cloud overview

When you are deciding on your environment for IBM App Connect Enterprise, consider your requirements and how you might want to implement a cloud solution.

Depending on your requirements, you might benefit from reduced operating costs and deployment flexibility for IBM App Connect Enterprise when compared to a static installation.

Using a cloud vendor usually has a higher operating cost than using a static network-based solution, but less upfront capital is required and parts of the infrastructure are automated. Review the following graph as an example of how this can reduce costs overall:



While the cost equivalent in computing power is slightly higher than using your own server, you pay for as much resource as you use, thereby reducing the average cost over a period of time. There are many different financial models for cloud vendors that offer different services.

You can use your own cloud solution, if you have the appropriate skills within your organization to ensure maximum cost-efficiency of your resource use.

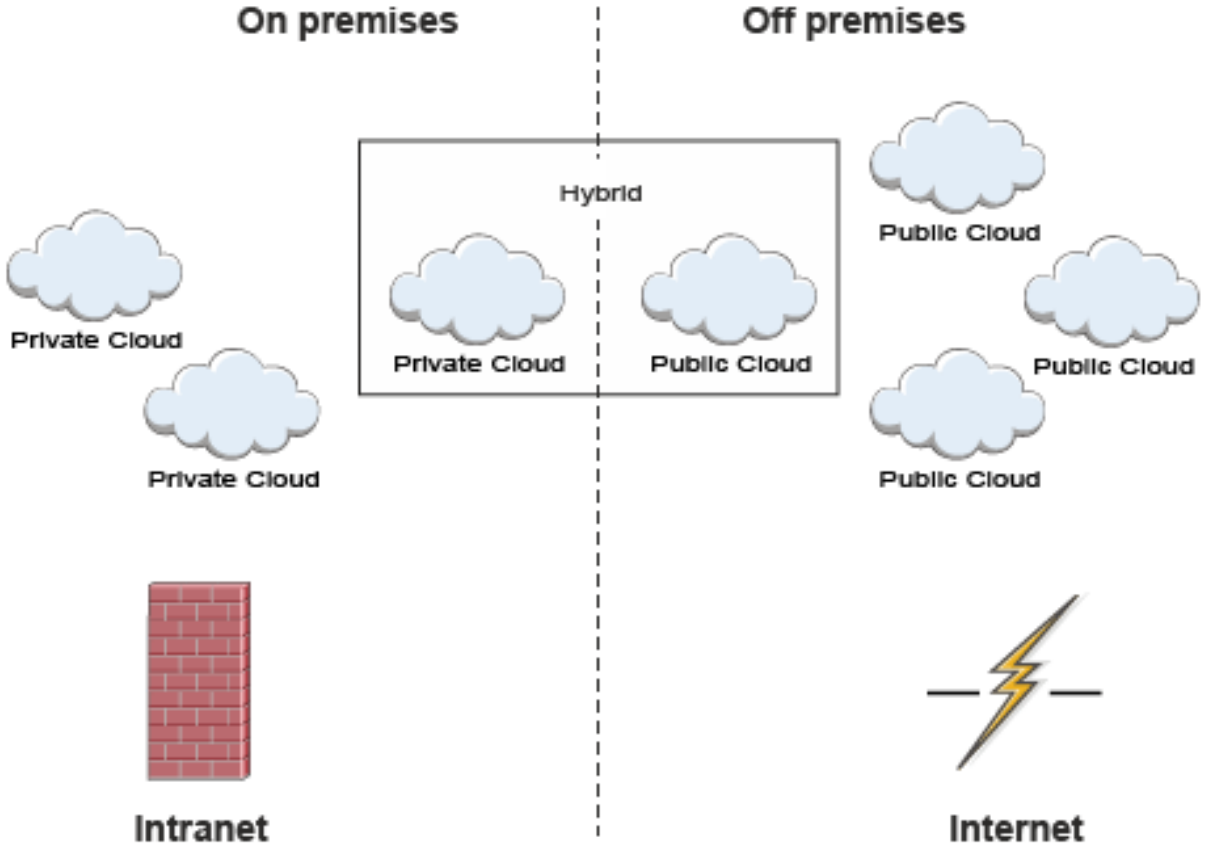
Types of cloud

You can choose how much control you retain over your cloud installation by deciding whether you want your solution to be *on premises* or *off premises*, and whether that cloud is public or private.

- An on-premises (or private) cloud is accessed and used by solely one organization. If you use a private cloud, you maintain absolute control of the maintenance and configuration, but setting up a private cloud requires significant technical skills, scrutiny of security implementation, time, and resources.

- An off premises (or public) cloud is a cloud that is available to multiple organizations, who each use parts of the cloud privately or publicly. There is little to no architectural difference to public or private clouds, except for extra and different security considerations for your services. The maintenance, configuration, and security of the hosting servers are controlled by the hosting vendor.
- A hybrid cloud service contains both on premises and off premises elements. For example, you might host client-sensitive data on premises in a private cloud, but connect to an application that is hosted in a public cloud that processes some of that data.

See the following diagram for a visual representation of the relationship between these concepts:



You can use IBM App Connect Enterprise in any of these configurations. For example, you might have a traditional installation of IBM App Connect Enterprise privately on premises, but deploy some of your integration servers in the cloud.

Cloud technologies

By using cloud technologies, you can choose to abstract parts of your network setup so that the physical components are instead virtual. You can then manipulate the non-physical components to meet the needs of your solution without the associated cost overheads of a physical change, such as changing physical servers or operating system.

This abstraction is collectively known as *XaaS* or *Everything as a Service*, and you can create any part of XaaS at different levels of system architecture.

For a cloud installation of IBM App Connect Enterprise, you can benefit from:

- Infrastructure as a Service (IaaS). IaaS is used and maintained by system architects, or the equivalent in your organization.
- Platform as a Service (PaaS). PaaS is used and maintained by application developers, or the equivalent in your organization.

Review these topics to learn about each level of XaaS and the advantages of using each layer with IBM App Connect Enterprise.

Note: Each level of XaaS is independent. You do not have to use any of these concepts together in an installation.

You can still install IBM App Connect Enterprise by using the provided installation images to a private file system. You might want to do this if you have a small-scale solution that is unlikely to change in size. To review what is required for a standard installation, see "Installing IBM App Connect Enterprise" on page 69.

Infrastructure as a Service

Learn what Infrastructure as a Service (IaaS) is, and how you might benefit from using IaaS with IBM Integration Bus.

Infrastructure as a Service acts as the equivalent to computing hardware by using virtual machines. An IaaS configuration reduces the cost overhead of managing many servers, whether on premises or off premises, as you do not need to manually configure each system. For example, you can apply security patches to all virtual machines simultaneously by using a script.

The advantage of using IaaS with IBM App Connect Enterprise is to create a scalable solution that does not require increasing configuration as it grows in size. By configuring scripts, you can scale and change attributes as required, instead of manually recoding the system infrastructure.

You can use IaaS on premises or off premises, but the primary benefit of IaaS is the ability to use a vendor to reduce the costs of maintaining and configuring the physical machines. If you want to use IaaS on premises, consider the skill availability of system architects in your organization to configure your architecture, and the associated costs.

The benefits of using an IaaS configuration are:

- Flexible (or elastic) hosting. An IaaS provider can provision new virtual machines for you quickly.
- If you use an IaaS provider, remove the responsibility and associated effort of applying fixes, security patches, and other upgrades.
- Removes or reduces capital expenditure on hardware and human resources.

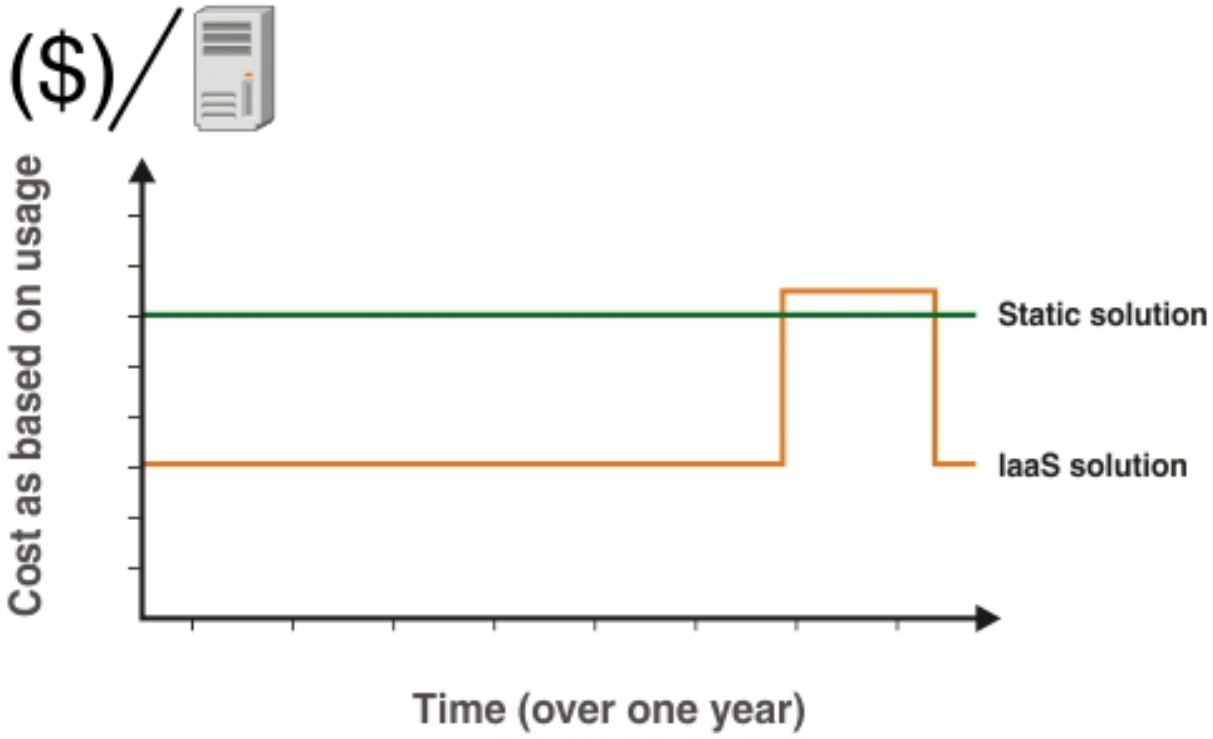
Considerations for using IaaS are:

- If you use IaaS without PaaS, the lack of dynamic scalability: you must predict your peak usage in advance.
- Choosing an IaaS vendor with the right cost model for your usage.
- The capability of the vendor to meet your ongoing business requirements.
- Security and data compliance, if you have restrictions for data use and sharing.
- Dependency on the IaaS vendor for uptime and potentially recovery.
- Requires new and different security measures.

For an example of an IaaS-based IBM App Connect Enterprise solution, review the following business context:

A retail company uses an IBM App Connect Enterprise solution that uses the IBM Retail Pack for its transaction system. The company knows that its peak message processing period is December. Their previous solution used their own on-premises servers, which met the peak demand. However, during the rest of the year, the full capacity of the servers was not used, but the company still had to pay the associating operating and maintenance costs for the entire year.

The retail company changes its infrastructure to an IaaS solution. The retail company now pays an IaaS provider for public cloud servers. The retail company pays the IaaS vendor monthly, by capacity required. The company pays for more IaaS capacity for December only to meet its peak demands. As the company now use less resources across most of the year, this solution is a cheaper option.



The graph shows how a static solution remains the same cost throughout one year, but the IaaS solution cost is consistently lower, except during peak usage. The result is that the retail company has capacity that it requires during its peak period, but does not continue to pay for that extra capacity for the rest of the year.

Chef

Chef software is an open source configuration management tool that you can use to create parts of an Infrastructure as a Service (IaaS). You can use Chef scripts to provision an IBM App Connect Enterprise installation.

Chef scripts, which are called *recipes*, are made of reusable definitions that are written in the Ruby programming language. Chef recipes that perform related functions are grouped in a single container, called a cookbook. Cookbooks and recipes automate common infrastructure tasks. The recipe definitions describe what your infrastructure consists of, and how each part of your infrastructure is deployed, configured, and managed. Chef applies these definitions to servers, to produce an automated infrastructure.

By using Chef, you can create scalable infrastructure with minimal configuration to maintain. Chef scripts form part of a recipe for your infrastructure configuration that is understood by multiple systems, services, and languages. By using Chef to configure your infrastructure deployment, you do not have to rewrite code if you change part of the underlying infrastructure, such as changing data service provider.

To learn more about Chef concepts, see the online Chef documentation About Cookbooks - Chef Docs.

Platform as a Service

Learn what Platform as a Service (PaaS) is, and how you might benefit from using PaaS with IBM App Connect Enterprise.

A PaaS cloud configuration automates the execution environment and solution deployment. For example, acting as an operating system that supports IBM App Connect Enterprise. A typical PaaS provider consists of many servers that each provide customized environments, and can dynamically allocate resources to that environment where and when they are required.

Applications are deployed into this environment, and are often charged by usage or capacity, which means that you pay only for as much as you use or specify, which can greatly reduce operating costs.

The benefits of using a PaaS configuration are:

- Reconfiguring and maintenance of the environment is faster and requires significantly less effort.
- If you use a PaaS provider, maintenance and optimization are provided, requiring less developer time.
- Dynamically scalable. PaaS automatically increases or decreases resources, which are based on demand. You usually pay only for the resources that are used.

Considerations for using PaaS are:

- Choosing a PaaS vendor with the right cost model for your usage.
- Whether the PaaS provider has any restrictions on what type of content and applications are allowed.
- What frameworks, languages and databases are supported.
- Vendor lock-in, and choosing standard or proprietary technologies. If your provider uses proprietary technologies, you might find it harder to switch vendors.
- Security and data compliance, if you have restrictions for data use and sharing.
- Dependency on the PaaS vendor for aspects of security and uptime.
- Requires new and different security measures.

Performance planning

When you design your IBM App Connect Enterprise environment and the associated resources, the decisions that you make can affect the performance of your applications.

About this task

If you are planning to create and maintain a small, stand-alone system with limited requirements for availability and performance, it is possible to achieve this relatively quickly. However, if you are planning a large or complex system, or if you have specific requirements for high availability or performance, it is worth taking time to understand the factors that can influence your design and the techniques that you can use to optimize it. As a starting point, consider the following aspects of your system and understand how these factors can influence performance:

Message flows

A message flow includes an input node that receives a message from an application over a particular protocol; for example, IBM MQ. The message must be parsed by the input node, and the performance impact of this parsing varies according to the parser that is used and the number of parses required. You can reduce the impact of parsing by using some optimization techniques such as parsing avoidance or partial parsing. For more information about parsing, see “Parsing and message flow performance” on page 2697.

The number and length of message flows have implications for performance, and it is important to keep the number of nodes to a minimum. See “Message flow design and performance” on page 2689 for more information about optimizing message flow performance. Other aspects of processing in a message flow that might affect performance are the amount, efficiency, and complexity of ESQL, access to databases, and how many message tree copies are made. For more guidance about these factors, see “Code design and performance” on page 2690.

It is also important to consider how you split your business logic; how much work should the application do, and how much should the message flow do? Every interaction between an application and a message flow involves I/O and message parsing, and therefore adds to processing time. Design your message flows, and design or restructure you applications, to minimize these interactions.

Messages and message models

The type, format, and size of the messages that are processed can have a significant effect on the performance of a message flow. For example, if you process persistent messages, they must be stored for safekeeping.

If you do not plan to interrogate the structure, you can use the BLOB domain.

If you are working with general text or binary messages, then you need to create a DFDL (or MRM) model to describe the message. The organization of the model can have a significant effect on performance. For fields that are choices, are optional, or are in arrays, the model must identify the field as efficiently as possible. Use tags (named initiators in DFDL) if they are available. To resolve a choice, DFDL provides a direct dispatch mechanism, which avoids parsing each branch in turn if there is a field that indicates which branch to take. If you are using a DFDL discriminator, ensure that the discriminator is placed so that it is evaluated as early as possible. While regular expressions can be used to identify and extract fields, they are generally slower than other techniques.

If you are working in XML, be aware that it can be verbose, and therefore produce large messages. However, XML message content is easier to understand than other formats, such as binary fixed-length format.

For more information about these factors, see Performance considerations for regular expressions in TDS messages.

Integration node configuration

You can create and configure one or more integration nodes, on one or more computers, and for each integration node you can create multiple integration servers, and multiple message flows. Your configuration decisions can influence message flow performance, and how efficiently messages can be processed.

For more information about these factors, see “Tuning the integration node” on page 2762, and “Optimizing message flow throughput” on page 2763.

Planning for security

It is important to be aware of security issues when you are planning to install and use IBM App Connect Enterprise.

About this task

On Linux® and UNIX systems, you must complete security tasks before you install IBM App Connect Enterprise. On Windows systems, security tasks are completed during and after installation.

After installation, refer to one of the following documents for further security considerations:

- For Windows, Linux and UNIX systems, see “Creating user IDs” on page 2633.

For an introduction to various aspects of security, see “Security overview” on page 2491.

Replicating your environment for multiple users

You can ensure that your environment is more easily reproducible by using scripting and virtualization, in addition to documentation.

About this task

You can create environment instances by using Chef scripts to automate installation. For more information about Chef, see “Chef” on page 15.

Procedure

1. Download the IBM App Connect Enterprise installation images.
2. Download the Chef Cookbook for IBM App Connect Enterprise from GitHub.
3. Add the IBM App Connect Enterprise cookbook to the Chef server.
   Alternatively, if you are using Chef solo, add the cookbook to your file system.
4. Set the recipe attributes to point to the FTP or HTTP server.

5. Run the Chef scripts.

Chapter 2. Migrating

To migrate an integration server or integration node from IBM App Connect Enterprise 11.0 or IBM Integration Bus 10.0 to IBM App Connect Enterprise 12.0, plan your migration strategy, perform pre-migration tasks, migrate your domain components, or server configuration and resources, then complete post-migration tasks.

Before you begin

Tip: Check for migration information updates on the IBM App Connect Enterprise support web page.

About this task

Video: IBM App Connect Enterprise - Migration and Extraction

In this demo, Ben Thompson gives an overview of migrating from IBM Integration Bus V10 to IBM App Connect Enterprise V11.

Note:

This video was created for App Connect Enterprise 11.0, but also applies to App Connect Enterprise 12.0.

Preparing for migration

Plan the order and extent of the migration of components and resources to IBM App Connect Enterprise 12.0.

About this task

To prepare for migration, complete the following steps.

Procedure

1. Check that your current installation of IBM App Connect Enterprise Version 11.0 or IBM Integration Bus 10.0 is at a supported level for migration (see “Supported migration paths” on page 20).

   For the latest details of all supported levels of hardware and software, see the IBM App Connect Enterprise system requirements website.
2. Some function that was available in IBM Integration Bus is not currently available in IBM App Connect Enterprise 12.0; elements of this function are to be made available in fix pack updates. For details of which commands, policy types, and other resources are unavailable in IBM App Connect Enterprise at this fix pack release, see the Frequently asked questions about website.
3. Determine your migration priorities by following the steps in “Migration planning” on page 20.
4. Review the options that are available to install IBM App Connect Enterprise 12.0 components on the same computer as components from IBM App Connect Enterprise Version 11.0 or IBM Integration Bus 10.0 (see “Coexistence of IBM App Connect Enterprise 12.0 with previous versions” on page 70).
5. Learn about new and changed function in Version 12.0 by reading What's new in ?.

   These changes might affect how you want to use your migrated components in the future.
6. Review the IBM MQ configuration options that you can include in your migration plan in “IBM MQ and migration to IBM App Connect Enterprise 12.0” on page 28.

   These changes might affect your choice of integration node migration option.
7. Review the options for migrating your integration nodes and integration servers, and decide whether to use extract migration or parallel migration (see “IBM App Connect Enterprise migration options” on page 29).

8. Review the technical changes in behavior in Version 12.0 in "Behavioral changes in Version 12.0" on page 22.

   These changes might affect your post-migration development tasks.
9. Check the requirements for other products on which Version 12.0 components might depend.

   If you configured your message flows to use external resources, such as databases or event monitoring applications, you might have to modify your configuration. You can find details of supported versions of complementary products on the IBM App Connect Enterprise system requirements web page.

What to do next

After you plan your migration, complete the pre-migration tasks by following the instructions in "Performing pre-migration tasks" on page 41.

Supported migration paths

You can migrate to IBM App Connect Enterprise 12.0 from IBM App Connect Enterprise Version 11.0 and IBM Integration Bus 10.0.

Note: For the latest details of all supported levels of hardware and software, see the IBM App Connect Enterprise system requirements website.

You can migrate from IBM App Connect Enterprise 11.0 or IBM Integration Bus 10.0 to either the Advanced Edition or Standard Edition of IBM App Connect Enterprise 12.0; do not migrate integration nodes or servers to the Developer Edition.

You can use either parallel or extract migration to migrate integration nodes and managed integration servers to IBM App Connect Enterprise 12.0, as described in "Performing parallel migration for an integration node " on page 61 and "Performing extract migration of an integration node or integration server" on page 57.

Independent integration servers that were created in IBM App Connect Enterprise 11.0 can be started in IBM App Connect Enterprise 12.0 without the need to migrate them or their resources. However, integration server work directories are typically created as transient rather than long-term artifacts, and many users prefer to rebuild them when moving from one version to another.

You can use the IBM Integration Explorer view of the IBM App Connect Enterprise Toolkit to add connections for integration servers and integration nodes. IBM App Connect Enterprise Toolkit Version 12.0 supports Version 12.0 integration servers and integration nodes only. Connections to integration servers and integration nodes that are running on previous releases are not supported.

Migration planning

The order in which you migrate your IBM App Connect Enterprise 11.0 or IBM Integration Bus 10.0 environment depends on whether your priority is to include new development features, take advantage of new operational features, or simply implement a fully supported version of IBM App Connect Enterprise 12.0.

If you are migrating from IBM Integration Bus 10.0, your existing environment might consist of any of the following components:

- Integration nodes that support production applications
- Build systems that create deployable resources from the development source files
- Integration nodes that are used for testing applications
- Integration nodes that are used for developing applications
- Instances of the IBM Integration Toolkit

The order in which you migrate your environment to IBM App Connect Enterprise 12.0 is likely to depend on which of the following factors is most important to you:

- “Supported version or new operational features” on page 21
- “New application features” on page 21

In both circumstances, you can use parallel migration. If you are migrating an integration server, you can use the **mqsiextractcomponents** command to migrate the configuration and resources that exist for your integration server to IBM App Connect Enterprise 12.0.

Supported version or new operational features

If your priority in migrating to IBM App Connect Enterprise 12.0 is simply to have an environment that is at a fully-supported version of IBM App Connect Enterprise 12.0, and you do not need to use any of the new Version 12.0 features immediately, there is a minimum number of steps you must complete.

If your priority in migrating to IBM App Connect Enterprise 12.0 is to use the new Version 12.0 operational features, you can update your integration nodes first. You can use existing development environments and application build processes, and deploy your existing BAR files until you are ready to migrate your development resources.

In either scenario, you migrate the components of your environment in the following order:

1. Migrate the integration nodes that support your test environment.
2. Implement new Version 12.0 operational functionality on your test environment or, at a minimum, update existing operational functionality:
   - If you are using IBM Integration Explorer in your existing IBM Integration Bus environment, define new operational procedures that use the web user interface. You cannot use previous versions of IBM Integration Explorer to administer IBM App Connect Enterprise 12.0.
   - If you are using scripts to administer your existing environment, update any scripts that use commands that connect to integration nodes. The parameters in IBM Integration Bus 10.0 that are used by commands that connect to integration nodes have changed in Version 12.0.
3. Migrate the integration nodes that support your production environment.
4. Implement new Version 12.0 operational functionality on your production environment or, at a minimum, update existing operational functionality.
5. If you have any integration nodes that support your development environment, migrate these integration nodes to Version 12.0.
6. Update your build system to create Version 12.0 deployable resources. If required, update build scripts to take advantage of new Version 12.0 operational functionality but, at a minimum, update any scripts that use commands that connect to integration nodes.
7. Install IBM App Connect Enterprise 12.0 on your developer workstations. If you cannot migrate all developer workstations at the same time, you must create separate development streams. You cannot use Version 12.0 development tools to build applications for an environment that is running a previous version of IBM App Connect Enterprise or IBM Integration Bus.
8. Import development resources from your previous Toolkit.

To migrate integration nodes, use parallel migration (see “IBM App Connect Enterprise migration options” on page 29).

When you have imported all the development resources, you can uninstall the previous versions of IBM Integration Toolkit, and any integration nodes that you do not want to migrate.

New application features

If your priority in migrating to IBM App Connect Enterprise 12.0 is to develop applications that take advantage of new functions and features in Version 12.0, you can install a new development environment alongside your existing development environment, and create new build, test, and production environments to support your Version 12.0 development.

In this scenario, you migrate the components of your environment in the following order:

1. Install IBM App Connect Enterprise 12.0 on your developer workstations. To maintain existing applications in your existing environment while you are building new applications for Version 12.0, you must run two development streams. You cannot use Version 12.0 development tools to build applications for an environment that is running a previous version of IBM App Connect Enterprise or IBM Integration Bus.
2. If you are updating an existing application, import development resources from your previous Toolkit.
3. Develop applications that take advantage of the Version 12.0 features.
4. Create a new build system that creates Version 12.0 deployable resources. You can use build scripts from your previous version but you must update any scripts that use commands that connect to integration nodes. The parameters in IBM Integration Bus 10.0 that are used by commands that connect to integration nodes have changed in Version 12.0.
5. Create one or more IBM App Connect Enterprise 12.0 integration nodes to support the testing of the Version 12.0 applications.
6. Update existing operational functionality:
   - If you are using IBM Integration Explorer in your existing IBM Integration Bus environment, define new operational procedures that use the web user interface. You cannot use previous versions of IBM Integration Explorer to administer IBM App Connect Enterprise 12.0.
   - If you are using scripts to administer your existing environment, update any scripts that use commands that connect to integration nodes.
7. Deploy Version 12.0 applications to the Version 12.0 testing environment as required.
8. Create one or more IBM App Connect Enterprise 12.0 integration nodes to support production use of the Version 12.0 applications.
9. Deploy Version 12.0 applications to the Version 12.0 production environment as required.
10. Migrate or deprecate applications from the original environment as required.

This type of migration is known as parallel migration (see “IBM App Connect Enterprise migration options” on page 29).

When all applications are migrated to Version 12.0, you can uninstall the original environment.

Behavioral changes in Version 12.0

Depending on your current version of IBM Integration Bus or App Connect Enterprise, IBM App Connect Enterprise 12.0 might introduce technical changes in behavior. These changes might affect your post-migration development tasks.

Review the following changes to see how your post-migration development tasks might be affected:

Platform support

IBM App Connect Enterprise 12.0 is available on:

- Windows
- Linux
- AIX®

For more information about the operating systems that are supported, see IBM App Connect Enterprise 12.0 system requirements.

Policies control and update message flow and message flow node properties

In IBM Integration Bus 10.0, configurable services were used to control and update connection properties and other operational properties of message flows and message flow nodes at run time. In IBM App Connect Enterprise 12.0, you can use policies for these tasks.

You can migrate your existing configurable policies by using the **mqsiextractcomponents** command. If you are performing parallel migration, you need to create policies to replace your configurable services.

For more information, see "Overriding properties at run time with policies" on page 324.

Nodes that are no longer available

Your message flows from earlier versions work in IBM App Connect Enterprise 12.0. However, a number of message flow nodes are not available in Version 12.0; if your earlier message flows include them, consider reworking them.

The following nodes are not available in IBM App Connect Enterprise 12.0:

- DataDelete node
- DataInsert node
- DataUpdate node
- Extract node.
- Mapping node from WebSphere® Message Broker Version 7.0 and earlier versions
- MQOptimizedFlow node
- Real-timeOptimizedFlow node
- Warehouse node

If you try to use a message flow that contains any of these nodes, the message flow does not start and message BIP2355 is written to the syslog. The message mapping (`.msgmap`) on these nodes can be viewed but they cannot be deployed to the run time environment in IBM App Connect Enterprise 12.0.

For more information, see Built-in nodes.

IBM App Connect Enterprise 12.0 REST administration API (REST API) Version 2 is available to issue administration commands

IBM App Connect Enterprise 12.0 does not include the IBM Integration API. Instead, you can use the REST API (Version 2) that is provided in IBM App Connect Enterprise 12.0 to issue administration commands.

For more information, see "Managing resources by using the administration REST API" on page 334.

Web user interface extended to support administration tasks

IBM App Connect Enterprise 12.0 does not include IBM Integration Explorer. Instead, the web user interface is extended to support integration node administration tasks such as creating and managing integration servers, and deploying and managing resources.

For more information, see web user interface.

Keystore format for administration security

The certificate store for use in securing the REST Administration port, which is used by the Web User Interface and IBM App Connect Enterprise Toolkit must be a `.pem` `.p12` or `.pfx` format. This certificate store cannot be in JKS format, and hence must be a separate certificate store from the certificate store that used by the integration server for things such as HTTPS message flow nodes.

For more information, see "Authorizing users for administration" on page 2516.

Additional options for administration security

In IBM App Connect Enterprise 12.0, you have two options for configuring administration security. As in previous versions, you can configure queue-based permissions by using IBM MQ queues on the queue manager that is specified on the integration node. Alternatively, you can configure file-based permissions on your integration node, which you set by using the **mqsichangefileauth** command.

If you configure administration security, then you perform parallel migration to integration nodes that are not configured with queue managers, you must reconfigure your administration security to use file-based permissions. Any security permissions that are set before migration are not retained after migration.

For more information, see "Authorizing users for administration" on page 2516.

Administration scripts might need to be updated

A number of commands are not available in this release. In addition, some parameters for administration commands that connect to integration nodes and integration servers were changed. For more information, see commands. The **MQBrokerConnectionParameters** IBM Integration API class is also deprecated (see the Javadoc for the IBM Integration API).

IBM App Connect Enterprise Toolkit help topics might include details of function that is not available to you

By default, the IBM App Connect Enterprise Toolkit is now configured to use online product documentation to provide context-sensitive help from the latest information that is available. In previous versions, the Toolkit contained local help documentation, which was not automatically updated when new information became available. The way that help is displayed in the IBM App Connect Enterprise Toolkit is not changed. However, the content of the IBM App Connect Enterprise section of the online product documentation is updated when fix packs are made available. If you do not deploy the latest fix pack, the help information might include details of function that is not available to you.

If you do not want to access the online product documentation, you can download and install a local source of product documentation. For more information about local documentation options, see Adding documentation to the IBM App Connect Enterprise Toolkit.

Message maps: change in behavior

In IBM App Connect Enterprise 12.0, the behavior of the **Assign** transform in the Graphical Data Mapping editor has been corrected when you assign an empty string to an element.

- In previous versions of IBM Integration Bus, when you perform an **Assign** transform on a target element that is defined as **xsd:string**, the Graphical Data Mapping editor sets the internal `NULL` value in the message tree for that element.
- In IBM App Connect Enterprise 12.0, when you perform an **Assign** transform on a target element that is defined as **xsd:string**, the Graphical Data Mapping editor sets the element value to the empty string `''` value.

For message formats such as XML, this change in behavior has no impact on the message flow. However, if your message flow has logic that tests that the value of an element is the internal `NULL` value, you must

modify the test to look for the empty string value. Alternatively, you must modify the map to use the new **iib:nullvalue()** function. To call the new function, you use a **Custom XPath** transform.

Message maps are validated at deployment time

In IBM App Connect Enterprise 12.0, message maps are prepared for execution on deployment instead of when the first message flows through the Mapping node. For more information, see Deploying message maps.

Java isolation is active and cannot be disabled

Previous versions of IBM Integration Bus did not support Java isolation in applications. All Java that was deployed to the execution group was loaded into a single class loader, which was used by all JavaCompute nodes in all applications. This behavior precluded the use of duplicate classes.

When you create an application in IBM Integration Bus 10.0, Java isolation is enabled by default. For each application, a Java class loader is built that contains only the Java that is deployed in that application and any included static libraries.

When you create an application in IBM App Connect Enterprise 11.0 or later, Java isolation is active and you cannot disable it.

Publication of statistics to the web user interface is enabled by default

When an integration node or integration server is created in IBM App Connect Enterprise Version 11.0.0.8 or later, the publication of resource statistics and message flow snapshot statistics is activated by default. The publication of archive statistics is turned off by default. The **publicationOn** property in the `server.conf.yaml` or `node.conf.yaml` file is explicitly set to `active` and the **outputFormat** property is set to `json`, which enables the publication of snapshot data to the web user interface. The **reportingOn** property is explicitly set to `true`, which enables resource statistics for the integration node or server to be published automatically to the web user interface.

For integration nodes and servers that were created before IBM App Connect Enterprise Version 11.0.0.8, the publication of all statistics was turned off by default. To enable the publication of statistics for integration nodes or servers that were created before V11.0.0.8, edit the relevant `.conf.yaml` file and activate the **publicationOn** and **reportingOn** properties, as required.

For more information, see “Managing resource statistics collection” on page 2741 and “Configuring the collection of message flow statistics by using a .yaml configuration file” on page 2729.

UUIDs are not assigned to the integration node, integration server, application, or message flow components

In IBM App Connect Enterprise 11.0 and later, UUIDs are not assigned to the integration node, integration server, application, or message flow components. When these fields are displayed (in monitoring events, for example), they are set to all zeros.

For more information, see “The monitoring event” on page 2778.

Message flow monitoring

Monitoring events are issued in a new format that provides additional information. However, the format that was used in IBM Integration Bus 10.0 can also be used in IBM App Connect Enterprise 12.0 by editing the `eventFormat` property in the `Monitoring.MessageFlow` section of the `.conf.yaml` file.

For more information, see “Activating monitoring” on page 2804.

LDAP authentication and local passwords

If a web user account has a local password, and LDAP authentication is enabled, the local password is ignored. When LDAP authentication is enabled, all web user logins must be authenticated by using LDAP.

Any local passwords are ignored. For more information, see “Enabling LDAP authentication” on page 2511 and command - , , and systems.

HTTPConnector and HTTPSConnector policies

HTTPConnector and HTTPSConnector policies were deprecated in IBM App Connect Enterprise 11.0 Fix Pack 5 and are not supported in IBM App Connect Enterprise 12.0. If you try to deploy one of these policy types in IBM App Connect Enterprise 12.0, you see an error and the policies are not loaded or used. Instead, configure the HTTPConnector or HTTPSConnector Resource Manager section of the `server.conf.yaml` file.

Enhanced flexibility in interactions with IBM MQ

Greater flexibility was introduced in IBM Integration Bus 10.0 in its interactions with IBM MQ. IBM App Connect Enterprise 12.0 maintains this enhanced flexibility.

You can configure local or client connections to IBM MQ, enabling your integration nodes to get messages from, or put messages to, queues on a local or remote queue manager. You can configure either a local or client connection between your integration node and your queue manager, depending on the configuration of your existing architecture. If your IBM MQ queue manager is running on the same machine as your integration node, you can specify a local connection to the queue manager. Alternatively, if the IBM MQ queue manager that you want to connect to is hosted on a separate machine from IBM App Connect Enterprise, you can configure a client connection from your integration node so that it can access the messages on the remote queue manager.

When you configure a connection from an MQ node to an IBM MQ queue manager, you can optionally configure the connection to use a security identity for authentication, SSL for confidentiality, or both. The security identity, which passes user name and password security credentials to the queue manager, can be used on connections to local or remote queue managers. For connections to remote queue managers, you can choose whether to use the SSL protocol to provide confidentiality on the client connection. IBM App Connect Enterprise supports a subset of the SSL functionality that is supported by IBM MQ. For more information, see “Connecting to a secured IBM MQ queue manager” on page 747.

Note: You cannot use a secured queue manager as the local default queue manager for an integration node or an integration server.

You can get messages from, or put messages to, IBM MQ queues on local or remote queue managers, by configuring the connection properties of the following MQ nodes:

- node
- node
- node
- node

Alternatively, you can specify a queue manager to be associated with the integration node by using the **-q** parameter on the **mqsicreatebroker** command. This queue manager is used by default for MQ processing in the message flow if no queue manager is specified explicitly on the MQ node. This queue manager is also used by some message flow nodes that require a queue manager to be specified on the integration node, such as the event-driven processing nodes used for aggregation, timeout, message collection, and message sequencing. The **-q** parameter specifies the name of a queue manager, but it does not create the queue manager automatically. You must define and start the queue manager as separate tasks, in addition to specifying it with the **mqsicreatebroker** command.

Message flows can contain multiple MQInput and MQOutput nodes, each of which can access different queue managers specified in the MQ node. For more information, see node and node.

IBM MQ is not a prerequisite for using IBM App Connect Enterprise, which means that you can develop and deploy applications with IBM App Connect Enterprise independently of IBM MQ. However, some IBM App Connect Enterprise features require access to IBM MQ, including the MQ nodes and the event-driven processing nodes that are used for aggregation and timeout flows, message collections, and message sequences. IBM MQ is not provided as part of the IBM App Connect Enterprise installation package;

however, when you purchase a license for IBM App Connect Enterprise, your license entitles you to install IBM MQ for use by App Connect Enterprise, within the terms of the license.

The following IBM App Connect Enterprise features require IBM MQ Server to be installed on the same machine as the integration node, and they are available for use only if you specify a queue manager on the integration node:

- Queue-based administration security (MQ is not required for file-based security)
- Global transactionality
- FTEInput and FTEOutput nodes
- CDInput and CDOutput nodes
- Integration nodes with HTTP listeners
- HTTP proxy servlet
- High availability configurations

The integration node listener requires access to IBM MQ Server, so you must install it if you want to use an integration node listener to manage HTTP messages in your HTTP or SOAP flows. However, if you use HTTP nodes or SOAP nodes with the integration server embedded listener, they do not require access to IBM MQ.

The following IBM App Connect Enterprise features require access to system queues on a local queue manager (running on the same machine as the integration node) for the storage and retrieval of state information:

- Queue-based administration security (system queues are not required for *file-based* security).
- Integration node HTTP listener.
- HTTP proxy servlet.

The following IBM App Connect Enterprise features require access to system queues on a either a local or remote queue manager for the storage and retrieval of state information:

- Record and replay.
- Event-driven processing nodes (aggregate, collector, sequence, resequence, and timeout nodes).

For information about creating the system queues, see “Creating the default system queues on an IBM MQ queue manager” on page 99.

On Linux and AIX systems only, you must also configure the IBM MQ environment that you want the integration node to use before you start it. If you do not set the environment, your integration node might not run in the expected location. For more information, see “Setting the IBM MQ environment on Linux and AIX” on page 84.

The MQInput, MQOutput, MQGet, and MQReply nodes require that IBM MQ is installed either locally or remotely, but they do not require a queue manager to be specified on the integration node unless you want to use this queue manager by default for your local MQ connection. For more information, see “Configuring a local connection to IBM MQ” on page 744 and “Configuring a client connection to IBM MQ” on page 745.

The SAPInput, SAPReply, and SAPRequest nodes require that either IBM MQ Client or Server is installed on the same machine as the integration node, and they require a queue manager to be specified on the integration node.

For a list of the main IBM App Connect Enterprise features, including information about the features that require the installation of IBM MQ Client or Server, see features.

For a summary of the features that are new to IBM App Connect Enterprise 12.0, see What's new in ?.

IBM MQ and migration to IBM App Connect Enterprise 12.0

During migration, you might want to configure IBM App Connect Enterprise 12.0 to take advantage of the increased flexibility that was introduced in IBM Integration Bus 10.0 for its interactions with IBM MQ.

Greater flexibility was introduced in IBM Integration Bus 10.0 in its interactions with IBM MQ; IBM App Connect Enterprise 12.0 maintains this enhanced flexibility. See “Enhanced flexibility in interactions with IBM MQ ” on page 26 and “IBM MQ topologies” on page 739.

In IBM Integration Bus 10.0, the integration layer of your architecture must contain IBM MQ (or IBM MQ) queue managers. If you have queues that you use in integration applications, you must have an existing IBM MQ (or IBM MQ) topology in which application messages are routed to the queue manager that is specified on the integration node by using IBM MQ (or IBM MQ) channels, remote queue definitions, and distributed messaging. It might be possible to simplify your system so that your message flows interact directly with remote queue managers, which might simplify the topology that you need to manage. This simplification requires that you redesign your message flows and your topology, and is more than just a migration of your existing solution. However, you might want to include these activities as part of your migration plans.

To determine which components of your existing deployment are using capabilities that require IBM MQ or (IBM MQ) queue managers to be a part of the integration layer of your IBM App Connect Enterprise 12.0 architecture, and which components are using capabilities that can integrate with IBM MQ application queues on a remote queue manager, see “Installing IBM MQ” on page 96.

Depending on whether you can change your IBM MQ topology during the migration process, you have the following options for migrating integration nodes:

- Create a new Version 12.0 integration node and associate the integration node with a new queue manager. Add the new queue manager into your IBM MQ network, migrate the applications from the original integration node, and redirect application queues as required (parallel migration).
- Create a new Version 12.0 integration node and associate the integration node with the same queue manager as the original integration node. Migrate the applications from the original integration node, and keep the IBM MQ application endpoints and IBM MQ topology the same (parallel migration).

  Note: This option cannot be used if your integration node has message flows that contain the following message flow nodes:

  – AggregateControl
  – AggregateReply
  – AggregateRequest
  – Collector
  – Sequence
  – Resequence
  – TimeoutControl
  – TimeoutNotification

  These nodes use MQ queues to save state, which cannot be shared between integration nodes.
- Create a new Version 12.0 integration node and do not associate the integration node with a queue manager. Migrate the applications from the original integration node, and configure message flows that require IBM MQ queues to connect to specified queue managers, either by directly configuring the message flow or by using a policy (parallel migration).

For more information, see “IBM App Connect Enterprise migration options” on page 29.

IBM App Connect Enterprise migration options

IBM App Connect Enterprise 12.0 supports parallel migration and extract migration to migrate your application logic to Version 12.0 systems.

If you want to reproduce the integration node function on another computer, you can use *parallel migration* to associate the application logic on your existing integration node with a separate Version 12.0 integration node. For more information, see “Performing parallel migration for an integration node ” on page 61.

By using *extract migration*, you can migrate the configuration and resources of existing integration nodes and servers to IBM App Connect Enterprise 12.0, as described in “Performing extract migration of an integration node or integration server” on page 57.

Independent integration servers that were created in IBM App Connect Enterprise 11.0 can be started in IBM App Connect Enterprise 12.0, without the need to migrate them or their resources. However, integration server work directories are typically created as transient rather than long-term artifacts, and many users prefer to rebuild them when moving from one version to another.

Restrictions

Consider the following restrictions before you decide whether to use parallel migration for your integration nodes.

IBM MQ enhancements

Greater flexibility was introduced in IBM Integration Bus 10.0 in its interactions with IBM MQ; IBM App Connect Enterprise 12.0 maintains this enhanced flexibility. Ensure that you are using a supported version of IBM MQ to take advantage of the greater flexibility.

If you use parallel migration, you can install and configure an IBM App Connect Enterprise 12.0 deployment that takes advantage of the IBM MQ flexibility, and then move your applications into the Version 12.0 deployment.

For more information, see “IBM MQ and migration to IBM App Connect Enterprise 12.0” on page 28.

Maintaining administration security

If you have administration security configured in your current environment by using IBM MQ queues, and you perform parallel migration, you must re-create the equivalent administration security settings by using file-based permissions on your new integration nodes (see “Authorizing users for administration” on page 2516).

Example migration scenarios

Example migration scenarios demonstrate how to migrate message flows and applications from IBM Integration Bus 10.0 to IBM App Connect Enterprise 12.0.

- “Migrating an integration node with configurable services ” on page 30

  This scenario shows how to migrate an IBM Integration Bus 10.0 integration node that has configurable services for external resources. The Version 10.0 node also has a specific user ID and password that is associated with one or more resources by using the **mqsisetdbparms** command.

- “Migrating an integration node with multiple integration servers” on page 31

  This scenario uses the **mqsiextractcomponents** command to migrate an IBM Integration Bus 10.0 integration node with multiple integration servers to IBM App Connect Enterprise 12.0 independent integration servers.

- “Migrating an integration server that contains applications and a shared library” on page 33

  This scenario shows how to migrate an IBM Integration Bus 10.0 integration server with applications and a shared library to IBM App Connect Enterprise 12.0.

- "Migrating an SAP integration flow" on page 34

  This scenario shows how to migrate an SAP integration flow that runs on IBM Integration Bus 10.0.

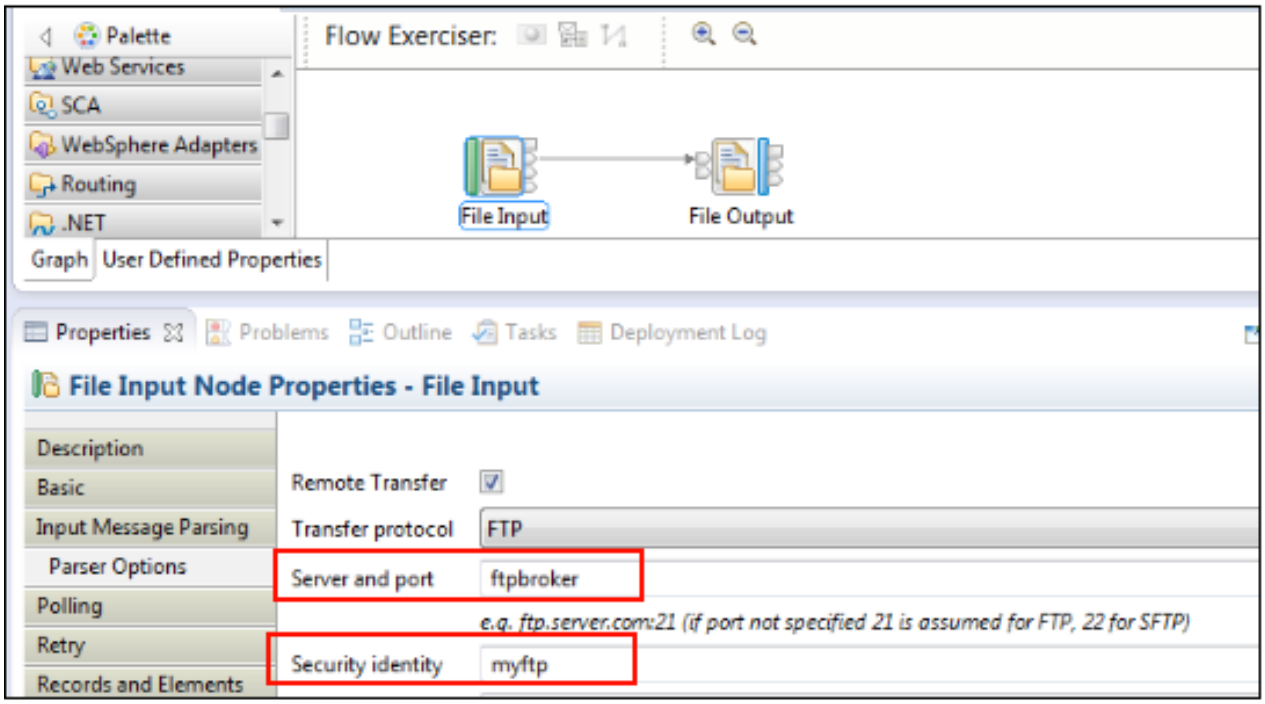
Migrating an integration node with configurable services

Migrate an IBM Integration Bus 10.0 integration node that has configurable services for external resources, and a specific user ID and password that is associated with one or more resources by using the **mqsisetdbparms** command.

About this task

In this scenario, a simple flow that contains a FileInput node and a FileOutput node is deployed to an IBM Integration Bus 10.0 integration server, then to an integration node. An FtpServer configurable server has been created by using the following command:

```
mqsicreateconfigurableservice MigrationNode -c FtpServer -o FtpServer01
-n serverName,scanDelay,transferMode,connectionType,securityIdentity
-v one.hursley.abc.com:123,20,Binary,ACTIVE,myftp
```



The following steps describe how to migrate the flow to IBM App Connect Enterprise 12.0.

Procedure

1. Back up the IBM Integration Bus 10.0 integration node by using the **mqsibackupbroker** command.

   ```
   mqsibackupbroker IntegrationNode -d  directory
   ```

   A file with a name in the format `intNodeName_yyMMdd_HHmmss.zip` is created in the specified directory.
2. In IBM App Connect Enterprise 12.0, use the **mqsicreatebroker** command to create a new integration node.

   `mqsicreatebroker IntegrationNode`
3. Start the integration node by running the command `mqsistart IntegrationNode`.

4. Create the directory structure `servers\IntegrationServer` under the integration node work path ($MQSI_WORKPATH).
   For example, on Windows: `C:\ProgramData\IBM\MQSI\components\IntegrationNode\servers\IntegrationServer`.
5. Stop the integration node by running the command `mqsistop IntegrationNode`.
6. Use the **mqsiextractcomponents** command to migrate the IBM Integration Bus 10.0 integration server and resources to IBM App Connect Enterprise 12.0.

   All deployed resources are migrated under the `/run` directory: `C:\ProgramData\IBM\MQSI\components\IntegrationNode\servers\IntegrationServer\run`.

   During migration, the IBM Integration Bus 10.0 configurable services are converted to policies in IBM App Connect Enterprise 12.0. The policy project resides in the `/run` subfolder in the work directory. No value was specified for the `policy_project_name`; therefore, policies are created in a policy project called `DefaultPolicies`. For example, if the FTPServer configurable service name is `ftpbroker`, a policy file with name `ftpbroker.policyxml` is created under the `run\DefaultPolicies` folder in the work path.
7. Start the integration node by running the command `mqsistart V12BRK`.

   You might see the following error message in the event viewer:

   ```
   File node "File Output" in message flow "FileInOutFlow". The remote user identifier supplied
    as "myftp" is invalid.
   The user identifier supplied by a securityIdentity is not valid. Either the user identifier
    is missing, or no securityIdentity definition exists, or the securityIdentity registry
    information could not be read due to a permissions problem. FTP processing for this node has
    been disabled.
   Ensure that the securityIdentity is correctly defined using the mqsisetdbparms command.
   ```

   Currently, the **mqsiextractcomponents** command does not migrate the credentials that are set by using the **mqsisetdbparms** command in IBM Integration Bus 10.0. Therefore, you need to set the security identity and other credentials by running the **mqsisetdbparms** again in IBM App Connect Enterprise 12.0:

   ```
   mqsisetdbparms V12BRK -n ftp::myftp -u user -p password
   ```
8. Restart the IBM App Connect Enterprise 12.0 integration node by running the **mqsistop** command, followed by the **mqsistart** command.

Migrating an integration node with multiple integration servers

Use the **mqsiextractcomponents** command to migrate an IBM Integration Bus 10.0 integration node with multiple integration servers to IBM App Connect Enterprise 12.0 independent integration servers.

Procedure

1. Create an application with a few message flows in the IBM Integration Bus 10.0 Toolkit.
2. Create an integration node called `Migration Node`.
3. Create three integration servers called `MigrationServer1`, `Migrationserver2`, and `MigrationServer3`.
4. Deploy the application to all of the three integration servers.
5. Back up the integration node by using the **mqsibackupbroker** command:

   ```
   mqsibackupbroker MigrationNode -d C:\temp\
   ```
6. Copy the broker backup file to the IBM App Connect Enterprise 12.0 server for migration.
7. In IBM App Connect Enterprise 12.0, use the **mqsiextractcomponents** command to create three independent integration servers:

   ```
   mqsiextractcomponents --source-integration-node MigrationNode --source-integration-server
    MigrationServer1 --backup-file C:\temp\MigrationNode_181114_120112.zip --target-work-
   directory C:\temp\MigrationServer1 --default-application DefApp
   ```

```
mqsiextractcomponents --source-integration-node MigrationNode --source-integration-server
 MigrationServer2 --backup-file C:\temp\MigrationNode_181114_120112.zip --target-work-
directory C:\temp\MigrationServer2 --default-application DefApp
mqsiextractcomponents --source-integration-node MigrationNode --source-integration-server
 MigrationServer3 --backup-file C:\temp\MigrationNode_181114_120112.zip --target-work-
directory C:\temp\MigrationServer3 --default-application DefApp
```

Note: We specify the –`default-application DefApp` option to ensure that any message flows that are deployed as independent projects are moved into the default application `DefApp`. In IBM App Connect Enterprise 12.0, all resources must be part of an application.

8. Start the independent integration server by using the **`IntegrationServer`** command:

```
IntegrationServer --name MigrationServer1 --work-dir C:\temp\MigrationServer1
```

9. To demonstrate that the configurable services that were defined for the IBM Integration Bus 10.0 integration nodes are copied with the migrated integration server, complete the following steps.

   a) Create a configurable service.
   `mqsicreateconfigurableservice MigrationNode -c FtpServer -o FtpServer01 -n serverName,scanDelay,transferMode,connectionType,securityIdentity -v one.hursley.abc.com:123,20,Binary,ACTIVE,secId`

   b) Modify your message flow to use the FTP configurable service.

   c) Save the message flow and redeploy the application to the integration server `MigrationServer1`.

   d) Create a new backup by using the **`mqsibackupbroker`** command in IBM Integration Bus 10.0.

```
mqsibackupbroker MigrationNode -d C:\temp\
```

   e) In IBM App Connect Enterprise 12.0, run the **`mqsiextractcomponents`** command:

```
mqsiextractcomponents --source-integration-node MigrationNode --source-integration-server
 MigrationServer1 --backup-file C:\temp\MigrationNode_181114_125348.zip --target-work-
directory C:\temp\MigrationServer4 --default-application DefApp
BIP8071I: Successful command completion.
```

   The folder `C:\temp\MigrationServer4\run\DefaultPolicies` contains the FTP configurable service policy under the IBM App Connect Enterprise 12.0 independent integration server. The FtpServer01 configurable service is available as a new policy. The `FtpServer01.policyxml` file contains configurations that match your FTP Server configurations.

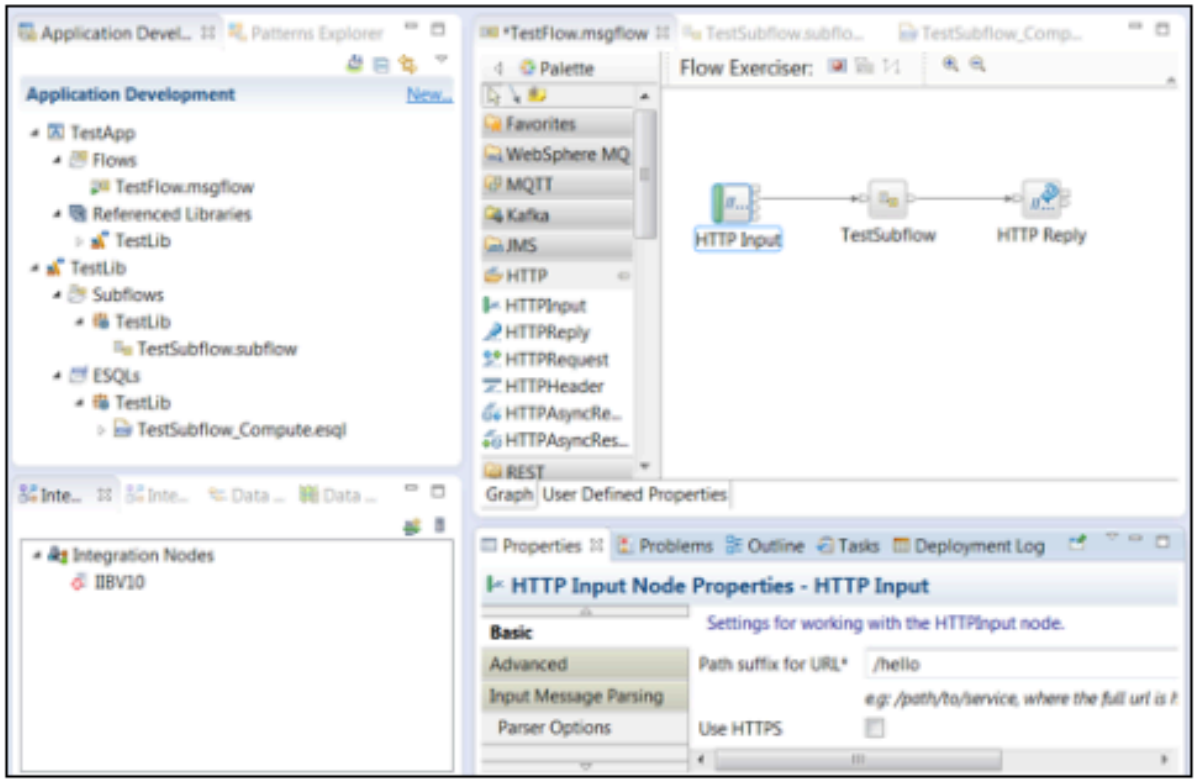
   f) Start the independent integration server by using the **`IntegrationServer`** command and verify the flow execution.

Migrating an integration server that contains applications and a shared library

Migrate an IBM Integration Bus 10.0 integration server that contains applications and a shared library to IBM App Connect Enterprise 12.0.

Procedure

1. In IBM Integration Bus 10.0, create a shared library to contain a simple subflow. Create an application with a simple message flow that uses the subflow from the shared library.



```
CREATE COMPUTE MODULE TestSubflow_Compute
    CREATE FUNCTION Main() RETURNS BOOLEAN
    BEGIN
        CALL CopyMessageHeaders();
        -- CALL CopyEntireMessage();
        SET OutputRoot.XMLNSC.out = 'Hello ' || InputRoot.XMLNSC.in;
        RETURN TRUE;
    END;
```

2. Deploy the shared library to the IBM Integration Bus 10.0 integration node `IIBV10`.
3. Back up the IBM Integration Bus 10.0 integration node `IIBV10` by using the **`mqsibackupbroker`** command.

```
mqsibackupbroker IIBV10 -d c:\temp
```

4. Create a new IBM App Connect Enterprise 12.0 integration node called ACEV12 by using the command `mqsicreatebroker ACEV12`.
5. Start the IBM App Connect Enterprise 12.0 node ACEV12 to set up the work directory.
6. Stop the IBM App Connect Enterprise 12.0 node.
7. Create a blank work directory for the integration server `IS1` to be migrated to IBM App Connect Enterprise 12.0.

8. Use the **mqsiextractcomponents** command to migrate the IBM Integration Bus 10.0 integration server IS1 to IBM App Connect Enterprise 12.0, then start the integration node ACEV12.

```
mqsiextractcomponents --source-integration-node IIBV10 --source-integration-server IS1 --
backup-file c:\temp\IIBV10_181118_220025.zip
--target-work-directory c:\ProgramData\IBM\MQSI\components\ACEV12\servers\IS1
```

```
mqsistart ACEV12
```

9. After you start the node, connect to the integration node from the IBM App Connect Enterprise Toolkit.

   The application and shared library resources that were migrated from the IBM Integration Bus 10.0 node appear under the integration node ACEV12.

10. Test the migrated flow.
    For example:

```
C:\user\curl_7_53_1_openssl_nghttp2_x64>curl -d "<in>Test</in>" http://localhost:7800/hello
<out>Hello Test</out>
```

Migrating an SAP integration flow

Migrate an SAP integration flow that runs on IBM Integration Bus 10.0 to IBM App Connect Enterprise 12.0.

About this task

The following steps describe how to create an SAP integration flow in IBM Integration Bus 10.0, then how to migrate it to IBM App Connect Enterprise 12.0. The steps describe two different migration options: migrating to an integration node or an independent integration server. This scenario uses an SAP outbound adapter as an example; the same steps apply to an inbound adapter.

Procedure

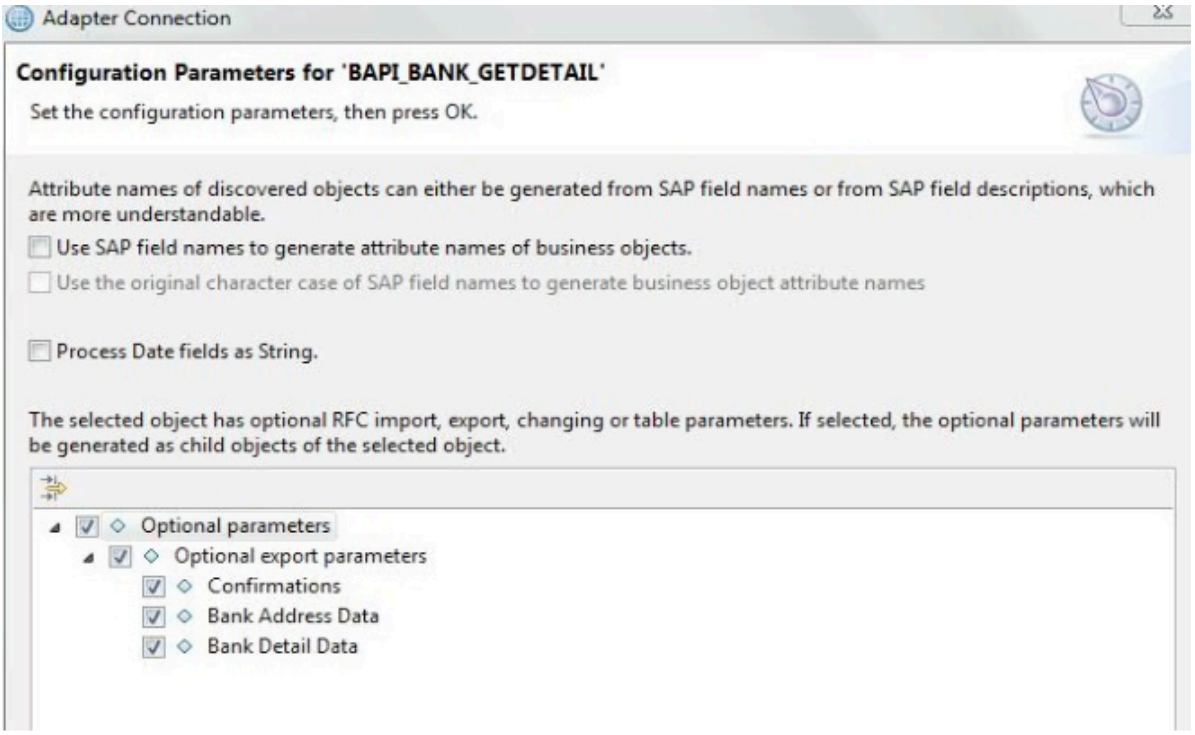
- “Creating an SAP integration flow in IBM Integration Bus 10.0” on page 35
- “Migrating an IBM Integration Bus 10.0 integration node to an IBM App Connect Enterprise 12.0 integration node” on page 39
- “Migrating an integration flow from an IBM Integration Bus 10.0 integration node to an IBM App Connect Enterprise 12.0 independent integration server” on page 40

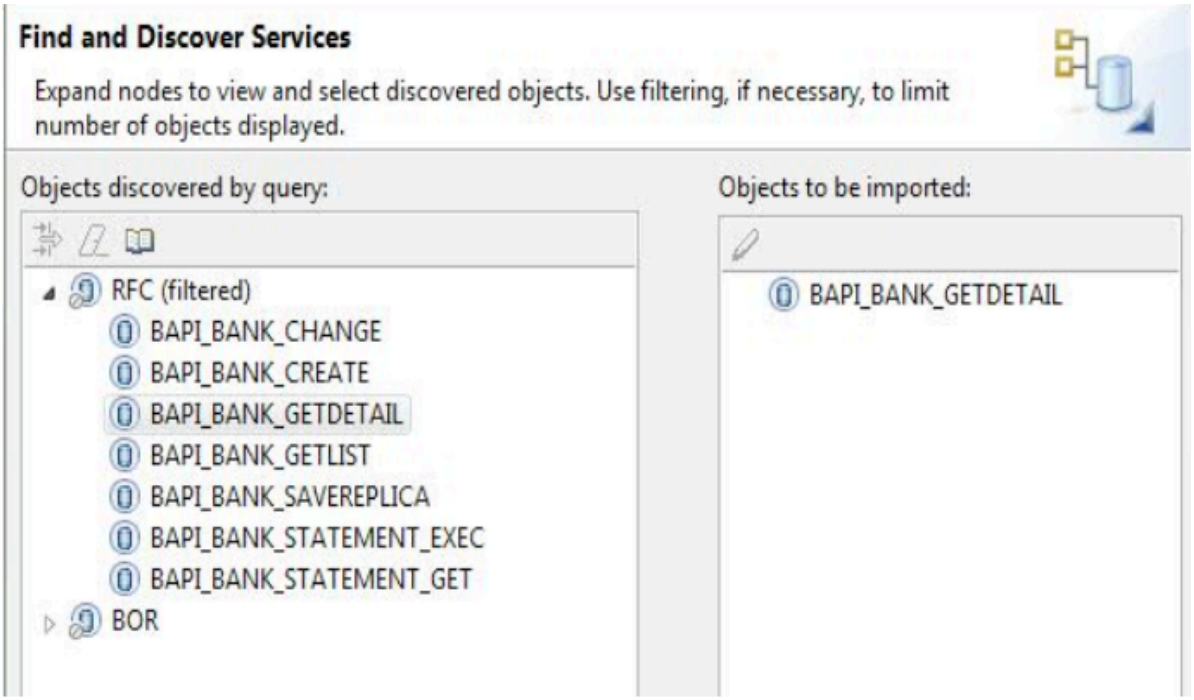
Creating an SAP integration flow in IBM Integration Bus 10.0

Procedure

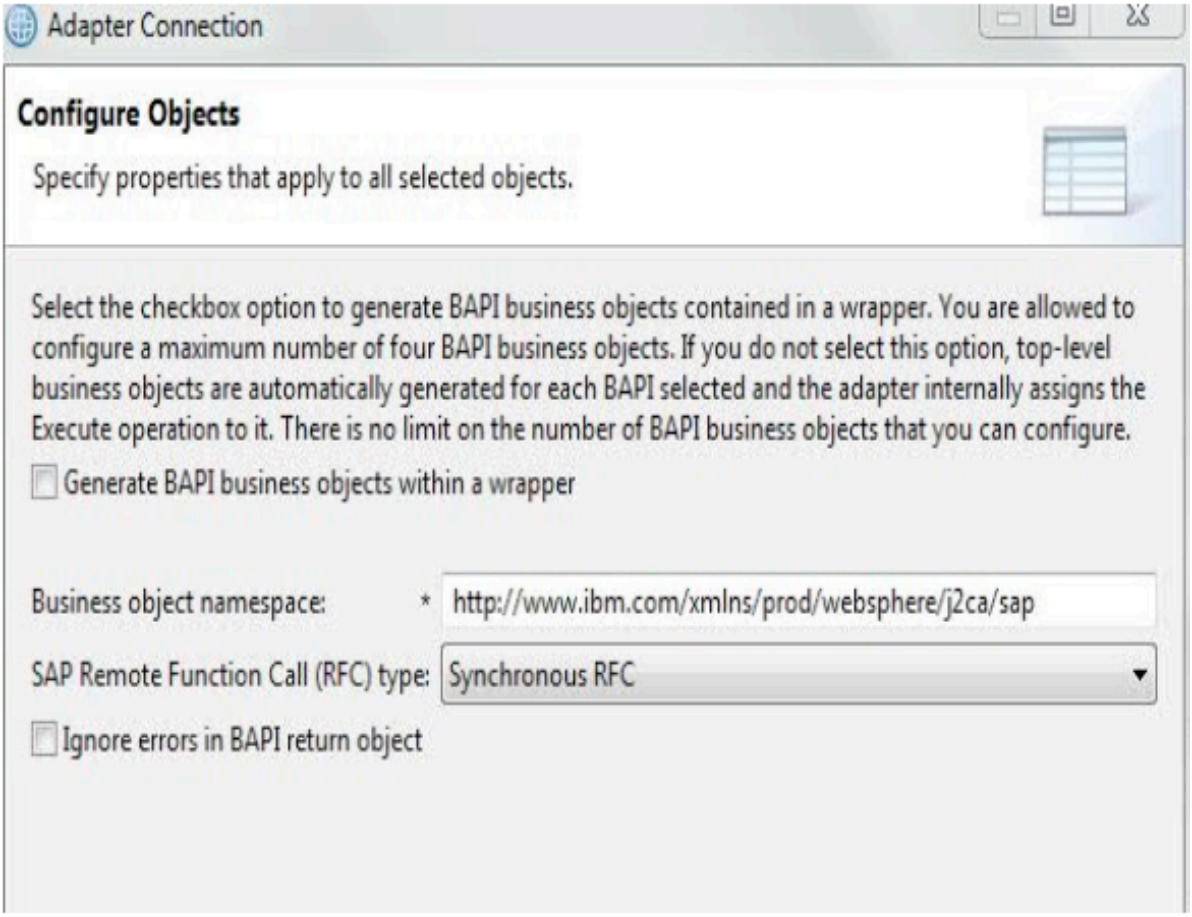
1. In IBM Integration Bus 10.0, create an SAP outbound adapter to fetch `BAPI_BANK_GETDETAILS`.
   a) In the IBM Integration Toolkit, click **File** > **New** > **Adapter connection**, then follow the instructions in the wizard.
   b) For service discovery, select **RFC** and set a filter to find objects for `BAPI_BANK_*`.

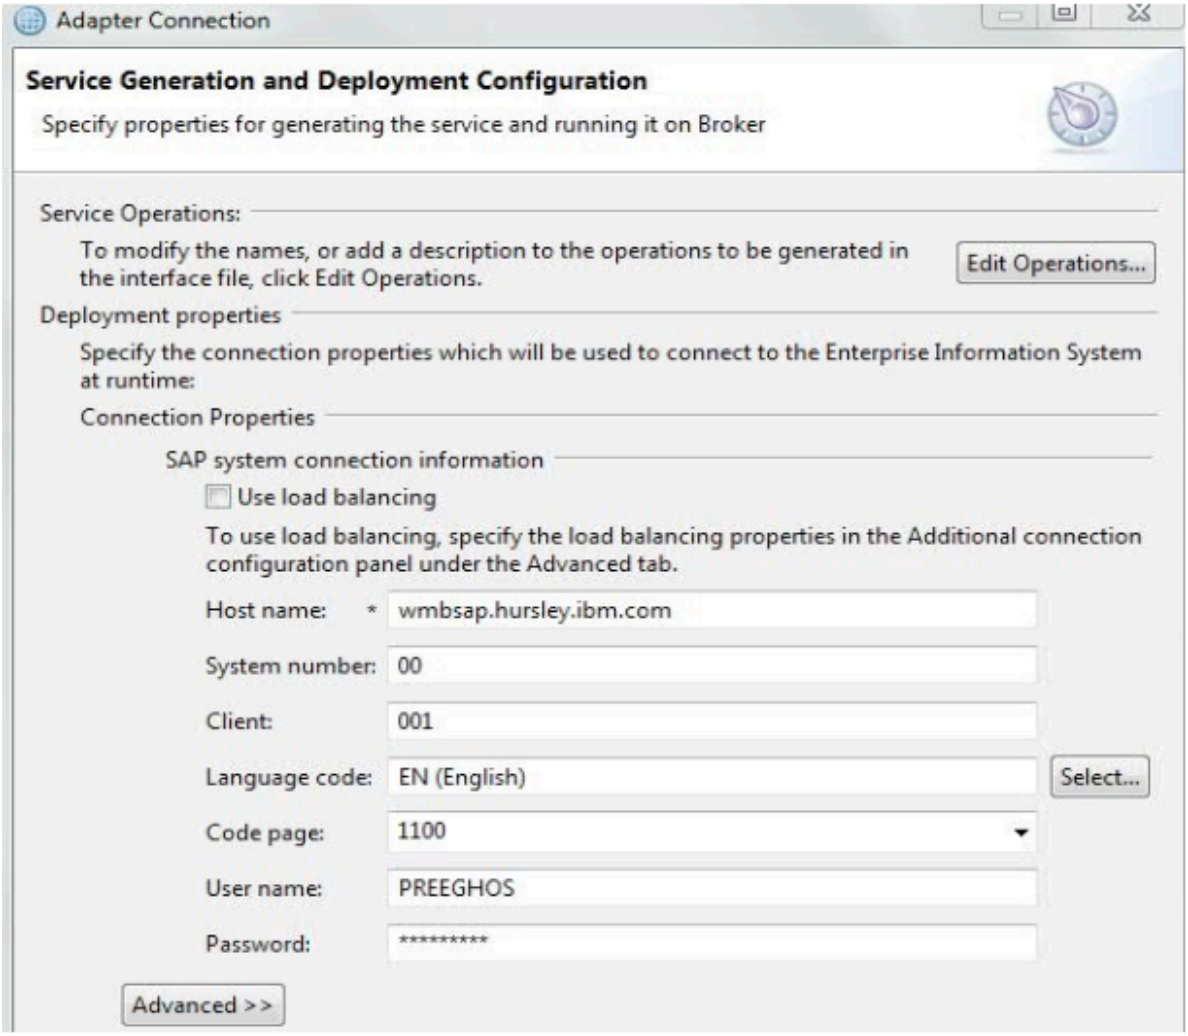
   c) For the the `BAPI_BANK_GETDETAIL` configuration parameters , select the objects to import.





d) Configure the objects.





2. Create a simple SAP application to fetch `BAPI BANK GETDETAILS`.
3. Configure the integration node with SAP JCo libraries by using the **`mqsichangeproperties`** command.

```
mqsichangeproperties IIBNODE -c EISProviders -o SAP -n jarsURL -v C:\SAP_JARS
mqsichangeproperties IIBNODE -c EISProviders -o SAP -n nativeLibs -v C:\SAP_JARS
```

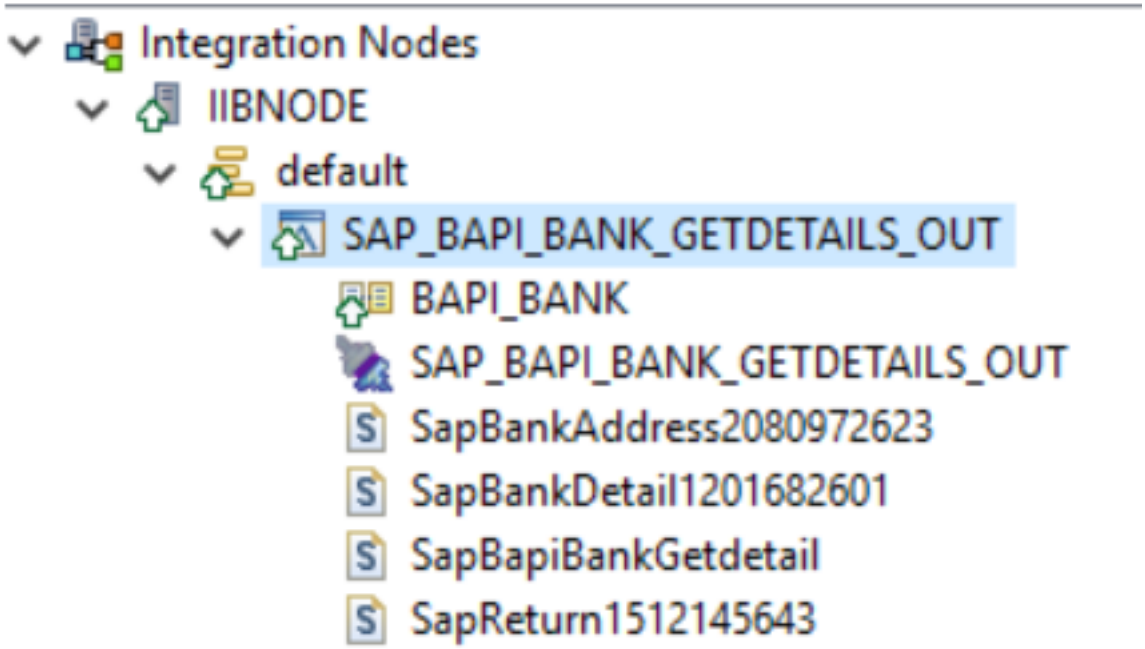
You can verify that the properties are set up correctly by running the command:
`mqsireportproperties IIBNODE -c EISProviders -o SAP -r`

```
C:\Program Files\IBM\IIB\10.0.0.16>mqsireportproperties IIBNODE -c EISProviders -o SAP -r

EISProviders
  SAP
    jarsURL='C:\SAP_JARS'
    nativeLibs='C:\SAP_JARS'

BIP8071I: Successful command completion.
```

4. Deploy the resources to the integration server.



5. Create a configurable service for the SAP adapters connection.

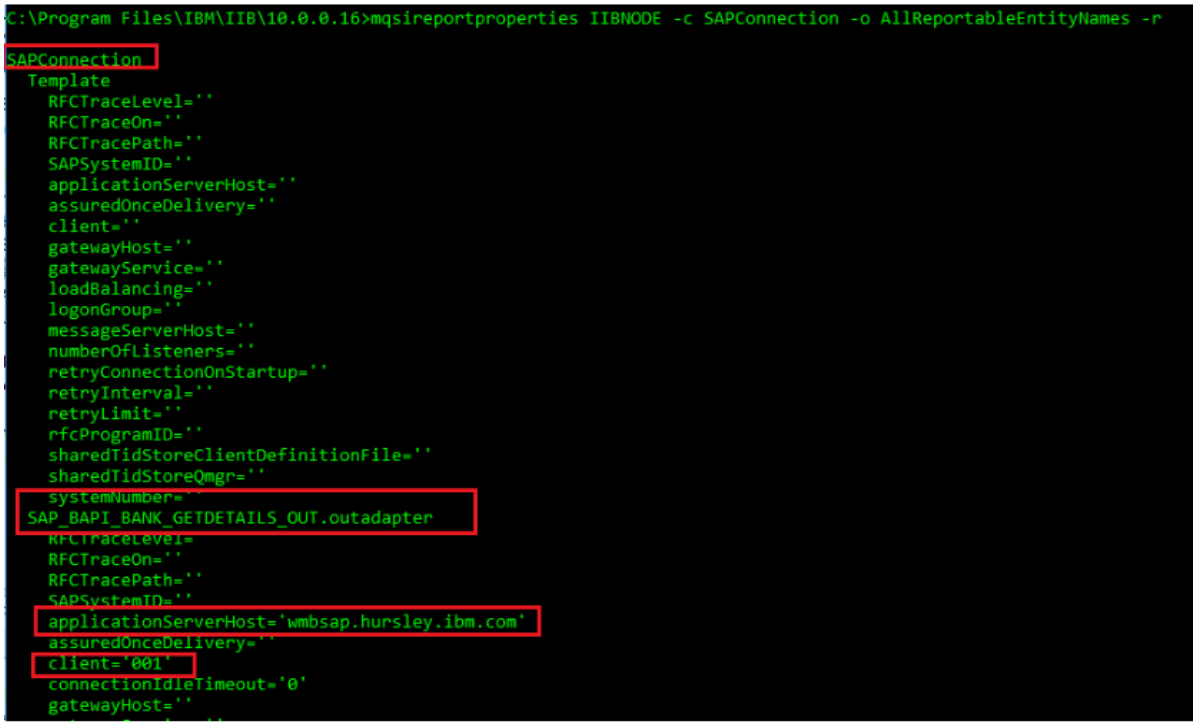
   By using a configurable service, you can change the host name that is set in the adapter file without needing to redeploy the resources.

   a) Use the SAPConnection configurable service to change connection details for an SAP adapter.

```
mqsicreateconfigurableservice IIBNODE -c SAPConnection -o
 SAP_BAPI_BANK_GETDETAILS_OUT.outadapter -n applicationServerHost,client -v
 wmbsap.hursley.ibm.com,001
```

   b) To display all SAPConnection configurable services, use the **mqsireportproperties** command:

```
mqsireportproperties IIBNODE -c SAPConnection -o AllReportableEntityNames -r
```



Migrating an IBM Integration Bus 10.0 integration node to an IBM App Connect Enterprise 12.0 integration node

Procedure

1. Back up the IBM Integration Bus 10.0 integration node by using the **mqsibackupbroker** command.

```
mqsibackupbroker IIBNODE -d C:\SAP_JARS
```

2. Migrate the IBM Integration Bus 10.0 integration node and resources to IBM App Connect Enterprise 12.0 by using the **mqsiextractcomponents** command.

```
mqsiextractcomponents --source-integration-node IIBNODE --target-integration-node ACENODE --
backup-file "C:\SAP_JARS\IIBNODE_190712_083247"
```

   This **mqsiextractcomponents** command creates a new integration node and integration server. If the integration node already exists, the **mqsiextractcomponents** command fails unless you

specify –delete-existing-node. In this case, the existing integration node is deleted and a new integration node is created with the same name.

All deployed resources are migrated under the /run directory of the created integration server. For example, on Windows: C:\ProgramData\IBM\MQSI\components\IntegrationNode\servers\IntegrationServer.

During migration, the IBM Integration Bus 10.0 configurable services are converted to policies in IBM App Connect Enterprise 12.0. You can find the policy project in the integration node work directory. If you do not specify a policy project name, policies are created in a policy project called DefaultPolicies. The policy file that is created has the same name as the adapter.

3. Start the IBM App Connect Enterprise 12.0 integration node by running the command mqsistart ACENODE.

   The application and policy files are listed under the IBM App Connect Enterprise 12.0 node in the Toolkit. You can confirm the location of the migrated JAR files by running the **mqsireportproperties** command on the IBM App Connect Enterprise 12.0 node.

```
mqsireportproperties ACENODE -c EISProviders -o SAP -r
```

4. Test the integration flow by sending a message to fetch the record for BAPI BANK GETDETAILS.

   The following example shows the expected output message.

```
<NS1:SapBapiBankGetdetail xmlns:NS1="http://www.ibm.com/xmlns/prod/websphere/j2ca/sap/sapbapibankgetdetail">
<SapBankAddress>
<NameOfBank>Laan og Spar</NameOfBank>
<HouseNumberAndStreet>Havnegade 6</HouseNumberAndStreet>
<City>1900 Copenhagen V</City>
<BankNumber>1200</BankNumber>
</SapBankAddress>
<SapBankDetail>
<DateOnWhichTheRecordWasCreated>1997-10-02</DateOnWhichTheRecordWasCreated>
<NameOfPersonWhoCreatedTheObject>SAP</NameOfPersonWhoCreatedTheObject>
</SapBankDetail>
<SapReturn>
<MessageNumber>000</MessageNumber>
<ApplicationLogInternalMessageSerialNumber>000000</ApplicationLogInternalMessageSerialNumber>
<LinesInParameter>0</LinesInParameter>
</SapReturn>
</NS1:SapBapiBankGetdetail>
```

Migrating an integration flow from an IBM Integration Bus 10.0 integration node to an IBM App Connect Enterprise 12.0 independent integration server

Procedure

1. Migrate an IBM Integration Bus 10.0 integration server to an IBM App Connect Enterprise 12.0 independent integration server by running the **mqsiextractcomponents** command.

```
mqsiextractcomponents --source-integration-node IIBNODE --source-integration-
server default --target-work-directory "C:\temp\ACESIS" --backup-file "C:\SAP_JARS
\IIBNODE_190712_083247.zip"
```

   If the work directory already exists, the **mqsiextractcomponents** command fails unless you specify –clear-work-directory. In this case, the configuration and resources are written to the work directory, and overwrite any data that might be present in the directory.

2. Start the IBM App Connect Enterprise 12.0 integration server by running the **IntegrationServer** command.

```
IntegrationServer --name default --work-dir C:\temp\ACESIS
```

All deployed resources are migrated to the `/run` subfolder in the work directory of the independent integration server.

During migration, the values that are set by using the **mqsichangeproperties** command in IBM Integration Bus 10.0 are added to the `server.conf.yaml` file in the `/overrides` subfolder in the work directory of the IBM App Connect Enterprise 12.0 integration server.

Also during migration, the IBM Integration Bus 10.0 configurable services are converted to policies in IBM App Connect Enterprise 12.0. You can find the policy project in the `/run` subfolder of the work directory for the integration server. If you do not specify the policy project name, policies are created in a policy project called `DefaultPolicies`. The name of the policy file that is created is the same as the adapter.

The application and policy files are listed under the IBM App Connect Enterprise 12.0 integration server in the Toolkit.

Performing pre-migration tasks

Perform the prerequisite tasks for migration to IBM App Connect Enterprise 12.0.

Procedure

Complete the following steps before you migrate your integration nodes or integration servers.

- Back up your resources by following the instructions in "Backing up resources before migration" on page 41.
- If your environment includes access to databases, create ODBC definitions for the databases and specify appropriate database drivers; see "Updating ODBC definitions when you migrate to IBM App Connect Enterprise 12.0" on page 42.
- Optional: If you plan to move your architecture to adopt containers, run the Transformation Advisor tool, as described in "Running the Transformation Advisor tool" on page 44.

What to do next

After you complete your pre-migration tasks, complete migration by following the instructions in "Migrating to IBM App Connect Enterprise 12.0" on page 57.

Backing up resources before migration

Back up your resources before you start to migrate to IBM App Connect Enterprise 12.0.

Before you begin

To plan your migration strategy, read "Preparing for migration" on page 19.

Procedure

Before you complete migration tasks, back up your current resources by completing the following steps.

1. Optional: If your message flows access user databases through an ODBC connection, back up the ODBC files that you use for these connections.

   Take a copy of these files and store them safely in a different location.

2. Back up your Toolkit workspace and resources, such as message flow files, message set definition files, Java files, ESQL files, mapping files, XML Schema files, and BAR files.
   - Export all the projects from your current Toolkit.
   - Archive your workspace resources.

     If you manage your workspace resources in a shared repository (for example, CVS), follow standard backup procedures for safeguarding versions. Create a version for storing Version 12.0 resources.

     If you maintain your workspace resources on a local or shared disk, copy your workspace directory to a different location.

Updating ODBC definitions when you migrate to IBM App Connect Enterprise 12.0

Before you migrate an integration server or integration node, create ODBC definitions for databases and specify appropriate database drivers for IBM App Connect Enterprise 12.0.

About this task

The database drivers that are supported by IBM App Connect Enterprise 12.0 might be at a later version than the drivers that are used by previous versions.

Follow the instructions that are provided for your operating system:

- "Updating ODBC definitions on Windows systems" on page 42
- "Updating ODBC definitions on Linux systems" on page 43

Updating ODBC definitions on Windows systems

Procedure

1. To change the ODBC connection definitions, open the **ODBC Data Source Administrator** window, then open the **System DSN** page.
2. For each Oracle and Sybase database that is accessed by the integration node, compare the ODBC driver against the entries that are listed in the following table, where *n* is the level of the installed fix pack (if appropriate).

DBMS	IBM App Connect Enterprise 12.0 ODBC driver name
Sybase	IBM App Connect Enterprise 12.0.1.*n* - DataDirect Technologies 64-BIT Sybase Wire Protocol
Oracle	IBM App Connect Enterprise 12.0.1.*n* - DataDirect Technologies 64-BIT Oracle Wire Protocol

   If the ODBC driver does not match, associate the data source name with the new ODBC driver by completing the following steps.

   a) Delete the data source by clicking **Remove**.

   b) Re-create the data source with the new ODBC driver by clicking **Add**.

3. To change the XA resource manager definitions, complete the following steps.
   a) Open the **Properties** window of the integration node queue manager by using the IBM MQ Services snap-in.
   b) Open the **Resources** page.
   c) For each Oracle and Sybase database that participates in a global unit of work that is coordinated by the integration node queue manager, change the contents of the **SwitchFile** field.

      The following table specifies the entries that you must change for each database management system (DBMS). *install_dir* represents the fully qualified path name of the directory in which you installed IBM App Connect Enterprise.

DBMS	Original entry	New entry
Oracle	*install_dir*\server\bin\ukor8dtc22.dll or *install_dir*\server\bin\ukor8dtc23.dll or *install_dir*\server\bin\ukora24.dll or *install_dir*\server\bin\ukora26.dll	*WBIMB*\bin\ukora95.dll
Sybase	*install_dir*\server\bin\ukase22.dll or *install_dir*\server\bin\ukase23.dll or *install_dir*\server\bin\ukase24.dll or *install_dir*\server\bin\ukase26.dll	*WBIMB*\bin\ukase95.dll

   d) For changes to the switch file configuration to take effect, restart the integration node queue manager.

Updating ODBC definitions on Linux systems

Procedure

1. To change the ODBC connection definition, create an ODBC definitions file by following the instructions in "Connecting to a database from Linux and UNIX systems by using the IBM Integration ODBC Database Extender" on page 189.

   Before you run the commands at the new service level, check that your ODBCINI environment variable points to the new file and not to the existing file. Check that the ODBCSYSINI environment variable is set to point to the directory that contains your odbcinst.ini file.

2. To change the XA resource manager definitions, edit the queue manager configuration file (`qm.ini`) of the queue manager that is associated with the integration node.

   The `qm.ini` file is in the directory `/var/mqm/qmgrs/`*`queue_manager_name`*, where *`queue_manager_name`* is the name of the queue manager that is associated with the integration node.

   In the *XAResourceManager* stanza for each Oracle and Sybase database that participates in a global unit of work that is coordinated by the integration node queue manager, change the entry for the switch file.

   The following table specifies the entries that you must change for each operating system and database management system (DBMS).

DBMS	Original entry	New entry

Oracle	`SwitchFile=UKor8dtc22.so`
	or
	`SwitchFile=UKoradtc22.so`
	or
	`SwitchFile=UKor8dtc23.so`
	or
	`SwitchFile=UKoradtc23.so`
	or
	`SwitchFile=UKoradtc24.so`
	or
	`SwitchFile=UKoradtc26.so`
		`SwitchFile=UKoradtc95.so`

Sybase (not supported on Linux on Z)	`SwitchFile=UKasedtc22.so`
	or
	`SwitchFile=UKasedtc23.so`
	or
	`SwitchFile=UKasedtc24.so`
	or
	`SwitchFile=UKasedtc26.so`
		`SwitchFile=UKasedtc95.so`

3. For changes to the switch file configuration to take effect, restart the integration node queue manager.

Running the Transformation Advisor tool

If you plan to move your architecture to adopt containers, run the Transformation Advisor tool before you migrate to IBM App Connect Enterprise 12.0. Use the tool to collect data about what is deployed to your IBM Integration Bus 10.0 or IBM App Connect Enterprise 11.0 integration node, then analyze the collected data for potential issues.

About this task

If you are planning to move to a containerized environment, the Transformation Advisor tool helps you to analyze your on-premises workloads for modernization. You can collect and assess data for a specific integration server in an integration node backup in App Connect Enterprise by using the **`TADataCollector`** command. You can also upload the results that are produced by the Transformation Advisor tool to IBM Cloud® Transformation Advisor. For more information, see IBM Cloud Transformation Advisor.

Procedure

To collect and analyze data about your IBM Integration Bus 10.0 or IBM App Connect Enterprise 11.0 integration node, complete the following steps.

1. Back up the resources that you want to migrate by using one of the following methods.
   - Create a backup file of your IBM Integration Bus 10.0 or IBM App Connect Enterprise 11.0 integration node by running the **mqsibackupbroker** command:

     ```
     mqsibackupbroker node10 -d C:\temp -a node10.zip
     ```

   - Add the resources that you want to migrate to a deployable BAR file by running the **mqsipackagebar** command:

```
mqsipackagebar -w C:\Workspace -a myapp.bar -c -i -k Application1 -y Shlib1 -v tracefile
```

2. Optional: In IBM App Connect Enterprise 12.0, create an output directory to write the logs from the **TADataCollector** command, and set the value of the environment variable *TADataCollectorDirectory* to the name of the output directory. If you do not create an output directory, the logs are written to a temporary folder in the home directory of the user who runs the command.
   a) Create an output directory by running the command `mkdir C:\TADemo`.
   b) Set the environment variable *TADataCollectorDirectory* to the path of the output directory by running the command `set TADataCollectorDirectory=C:\TADemo`.
3. In IBM App Connect Enterprise 12.0, run the **TADataCollector** command with one of the following options:
   - To collect data, run the command:

     ```
     TADataCollector ace collect C:\temp\node10.zip
     ```

   - To collect and assess data, run the command:

     ```
     TADataCollector ace assess C:\temp\node10.zip
     ```

   - To generate reports on data that is collected and assessed by the previous two options, run the command:

     ```
     TADataCollector ace report
     ```

   - To collect and assess data, and generate reports, run the command:

     ```
     TADataCollector ace run C:\temp\node10.zip
     ```

   For more information about the **TADataCollector** command, see command.

   When you run the **TADataCollector** command, output is written to an output directory. If you created the output directory and set the *TADataCollectorDirectory* environment variable, the output is written to that directory. Otherwise, the output is written to a temporary folder in the home directory of the user who runs the command. For example, `C:\Users\`*`username`*`\AppData\Local\Temp\TADataCollector`.

   The following subdirectories are created in the output directory:

   - `logs`: This folder contains the log *ta_util.log* that you can use to check for errors in the process.
   - `output`: This folder contains a file `environment.json`, which shows the details of the environment where the integration node was created. The folder also contains a subfolder for each integration server (for example, `node10/server10`), which contains a `.json` file. The `.json` file contains details of what is deployed to the integration server. It also contains configuration details that were generated when you ran the **TADataCollector** command.

4. Review the contents of the `output` folder in the output directory.

   If you ran the **`TADataCollector`** command with the `run` parameter, a static HTML report is produced; for example, `C:\TADemo\output\node10\recommendations.html`. The report lists any issues that are found for each integration server under the integration node.

   To view more detailed information about the issues, follow the links in the summary table or scroll down the page. Each issue has an *Overall Complexity Score* that denotes the type of action that is needed:

   - `Simple`: An administrative change is needed.
   - `Moderate`: A development change is needed.
   - `Complex`: A difficult development task is involved or an alternative strategy is needed.

   The Transformation Advisor tool also provides a severity classification for each issue it uncovers:

   - `Green (info)`: No immediate action is necessary, but you might want to be aware.
   - `Yellow (warning)`: Immediate action is probably needed or advised before you proceed.
   - `Red (error)`: You must take remedial action before you can proceed.

   The following example shows a complex issue with a severity classification of red that was identified when the tool was run against the IBM Integration Bus 10.0 integration node, *node10* with one integration server, *server10*.

Table 1. Recommendation report for assessment: node10

Assessment unit	Overall complexity score	Issues	Total effort (days)
server10	COMPLEX	1	10

Table 2. Recommendation report for assessment unit: server10

Product name	Product version	Runtime	Platform	Location
ACE	11.0	ACE	Docker	Private

Table 3. Overall complexity score: COMPLEX

RED issues: 1	Yellow issues: 0	Green issues: 0

Table 4. Issues with a COMPLEX complexity rating can be resolved by making significant development changes or by choosing an alternative technology:

ID	Title	Cost	Severity	Solution
IIB01	Consider a different transformation mechanism in place of .NET.	10	RED	The message flow contains an instance of a.NETInput or .NETCompute message flow node. While IBM App Connect Enterprise 12.0 software continues to support .NET, it does not support running the .NET CLR during deployment to Linux Docker containers on App Connect Enterprise Certified Containers. Other message flow nodes are available for transformation such as Compute, JavaCompute, and Mapping nodes.

For more information about the rules that apply to the Transformation Advisor tool, see “Rules for the Transformation Advisor tool” on page 47.

5. Complete any actions that are advised by the report, then run the Transformation Advisor tool again to confirm that all issues are resolved.

Rules for the Transformation Advisor tool

When you use the Transformation Advisor tool to analyze your deployed resources, different rules apply depending on whether you back up your resources to a backup file or a BAR file.

If you plan to move your architecture to adopt containers, you can run the Transformation Advisor tool to collect data about what is deployed to your IBM Integration Bus 10.0 or IBM App Connect Enterprise 11.0 integration node. You can then analyze the collected data for potential issues before you migrate. For more information, see “Running the Transformation Advisor tool” on page 44.

The following table shows the rules that apply to the Transformation Advisor tool and whether they apply to a backup file, a BAR file, or both.

Table 5. Rules for the Transformation Advisor tool:

ID	Title	Can be found in a backup file	Can be found in a BAR file	Solution
IIB001	Consider a different transformation mechanism in place of .NET.	True	True	The message flow contains an instance of a .NETInput or .NETCompute message flow node. While IBM App Connect Enterprise 12.0 software continues to support .NET, it does not support running the .NET CLR when it is deployed to Linux Docker containers on App Connect Enterprise Certified Containers. Other message flow nodes are available for transformation such as Compute, JavaCompute, and Mapping nodes.
IIB002	Consider a different transformation mechanism in place of PHP.	True	True	The message flow contains an instance of a PHPCompute message flow node. The PHPCompute node was deprecated in IBM Integration Bus 10.0 and it was removed from IBM App Connect Enterprise 11.0. Other message flow nodes are available for transformation, such as Compute, JavaCompute, and Mapping nodes.

Table 5. Rules for the Transformation Advisor tool: (continued)

ID	Title	Can be found in a backup file	Can be found in a BAR file	Solution
IIB003	Consider an alternative mechanism to SCA to communicate with WebSphere Process Server.	True	True	The message flow contains an instance of an SCA message flow node (SCAInput, SCAReply, SCARequest, SCAAsyncRequest, SCAAsyncResponse). IBM App Connect Enterprise 12.0 does not support the SCA message flow nodes that were available in IBM Integration Bus 10.0. HTTP, IBM MQ, or JMS transport options are available for communication between message flows and SCA components in WebSphere Process Server.
IIB004	Consider a different mechanism to run IBM Operational Decision Management Business Rules.	True	True	The message flow contains an instance of a DecisionService message flow node. App Connect Enterprise v11.0.0.8 and later provides a replacement message flow node, the ODMRules node. The purpose of this node is to run ODM rules in the integration server. Alternatively, you can use the ODM SOAP or REST API to run business rules in the ODM engine.
IIB005	Consider a different protocol instead of relying on local file integration.	True	True	The message flow contains an instance of a FileInput message flow node that relies on local file interaction, and is not configured to use FTP. Although IBM App Connect Enterprise 12.0 continues to support local files with the FileInput node, if you want to use a container-based architecture, this choice has architectural drawbacks. Consider changing your configuration to use FTP or a more suitable messaging-based transport.
IIB006	Consider your use of WebSphere Service Registry and Repository.	True	True	The message flow contains an instance of a RegistryLookup or EndpointLookup message flow node, which communicates with WebSphere Service Registry and Repository. Releases before App Connect Enterprise 11.0.0.7 do not support these message flow nodes. If you have an urgent need, or a simple use case, you can use the SOAP nodes to communicate with WebSphere Service Registry and Repository. Alternatively, contact IBM to learn more about plans in this area.

Table 5. Rules for the Transformation Advisor tool: (continued)

ID	Title	Can be found in a backup file	Can be found in a BAR file	Solution
IIB07	A Publication message flow node was found. You might want to consider altering your IBM MQ topology.	True	True	The message flow contains an instance of a Publication message flow node. In IBM Integration Bus 10.0 and in versions of IBM App Connect Enterprise 11.0 before Fix Pack 6, this message flow node requires a local server binding connection to an IBM MQ queue manager. IBM App Connect Enterprise 11.0 Fix Pack 6 and later supports the Publication node by using a remote client connection to an IBM MQ queue manager. Consider altering your IBM MQ topology as part of your move to a container-based architecture.
IIB08	A Sequence or Resequence message flow node was found. Consider altering your IBM MQ topology.	True	True	The message flow contains an instance of a Sequence or Resequence message flow node. In versions of IBM App Connect Enterprise 11.0 before Fix Pack 7, this message flow node requires a local server binding connection to an IBM MQ queue manager. Consider altering your IBM MQ topology as part of your move to a container-based architecture.
IIB09	A Collector message flow node was found. Consider altering your IBM MQ topology.	True	True	The message flow contains an instance of a Collector message flow node. In versions of IBM App Connect Enterprise 11.0 before Fix Pack 7, this message flow node requires a local server binding connection to an IBM MQ queue manager. Consider altering your IBM MQ topology as part of your move to a container-based architecture.
IIB10	A TimeoutControl or TimeoutNotification message flow node was found. You might want to consider altering your IBM MQ topology.	True	True	The message flow contains an instance of a TimeoutControl or TimeoutNotification message flow node. In versions of IBM App Connect Enterprise 11.0 before Fix Pack 7, these message flow nodes require a local server binding connection to an IBM MQ Queue Manager. Consider altering your IBM MQ topology as part of your move to a container-based architecture.

Table 5. Rules for the Transformation Advisor tool: (continued)

ID	Title	Can be found in a backup file	Can be found in a BAR file	Solution
IIB11	An AggregateControl, AggregateRequest, or AggregateReply message flow node was found. You might want to consider altering your IBM MQ topology.	True	True	The message flow contains an instance of an AggregateControl, AggregateRequest, or AggregateReply message flow node. In versions of IBM App Connect Enterprise 11.0 before Fix Pack 7, these message flow nodes require a local server binding connection to an IBM MQ queue manager. Consider altering your IBM MQ topology as part of your move to a container-based architecture. In IBM App Connect Enterprise 12.0 the Group nodes are suitable for similar aggregation use-cases but they use in-memory queuing and have no IBM MQ dependency.
IIB12	A KafkaConsumer or KafkaProducer message flow node was found. You might want to consider changing the version of your Kafka broker.	True	True	The message flow contains an instance of a KafkaConsumer or KafkaProducer message flow node. In App Connect Enterprise v11.0.0.4 (and earlier fix packs), the product uses a Kafka client at version 0.10.0.1. In App Connect Enterprise v11.0.0.5 (and later fix packs), the product uses a Kafka client at version 2.20. You might want to change to a different client version when you consider the compatibility of your Kafka broker.
IIB13	A JDEdwardsInput, JDEdwardsRequest, PeopleSoftInput, PeopleSoftRequest, SiebelInput, or SiebelRequest message flow node was found. You might want to consider the version of your App Connect Enterprise installation.	True	True	The message flow contains an instance of a JDEdwardsInput, JDEdwardsRequest, PeopleSoftInput, PeopleSoftRequest, SiebelInput, or SiebelRequest message flow node. These message flow nodes are also supported in IBM App Connect Enterprise 12.0. If you used configurable service definitions with these message flow nodes in IBM Integration Bus 10.0, you might want to consider the introduction of JDEdwards, PeopleSoft, and Siebel policy types in IBM App Connect Enterprise 12.0.

Table 5. Rules for the Transformation Advisor tool: (continued)

ID	Title	Can be found in a backup file	Can be found in a BAR file	Solution
IIB14	An SAPInput or SAPRequest message flow node was found. You might want to consider changing the configuration of your App Connect Enterprise installation.	True	True	The message flow contains an instance of an SAPInput or SAPRequest message flow node. These message flow nodes are also supported in IBM App Connect Enterprise 12.0, but IBM Integration Bus configurable services are replaced with policies. When you move to a container-based architecture, consider how to make the SAP JCo libraries available to your containers and the settings in `server.conf.yaml`.
IIB15	A deprecated graphical mapping message flow node was found. Convert this node to the newer Mapping node.	True	True	The message flow contains an instance of the old graphical mapping message flow node. This type of message flow node is no longer supported. You must convert message maps to graphical data maps. The Toolkit provides a conversion tool for this purpose.
IIB16	A TCPIPServer message flow node was found. Consider altering the configuration of your containers to open the TCPIP port.	True	True	The message flow contains an instance of a TCPIPServer message flow node. If you intend to use a non-default TCPIP port in your containers, consider changing your `values.yaml` file.
IIB17	A LoopBackRequest message flow node was found. Consider altering the configuration of your containers to support this node.	True	True	The message flow contains an instance of a LoopBackRequest message flow node. Your IBM App Connect Enterprise 12.0 installation provides Node Package Manager (NPM) to configure the Loopback Java™ script modules to support this node. When you move to a container-based architecture, consider your build pipeline and its abilities to configure these supporting files in your container.
IIB18	A WebSphere Transformation Extender or IBM Transformation Extender message flow node was found. Consider changing the configuration of your containers to support this node.	True	True	The message flow contains an instance of a WebSphere Transformation Extender or IBM Transformation Extender message flow node. IBM App Connect Enterprise 11.0 Fix Pack 4 (and later) supports the use of this type of message flow node, which is used with IBM Transformation Extender v10. When you move to a container-based architecture, consider this version information.

Table 5. Rules for the Transformation Advisor tool: (continued)

ID	Title	Can be found in a backup file	Can be found in a BAR file	Solution
IIB19	An MQInput, MQOutput, or MQGet message flow node that uses server bindings to a queue manager was found. You might want to consider changing the node to use IBM MQ Client bindings when you move to containers.	True	True	You might want to consider changing to use IBM MQ client bindings when you move to containers so that you can use smaller containers. Independently scaling the integration servers in your architecture from your queue managers is easier to achieve if you use client bindings rather than server bindings.
IIB20	A Healthcare Pack artifact is deployed to this server.	True	True	A Healthcare Pack artifact is deployed to this server. The IBM Integration Bus Healthcare Pack is not supported in IBM App Connect Enterprise 12.0. In App Connect Enterprise v11.0.0.8 (and later), support is provided for applications in healthcare environments through IBM App Connect for Healthcare v5.0.0.0. Consider upgrading to App Connect Enterprise v11.0.0.8 or later and investigate the features that are provided by App Connect for Healthcare V5.0.0.0.
IIB21	A top-level message flow was found that originates in an integration project. These artifacts must be moved to the default application in IBM App Connect Enterprise 12.0.	True	True	A top-level message flow was found that originates in an integration project. When top-level resources are migrated by using the **mqsiextractcomponents** command, they are moved to the default application in IBM App Connect Enterprise 12.0. Ensure that you consider the groupings that you require for all top-level resources. The groupings are likely to involve the adoption of application projects instead of integration projects. Applications and libraries (which were first introduced in WebSphere Message Broker Version 8.0) provide a more efficient way to isolate and group message flows and their associated artifacts. While BAR files that contain top-level message flows can still be deployed to IBM App Connect Enterprise 12.0, these artifacts replace previously deployed default application content on each deployment. Consider the groupings of message flows in light of this change in iterative deployment behavior.

Table 5. Rules for the Transformation Advisor tool: (continued)

ID	Title	Can be found in a backup file	Can be found in a BAR file	Solution
IIB22	A top-level resource was found that originates in an integration project. These artifacts are moved to the default application in IBM App Connect Enterprise 12.0.	True	True	A top-level resource was found. Top-level resources are moved to the default application when they are migrated to IBM App Connect Enterprise 12.0 by using the **mqsiextractcomponents** command. When you migrate to IBM App Connect Enterprise 12.0, consider your groupings for all top-level resources. The top-level resource that this rule detected is likely to be a dependency of a top-level message flow. Consider which message flows depend on this resource. Group the resource so that it continues to be available to the message flow when the flow is moved from its integration project to an application project. You can look for instances of rule IIB21, which detects top-level message flows that might have a dependency on the top-level resource that is highlighted by this rule.
IIB23	A SOAPInput or HTTPInput message flow node was found that is using the integration node-wide listener.	True	False	The message flow contains an instance of a SOAPInput or HTTPInput message flow node that is using the integration node-wide listener. When you run App Connect Enterprise in a container architecture, you do not use an integration node or the integration node-wide listener. Instead, you use an independent integration server with its own embedded HTTP listener.
IIB24	A configuration indicates the use of the Record and Replay feature.	True	False	Record and Replay is available in IBM App Connect Enterprise 12.0. While you can run this capability in a container-based architecture, it depends on a relational database and IBM MQ publications.
IIB25	A SOAPInput or HTTPInput message flow node that uses HTTPS was found.	True	True	The message flow contains an instance of a SOAPInput or HTTPInput message flow node that is using HTTPS. IBM App Connect Enterprise 12.0 uses TLSv1.2, and can also use TLSv1.3 for inbound HTTPS communications. Ensure that TLSv1.2, or TLSv1.3, are acceptable to your Business Partner applications.

Table 5. Rules for the Transformation Advisor tool: (continued)

ID	Title	Can be found in a backup file	Can be found in a BAR file	Solution
IIB26	A globally coordinated message flow was found.	True	True	A globally coordinated message flow was detected. When you adopt a container-based architecture, you are unlikely to want to use globally coordinated message flows in your containers. You might want to reconsider your architecture to avoid global coordination, or to enable these flows to keep running outside containers.
IIB27	Configuration indicates the use of the embedded global cache feature.	True	False	The embedded global cache feature is available in IBM App Connect Enterprise 12.0. It is not advisable to use this capability to share information between integration servers in a container-based architecture. If you do use this capability, consider the placement and persistence of your catalog servers.
IIB28	Configuration indicates the use of the multi-instance high availability feature.	True	False	The multi-instance high availability feature for integration nodes is available in IBM App Connect Enterprise 12.0. You are unlikely to use this model to achieve high availability if you move to a container-based architecture. If you do use this model, consider the persistence and disk requirements.
IIB29	An MRM message set dictionary was detected.	True	True	An MRM message set dictionary was detected. These artifacts are supported for use in IBM App Connect Enterprise 12.0, but consider using DFDL message modeling technology instead.

Table 5. Rules for the Transformation Advisor tool: (continued)

ID	Title	Can be found in a backup file	Can be found in a BAR file	Solution
IIB30	A message flow with user-defined properties was found.	True	True	A message flow with user-defined properties was detected. Message flows can continue to use user-defined properties when deployed to IBM App Connect Enterprise 12.0. If you are moving to a container architecture, you will probably not want to dynamically change the value of user-defined properties after deployment. Instead, when you change configuration data, you are likely to stop your container and restart it with the new configuration applied. In the unlikely event that you want to dynamically update message flow user-defined properties after deployment, an administrative API function is available in IBM App Connect Enterprise 12.0. In general, when you use container-based architectures, other methods for providing configuration to an independent integration server might be preferable, such as a user-defined policy.
IIB31	An IBM Integration Bus Activity Log configurable service was detected, which wrote to local files.	True	False	When you migrate to IBM App Connect Enterprise 12.0, IBM Integration Bus Activity Log configurable services are converted into Activity Log policy documents. When you move to a container-based architecture, you might want to reconsider your chosen output format for Activity Logging.
IIB32	An integration server was associated with an integration node that specified a product edition (that uses the **mqsimode** command) that is no longer available.	True	False	While artifacts can be carried forward, due to changes in licensing, not all IBM Integration Bus software editions have direct IBM App Connect Enterprise 12.0 equivalents. Check with your IBM representative to ensure that you move to the appropriate App Connect Enterprise edition and remain licensed correctly in future.

Table 5. Rules for the Transformation Advisor tool: (continued)

ID	Title	Can be found in a backup file	Can be found in a BAR file	Solution
IIB33	An IBM Integration Bus configurable service was detected that cannot be updated dynamically when it is converted to a policy in IBM App Connect Enterprise 12.0.	True	False	When you migrate to IBM App Connect Enterprise 12.0, IBM Integration Bus configurable services are converted into policy documents. Policy documents have several advantages, such as they can be created by using Toolkit templates and deployed in a BAR file. Some policies cannot be updated dynamically without the need to restart an integration server. This requirement does not typically apply in container-based architectures. However, depending on your use cases, you might want to consider this requirement when you migrate to IBM App Connect Enterprise 12.0.
IIB34	A message flow that uses an MQTT Server was found.	True	True	A message flow uses an MQTT Server because it contains either an MQTTPublish or MQTTSubscribe message flow node. The built-in MQTT Server that is provided by IBM App Connect Enterprise 12.0 is not turned on by default in a container.
IIB35	A message flow that uses an MQTTSubscribe node to monitor IBM Integration Bus events was found.	True	True	A message flow contains an MQTTSubscribe message flow node with a topic root of `IBM/IntegrationBus`. The presence of this node might mean that you have a message flow that is designed to monitor the product itself, and to take further action when data is received. You might want to review this design pattern when you move to a container-based architecture. IBM Integration Bus 10.0 can be configured to publish the following types of information to MQTT: operational events, admin events, business events, flow statistics, and resource statistics. IBM App Connect Enterprise 12.0 can be configured to publish the following types of information to MQTT: business events, flow statistics, and resource statistics. The App Connect Enterprise REST Administration API provides methods that can be called to provide operational and administration information.

Migrating to IBM App Connect Enterprise 12.0

Complete the tasks to migrate to IBM App Connect Enterprise 12.0.

Before you begin

- Plan your migration by reading the topics in “Preparing for migration” on page 19.
- Complete pre-migration tasks by following the instructions in “Performing pre-migration tasks” on page 41.

About this task

Note: IBM App Connect Enterprise 12.0 does not include IBM Integration Explorer; therefore, you cannot migrate IBM Integration Explorer. In IBM App Connect Enterprise 12.0, all integration node administration is done by using the web user interface, the IBM Integration API, or commands. For more information, see the following topics:

- web user interface
- #unique_95
- commands

Procedure

To migrate to IBM App Connect Enterprise 12.0, use one of the following methods.

- Use extract migration to migrate your integration servers and integration nodes by completing the steps in “Performing extract migration of an integration node or integration server” on page 57.

  You can use extract migration to migrate individual integration servers. Extract migration involves the extraction of configuration and resources from your source system to IBM App Connect Enterprise 12.0.
- Alternatively, you can migrate your integration nodes by using parallel migration, as described in “Performing parallel migration for an integration node ” on page 61.
- Migrate your development resources to IBM App Connect Enterprise 12.0 by following the instructions in “Migrating development resources to IBM App Connect Enterprise 12.0” on page 62.

Performing extract migration of an integration node or integration server

You can use the **mqsiextractcomponents** command to migrate from IBM Integration Bus 10.0 or IBM App Connect Enterprise 11.0 to IBM App Connect Enterprise 12.0. Use this command to migrate the configuration and resources of an integration node and of integration servers that are managed by an integration node.

Before you begin

- Plan your migration by reading the topics in “Preparing for migration” on page 19.
- Perform any pre-migration tasks by following the instructions in “Performing pre-migration tasks” on page 41.
- Find out about extract migration and the folder structure that it creates, by reading “Extract migration overview” on page 59.

About this task

Use the **mqsiextractcomponents** command to migrate integration nodes and managed integration servers. Independent integration servers that were created in IBM App Connect Enterprise 11.0 can be started in IBM App Connect Enterprise 12.0 without the need to migrate them or their resources.

However, integration server work directories are typically created as transient rather than long-term artifacts, and many users prefer to rebuild them when moving from one version to another.

Procedure

To complete extract migration for an integration node or a managed integration server, follow the appropriate set of steps:

- "Performing extract migration of an integration node" on page 58
- "Performing extract migration of a managed integration server" on page 58

Performing extract migration of an integration node

Procedure

1. On your source system, run the **mqsibackupbroker** command, specifying the name of the integration node that you intend to migrate to IBM App Connect Enterprise 12.0.

   The following example backs up integration node INODE on Windows, and saves it in the archive file `C:\MQSI\BACKUP\INODE.zip`:

   ```
   mqsibackupbroker INODE -d C:\MQSI\BACKUP -a C:\MQSI\BACKUP\INODE.zip
   ```

   For more information, see command.
2. Transfer the backup file that is created by the **mqsibackupbroker** command to an appropriate location.

   You can transfer the backup file to a location on the same system as the existing integration node, or to a location on a different system.
3. Run the **mqsiextractcomponents** command on the system to which you transferred the backup file.

   On the **mqsiextractcomponents** command, you must specify the following values:

   - The name of the backup file that is created when you run the **mqsibackupbroker** command on the source system
   - The name in the backup file of the integration node from which you are migrating
   - The name of the integration node to which to write the extracted configuration and resources

   You can also specify one or more optional parameters on the **mqsiextractcomponents** command. For more information, see command.
4. Optional: If you plan to run the migrated integration node on the same system as the existing integration node, stop the existing integration node by running the **mqsistop** command before you start the migrated integration node. For more information, see command.
5. Optional: If you plan to run the migrated integration node on the same system as the existing integration node, and with the same name as the existing integration node, delete the existing integration node by running the **mqsideletebroker** command before you start the migrated integration node. For more information, see command.
6. Start the migrated integration node by using the **mqsistart** command. For more information, see command.
7. After the **mqsistart** command completes, check the syslog, or the Windows Event log to confirm that the integration node has started successfully with no errors.

Performing extract migration of a managed integration server

Procedure

1. On your source system, run the **mqsibackupbroker** command, specifying the name of the integration node that is associated with the integration server that you intend to migrate to IBM App Connect Enterprise 12.0.

2. Transfer the backup file that is created by the **mqsibackupbroker** command to an appropriate location on your Version 12.0 system.
3. Run the **mqsiextractcomponents** command on your Version 12.0 system.

   On the **mqsiextractcomponents**, you must specify the following values:

   - The name of the backup file that is created when you run the **mqsibackupbroker** command on the source system
   - The name of the integration node with which the integration server that you are migrating is associated
   - The name of the integration server that you are migrating
   - The work directory to which the integration server components are to be extracted

   You can also specify one or more optional parameters on the **mqsiextractcomponents** command. For more information, see command.
4. When the **mqsiextractcomponents** command completes successfully, start the integration server on your Version 12.0 system by using the **IntegrationServer** command.

What to do next

When you complete migration, see the tasks in "Performing post-migration tasks" on page 64 for information about tasks that you might want to complete after migration.

Extract migration overview

You can use the **mqsiextractcomponents** command to migrate the configuration and resources of integration servers and integration nodes from your source system to your IBM App Connect Enterprise 12.0 system. The command extracts the configuration and resources from your source system and re-creates them in a directory structure on your target system. You can extract the configuration and resources from an integration node, including the configuration and resources from all of the integration servers that are associated with the integration node, or from individual integration servers on your source system.

The following information describes the folder structure that is created when you use extract migration on an integration node or an integration server.

Extract migration of an integration node

The extract migration of the configuration of an integration server or integration node from an earlier version results in the re-creation of the integration server or integration node on your IBM App Connect Enterprise 12.0 system. A node folder is created in the installation directory, or in the directory in which you have your registry. The resources that comprise the integration node configuration on your source system are put into the node folder. The configuration of all the integration servers that are associated with the integration node is also extracted, resulting in the re-creation of these integration servers on your Version 12.0 system. A server sub-folder is created in the node folder for each integration server. The resources that comprise each integration server configuration on your source system are put into the corresponding server sub-folder.

The following table summarizes the folder structure that is created when you perform extract migration of an integration node.

Table 6.

Folder	Sub-folder	Sub-folder	Sub-folder	Contents/description
<node name>				`node.conf.yaml` file. This file contains the settings for your migrated integration node. You can override the settings in the `node.conf.yaml` file by using the **mqsichangeproperties** command.

Table 6. (continued)				
Folder	**Sub-folder**	**Sub-folder**	**Sub-folder**	**Contents/description**
	`servers`			Sub-folders for every integration server that is server associated with the integration node. One sub-folder exists for each integration server.
		<server name>		Sub-folders containing the integration server configuration and resources. The name of the sub-folder is the same as the name of the integration server.
			`run`	Deployed resources.
			`overrides`	`server.conf.yaml` file. This file contains the settings for the integration server. You can override the settings in the `server.conf.yaml` file by using the **mqsichangeproperties** command.
	`policies`			Sub-folders for every policy that is created from a configurable service on the integration node on the source system.
		`NodePolicies`		
			policy_name`.policy.xml`	One policy file per migrated configurable service. The file contains the policy information.

Extraction of configuration and resources of an integration server

The extract migration of the configuration of an integration server from an earlier version results in the re-creation of an independent integration server on your IBM App Connect Enterprise 12.0 system. You might want to migrate an integration server in this way if you are operating in a container-based environment. The resources that comprise the integration server configuration are put into a work directory on your Version 12.0 system. You specify the work directory when you use the **mqsiextractcomponents** command.

The following table summarizes the directory structure that is created when you perform extract migration of an integration server.

Table 7.		
Folder	**Sub-folder**	**Contents/description**
<work_directory_name>		`server.conf.yaml` file. This file contains the settings for your migrated integration server. You can override the settings in the `server.conf.yaml` file by using the **mqsichangeproperties** command.
	`run`	Deployed resources, including policy projects, libraries, and applications.
	`overrides`	`server.conf.yaml` file. This file exists if you dynamically override settings in the integration server `server.conf.yaml` by using the **mqsichangeproperties** command.

Table 7. (continued)		
Folder	**Sub-folder**	**Contents/description**
	`log`	Files containing event log and syslog entries. By default, file names are of the format `integration_server.`*`integration_server_name`*`.entries.txt.`*`n`* where *n* is an integer in the range 1 through 9. When the integration server generates log entries, the most recent log data is held in a file that does not have the *n* suffix. As the data ages, it is held in files with the *n* suffix where the value of *n* increments with the age of the log data: the oldest data is held in the file that is suffixed 9. The files fill in an incremental fashion; when one file becomes full, entries are written to the next consecutive file.
	`config`	Files containing other configuration information such as security configuration.

To complete extract migration, follow the instructions in "Performing extract migration of an integration node or integration server" on page 57.

Performing parallel migration for an integration node

You can use parallel migration to do a staged migration process by creating a new Version 12.0 integration node to run in parallel with your existing integration node. You can then migrate your application logic from your existing integration node to your new integration node.

Before you begin

- Plan your migration by reading the topics in "Preparing for migration" on page 19.
- Complete pre-migration tasks by following the instructions in "Performing pre-migration tasks" on page 41.
- If your deployment uses functions that integrate with IBM MQ, or requires that the integration node has a specified queue manager, make sure that you have a supported version of IBM MQ. For more information, see "Installing IBM MQ" on page 96.
  - If you are reusing an existing IBM MQ deployment, migrate your queue managers and other resources to a supported version of IBM MQ by following the instructions in the IBM MQ product documentation.

    Note: If you are reusing an existing IBM MQ deployment, you can configure the new IBM App Connect Enterprise 12.0 integration nodes to use the same queue managers as the existing integration nodes. You do not have to create new queue managers for the new integration nodes.
  - If you are installing a new IBM MQ deployment, create one or more queue managers to support the necessary configuration for your IBM App Connect Enterprise 12.0 integration nodes.
- Check that you have no aggregations in progress on this integration node. When you migrate an integration node to Version 12.0, all live data that is being stored for aggregations in progress is lost.

Procedure

1. Install IBM App Connect Enterprise 12.0 on the same computer as your existing version, or on a different computer.

   If you are installing on the same computer, you must specify a different location.
2. Migrate your development resources to the IBM App Connect Enterprise Toolkit Version 12.0 (see "Migrating development resources to IBM App Connect Enterprise 12.0" on page 62).

3. Set up the correct Version 12.0 command environment for your operating system.
   - Linux On Linux systems, open a new shell and run the environment profile **mqsiprofile** for this Version 12.0 installation.
   - Windows On Windows, click **Start**, and open the Command Console that is associated with this Version 12.0 installation.
4. Create a Version 12.0 integration node by using the **mqsicreatebroker** command or the IBM App Connect Enterprise Toolkit. Give the integration node a name that is different from the name of the existing integration node.

   If any of the resources on the existing integration node require IBM MQ, specify a suitable queue manager for the new integration node (see "Installing IBM MQ" on page 96).
5. Start the Version 12.0 integration node by using the **mqsistart** command.

   You can also start a local integration node by using the IBM App Connect Enterprise Toolkit.
6. Make a list of the integration servers that you have on the existing integration node, and create these same integration servers on the Version 12.0 integration node.

   Use the web user interface, the IBM App Connect Enterprise Toolkit Version 12.0, or the **mqsicreateexecutiongroup** command to complete this step.
7. Deploy the message flows, applications, and libraries that are in use by the existing integration node to the Version 12.0 integration node from the Version 12.0 IBM App Connect Enterprise Toolkit.
8. Configure all other relevant properties of the existing integration node on the Version 12.0 integration node.
9. To delete your existing integration node, complete the following steps:
   a) In a command environment for your previous version, stop the original integration node by using the **mqsistop** command.
   b) Remove the original integration node from the IBM App Connect Enterprise Toolkit.
   c) In a command environment for your previous version, delete the original integration node by using the **mqsideletebroker** command.

What to do next

When you complete migration, check whether you need to complete any post-migration tasks in "Performing post-migration tasks" on page 64.

Migrating development resources to IBM App Connect Enterprise 12.0

You cannot migrate the IBM Integration Toolkit from previous versions, but you can install IBM App Connect Enterprise 12.0 to coexist with a previous version. You can then migrate the development resources to the IBM Integration Toolkit Version 12.0 by using a project interchange file.

Before you begin

Be aware of the following restrictions that apply after you migrate resources to IBM App Connect Enterprise Toolkit Version 12.0.

- You cannot share the development resources with previous versions of the IBM Integration Toolkit. When you create a new project in IBM App Connect Enterprise Toolkit Version 12.0, it is created in

a format that cannot be used in previous versions of the IBM Integration Toolkit. You can take the following steps to manage development with different versions of the IBM Integration Toolkit.

  - If you are using a version control system, create a new stream for use with the new version of your project.
  - If you expect to continue development of a project for an integration node at a version before Version 12.0, you must retain an IBM Integration Toolkit at the previous version.
  - If you need to continue development of the same project for integration nodes on both Version 12.0 and a previous version, ensure that you use the IBM Integration Toolkit from the previous version for development.
- You cannot deploy resources from IBM App Connect Enterprise Toolkit Version 12.0 to integration nodes at a previous version to Version 12.0.
- You can use the IBM Integration Explorer view of the IBM App Connect Enterprise Toolkit to add connections for integration servers and integration nodes. IBM App Connect Enterprise Toolkit Version 12.0 supports Version 12.0 integration servers and integration nodes only. Connections to integration servers and integration nodes that are running on previous releases are not supported.
- If any of the following actions cause an error in the project, the IBM App Connect Enterprise Toolkit marks the error, and you can use a Quick Fix to rectify the error.
  - Creating the metadata information for the user-defined node project
  - Correcting the plug-in identifier if it does not match the project name
  - Ensuring all the user-defined nodes are in the same category

  For more information, see "Applying a Quick Fix to a task list error" on page 2318. However, if you have different user-defined nodes that depend on different resources that have identical names, the BAR file compiler produces an error that indicates a naming conflict in the dependent resources.

About this task

You can continue to use resources from a previous version of IBM Integration Bus by importing them into an IBM App Connect Enterprise Toolkit Version 12.0 workspace. After you import resources, you can no longer use them in a previous version of the IBM Integration Toolkit.

Procedure

1. In the previous version of the Toolkit, export the resources that you want to use in IBM App Connect Enterprise Toolkit Version 12.0.
   a) Click **File** > **Export**.
      The **Export** wizard opens.
   b) Expand **Other**, click **Project Interchange**, then click **Next**.
   c) Select the projects that you want to export, and specify the location for the compressed file that is created. You can save the file to a folder on your file system, or to a disk drive.
   d) Click **Finish**.
      The project interchange file is created in the specified location.
2. Create an IBM App Connect Enterprise Toolkit Version 12.0 workspace, or open an existing one.
3. Import the project interchange file into the Version 12.0 workspace.
   a) Click **File** > **Import**.
      The **Import** wizard opens.
   b) Expand **IBM Integration**, click **Project Interchange**, then click **Next**.
   c) Specify the location of the project interchange file that you created in step 1.
   d) Specify the location of the open Version 12.0 workspace.
   e) Select the projects that you want to import into your Version 12.0 workspace, then click **Finish**.

Performing post-migration tasks

After you migrate to IBM App Connect Enterprise 12.0, finish setting up your environment.

About this task

Test the IBM App Connect Enterprise 12.0 integration node and integration server resources and components to verify that they are all present and working correctly. Some changes in behavior might be caused by defects that were fixed between versions.

The following topics describe tasks that you can complete after migration.

Procedure

- "Setting up a command environment" on page 64
- "Reconfiguring administration security after migration" on page 65
- "Setting up a global cache" on page 65
- "Migrating deployable resources" on page 66

What to do next

After you complete migration, use the product documentation for the previous version to complete the following tasks.

- Delete the components from the previous version.
- Remove the installed code for the previous version.

Setting up a command environment

Runtime components and commands that administer runtime components must be run from a command environment. You must initialize this environment by running the **mqsiprofile** command.

About this task

The **mqsiprofile** command places the Version 12.0 commands and libraries at the front of your search path, and can override any combination of PATH, CLASSPATH, or library PATH.

ODBC settings on Linux systems are found in a text file that is defined by the ODBCINI environment variable. If you are using Linux, set ODBCINI to point to a copy of the sample file *install_dir*/server/ODBC/unixodbc/odbc.ini, where *install_dir* is the IBM App Connect Enterprise installation directory.

On Linux, if you want to use IBM MQ features, you must set the IBM MQ environment where you want the integration server to run; for more information, see "Setting the IBM MQ environment on Linux and AIX" on page 84.

Ensure that you use this environment each time you run an administrative command, or start an integration server.

The **mqsiprofile** command also runs extra scripts that are copied to the common\profiles directory (on Windows) or the common/profiles directory (on Linux systems). These scripts can be used to initialize the environment for runtime components and other resources, such as databases.

The following steps explain how to initialize your command environment, either by explicitly running the **mqsiprofile** command (on Linux) or by starting the command console (on Windows).

Procedure

- On Windows, open a command console by searching for **IBM App Connect Enterprise Console**. If you have multiple installations of IBM App Connect Enterprise, make sure that you are running the IBM

App Connect Enterprise Console from the build of the IBM App Connect Enterprise installation that you want to administer.

- On Linux systems, locate and run the `mqsiprofile.sh` script in the directory in which you installed the appropriate product.

  ```
  . install_dir/server/bin/mqsiprofile
  ```

  You must include the period and space for this command to work correctly. If you want to run this command at the start of every session, add it to your login profile.

  If you use the `zsh` shell, running the **mqsiprofile** might cause the terminal session to exit. To resolve this issue, run the **unsetopt function_argzero** command before you run the **mqsiprofile** command.

What to do next

From the command line in the initialized environment, you can run commands to administer IBM App Connect Enterprise. For example, you can configure and start an integration server, as described in "Configuring an integration server by modifying the server.conf.yaml file" on page 172 and "Starting an integration server" on page 250.

Reconfiguring administration security after migration

After migration, you can reconfigure your administration security to use file-based permissions that are set on your integration nodes.

About this task

In IBM Integration Bus 10.0, you can configure administration security by using queue-based permissions or file-based permissions on your integration nodes. In IBM App Connect Enterprise 12.0, you must use file-based permissions. For more information, see "Configuring administration security to use file-based, queue-based, or LDAP authorization" on page 2523.

Setting up a global cache

After migration of an integration node that is configured with a global cache, extra steps might be needed to complete the global cache configuration.

About this task

In IBM App Connect Enterprise 12.0, the global cache configuration involves setting the **cacheServerName** parameter, which must be unique in your global cache system.

If the name of the target integration node is the same as the name of the source integration node, no further configuration is needed. However, if the name of the target integration node is different from the name of the source integration node, make the following changes to complete the configuration of the global cache.

Procedure

- Define a unique **cacheServerName** in the `server.conf.yaml` files for the integration servers, and update the *cacheServerName* value in the **catalogClusterEndPoints** property.

  Consider this example: if the node `IB10NODE` is migrated from IBM Integration Bus 10.0 to IBM App Connect Enterprise 12.0 with the name `ACE12NODE`, the value of **catalogClusterEndPoints** is `IB10NODE_localhost_2800:localhost:2803:2801`. After migration, specify a value of, for example, `ACE12CatalogServer` in **cacheServerName** and update the value in

catalogClusterEndPoints to be ACE12CatalogServer:localhost:2803:2801, as shown in the following sample global cache stanza for a catalog server.

```
GlobalCache:
    cacheOn: true
    cacheServerName: 'ACE12CatalogServer'
    catalogClusterEndPoints: 'ACE12CatalogServer:localhost:2803:2801'
    catalogDomainName: 'WMB_IB10NODE_localhost_2800'
    catalogServiceEndPoints: 'localhost:2800'
    enableCatalogService: true
    enableContainerService: true
    enableJMX: true
    haManagerPort: 2801
    jmxServicePort: 2802
    listenerHost: 'localhost'
    listenerPort: 2800
```

Similarly, define a unique **cacheServerName** for the container server too. The value of **catalogClusterEndPoints** is the same for all the integration servers that participate in the global cache configuration. The global stanza for a container server, with a **cacheServerName** of ACE12ContainerServer2 looks like the following example:

```
GlobalCache:
    cacheOn: true
    cacheServerName: 'ACE12ContainerServer2'
    catalogClusterEndPoints: 'ACE12CatalogServer:localhost:2803:2801'
    catalogDomainName: 'WMB_IB10NODE_localhost_2800'
    catalogServiceEndPoints: 'localhost:2800'
    enableCatalogService: false
    enableContainerService: true
    enableJMX: true
    haManagerPort: 2805
    jmxServicePort: 2806
    listenerHost: 'localhost'
    listenerPort: 2804
```

Migrating deployable resources

You can continue to use existing resources in IBM App Connect Enterprise. However, if you want to continue developing resources created in previous versions, you must migrate them.

About this task

The following table summarizes the type of resource that you must migrate into IBM App Connect Enterprise 12.0 if you want to continue developing them.

Table 8. Existing resources that require extra migration tasks

Resource to continue developing in Version 12.0	**Resource that is created in Version 10.0**
Message sets	You must enable the menus for message set development (see “Migrating message sets” on page 67).
Message maps	You must complete the migration of message maps to graphical data maps for those existing message maps that you did not convert when you migrated to Version 10.0. New maps that are created in Version 10.0 are graphical data maps. See “Migrating message maps” on page 67.
Message flows	If your message flows include message flow nodes that are no longer available, rework your message flows to use available message flow nodes. See “Migrating message flows” on page 68.

Table 8. Existing resources that require extra migration tasks (continued)	
Resource to continue developing in Version 12.0	**Resource that is created in Version 10.0**
Subflows	You must complete the migration of the existing subflows that you did not convert when you migrated to Version 10.0. New subflows that are created in Version 10.0 are created as `.subflow` files. See "Migrating subflows" on page 68.
Custom integration applications	If you have applications that use the IBM Integration API, check that they access the correct resources. See "Migrating custom integration applications" on page 68.

Migrating message sets

About this task

In IBM App Connect Enterprise, *message model schema* files contained in applications, integration services, and libraries are the preferred way to model messages for most data formats. Message sets are required if you use the MRM or IDOC domains. For more information about message modeling, see "Message modeling concepts" on page 2134.

You can import message flows that contain message sets from previous versions into IBM App Connect Enterprise 12.0. Your existing message sets can be viewed, modified, and deployed in the usual way. However, by default, the menu options for creating new message sets or message definition files are hidden. To complete these tasks, you must first enable message set development in the IBM App Connect Enterprise Toolkit Preferences. For more information, see "Enabling message set development" on page 2248.

Migrating message maps

About this task

IBM App Connect Enterprise 12.0 includes a graphical data mapping capability, which is used when you add a Mapping node to a message flow.

You can import message flows containing the following nodes, which use message mapping into IBM App Connect Enterprise 12.0:

- DataDelete
- DataInsert
- DataUpdate
- Extract
- Mapping
- Warehouse

The message map (`.msgmap`) on these nodes can be viewed but they cannot be deployed to the runtime environment because they are not available in IBM App Connect Enterprise 12.0. The message-mapping operations from previous versions are accessible only in read-only mode and cannot be modified or deployed.

To deploy a message flow that uses an existing message map (`.msgmap` file), you must first replace the existing node with a new Mapping node. You must also convert the existing message map to a graphical data map that can be used by the new Mapping node (`.map` file). For more information, see Converting a message map from a `.msgmap` file a `.map` file.

Migrating message flows

About this task

The message flow nodes that are available in IBM App Connect Enterprise 12.0 might be different from the nodes that are available in the version from which you are migrating. If your message flows contain message flow nodes that are no longer available, you must rework them to use only those message flow nodes that are available at IBM App Connect Enterprise 12.0.

Migrating subflows

About this task

Since WebSphere Message Broker Version 8, you create subflows as `.subflow` files.

Subflows from earlier versions of the product were created as `.msgflow` files. You must convert them into `.subflow` files if you want to continue developing them in IBM App Connect Enterprise 12.0. You convert these subflows by using the function **Convert to subflow**. For more information, see "Converting between message flows and subflows" on page 576.

Migrating custom integration applications

About this task

Your existing Version 10.0 custom integration applications can be migrated to work with Version 12.0 integration nodes. However, if you are writing new applications, ensure that you use the `com.ibm.integration.admin.proxy.*` classes rather than the deprecated `com.ibm.broker.proxy.*`.

The IBM Integration API is no longer asynchronous because it is backed by synchronous REST calls. As a result, the `AdministeredObjectListener` framework is no longer available, and no `processModify()`, `processDelete()` callbacks exist. You must call refresh on the proxy objects to get the latest property values, such as for the deprecated Execution Group Proxy `myExecutionGroupProxy.refresh()`.

Procedure

1. For custom integration applications that connect to an integration node, update the connection details that are used by your custom integration applications to connect to the appropriate integration node.

   In IBM App Connect Enterprise 12.0, the IBM Integration API connections are no longer dependent on IBM MQ, and so connections are no longer made by using IBM MQ queues.
2. If you are connecting to a remote integration node, update your connection details to use the web administration port. For more information, see "Configuring the IBM App Connect Enterprise web user interface" on page 87.

   For information about using SSL on these connections, see "Connecting to an integration node by using the Toolkit" on page 245. If you are connecting to a local integration node, you can use a direct local connection.
3. If administration security is enabled, in IBM App Connect Enterprise 12.0, user credentials are needed by integration applications that use a remote connection. If the connection is local, you must run the application under a user ID that is part of the mqbkrs group. For new integration applications, you can provide user details during application development. For existing compiled applications, you must supply the security credentials by using one of the methods that is described in "Connecting to an integration node from a custom integration application" on page 447.

Chapter 3. Installing and uninstalling IBM App Connect Enterprise

Install and uninstall IBM App Connect Enterprise and complementary products.

About this task

Use the following topics to learn how to install and uninstall IBM App Connect Enterprise and optional complementary products on all supported platforms.

Installing IBM App Connect Enterprise

Review the tasks that are involved in the installation of IBM App Connect Enterprise.

About this task

The tasks that you perform to complete the installation are listed in the following steps; each task indicates whether it is required or optional. A summary of each task is provided, along with pointers to topics or sections that describe the task in more detail.

Service updates and other fixes are delivered occasionally in the form of fix packs. You can find information about available fix packs on the IBM App Connect Enterprise support web page. IBM App Connect Enterprise fix packs are complete App Connect Enterprise installations and are installed in the same way as the initial product release. You can install a fix pack on the same computer as a previous release, or on a different computer; for information about installing more than one fix pack (at the same or different levels) on a single computer, see “Coexistence of IBM App Connect Enterprise 12.0 with previous versions” on page 70. For more information about applying service updates, see “Applying service to IBM App Connect Enterprise” on page 90.

Procedure

1. Required: Make sure that you have acquired the product packages that you need for installation.

   Electronic images of IBM App Connect Enterprise are available from the IBM Passport Advantage® website.
2. Required: Make sure that you have access to the product documentation that you need for installation; see “Finding the latest information” on page 1.
3. Required: Determine the platforms on which to install IBM App Connect Enterprise.

   On Windows and Linux, the IBM App Connect Enterprise installation includes IBM App Connect Enterprise Toolkit. For more information, see #unique_127.
4. Required: Prepare each computer on which you are installing IBM App Connect Enterprise.
   a) Required: Check that your target computers meet the initial hardware, storage, and software requirements.

      For more information, see the IBM App Connect Enterprise system requirements web page.
   b) Required: Understand the security requirements for running IBM App Connect Enterprise; see “Security requirements” on page 72.
   c) Optional: Configure temporary directory space to enable IBM App Connect Enterprise Java components to operate correctly; see “Configuring temporary space on distributed systems” on page 74.
   d) Optional: If you are installing IBM App Connect Enterprise on Linux or AIX, check your kernel configuration; see “Checking the kernel configuration on Linux and AIX” on page 75.

5. Required: Install IBM App Connect Enterprise; see “Installing IBM App Connect Enterprise software” on page 75.
6. Optional: If required, install one or more language packs for IBM App Connect Enterprise Toolkit; see Installing language packs for the IBM App Connect Enterprise Toolkit.
7. Optional: Set up a command environment so that you can run administrative commands; see “Setting up a command environment” on page 64.
8. Optional: If required, install any complementary products; see “Installing and uninstalling complementary products” on page 96.

Results

You have reviewed the installation steps.

Coexistence of IBM App Connect Enterprise 12.0 with previous versions

IBM App Connect Enterprise 12.0 can coexist with IBM App Connect Enterprise 11.0 and IBM Integration Bus 10.0, so that you can test and compare functional differences between the versions.

You can control your migration to IBM App Connect Enterprise 12.0 by migrating individual integration nodes and integration servers; you do not have to migrate all integration nodes or servers at the same time. For more information, see Chapter 2, “Migrating,” on page 19.

The following sections describe how to achieve coexistence, and explain the restrictions that apply for each platform:

- “Coexistence on Windows” on page 70
- “Coexistence on Linux and AIX” on page 71

When you have an environment that contains different versions of IBM App Connect Enterprise and IBM Integration Bus, the following tasks have limitations:

Editing source artifacts in the IBM App Connect Enterprise Toolkit
Artifacts cannot be shared between different versions of the IBM App Connect Enterprise Toolkit and IBM Integration Toolkit. Changes made to an artifact by using the IBM App Connect Enterprise Toolkit make the artifact incompatible with earlier versions of the IBM Integration Toolkit. Consider branching your version control system when you migrate to a new version.

Building BAR files from artifacts
Your build system must use the same or later version as the IBM App Connect Enterprise Toolkit or IBM Integration Toolkit system that was used to create the artifact. A build system cannot build a BAR file from an artifact that was created or edited in a later version of the IBM App Connect Enterprise Toolkit or IBM Integration Toolkit.

Deploying BAR files to an integration node
You can deploy BAR files that are built with one version of IBM Integration Bus (by using the IBM Integration Toolkit, **`mqsicreatebar`**, or **`mqsipackagebar`**) to an integration node at a later version. You do not have to rebuild your BAR files. However it is not supported to deploy BAR files to an integration node at an earlier version. The BAR files are likely to contain new properties that cause deployment errors.

Coexistence on Windows

The following restrictions apply to coexistence on Windows.

- You can install multiple instances of IBM App Connect Enterprise on the same computer, but you cannot install multiple instances of a product version at the same modification or fix pack level. For example, you can install Version 12.0.2.0 on the same computer as Version 12.0.1.0, but you cannot install two instances of Version 12.0.1.0 on the same computer.
- All integration nodes from all versions are accessible by all users of the Windows system, and must have unique names.

- Each integration node is associated with the product code from a specific installation location and uses that product code when the integration node is started.
- If you have more than one installation on a single computer, ensure that the commands that you issue to integration nodes on that computer are using the correct version of installed code. On Windows, an IBM App Connect Enterprise Console is available for each installation. You must run commands in the correct instance of the IBM App Connect Enterprise Console for a particular installation.

  If you prefer, you can run the **mqsiprofile** command. By default, this command is stored in `C:\Program Files\IBM\ACE\12.0.n.0\server\bin`.

Coexistence on Linux and AIX

The following restrictions apply to coexistence on Linux and AIX:

- You can install multiple instances of IBM App Connect Enterprise and IBM Integration Bus on the same computer, including multiple instances of a product version at the same modification or fix pack level.
- Each integration node can be either part of a shared installation or part of a single-user installation. Integration nodes that are part of a shared installation are accessible by all users of the IBM App Connect Enterprise installation. Integration nodes that are part of a single-user installation are only accessible by a specific user.
- Integration nodes are not automatically associated with product code from specific installation locations. Before you start the integration node, you must run the **mqsiprofile** command that is associated with the product code that the integration node should use. The command is stored in *install_dir*`/ace-12.0.n.0/server/bin`, where *install_dir* is the directory where you unpacked the IBM App Connect Enterprise software. If you add the **mqsiprofile** command to your system login profile, it is run automatically whenever you log on.
- If you have more than one installation on a single computer, you must ensure that the commands that you issue to integration nodes on that computer are using the correct version of installed code. You must run the **mqsiprofile** command to set up the correct environment before you run other IBM App Connect Enterprise commands, such as **mqsicreatebroker**.

  If you installed an earlier version of this product on the same computer, check that the earlier **mqsiprofile** command is not included in the system profile for the current user ID. The environment that is set up by the **mqsiprofile** command of a previous version of IBM Integration Bus is not compatible with a later version of IBM App Connect Enterprise. To avoid potential problems, consider using a different user ID for each version and add the correct command for each version to the system profile of each user ID. For more information about the **mqsiprofile** command, see “Setting up a command environment” on page 64

Preparing the system

Complete the prerequisite tasks for your operating system before you install IBM App Connect Enterprise.

About this task

Before you install IBM App Connect Enterprise, read the topics that are relevant to your operating system:

- For Windows:
  1. “Security requirements” on page 72
  2. “Configuring temporary space on distributed systems” on page 74
- For Linux or UNIX systems:
  1. “Security requirements” on page 72
  2. “Configuring temporary space on distributed systems” on page 74
  3. “Checking the kernel configuration on Linux and AIX” on page 75

If you are using IBM MQ, configure the default settings for the log; see Default IBM MQ log settings.

For performance reasons, set the log size to the largest that the IBM MQ version that are using can support. If you are using a production system, consider using linear logging. By default, queue manager logs default to circular logging and use 3 x 1 MB log files.

What to do next

- On distributed systems, install IBM App Connect Enterprise; see "Installing IBM App Connect Enterprise software" on page 75.

Security requirements

Understand the security requirements before you install IBM App Connect Enterprise.

The security of IBM App Connect Enterprise components, resources, and tasks depends on the definition of users and groups configured in the operating system.

Some operating systems and other products impose restrictions on the structure and composition of user IDs:

- On Windows systems, user IDs can be up to 12 characters long, but on Linux and UNIX systems they are restricted to 8 characters. Database products, for example DB2®, might also restrict user IDs to 8 characters. If you have a mixed environment, ensure that the user IDs in the IBM App Connect Enterprise environment are limited to a maximum of 8 characters.
- Ensure that the case (upper, lower, or mixed) of user IDs in your IBM App Connect Enterprise environment is consistent. In some environments, uppercase and lowercase user IDs are considered the same, but in other environments, user IDs of different case are considered unique. For example, on Windows the user IDs 'tester' and 'TESTER' are identical, but on Linux and UNIX systems they are recognized as different user IDs.
- Check the validity of spaces and special characters in user IDs to ensure that, if used, these characters are accepted by all relevant systems and products in your IBM App Connect Enterprise environment.

If your user ID does not conform to these restrictions, you might have problems with installation or verification. If so, use an alternative user ID, or create a new one, to complete installation and verification.

Understand the security requirements that are associated with the operating systems that you are using:

- If you are installing on Linux or UNIX systems, see "Security on Linux and UNIX systems" on page 72.
- If you are installing on Windows, see "Security on Windows" on page 73.
-

When you have installed IBM App Connect Enterprise, check the *Security* topics in the IBM App Connect Enterprise product documentation to review and implement the security requirements for the performance of other tasks; see Chapter 8, "Security," on page 2491.

Security on Linux and UNIX systems

Understand the security requirements on Linux and UNIX systems before you install IBM App Connect Enterprise.

To deploy a single-user installation of IBM App Connect Enterprise on Linux or UNIX systems, you must have a user account on the system where you install IBM App Connect Enterprise. The user account does not need super user access to the system. After the deployment, the IBM App Connect Enterprise installation can be used by only you.

To deploy a shared installation of IBM App Connect Enterprise on Linux or UNIX systems, you must log in as root or as a super user who has write access to the `/var` directory. After the deployment, a security group that is called mqbrkrs is created (if this group does not already exist). To enable users to use the shared installation of IBM App Connect Enterprise, add the users to the mqbrkrs group by using the security facilities that are provided by your operating system; for example, the Systems Management Interface Tool (SMIT) on AIX, or the System Administration Manager on HP-Itanium.

Security on Windows

Understand the security requirements on Windows before you install IBM App Connect Enterprise.

To install IBM App Connect Enterprise on Windows, you must have the authority to install software on the system.

When you install IBM App Connect Enterprise, the installation wizard calls the **mqsisetsecurity** command, which completes the following tasks:

- Creates a security group called mqbrkrs.
- Adds your current user ID to the group mqbrkrs.

If you want to use IBM App Connect Enterprise with a different user ID from the ID that you use to install the product, you must add that user ID to the mqbrkrs group. Use either the Windows security facilities or the **mqsisetsecurity** command to complete this task; see command.

For an example that uses a Windows domain group topology to run IBM App Connect Enterprise in a Windows domain environment, see "Security in a Windows domain environment" on page 73.

Windows Terminal Services

If you are installing IBM App Connect Enterprise on a computer that runs Terminal Services, change the user mode to `install` before you start the installation, to ensure that actions taken during the installation are completed correctly; for example, that `.ini` files and other related files are created in the default system directory (`C:\Windows`). Restore the user mode to `execute` after the installation.

Security in a Windows domain environment

An example that uses a Windows domain group topology to run IBM App Connect Enterprise in a Windows domain environment.

About this task

You can use Windows domain groups to organize different levels of authorization to selective IBM App Connect Enterprise resources across your domain. To design and implement this domain group topology, add each domain group to the relevant local security groups on the domain workstations. You can now manage authorities by adding domain user accounts to the appropriate domain groups.

Procedure

1. Design your authorization group categories, and define domain groups on the domain controller system that correspond to these authorization categories, by using Windows security.
   For example, suppose that you have a single domain that contains three distinct sets of systems, which are used in development, testing, and production. Within your organization, various user roles require different levels of authorization to IBM App Connect Enterprise resources on those systems.

   Here is an example of how those authorization categories might map to domain groups:

Domain group	Description
ADM-MBprd	IBM App Connect Enterprise administrator authorities on production systems
ADM-MBuat	IBM App Connect Enterprise administrator authorities on test systems
ADM-MBdev	IBM App Connect Enterprise administrator authorities on development systems

2. Define and configure domain user accounts on the domain controller, by using Windows security. Add each domain user account to one or more domain groups to configure the access for that account. For example:

Table 9.

Domain user account	Role	Domain group membership
MBadmPRD	IBM App Connect Enterprise administrator for production systems	ADM-MBprd
MBadmUAT	IBM App Connect Enterprise administrator for test systems	ADM-MBuat
MBadmDEV	IBM App Connect Enterprise administrator for development systems	ADM-MBdev
john.smith	IBM App Connect Enterprise administrator for test and development systems	ADM-MBuat, ADM-MBdev

3. Install and configure IBM App Connect Enterprise on domain workstations.
   a) Install IBM App Connect Enterprise on the workstation.
   b) Add your domain groups to the local mqbrkrs group as appropriate.
      In this example, if a particular workstation is to serve as a development system, add the domain group `ADM-MBdev` to the local mqbrkrs group.

Configuring temporary space on distributed systems

Configure temporary directory space to enable IBM App Connect Enterprise Java components to operate correctly.

About this task

IBM App Connect Enterprise contains Java components. Some of these components require temporary directory space on the file system in order to extract class files from node packages (PAR files) and Java packages (JAR files).

The extracted files might not be visible to interactive users on the system, however, they consume space in the temporary directory.

The Java Runtime Environment also creates files in the temporary directory to support debug facilities.

To enable correct operation, allow at least 50 MB of space per integration server in the file system temporary directory for IBM App Connect Enterprise components. This space is required in addition to any space required for operation of user developed artifacts. Use of JavaCompute nodes, Java user-defined nodes, or additional plug-in nodes implemented in Java might require further temporary directory space.

On Linux, UNIX, and z/OS® computers, the TMPDIR directory is typically `/tmp`; on Windows computers, it is `c:\temp`. If this directory is not large enough to hold the JAR files, the integration node does not start.

To change the location of the temporary directory, use one of the following methods:

Procedure

- Use the environment variable `TMPDIR`.
- Set the system property `java.io.tmpdir`.

Checking the kernel configuration on Linux and AIX

Check the kernel configuration parameters on Linux and AIX for prerequisite and corequisite products.

About this task

IBM App Connect Enterprise has no specific requirements for kernel configuration parameters; however, other products might require particular settings. If you do not tune your kernel parameters to suit the products that you have installed, you might see unexpected results or a deterioration in performance.

Follow these steps to configure your kernel parameters:

Procedure

1. Check the documented values for the following products:
   - IBM MQ (if it is installed)
   - DB2 (if it is installed)
   - Other software that you have installed to work with IBM App Connect Enterprise, including other databases.

   You can access the relevant information for IBM products online at IBM Documentation.
2. Take the highest value for each parameter and compare it to the corresponding value in your kernel configuration.
3. If the current value is lower than the highest documented value, update the current setting by using the appropriate tooling that is supplied by the operating system provider. If the current value is higher, leave it unchanged.
4. If you have changed any kernel values, you might need to restart your system for these changes to take effect. Check the documentation for your operating system for further information about these parameters.

Installing IBM App Connect Enterprise software

You can install IBM App Connect Enterprise on a number of platforms.

About this task

To install IBM App Connect Enterprise, complete the following steps:

Procedure

1. Check the `readme.html` file for any updates to the installation instructions.

   For more details, see “Finding the latest information” on page 1.
2. Check that you have enough memory and disk space; see IBM App Connect Enterprise system requirements.
3. Depending on your operating system, complete the instructions to install IBM App Connect Enterprise:
   - 

See “Installing IBM App Connect Enterprise on Windows” on page 76.
   - 

See “Installing IBM App Connect Enterprise on Linux” on page 79.
   - 

See “Installing IBM App Connect Enterprise on AIX” on page 81.
4. Optional: To use IBM App Connect Enterprise Toolkit, in a supported language other than English; see Installing language packs for the IBM App Connect Enterprise Toolkit.

Installing IBM App Connect Enterprise on Windows

Install IBM App Connect Enterprise on Windows.

Before you begin

- Check the `readme.html` file for any updates to these installation instructions; see the product readme web page.
- Check that you have enough memory and disk space; see IBM App Connect Enterprise system requirements.
- Complete any prerequisite steps; see “Preparing the system” on page 71.

Installing the software

Procedure

To install IBM App Connect Enterprise, complete the following steps.

1. Extract the downloaded `.zip` file for the version of IBM App Connect Enterprise that you want to install to unpack the installation files into a local directory:
   For example, if you extract the file `ACESetup12.0.2.0.zip` into `C:\temp`, the following extracted files appear in `C:\Temp\ACESetup12.0.2.0`
   - `ACESetup12.0.2.0.exe`. This file is the installation executable file.
   - `ACEtk1.cab`. This file contains the product files for the IBM App Connect Enterprise Toolkit component.
   - `ACEae1.cab`. This file contains the product files for the OpenAPI editor component.
   - `ACEws1.cab`. This file contains the product files for the WebSphere Service Registry and Repository nodes component.
   - `readmes`. This folder contains the `readme` files for all of the supported national languages.

   All of the extracted files are required to do a full installation of the product. If you want to package the installation files into a scripted deployment of IBM App Connect Enterprise on your server environment, you can omit the files for the components that you do not want. If you want to install the OpenAPI editor component, then you must also install the IBM App Connect Enterprise Toolkit component.

   If you want to install by using the command-line, complete step 2. If you want to install by using the **Install** wizard, complete step 3.
2. Optional: To install IBM App Connect Enterprise on Windows by using the command-line options, run the following command with the options that you require:

   ```
   ACESetup12.0.n.0.exe
   ```

   For example, if you do not want to install the IBM App Connect Enterprise Toolkit component, run the command with the following options:

   ```
   ACESetup12.0.n.0.exe InstallToolkit=0
   ```

   For more information about command-line options you can use, for example, to initiate an installation in silent mode, see “Command-line options for installing IBM App Connect Enterprise on Windows” on page 78.
3. Optional: To install IBM App Connect Enterprise on Windows by using the **Install** wizard, by completing the following steps:
   a) Required: In the directory where you unpacked the installation files, right -click on the file `ACESetup12.0.n.0Setup.exe` to open the menu, and then select **Run as administrator** to

open the **Install** wizard. Alternatively, in the command prompt, navigate to the directory where you unpacked the installation files and run the following command to open the **Install** wizard:

```
ACESetup12.0.n.0.exe
```

The **Install** wizard opens in which you select the components that you want to install.

b) Click **Options** to display the components that you can install and the path for the install location.

c) Optional: By default, both the IBM App Connect Enterprise Toolkit and the IBM App Connect Enterprise runtime component are installed. If you do not want to install the IBM App Connect Enterprise Toolkit, deselect the **Install IBM App Connect Enterprise Toolkit** checkbox.

d) Optional: By default, the OpenAPI editor is installed. If you do not want to install the OpenAPI editor, deselect the **Install IBM App Connect Enterprise Open API editor** checkbox. If you want to install the OpenAPI editor component, then you must also install the IBM App Connect Enterprise Toolkit component.

e) Optional: By default, the WebSphere Service Registry and Repository nodes are not installed. If you want to install the WebSphere Service Registry and Repository nodes, select the **Install IBM App Connect Enterprise WebSphere Service Registry and Repository message flow nodes** checkbox.

If you choose not to install the WebSphere Service Registry and Repository nodes, the `<install_dir>/server/wsrrcomponent directory is not created during the installation. However, the` WebSphere Service Registry and Repository nodes still appear in the IBM App Connect Enterprise Toolkit.

f) Optional: By default IBM App Connect Enterprise is installed in `C:\Program Files\IBM\ACE \12.0.n.0`. If you want to change the installation directory, type or navigate to the directory path that you want to use.

If you specify your own directory path, be aware of the following restrictions:

- Specify a directory path to a new or empty directory. Do not install IBM App Connect Enterprise 12.0 over an existing deployment of IBM App Connect Enterprise. To upgrade the product, you can uninstall the existing version of IBM App Connect Enterprise before you install the new version of the product. Alternatively, you can install the new version alongside the existing version and migrate your resources to the new version.
- The Windows operating system has a file system limit of 256 characters for the combination of a directory path and file name. If the combination of path and resource name (for example, a message flow) exceeds this length, you might have access problems. Choose a short name for your directory path to avoid problems that are associated with this restriction.

g) Accept the license terms and conditions and then click **Install** to start the installation.

If the Microsoft.NET framework is not already installed on your computer, then the framework is installed as part of the IBM App Connect Enterprise installation. The installation of the Microsoft.NET framework might involve communicating with Microsoft servers over the internet. Depending on the configuration of your firewall, you might need to accept a prompt to allow this communication.

Results

The installation wizard proceeds to install the IBM App Connect Enterprise software. After some minutes, the installation process finishes with the message "Installation successfully completed". You can then close the installation wizard.

What to do next

If you install the IBM App Connect Enterprise Toolkit, you can verify your installation by starting the toolkit by using either of the following methods:

- Use the Windows **Start** menu option for **IBM App Connect Enterprise 12.0.*n*.0** > **12.0.*n*.0**.
- From the IBM App Connect Enterprise Console, type `ace toolkit`.

Command-line options for installing IBM App Connect Enterprise on Windows

You can use command-line options to customize the installation process.

You can use one or more of the following options with the ACESetup12.0.*n*.0.exe command:

Purpose	Command-line option
Accept the license. This option is mandatory when you run the installation in silent or passive mode.	LICENSE_ACCEPTED=true
Run the installation in silent mode; the installation is completed in the background. **Note:** You must run the command from an elevated command prompt (a command prompt where you have administrative privileges), otherwise you are prompted for an administration password.	/quiet, /q, /silent, or /s For example: `ACESetup12.0.n.0.exe /quiet LICENSE_ACCEPTED=true`
Run the installation in passive mode; installation progress is displayed but no user interaction is required. **Note:** You must run the command from an elevated command prompt (a command prompt where you have administrative privileges), otherwise you are prompted for an administration password.	/passive For example: `ACESetup12.0.n.0.exe /passive LICENSE_ACCEPTED=true`
Install IBM App Connect Enterprise to a directory of your choice.	InstallFolder="*install_location*", where *install_location* is the fully qualified path of the directory where you want to install IBM App Connect Enterprise. For example: `ACESetup12.0.n.0.exe InstallFolder="C:\ACEV12"`
Save the installation log file in a custom location. By default, the installation log is saved in the system temporary directory.	/log "*log_location*", where *log_location* is the fully qualified path to the file where you want to save the log information for the IBM App Connect Enterprise installation. For example: `ACESetup12.0.n.0.exe /log "C:\InstallLogs\ace_v12.log"`
Do not install the IBM App Connect Enterprise Toolkit.	InstallToolkit=0 For example: `ACESetup12.0.n.0.exe InstallToolkit=0`
'Do not install the OpenAPI editor.	`ACESetup12.0.n.0.exe InstallAPICeditor=0`
Install the WebSphere Service Registry and Repository nodes.	InstallWSSRnodes=1 For example: `ACESetup12.0.n.0.exe InstallWSRRnodes=1`

Purpose	Command-line option
Change the language that is used by the installation wizard. **Note:** The language of the IBM App Connect Enterprise installation wizard defaults to the language set in **Control Panel** > **Region and Language** > **Format**.	`/lang localeID`, where *localeID* is the locale ID for the language that you want the installation wizard to use. Table 10 on page 79 lists the options that you can use for the locale ID. For example, to display the installation wizard in English when your operating system locale is not set to English, use the command: `ACESetup12.0.n.0 /lang 1033`
Uninstall IBM App Connect Enterprise.	`/uninstall`. For example: `ACESetup12.0.n.0.exe /uninstall`

List the most commonly used command-line options.	`/?` or `/help`
	
	For example:
	
	`ACESetup12.0.n.0.exe /?`

Table 10. Locale ID table

Locale ID	Language code	Language
1028	zh_TW	Chinese (Traditional)
1031	de_DE	German
1033	en_US	English
1036	fr_FR	French
1040	it_IT	Italian
1041	ja_JP	Japanese
1042	ko_KR	Korean
1045	pl_PL	Polish
1046	pt_BR	Portuguese (Brazil)
1049	ru_RU	Russian
1055	tr_TR	Turkish
2052	zh_CN	Chinese (Simplified)
3082	es_ES	Spanish

Installing IBM App Connect Enterprise on Linux

You can install IBM App Connect Enterprise on Linux, either for use by a single user or for use by multiple users.

Before you begin

- Check the `readme.html` file for any updates to these installation instructions; see the product readme web page.

- Check that you have enough memory and disk space; see IBM App Connect Enterprise system requirements.
- Check that you completed any prerequisite steps; see "Preparing the system" on page 71.

About this task

As a user without administrative privileges, you can create a single-user installation of IBM App Connect Enterprise in your home directory. This single-user installation is then accessible only by your user ID.

As a user with administrative privileges, you can create a shared installation of IBM App Connect Enterprise. To authorize any users of the computer to access the shared installation of IBM App Connect Enterprise, add the users to the mqbrkrs group by using the security facilities that are provided by your operating system.

Installing the software

Procedure

To install IBM App Connect Enterprise, complete the following steps:

1. Log in to the system where you are installing IBM App Connect Enterprise.
   - If you are deploying a single-user installation, log in with your personal user ID.
   - If you are deploying a shared installation, either:
     - Log in as root or as a super user who has write access to the `/var` directory, or
     - Log in as a non-root user who is a member of mqbrkrs and has write access to the `/var/mqsi` directory.
2. Unpack the installation image by completing the following steps:
   a) Create or navigate to a directory where you have write access.
   For example, `$HOME` for a single-user installation, or `/opt/IBM` for a shared installation.
   b) Run the following command to unpack the installation image:

   ```
   tar -xzvf ace-12.0.n.0.tar.gz
   ```

   Note: On all Linux systems, except for Linux on Z, and Linux on POWER®, the installation includes the IBM App Connect Enterprise Toolkit and the WebSphere Service Registry and Repository nodes. If you do not want to install the IBM App Connect Enterprise Toolkit, you can run the following command instead:

   ```
   tar -xzvf ace-12.0.n.0.tar.gz --exclude ace-12.0.n.0/tools
   ```

   If you do not want to install the WebSphere Service Registry and Repository nodes, you can run the following command instead:

   ```
   tar -xzvf ace-12.0.n.0.tar.gz --exclude ace-12.0.n.0/server/wsrrcomponent
   ```

   If you do not want to install the IBM App Connect Enterprise Toolkit or the WebSphere Service Registry and Repository nodes, you can run the following command instead:

   ```
   tar -xzvf ace-12.0.n.0.tar.gz --exclude ace-12.0.n.0/server/wsrrcomponent
   --exclude ace-12.0.n.0/tools
   ```

   If you choose not to install the WebSphere Service Registry and Repository nodes, the `<install_dir>\server\wsrrcomponent directory is not created during the installation. However, the` WebSphere Service Registry and Repository nodes still appear in the IBM App Connect Enterprise Toolkit.

3. Accept the IBM App Connect Enterprise license by completing the following steps:
   a) Navigate to the installation directory.
      For example, *install_dir*/ace-12.0.*n*.0 where *install_dir* is the directory where you unpacked the installation image.
   b) Type one of the following commands:
      - For a single-user installation:
        - `./ace accept license`. If you use this command, you are prompted to accept the license.
        - `./ace accept license silently`. If you use this command, the license is accepted even though the license dialog is not displayed.

        The following directory is created: `$HOME/aceconfig`. This directory is the work path for IBM App Connect Enterprise, and stores the IBM App Connect Enterprise configuration files.
      - For a shared installation:
        - `./ace make registry global accept license`. If you use this command, you are prompted to accept the license.
        - `./ace make registry global accept license silently`. If you use this command, the license dialog is suppressed and the license is automatically accepted.

        The following directory is created: `/var/mqsi`. This directory is the work path for IBM App Connect Enterprise, and stores the IBM App Connect Enterprise configuration files.
4. Optional: If you installed a shared installation of IBM App Connect Enterprise, grant users access to the installation by adding them to the mqbrkrs user group.

   Note: On Linux, the user ID that installed IBM App Connect Enterprise is not automatically added to the mqbrkrs group. If you want to use this user ID with IBM App Connect Enterprise, you must add the user ID to the mqbrkrs group.

Installing IBM App Connect Enterprise on AIX

You can install IBM App Connect Enterprise on AIX, for use by a single user or multiple users.

Before you begin

- Check the `readme.html` file for any updates to these installation instructions; see the product readme web page.
- Check that you have enough memory and disk space; see IBM App Connect Enterprise system requirements.
- Check that you have completed any prerequisite steps; see “Preparing the system” on page 71.

About this task

As a user without administrative rights, you can create a single-user installation of IBM App Connect Enterprise in your home directory. This single-user installation is then accessible only by your user ID.

As a user with administrative rights, you can create a shared installation of IBM App Connect Enterprise. To authorize any users of the computer to access the shared installation of IBM App Connect Enterprise, add the users to the mqbrkrs group by using the security facilities that are provided by your operating system.

Installing the software

Procedure

To install IBM App Connect Enterprise, complete the following steps:

1. Log in to the system where you are installing IBM App Connect Enterprise.
   - If you are deploying a single-user installation, log in with your personal user ID.
   - If you are deploying a shared installation, either:
     - Log in as root or as a super user who has write access to the `/var` directory, or
     - Log in as a non-root user who is a member of mqbrkrs and has write access to the `/var/mqsi` directory.
2. Unpack the installation image by completing the following steps:
   a) Create or navigate to a directory where you have write access.
   For example, `$HOME` for a single-user installation, or `/opt/IBM` for a shared installation.
   b) Run the following command to unpack the installation image:

   ```
   zcat ace-12.0.n.0.tar.Z | tar -xvf -
   ```

3. Accept the IBM App Connect Enterprise license by completing the following steps:
   a) Navigate to the installation directory.
   For example, *`install_dir`*`/ace-12.0.`*`n`*`.0` where *install_dir* is the directory where you unpacked the installation image.
   b) Type one of the following commands:
   - For a single-user installation:
     - `./ace accept license`. If you use this command, you are prompted to accept the license.
     - `./ace accept license silently`. If you use this command, the license is accepted even though the license dialog is not displayed.

     The following directory is created: `$HOME/iibconfig`. This directory is the work path for IBM App Connect Enterprise, and stores the IBM App Connect Enterprise configuration files.

     Note: After you accept the license, IBM App Connect Enterprise does not function correctly if you copy the program code to another location. To relocate the IBM App Connect Enterprise program code, choose one of the following options:
     - To refer to IBM App Connect Enterprise as if it is installed in another location, leave the IBM App Connect Enterprise program where it is currently installed and create a symbolic link to the program. See your operating system instructions for information about creating symbolic links.
     - To move IBM App Connect Enterprise to another physical location, uninstall the IBM App Connect Enterprise program and reinstall the program in the required location.
   - For a shared installation:
     - `./ace make registry global accept license`. If you use this command, you are prompted to accept the license.
     - `./ace make registry global accept license silently`. If you use this command, the license is accepted even though the license dialog is not displayed.

     The following directory is created: `/var/mqsi`. This directory is the work path for IBM App Connect Enterprise, and stores the IBM App Connect Enterprise configuration files.
4. Optional: If you installed a shared installation of IBM App Connect Enterprise, grant users access to the installation by adding them to the mqbrkrs user group.

   On AIX, the user ID that installed IBM App Connect Enterprise is not automatically added to the mqbrkrs group. You must add this user ID to the mqbrkrs group if you want to use the user ID with IBM App Connect Enterprise.

Setting up a command environment

Runtime components and commands that administer runtime components must be run from a command environment. You must initialize this environment by running the **mqsiprofile** command.

About this task

The **mqsiprofile** command places the Version 12.0 commands and libraries at the front of your search path, and can override any combination of PATH, CLASSPATH, or library PATH.

ODBC settings on Linux systems are found in a text file that is defined by the ODBCINI environment variable. If you are using Linux, set ODBCINI to point to a copy of the sample file *install_dir*/server/ODBC/unixodbc/odbc.ini, where *install_dir* is the IBM App Connect Enterprise installation directory.

On Linux, if you want to use IBM MQ features, you must set the IBM MQ environment where you want the integration server to run; for more information, see "Setting the IBM MQ environment on Linux and AIX" on page 84.

Ensure that you use this environment each time you run an administrative command, or start an integration server.

The **mqsiprofile** command also runs extra scripts that are copied to the common\profiles directory (on Windows) or the common/profiles directory (on Linux systems). These scripts can be used to initialize the environment for runtime components and other resources, such as databases.

The following steps explain how to initialize your command environment, either by explicitly running the **mqsiprofile** command (on Linux) or by starting the command console (on Windows).

Procedure

- On Windows, open a command console by searching for **IBM App Connect Enterprise Console**. If you have multiple installations of IBM App Connect Enterprise, make sure that you are running the IBM App Connect Enterprise Console from the build of the IBM App Connect Enterprise installation that you want to administer.
- On Linux systems, locate and run the mqsiprofile.sh script in the directory in which you installed the appropriate product.

  ```
  . install_dir/server/bin/mqsiprofile
  ```

  You must include the period and space for this command to work correctly. If you want to run this command at the start of every session, add it to your login profile.

  If you use the zsh shell, running the **mqsiprofile** might cause the terminal session to exit. To resolve this issue, run the **unsetopt function_argzero** command before you run the **mqsiprofile** command.

What to do next

From the command line in the initialized environment, you can run commands to administer IBM App Connect Enterprise. For example, you can configure and start an integration server, as described in "Configuring an integration server by modifying the server.conf.yaml file" on page 172 and "Starting an integration server" on page 250.

Running database setup scripts before starting an integration node

Configure an integration server to access databases from deployed message flows by customizing the command environment. This process is relevant only when you are starting an integration node.

When you install a database product, the relevant settings might be made to the system environment (typical for Windows systems). However, some database managers provide a profile to perform this setup,

or provide details of actions that you must take. Always check the database product documentation for environment setup details; the information that is provided here is for general guidance only.

If a profile is provided for the database that you are using, complete the following process:

If you can update the profile to provide permanent values for the details that are required (for example, the database server name or the installation directory), complete Step "1" on page 84. You must also complete either Step "2" on page 84 or Step "3" on page 84. If you cannot update the profile to provide permanent values, then you must complete Step "4" on page 84

1. Complete the changes to the database profile.
2. If your platform is Windows copy the profile file to the appropriate directory:
   - For an HA integration node, use *shared_work_path**config**node_name**profiles*.
   - If the integration node was created with a specified work path, which has a subdirectory *workPath**config**node_name**profiles*, then use that profiles directory.
   - In the default case, use *%MQSI_REGISTRY%**config**node_name**profiles*.
3. If your platform is Linux or UNIX copy the profile file to the appropriate directory:
   - For an HA integration node, use *shared_work_path/common/profiles*.
   - If the integration node was created with a specified work path, under which has a subdirectory *work_path/config/node_name/profiles*, then use that profiles directory.
   - In the default case, use *${MQSI_REGISTRY}/config/node_name/profiles*.
4. If you cannot update the profile permanently, but need to make changes repeatedly, you must edit it in the appropriate directory as specified in Step "2" on page 84 or Step "3" on page 84. You must edit the profile each time before you start the integration node.

Note:

The directory, *workPath* is the machine-wide IBM App Connect Enterprise working directory. To verify the machine-wide IBM App Connect Enterprise working directory, enter the following command in a command console:

```
echo %MQSI_WORKPATH%
```

The directory, *shared_work_path* is the working directory for a multi-instance integration node.

For more information about the parameters for the working directory of an integration node, see command, and command - systems.

Setting the IBM MQ environment on Linux and AIX

On Linux and AIX, configure an integration server to use the specified IBM MQ environment.

In addition to the scripts that you must run to create your default system queues (as described in "Creating the default system queues on an IBM MQ queue manager" on page 99), on Linux and AIX systems, you must configure the IBM MQ environment where you want the integration server to run, before you start it. If you do not set the environment, your integration server might not run in the expected location.

Set the environment by using the IBM MQ **setmqenv** command; for more information see the setmqenv command in the IBM MQ product documentation. For example, if you want the integration server to use the IBM MQ installation path `/opt/mqm`:

```
. /opt/mqm/setmqenv -s -x 64
```

Because the **setmqenv** command is not persistent, you can create an IBM App Connect Enterprise common profile to run this command in either of the following ways:

- Run **setmqenv** when **mqsiprofile** is run.
- Run **setmqenv** when the integration server is started.

Configuring your IBM App Connect Enterprise installation to conform to your license

You must ensure that your installation conforms to the terms of your license.

Before you begin

For a full description of the operation mode, see “Operation modes” on page 3.

Procedure

- **Upgrading from IBM App Connect Enterprise for Developers (Developer Edition)**

  If you installed the Developer Edition, and you have now purchased a fully supported version of the product such as the Advanced Edition, you can keep the components and all the associated resources that you have already created and configured. Before you install the purchased product, uninstall the Developer Edition. You can retain your existing integration servers and workspace, and any Developer mode resources remain in Developer mode by default. You can leave them in Developer mode, or you can use the **mqsimode** command to change the operation mode to reflect the license that you have purchased.

  To change the operation mode, complete the following steps.

  – If you intend to keep the integration servers that you created with the Developer Edition for further development and unit test by your developers, change the operation mode to `advanced`, as described in “Changing the operation mode” on page 86.

    Check the license agreement file to ensure that your configuration conforms to any restrictions for development and unit test. Development and unit test conditions are described in “License requirements” on page 5.

  – If you intend to use the integration nodes that you created with Developer Edition for production purposes, change the operation mode to conform to the license that you have purchased:

    - If you have purchased Standard Edition, change the operation mode to `standard`.
    - If you have purchased the Nonproduction license, change the operation mode to `nonproduction`.
    - If you have purchased the full IBM App Connect Enterprise license, change the operation mode to `advanced`.

  If you reinstall IBM App Connect Enterprise with the new package for your purchased product, the default operation mode is `advanced`. If you have purchased a full IBM App Connect Enterprise license, you can leave the operation mode as `advanced`, otherwise you must change the mode of your integration nodes to conform to the license that you have purchased (for example, `standard` mode).

- **Standard Edition**

  If you have purchased IBM App Connect Enterprise Standard Edition, and installed components from the full runtime package, read the following information.

  – All integration servers that you have created have an operation mode set to `advanced`, which is the default setting for this installation. You can keep them for further development and unit test, subject to any restrictions that apply for unit test environments, as indicated in your license. Development and unit test conditions are described in “License requirements” on page 5.

  – If you intend to use the integration servers for production purposes, follow the instructions in “Changing the operation mode” on page 86, to conform to the license that you have purchased.

    - If you have purchased Standard Edition, change the operation mode to `standard`.

- **Full (unrestricted) license for IBM App Connect Enterprise**

  If you have purchased a full (unrestricted) license and installed components from the full runtime package, all components that you create have an operation mode set to the default value of `advanced`, which is the correct setting for your license.

  You can continue to work with all the components and associated resources that you have already created. For example, after you have completed verification, you might keep the resources that you have created for further development and unit test (subject to any restrictions that apply for unit test environments, as indicated in your license). Development and unit test conditions are described in "License requirements" on page 5.

Changing the operation mode

Change the operation mode in which your integration servers are working by using the **mqsimode** command.

About this task

You must change your configuration to ensure that your integration servers are running in the operation mode for which you have purchased a license. You can change the mode to `standard`, `nonproduction`, `nonproductionfree`, or `advanced`.

Procedure

1. Run the **mqsimode** command with the **-o** parameter to change the operation mode, or without the **-o** parameter to view the current setting; for more information, see command.
2. Check for error messages. If you attempt to reconfigure your installation to a mode that is not sufficient for the deployed resources, the **mqsimode** command issues a warning indicating that changing the mode is not allowed. Resolve any violations, if required.
3. (Optional) Run the **mqsimode** command again to confirm that there are no violations.

Moving from Developer Edition

If you want to move from Developer Edition to an alternative edition, you must uninstall Developer Edition before installing the new edition.

Before you begin

Contact your IBM representative to upgrade your license.

Procedure

To move from Developer Edition to an alternative edition, complete the following steps.

1. Stop all running integration servers, as described in "Starting an integration server" on page 250.
2. Uninstall the Developer Edition.
3. Install your new licensed edition.
4. Restart your integration servers, which will now run in an unrestricted mode.

Checking the operation mode

Run the **mqsimode** command to report the operation mode that is being used by your IBM App Connect Enterprise installation.

About this task

Use the **mqsimode** command on its own, without the **-o** parameter, to receive a report about the operation mode that is being used by your installation of IBM App Connect Enterprise, and a report about any mode violations. For example:

```
mqsimode
```

Configuring the IBM App Connect Enterprise web user interface

You can use the `node.conf.yaml` and `server.conf.yaml` configuration files to configure the port that is used to connect to the web user interface, and to secure the connection.

Before you begin

Configure an integration node or server, by following the instructions described in "Configuring an integration node by modifying the node.conf.yaml file" on page 118 or "Configuring an integration server by modifying the server.conf.yaml file" on page 172.

About this task

The IBM App Connect Enterprise web user interface enables you to access integration node or integration server resources by using a web browser, and it provides integration administrators with a method of administering those resources. For more information about the web user interface, see web user interface. To learn some basics about administering IBM App Connect Enterprise with the web user interface, see the tutorial "Getting started - Exploring the Web UI" in the IBM App Connect Enterprise Toolkit.

Procedure

1. Open the `node.conf.yaml` or `server.conf.yaml` configuration file for your integration node or server, by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor. However, you must ensure that you do not include any tab characters, which are invalid characters in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

Set the **RestAdminListener** properties, which control the settings for the web user interface:

2. Set the **port** property to the port to be used by the web user interface and the IBM App Connect Enterprise Toolkit. By default, this port is set to 4414.

3. Optional: If you want to secure the connection, set the following properties:
   a) Set `host: 'hostname'`

      Specify the hostname where the integration node or integration server is running.

   b) If you want to use basic authentication for users who log in to the web user interface, uncomment the following property:

      basicAuth: true
      Specify whether clients require a web username and password (`true` or `false`).

      You also need to create at least one username and password, by running the **mqsiwebuseradmin** command as described in the later step section "Additional steps for security configuration".

   c) If you want to use SSL or TLS to secure the connection:

      Set the following properties:

      sslCertificate
      Specify the path to a certificate store for use in securing the REST Administration port, which is used by the Web User Interface and IBM App Connect Enterprise Toolkit, in the form `/path/to/serverPKCS.p12`.

      If you are using a `.pem` certificate, the **sslCertificate** is the full path to the server certificate key.

      If you are using `.p12` or `.pfx` certificate, the **sslCertificate** is the full path to the server certificate store file.

      The certificate store cannot be in JKS format, and hence must be a separate certificate store from the certificate store that is used by the integration server for things such as HTTPS message flow nodes.

      sslPassword
      Specify the server certificate password alias, in the form `adminRestApi::sslpwd`.

      If you are using a `.pem` certificate, the **sslPassword** is the full path to the server private key, which must be a standard private key and not an encrypted one.

      If you are using `.p12` or `.pfx` certificate, the **sslPassword** is the passphrase or alias to the passphrase of the certificate store.

      You also need to set the password to be used for your server certificate, by running the **mqsisetdbparms** command as described in the later step section "Additional steps for security configuration".

   d) If you want to use SSL client certificates (mutual authentication):

      requireClientCert
      Specify whether a certificate is to be requested from the client (true or false).

      caPath
      Specify the file path that contains certificate authority certificates; all files in this path are read.

4. If you want to view message flow statistics in the web user interface, you must also enable the reporting of message flow statistics and accounting data, as described in “Configuring the collection of message flow statistics by using a .yaml configuration file” on page 2729. The web user interface consumes message flow statistics and accounting data in JSON format, which means that you must include `json` as one of the values in the **outputFormat** property in the `.conf.yaml` configuration file.
5. If you want to view resource statistics in the web user interface, you must enable the reporting of these statistics as described in “Managing resource statistics collection” on page 2741.
6. Save the .yaml file. The properties that you set in the .yaml file take effect when the integration node or server is started. If you modify these properties again, you must also restart the integration node or server.
7. Restart the integration node or server for the changes to take effect.

Additional steps for security configuration:

8. If you set `basicAuth: true`, create one or more usernames and passwords that users must specify when they start the web user interface.

   In the IBM App Connect Enterprise command console, create a username and password by issuing the **mqsiwebuseradmin** command. For example:

   ```
   mqsiwebuseradmin -w c:\workdir\ACEServ1 -u admin -a password -c
   ```

   For more information about configuring basic authentication, see "Configuring HTTP basic authentication for an integration node or server" on page 2548.
9. If you set `sslCertificate` and `sslPassword` to use SSL or TLS to secure the connection.

   In the IBM App Connect Enterprise command console, use the **mqsisetdbparms** command to set the password to be used for your server certificate. For example:

   ```
   mqsisetdbparms -w c:\workdir\ACEServ1 -n adminRestApi::sslpwd -u dummy -p password
   ```

   For more information about configuring use of SSL or TLS to secure the connection, see "Configuring SSL or TLS for an integration node or server" on page 2548.

Results

You can now access the web user interface by opening a browser and specifying the host and port that you configured in the `.yaml` configuration file. For more information, see "Accessing the web user interface" on page 89.

Accessing the web user interface

You can use the IBM App Connect Enterprise web user interface to access integration node and integration server resources through a web browser.

Before you begin

Configure the web user interface, by completing the steps in "Configuring the IBM App Connect Enterprise web user interface" on page 87.

About this task

When the web user interface has been configured (by modifying the `node.conf.yaml` or `server.conf.yaml` configuration file), you can access it by completing the following steps:

Procedure

1. Start the web user interface, by using one of the following methods:
   - **From the IBM App Connect Enterprise Toolkit:** In the toolkit, right-click the integration node or server and select **Start web user interface** from the menu.
   - **From a web browser:** Enter the URL for the web user interface into a web browser, in the following form:

     protocol`://`*hostname*`:`*port*

     where:

     – *protocol* is either `http` or `https`
     – *hostname* is the host that you specified in the **`host`** property in the `.yaml` configuration file for the integration node or server (for example, `localhost` or `127.0.0.1`)
     – *port* identifies the port that is to be used for the web user interface and the toolkit, and must match the value that you set for the **`port`** property in the `.yaml` configuration file; by default this is set to 4414.

     For example:

     ```
     https://localhost:4414
     ```

     or

     ```
     https://127.0.0.1:4414
     ```

   If the integration server is configured to require authentication for administrative tasks (that is, if the **`basicAuth`** property in the `.yaml` configuration file is set to `true`), you are prompted to enter your user ID and password.
2. If prompted, enter your user ID and password and log in to the system.

   If the connection to the web user interface is not secured, you can access all data and resources without logging in. Users have permissions granted to them according to their role, so administrators and web users can have different access to resources based on their role. For more information about roles, see “Role-based security” on page 2503. For information about creating user accounts, see “Managing web user accounts” on page 2510.

Results

A web browser window opens, in which you can view and administer your resources.

Applying service to IBM App Connect Enterprise

Install IBM App Connect Enterprise fix packs to get the latest service updates and fixes.

About this task

Service updates and other fixes are delivered occasionally in the form of fix packs. You can find information about available fix packs on the IBM App Connect Enterprise support web page.

IBM App Connect Enterprise fix packs are complete App Connect Enterprise installations and are installed in the same way as the initial product release. For more information, see “Installing IBM App Connect Enterprise software” on page 75. You can install a fix pack on the same computer as a previous release, or on a different computer. For more information about installing more than one fix pack (at the same or different levels) on a single computer, see “Coexistence of IBM App Connect Enterprise 12.0 with previous versions” on page 70.

When you have installed a fix pack, see New function added in and subsequent modification and fix packs for information about the function that is provided in that fix pack and in any previous fix packs.

IBM App Connect Enterprise supports interoperability between different fix packs of the same version. However, errors might occur if you create (or edit) an artifact or enable a new feature, and then use the artifact with a component that is using an earlier fix pack. For example, the following situations might generate errors:

- Editing source artifacts in the IBM App Connect Enterprise Toolkit that were created on an IBM App Connect Enterprise Toolkit that is using a later fix pack.
- Building BAR files from artifacts that were created on an IBM App Connect Enterprise Toolkit that is using a later fix pack than the build system.
- Deploying BAR files that were built by using a component that is using a later fix pack than the target integration server.
- Connecting a REST administration application (including the IBM App Connect Enterprise Toolkit and commands) to a remote integration server that is using a later fix pack.

It is good practice to ensure that downstream components (such as integration servers and build systems) are using the same or later fix pack as upstream components (such as the IBM App Connect Enterprise Toolkit). An alternative option is to ensure that you install the earliest common fix pack on the build systems so that you are warned about any incompatible options as early as possible.

If you installed the fix pack on the same computer as an existing installation of IBM App Connect Enterprise 12.0, complete the following steps to convert your integration nodes to run with the new code. These methods are valid only for switching an integration node between different fix pack levels that are associated with the same product code version. You must use the **mqsiextractcomponents** command to migrate an integration node to a different version and release.

Procedure

- Windows

  On Windows, complete one of the following steps:

  - Start the IBM App Connect Enterprise Console for the new fix pack level, and then start the integration node by using the **mqsistart** command.
  - Start the IBM App Connect Enterprise Toolkit for the new fix pack level. Any local integration nodes that are stopped and configured to start automatically with the IBM App Connect Enterprise Toolkit use the product code that is associated with the version of the IBM App Connect Enterprise Toolkit.
  - Start the integration node by using a script that first runs the **mqsiprofile** for the new fix pack level.
  - If your integration node is configured to start as an IBM MQ service, you must manually update the IBM MQ Service definition on the queue manager that is associated with the integration node. This update enables the integration node to use the new code. For more information, see “Applying service to an integration node that starts under the control of an IBM MQ queue manager” on page 92.

- Linux

  On Linux:

  - Start the IBM App Connect Enterprise Toolkit for the new fix pack level. Any local integration nodes that are stopped and configured to start automatically with the IBM App Connect Enterprise Toolkit use the product code that is associated with the version of the IBM App Connect Enterprise Toolkit.
  - Run the **mqsiprofile** command from the new fix pack level, and start your integration node by using the **mqsistart** command.
  - If your integration node is configured to start as an IBM MQ service, you must manually update the IBM MQ Service definition on the queue manager that is associated with the integration node. This update enables the integration node to use the new code. For more information, see “Applying service to an integration node that starts under the control of an IBM MQ queue manager” on page 92.

- AIX
  On AIX :
  - Run the **mqsiprofile** command from the new fix pack level, and start your integration node by using the **mqsistart** command.
  - If your integration node is configured to start as an IBM MQ service, you must manually update the IBM MQ Service definition on the queue manager that is associated with the integration node. This update enables the integration node to use the new code. For more information, see "Applying service to an integration node that starts under the control of an IBM MQ queue manager" on page 92.

What to do next

You can use any Version 11.0 fix pack level of the IBM App Connect Enterprise Toolkit to deploy integration solutions to an integration server that runs any Version 11.0 fix pack level.

Applying service to an integration node that starts under the control of an IBM MQ queue manager

If an integration node starts under the control of an IBM MQ queue manager, you must manually update the WebSphere MQ Service definition on the queue manager that is associated with the integration node. This update enables the integration node to use the new code.

Procedure

To update the IBM MQ Service definition on the queue manager, complete the following steps:

1. At a command line, type `runmqsc qmgr` where *qmgr* is the name of the queue manager that is associated with the integration node.
2. To display the current settings for the integration node type `display service('serviceName')`, where *serviceName* is the name of your IBM MQ service.

   The output details the current settings, for example, when your integration node is running the IBM App Connect Enterprise Version 11.0 code, you might see the following output:

   ```
   AMQ8629: Display service information details.
   SERVICE(MQSI_integrationNodeName) CONTROL(QMGR) SERVTYPE(COMMAND)
   STARTCMD(C:\PROGRA~1\IBM\ACE\1100~1.0\server\bin\runMQService.bat)
   STARTARG(C:\PROGRA~1\IBM\ACE\1100~1.0\server\bin integrationNodeName)
   STOPCMD(C:\PROGRA~1\IBM\ACE\1100~1.0\server\bin\endMQService.bat)
   STOPARG(C:\PROGRA~1\IBM\ACE\1100~1.0\server\bin integrationNodeName)
   STDOUT(C:\PROGRA~3\IBM\MQSI\common\log\integrationNodeName.mqservice.log)
   STDERR(C:\PROGRA~3\IBM\MQSI\common\log\integrationNodeName.mqservice.log)
   DESCR( ) ALTDATE(2019-12-19) ALTTIME(11.07.52)
   ```

3. Provide new fully qualified values for the following parameters: **STARTCMD**, **STARTARG**, **STOPCMD**, and **STOPARG**, but preserve the existing command names.

   For example, you might type the following command (on a single line) at the **runmsc** command line to change the integration node to use the IBM App Connect Enterprise Version 11.0.0.n code:

   Note: If you are on Windows, you must use short names .

   ```
   alter service('MQSI_integrationNodeName')
   startcmd('C:\PROGRA~1\IBM\ACE\1100~1.n\server\bin\runMQService.bat')
   startarg('C:\PROGRA~1\IBM\ACE\1100~1.n\server\bin integrationNodeName')
   stopcmd('C:\PROGRA~1\IBM\ACE\1100~1.n\server\bin\endMQService.bat')
   stoparg('C:\PROGRA~1\IBM\ACE\1100~1.n\server\bin integrationNodeName')
   ```

   where `C:\PROGRA~1\IBM\ACE\1100~1.1` is the short name for `C:\Program Files\IBM\ACE\11.0.0.1`

   If the IBM MQ service definition is changed, the message `AMQ8624: IBM MQ service changed.` is displayed.

Uninstalling IBM App Connect Enterprise

Remove IBM App Connect Enterprise, IBM App Connect Enterprise service, or other IBM App Connect Enterprise features from your computer.

Procedure

1. Check that your user ID has the correct permissions to uninstall IBM App Connect Enterprise or IBM App Connect Enterprise features.

   The requirements are defined in "Security requirements" on page 72.
2. Follow the instructions that are provided in the appropriate topic:
   - "Uninstalling IBM App Connect Enterprise on Windows" on page 93
   - "Uninstalling IBM App Connect Enterprise on Linux and UNIX systems" on page 94

What to do next

You might also want to uninstall complementary products. See the documentation that is provided by those products to complete this task.

- IBM DB2: See the DB2 product documentation.
- IBM License Metric Tool: See the IBM License Metric Tool website.

Uninstalling IBM App Connect Enterprise on Windows

You can uninstall IBM App Connect Enterprise on Windows by using the Windows Control Panel, or by using silent mode.

Before you begin

Delete any integration servers that are not required by removing the contents of their work directories.

Procedure

Uninstall IBM App Connect Enterprise on Windows by completing the following steps.

1. Log on to the computer on which IBM App Connect Enterprise is installed.
2. Uninstall IBM App Connect Enterprise by using one of the following methods:
   - Windows Control Panel: Select **Control Panel** > **Programs** > **Programs and Features**, select the IBM App Connect Enterprise deployment that you want to uninstall, and click **Uninstall**.
   - Silent mode: Navigate to the directory where the installation file is located, and type the following command from an elevated command prompt (a command prompt where you have administrative privileges):

     ```
     ACESetup12.0.n.0.exe /q /uninstall
     ```

Results

You uninstalled IBM App Connect Enterprise.

Note: The following entities are created after the installation of IBM App Connect Enterprise and so they are not removed by the uninstallation wizard. You can manually remove the entities if you do not want to keep them.

- The IBM App Connect Enterprise configuration information in the work path directory; by default the work path directory is `C:\ProgramData\IBM\MQSI`.
- The IBM App Connect Enterprise Toolkit workspace; by default the workspace is `C:\Users\user_name\IBM\ACET12\workspace`.

- The IBM App Connect Enterprise Toolkit configuration folder; by default the configuration folder is `C:\Users\user_name\AppData\Local\IBM\ACET12-config\12.0.n.0`.
- The Windows services that are associated with each local integration node that is defined on your computer (if you did not delete the integration nodes before you uninstalled IBM App Connect Enterprise). For example, IBM Integration Bus Component TESTNODE_*user_name*.

Uninstalling IBM App Connect Enterprise on Linux and UNIX systems

You can uninstall IBM App Connect Enterprise on Linux and UNIX systems by using the same user ID that you used to install the product.

Before you begin

Delete any integration servers that are not required, by removing the contents of their work directories.

Procedure

1. Log on with the user ID that you used to install IBM App Connect Enterprise.
2. Delete the IBM App Connect Enterprise entities that you do not want to keep:
   - The IBM App Connect Enterprise installation directory. For example, `install_dir/ace-12.0.n.0`.
   - (Linux only) The IBM App Connect Enterprise Toolkit workspace directory. For example, `$HOME/IBM/ACET12/workspace`. Do not delete the workspace if you want to keep any development resources that you created, such as applications or libraries. You can use existing applications and libraries with another installation of IBM App Connect Enterprise.
   - The IBM App Connect Enterprise work path directory. For example, `$HOME/iibconfig` for a single-user deployment or `/var/mqsi` for a shared deployment. Do not delete the work path directory if you want to keep any integration nodes and integration servers that you created. You can use existing integration nodes and integration servers with another installation of IBM App Connect Enterprise.

Results

You uninstalled IBM App Connect Enterprise.

Uninstalling language packs from the IBM App Connect Enterprise Toolkit

You can remove language packs from the IBM App Connect Enterprise Toolkit.

About this task

If you have installed one or more language packs for the IBM App Connect Enterprise Toolkit, you can remove any of these language packs by using one of the following methods:

- "Uninstalling language packs by using the IBM App Connect Enterprise Toolkit" on page 94
- "Uninstalling language packs by using the command line" on page 95

Uninstalling language packs by using the IBM App Connect Enterprise Toolkit

Procedure

1. Start the IBM App Connect Enterprise Toolkit.
2. From the menu, click **Help** > **About IBM App Connect Enterprise Toolkit**.

   The **About IBM App Connect Enterprise Toolkit** dialog is displayed.
3. Click **Installation Details**.

   The **IBM App Connect Enterprise Toolkit Installation Details** dialog is displayed and all the language packs that are installed are listed.

4. Select the language packs that you want to remove, click **Uninstall**, and then click **Finish**.

   The selected language packs are uninstalled and you are prompted to restart the IBM App Connect Enterprise Toolkit.
5. Click **Yes** to restart the IBM App Connect Enterprise Toolkit.

   If your operating system locale is configured for one of the languages that is supported by the language packs you uninstalled, the IBM App Connect Enterprise Toolkit user interface is now displayed in English.

Results

You have uninstalled one or more language packs from the IBM App Connect Enterprise Toolkit.

Uninstalling language packs by using the command line

Procedure

At the command line, type the following command on a single line:

- On Windows:

```
InstallPath\common\jdk\jre\bin\java
-jar InstallPath\tools\plugins\org.eclipse.equinox.launcher_1.3.0.v20130327-1446.jar
-launcher InstallPath\tools\eclipse
-application org.eclipse.equinox.p2.director
-uninstallIU LanguagePack
```

- On Linux:

```
InstallPath/common/jdk/jre/bin/java
-jar InstallPath/tools/plugins/org.eclipse.equinox.launcher_1.3.0.v20130327-1446.jar
-launcher InstallPath/tools/eclipse
-application org.eclipse.equinox.p2.director
-uninstallIU LanguagePack
```

where:

InstallPath
Specifies the directory where IBM App Connect Enterprise is installed.

LanguagePack
Specifies the language pack or language packs that you want to uninstall:

- To uninstall Language Pack 1 only, type `com.ibm.etools.ace.toolkit.nl1.feature.group`
- To uninstall Language Pack 2 only, type `com.ibm.etools.ace.toolkit.nl2.feature.group`
- To uninstall Language Pack 2a only, type `com.ibm.etools.ace.toolkit.nl2a.feature.group`
- To uninstall more than one language pack, separate the entries with a comma.

For example, to uninstall Language Pack 1 and Language Pack 2 on Windows, where IBM App Connect Enterprise is installed in the default location, type the following command on a single line:

```
"C:\Program Files\IBM\ACE\12.0.n.0\common\jdk\jre\bin\java"
-jar "C:\Program Files\IBM\ACE\12.0.n.0\tools\plugins
\org.eclipse.equinox.launcher_1.3.0.v20120522-1813.jar"
-launcher "C:\Program Files\IBM\ACE\12.0.n.0\tools\eclipse"
-application org.eclipse.equinox.p2.director
-uninstallIU
 com.ibm.etools.ace.toolkit.nl1.feature.group,com.ibm.etools.ace.toolkit.nl2.feature.group
```

A message is displayed listing the language packs that are being uninstalled. When the uninstallation is complete, a message is displayed that details how long the uninstallation took. For example:

```
Uninstalling com.ibm.etools.ace.toolkit.nl1.feature.group 11.0.0.v20180911-1900.
Uninstalling com.ibm.etools.ace.toolkit.nl2.feature.group 11.0.0.v20180911-1900.
Operation completed in 53088 ms.
```

Results

You have uninstalled one or more language packs by using the command line.

Installing and uninstalling complementary products

IBM App Connect Enterprise works with several other products to provide complementary services.

About this task

If you want to use these optional services in your IBM App Connect Enterprise environment, refer to the following installation information:

Installing IBM MQ

When you purchase a license for IBM App Connect Enterprise, your license entitles you to install IBM MQ for use by App Connect Enterprise, within the terms of the license.

About this task

IBM MQ is fully supported by IBM App Connect Enterprise, and a subset of IBM App Connect Enterprise capabilities require access to IBM MQ components.

- Some capabilities require IBM MQ to be part of the IBM App Connect Enterprise infrastructure, and you must associate a queue manager with the integration server.
- Some capabilities do not require IBM MQ to be part of the IBM App Connect Enterprise infrastructure, and you do not always need to associate a queue manager with the integration server.
- Some capabilities require access to IBM MQ, either locally or on a remote server.

Capabilities that require IBM MQ to be part of the IBM App Connect Enterprise infrastructure

For these capabilities, you must install an IBM MQ server on the same machine as the integration server that is to use the capabilities, and you must associate a queue manager with the integration server or integration node by setting the **`defaultQueueManager`** configuration property. For more information about setting the configuration property, see either “Configuring an integration server by modifying the server.conf.yaml file” on page 172 or “Configuring an integration node by modifying the node.conf.yaml file” on page 118.

For some capabilities, you must also complete additional configuration actions indicated in the "Additional configuration notes" column.

Capability	Detail	Additional configuration notes
Managed file support	You have any of the following nodes in your message flows: • node • node • node • node	
High availability	You have multi-instance integration nodes.	
High availability	You are using the HTTP proxy servlet with your integration node.	You must create the set of IBM App Connect Enterprise queues on your queue manager; see “Creating the default system queues on an IBM MQ queue manager” on page 99.

Capability	Detail	Additional configuration notes
Load balancing	You are using an integration node listener (instead of embedded listeners) with your integration node.	You must create the set of IBM App Connect Enterprise queues on your queue manager; see “Creating the default system queues on an IBM MQ queue manager” on page 99.
Global coordination of transactions (XA)	You are using globally-coordinated (XA) transactions.	

Capabilities that do not require IBM MQ to be part of the infrastructure for your IBM App Connect Enterprise deployment

For these capabilities, you must install either an IBM MQ client or an IBM MQ server on the same machine as the integration server or integration node that is to use the capabilities, but you do not need to associate a queue manager with the integration server or integration node unless specified in the "Additional configuration notes" column:

Capability	Detail	Additional configuration notes
Java connectivity and JDBC	You have one of the following nodes in your message flows: • node • node • node	

Capabilities that require access to IBM MQ, either locally or on a remote server

For these capabilities, you must install an IBM MQ client or server either on the same machine as the integration server or on another machine that can be accessed through a client connection:

Capability	Detail	Additional configuration notes
IBM MQ connectivity	You have any of the following nodes in your message flows: • node • node • node • node	You need to specify a queue manager on the integration server or integration node only if you want to use the queue manager by default for your MQ connection. For more information, see “Configuring a local connection to IBM MQ” on page 744 and “Using a remote default queue manager” on page 750.
Advanced data processing	You have any of the following nodes in your message flows: • node • node • node • node • node • node • node	You must create the set of IBM App Connect Enterprise queues on your queue manager, as described in “Creating the default system queues on an IBM MQ queue manager” on page 99. You must configure the default queue manager by setting either the **defaultQueueManager** or **remoteDefaultQueueManager** property. For more information, see “Processing events” on page 1819.

Capability	Detail	Additional configuration notes
	• node	An integration server that supports this capability must not share a queue manager with another integration server unless a unique queue prefix is set. You set a unique queue prefix either by using a policy or, if a remote default queue manager is being used, by setting the **replacementQueuePrefix** property. For more information, see "Configuring an integration server to use a remote default queue manager" on page 751. For TimeoutNotification nodes using `Controlled` mode on a managed integration server, a local default queue manager is required. For TimeoutNotification nodes using `Controlled` mode on an independent integration server, either a local default queue manager or a remote default queue manager is required. For TimeoutNotification nodes using `Automatic` mode, no queue manager is required.
Publish and subscribe	You are using publish and subscribe capabilities to emit events or accounting and statistics data over IBM MQ and MQTT. For more information, see "Configuring the publication of event messages" on page 2807.	By default, events use the queue manager that is associated with the integration server or integration node. However, you can use a policy to configure events to use a different queue manager.
Transactional support for SAP	You have any of the following nodes in your message flows: • node • node • node	You must associate a queue manager with the integration server or integration node, or use a SAPConnection policy and specify a CCDT through the **Shared TID store client definition file** property. The **remoteDefaultQueueManager** setting does not apply to these nodes, but the CCDT can specify a remote queue manager to achieve the same effect.

Procedure

1. To install IBM MQ components, see the IBM MQ product documentation: http://www.ibm.com/support/knowledgecenter/SSFKSJ_8.0.0/com.ibm.mq.ins.doc/q008250_.htm.
2. For capabilities listed in Capabilities that require IBM MQ to be part of the IBM App Connect Enterprise infrastructure, associate a queue manager with the integration server or integration node that is to use the capabilities.
3. Complete any additional configuration actions for the capability that you want to use, as indicated in the "Additional configuration notes" column of the tables above.

Creating the default system queues on an IBM MQ queue manager

You can create the default system queues on the queue manager that is associated with your integration server, by running a script.

Before you begin

- You must have an IBM MQ server and a queue manager to use with your IBM App Connect Enterprise deployment. For more information about installing IBM MQ components, see the IBM MQ product documentation: https://www.ibm.com/support/knowledgecenter/SSFKSJ_9.1.0/com.ibm.mq.ins.doc/q008320_.htm.
- You must be a member of the mqm and mqbrkrs operating system groups.
- Linux Ensure that the command environment is initialized, by running the **mqsiprofile** script command. For more information, see "Setting up a command environment" on page 64.

About this task

Some IBM App Connect Enterprise capabilities require access to IBM MQ components. Some of these capabilities require a set of default system queues to be created on the queue manager that is associated with the integration server. The default system queues are used to store information about in-flight messages. For more information about the capabilities that require the default system queues, see "Installing IBM MQ" on page 96.

Note: By default, running the **iib_createqueues** command disables IBM MQ channel authentication for the specified queue manager. If you want to enable channel authentication, you can modify the sample MQSC script, **iib_queues_create.mqsc**, that the command **iib_createqueues** uses to define queues.

You cannot use a secured queue manager as the local default queue manager for an integration node or an integration server.

Complete the following steps to create the default system queues on Windows and Linux.

Procedure

1. From the command environment (on Linux) or the IBM App Connect Enterprise Console (on Windows), navigate to the following directory:
   - Windows *install_dir*\server\sample\wmq
   - Linux *install_dir*/server/sample/wmq
2. Run the following command:
   - Windows iib_createqueues.cmd *qmgr_name*
   - Linux ./iib_createqueues.sh *qmgr_name iib_group*

   The *qmgr_name* parameter specifies the name of the IBM MQ queue manager where you want to create the queues.

   The *iib_group* parameter specifies the primary group of the system account that runs the integration server.

Results

The default IBM App Connect Enterprise queues are created on the queue manager.

To check that the queues were created, type the following commands:

```
runmqsc qmgr_name
```

```
display queue(SYSTEM.BROKER*)
```

A message is returned that lists the queues that were created:

```
1 : display queue(SYSTEM.BROKER*)
AMQ8409: Display Queue details.
 QUEUE(SYSTEM.BROKER.ADAPTER.FAILED)     TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.ADAPTER.INPROGRESS) TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.ADAPTER.NEW)        TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.ADAPTER.PROCESSED)  TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.ADAPTER.UNKNOWN)    TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.ADMIN.STREAM)       TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.AGGR.CONTROL)       TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.AGGR.REPLY)         TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.AGGR.REQUEST)       TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.AGGR.TIMEOUT)       TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.AGGR.UNKNOWN)       TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.AUTH)               TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.CD.MODEL)           TYPE(QMODEL)
   QUEUE(SYSTEM.BROKER.CONTROL.QUEUE)      TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.DC.AUTH)            TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.DC.BACKOUT)         TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.DC.RECORD)          TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.DEFAULT.STREAM)     TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.EDA.COLLECTIONS)    TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.EDA.EVENTS)         TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.FTE.MODEL)          TYPE(QMODEL)
   QUEUE(SYSTEM.BROKER.INTER.BROKER.COMMUNICATIONS) TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.MODEL.QUEUE)        TYPE(QMODEL)
   QUEUE(SYSTEM.BROKER.SEQ.EXPIRY)         TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.SEQ.GROUP)          TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.SEQ.NUMBER)         TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.TIMEOUT.QUEUE)      TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.WS.ACK)             TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.WS.INPUT)           TYPE(QLOCAL)
   QUEUE(SYSTEM.BROKER.WS.REPLY)           TYPE(QLOCAL)
```

Note: You can delete the queues that are created for an integration server on a specified queue manager, by running the following MQSC command from the same directory:

```
runmqsc qmgr_name < iib_queues_delete.mqsc
```

For more information about the **runmqsc** command, see https://www.ibm.com/support/knowledgecenter/SSFKSJ_9.1.0/com.ibm.mq.ref.adm.doc/q083460_.htm.

Installing IBM License Metric Tool

IBM License Metric Tool (ILMT) enables you to monitor the use of IBM (and other) software products.

About this task

Use ITLM to perform the following software auditing functions:

- Monitor the licenses used by different machines.
- Help keep unnecessary licenses to a minimum.
- Guard against software license compliance problems.

Ensure that you choose the correct ILMT license for the IBM App Connect Enterprise edition that you have purchased. See “Operation modes” on page 3.

If you are using one or more of the WebSphere Adapters with IBM App Connect Enterprise, you must activate ILMT to include those adapters, for example in monitoring activities. If you require this support, follow the instructions in “Activating IBM License Metric Tool for WebSphere Adapters” on page 1108.

If you intend to use any of the IBM App Connect Enterprise features that require MQ functionality, you can install and use IBM MQ within the terms of your IBM App Connect Enterprise license. For more information about using IBM MQ with IBM App Connect Enterprise, see “Installing IBM MQ” on page 96.

To find out more about using ILMT to monitor usage of IBM App Connect Enterprise and other IBM products, or to purchase ILMT, see the IBM License Metric Tool website.

For information about installing this product, see the IBM License Metric Tool website.

Chapter 4. Configuring IBM App Connect Enterprise

You can set up your application development environment to create, test, and deploy message flows and associated resources, and then configure IBM App Connect Enterprise to run in a production environment, either on premises or in a container. Alternatively, you can download an image from `https://hub.docker.com/r/ibmcom/ace/` and run it in a Docker container, or you can create your own Docker images.

About this task

IBM App Connect Enterprise provides an integration server component and an integration node component. You can configure an integration node as the central point of administrative control over a set of owned integration servers (typically in an on-premise environment), or you can configure integration servers that are run independently from any integration node (typically in a container environment).

This flexibility enables you to develop a solution that is best suited to the environment in which you intend to run your App Connect Enterprise applications. You can use integration nodes to provide management and control of your integration server processes, and to configure administration security for your resources. Alternatively, you can choose to develop and deploy your applications to an independent integration server quickly and easily, without the need to create and configure an integration node.

For information about configuring integration nodes and integration servers, see “Configuring integration nodes” on page 113 and “Configuring integration servers” on page 167.

Procedure

1. Set up your development environment, as described in “Configuring the IBM App Connect Enterprise Toolkit” on page 103.
2. Configure IBM App Connect Enterprise to run in a production environment, by following the instructions in one of the following topics:
   - “Configuring App Connect Enterprise to run on premises (on a physical or virtual machine)” on page 110
   - “Configuring App Connect Enterprise to run in a container” on page 111
   - “Configuring App Connect Enterprise to run in Docker” on page 111

Configuring the IBM App Connect Enterprise Toolkit

Set up your application development environment on Linux on x86-64 or Windows 64-bit to create, test, and deploy message flows and associated resources. You can configure various settings in the IBM App Connect Enterprise Toolkit to suit your requirements and your working environment.

About this task

Use the IBM App Connect Enterprise tutorials to help you get started with developing integration solutions. The tutorials are in the Tutorials Gallery, which you can find by clicking **Help** > **Tutorials Gallery** in the IBM App Connect Enterprise Toolkit. When you have tried out your first few tutorials, you can set up an environment that can support your application developers.

When you start the IBM App Connect Enterprise Toolkit, a workbench session opens, which you can use to create, configure, and manage your application development resources. You can configure your workbench session in various ways to suit your working environment and preferences. These options are described in “Configuring the IBM App Connect Enterprise Toolkit” on page 103.

If you are planning to run your IBM App Connect Enterprise integrations in a container, you will need to create and configure your integration servers. If you are planning to run your integrations on premises (on

a physical or virtual machine), you will need to create your integration servers and at least one integration node.

The following topics show you how to configure aspects of the IBM App Connect Enterprise Toolkit.

Results

A minimum display resolution of at least 1024 x 768 is required for some dialog boxes, such as the **Preferences** dialog box.

Starting the App Connect Enterprise Toolkit

Use the development environment on Linux or Windows to develop your message flows.

Before you begin

Install the IBM App Connect Enterprise Toolkit; for more information, see "Installing IBM App Connect Enterprise software" on page 75.

Procedure

To start using your development environment, complete the following steps.

1. Start the App Connect Enterprise Toolkit in the following way:

   - Linux From the installation directory, for example `$HOME/ace-11.0.0.0`, type the following text:

     ```
     ./ace toolkit
     ```

   - Windows Search for **IBM App Connect Enterprise Toolkit 12.0.n** and start it.

   Your IBM App Connect Enterprise Toolkit session opens, and displays the **Welcome** page. You can tailor various settings in the IBM App Connect Enterprise Toolkit to suit your requirements and your working environment; for example, the colors and fonts. These options are described in "Configuring the IBM App Connect Enterprise Toolkit" on page 103.

2. Close the **Welcome** page.

   You can return to the **Welcome** page later by clicking **Help** > **Welcome**. If more than one option is listed, select IBM App Connect Enterprise.

3. In the Integration Development perspective, select the Integration Explorer view.

   Your configuration might be affected by the operation mode in which IBM App Connect Enterprise is running. The default operation mode is advanced mode, in which your integration servers run with no restrictions. Check with your integration administrator which operation mode applies to your organization; you might have to change the mode of your integration node or servers after you have created them. For more information about operation modes, see "Operation modes" on page 3.

4. If you are planning to run your integration in a container, you must configure at least one integration server.

   For more information, see "Configuring an integration server by modifying the server.conf.yaml file" on page 172.

5. If you are planning to run your integration on premises (on a physical or virtual machine), you must have at least one integration node with at least one associated integration server.

   For information about how to create an integration node, see "Creating an integration node" on page 114. To add integration servers to your integration node, right-click the integration node, and click **New** > **Integration Server**. Enter a name for your integration server, and click **OK**.

   The integration server is the runtime environment in which your message flows run. You can create many integration servers on a single integration node, and you can deploy your message flows to one or more integration servers on one or more integration nodes.

   For more detailed instructions about this task, see "Creating an integration server" on page 168.

Results
Your configuration is now ready to use.

What to do next
You can start to develop resources to deploy to your integration server. You can create your own message flows, or you can use the patterns and samples that are provided to get you started. For details of these options, see Chapter 6, "Developing integration solutions," on page 481.

This task has covered the minimum set of steps that you must complete to create an integration server and (optionally) an integration node, and to configure your development environment. Typically, as an application developer, you are working in a single platform environment to create, deploy, and test your message flows before they are ready for use in a test of production environment.

More options are available for enhanced configurations, including policies. When the requirements of your message flows extend beyond this basic configuration, and you need additional configuration to support those requirements, you can find details of these more advanced options in "Configuring App Connect Enterprise to run on premises (on a physical or virtual machine)" on page 110 and "Configuring App Connect Enterprise to run in a container" on page 111.

Changing IBM App Connect Enterprise Toolkit preferences

The IBM App Connect Enterprise Toolkit has many preferences that you can change to suit your requirements. Some of these preferences are specific to IBM App Connect Enterprise. Other preferences control more general options, such as the colors and fonts in which information is displayed.

Procedure

To access the IBM App Connect Enterprise Toolkit preferences, complete the following steps.

1. Select **Window** > **Preferences**.
2. Click the plus sign that is associated with **General**, typically the first entry in the left pane.

   An expanded list of options appears, Select the aspect of the IBM App Connect Enterprise Toolkit that you want to modify. These options might be of interest:

   Startup and shutdown
   Display or suppress the dialog that prompts you to confirm the workspace location when you start IBM App Connect Enterprise Toolkit. By default, the dialog is suppressed.

   Specify whether to display the dialog box that prompts you to confirm shutdown of the IBM App Connect Enterprise Toolkit.

   Appearance
   Change the default fonts and colors that appear in the IBM App Connect Enterprise Toolkit.

   Perspectives
   Choose whether to open a new perspective in a new window.
3. When you have made your changes, click **OK** to close the Preferences dialog.

What to do next

Below the General category in the Preference dialog, there are items that refer specifically to IBM App Connect Enterprise resources, such as message flows. Review the following topics for information about setting preferences and other values that are specific to your use of these resources:

- Message flow preferences
- "Changing ESQL preferences" on page 1625
- "Message Sets: Configuring message set preferences" on page 2249
- "Testing and troubleshooting message flows" on page 647

Changing workbench capabilities

You can configure the workbench to disable access to some of the functional capabilities of IBM App Connect Enterprise.

About this task

Capabilities is an Eclipse concept that allows you to enable or disable the components of a product. By default, all components of the workbench are enabled.

To access the workbench capabilities:

Procedure

1. Select **Window** > **Preferences**.
2. Click the plus sign associated with **General**.

   An expanded list of options appears.
3. Click **Capabilities**.

   You can use the capabilities that are listed to enable or disable various product components; the capabilities are grouped according to a set of predefined categories.
4. Select **IBM Integration Toolkit** from the list of capabilities that is displayed, and select the **Advanced** button.

   A window opens that has a check box for each of the predefined categories.
5. Select the check boxes for the categories that you want to either enable or disable; click either the **Enable All** or **Disable All** button and click **OK**.

   A pane describes the functionality that is enabled following this action.

What to do next

The predefined categories for the workbench are listed together with a reference to more information about the relevant functional area of IBM App Connect Enterprise:

- **IBM Integration Toolkit - Administration**. See Chapter 5, “Administering IBM App Connect Enterprise,” on page 243.
- **IBM Integration Toolkit - Core**. See #unique_127.
- **IBM Integration Toolkit - Development**. See Chapter 6, “Developing integration solutions,” on page 481.

Configuring CVS to run with the IBM App Connect Enterprise Toolkit

Install CVS as a normal program by following the usual prompts. Not all versions of *CVSNT* are supported by Eclipse.

Procedure

1. Configure CVS by carrying out the following tasks:
   a) Create a directory on your computer, for example, on Windows - `c:\CVSRepository`.
   b) Start the *CVSNT* control panel.
      Select **Start** > **Programs** > **CVSNT** to see the icon on the desktop.
   c) Stop both the `CVS Service` and the `CVS Lock Service`.
   d) Select the `Repositories` tag, click **Add** and create a new repository.
      Note that no entry appears on the screen the first time that you do this.
   e) Use the `...` button on the next window to select the directory that you created in step "1.a" on page 107 and click **OK**.
      Note that when CVS has finished formatting its repository the backslash in the directory name is changed to a forward slash.
   f) Select the `Service Status` tab and restart both the `CVS Service` and the `CVS Lock Service`.
2. Enable the CVS Revision tag to be populated in the Eclipse Version fields in the IBM App Connect Enterprise Toolkit.
   To do this on Windows:
   a) Select `Window->Preferences`
   b) Expand the `Team` section and click **CVS**
   c) Use the drop down in the **Default keyword substitution:** field and set the value to `ASCII with keyword expansion(-kkv)`
3. Add the IBM App Connect Enterprise file types to the Eclipse CVS configuration.
   To do this:
   a) Select **File Content** in the `Team` section of the window you opened in step "2" on page 107
   b) Click **Add** and add `msgflow` as an allowable file extension.
      Ensure that the value is set to ASCII.
   c) Repeat the above procedure for the following file extensions that the integration node uses:
      - `esql`
      - `mset`
      - `mxsd`

      If you use CVS to store other file types, for example, COBOL copybooks add the appropriate file types as well.
   d) Click **OK** when you have finished.

Configuring the IBM App Connect Enterprise Toolkit to run Rational ClearCase

To use Rational® ClearCase® with the IBM App Connect Enterprise Toolkit, install Rational ClearCase Remote Client for Eclipse.

About this task

To enable Rational ClearCase in the IBM App Connect Enterprise Toolkit you must install Rational ClearCase Remote Client for Eclipse version 7.1.2.9 or later; see http://www.ibm.com/support/knowledgecenter/SSSH27_7.1.2/com.ibm.rational.clearcase.cc_ms_install.doc/topics/

t_install_ccrc_eclipse.htm. Follow the instructions to install Rational ClearCase Remote Client for Eclipse on Eclipse 3.4.

For information about the system requirements for Rational ClearCase Remote Client for Eclipse, see http://www.ibm.com/support/docview.wss?uid=swg21224586.

Results

After you enable the ClearCase capability, the ClearCase menu is displayed in the Integration Development perspective.

What to do next

To work with ClearCase:

1. Click **ClearCase** > **Connect to Rational ClearCase**.
2. Right-click your project and click **Team** > **Add to Version Control** to add your projects to the ClearCase source control.
3. After you add your projects to the ClearCase source control, you can perform ClearCase operations.

Creating a working set

Create a working set to limit the number of resources that are displayed in the Application Development view.

Before you begin

To read about working sets, see Working sets.

About this task

By creating and using a working set, you can reduce the visual complexity of what is displayed in the Application Development view, making it easier to manage and work with your projects.

To create a new working set, complete the following steps:

Procedure

1. Click the arrow on the toolbar of the Application Development view, then click **Select Working Set**.

   A list is displayed containing existing working sets. A working set is created automatically when you create an application or library. The names of these working sets are enclosed by brackets; for example [Application1].
2. To open the **New Working Set** wizard, click **New**.
3. Select a type for the new working set (for example, Integration node), then click **Next**.
4. Enter a name for the working set.
5. Select the resources that you want to include in this working set. You can also include all the projects that are dependent on your selected resources by selecting **Automatically include dependent projects in this working set**.
6. Click **Finish**.

Results

The new working set is created.

What to do next

- To show only the resources in a working set, click the arrow on the toolbar of the Application Development view, click **Select Working Set**, then select the relevant working set. If you select the

working set that is created automatically for an application or library (as indicated by brackets; for example, [Application1]), the Application Development view shows only the selected container and its contents.

- To edit the selected working set, click the arrow on the toolbar of the Application Development view, then click **Edit Active Working Set**. When you delete the active working set, all resources are shown automatically. You cannot edit the working sets that are created automatically for an application or library, as indicated by brackets; for example, [Application1].
- To delete the selected working set, click the arrow on the toolbar of the Application Development view, click **Select Working Set**, then click **Remove**.
- To show all resources, click the arrow on the toolbar of the Application Development view, then click **Deselect Working Set**. Alternatively, click the **Remove all filters** icon  on the toolbar of the Application Development view.

Integrating the Rational Team Concert client with the IBM App Connect Enterprise Toolkit

You can integrate the Rational Team Concert client with the IBM App Connect Enterprise Toolkit.

About this task

To integrate the Rational Team Concert client with the IBM App Connect Enterprise Toolkit, complete the following steps.

The supported versions of Rational Team Concert are V4.0.3 or later, and V5.0 or later, with Eclipse 4.2.2 support.

Procedure

1. Download the Rational Team Concert client.
   a) Navigate to the Rational Team Concert download site: https://jazz.net/downloads/rational-team-concert/.
   b) Select the client that you want and click **More download options**.
      For example, select **Rational Team Concert 5.0.2** if you want the Rational Team Concert V5.0.2 client.
   c) Select **p2 Install Repository** in the **Plain .zip Files** section to select the p2 install repository.
   d) Sign in to Jazz® and locate the p2 install directory.
      For example, the p2 install repository for the Rational Team Concert V5.0.2 client is `RTC-Client-p2Repo-5.0.2.zip`.
   e) Unzip the p2 install repository into a local directory.
2. Start the IBM App Connect Enterprise Toolkit and select **Help** > **Install New Software**.
3. In the **Available Software** window, click **Add**.
4. In the **Add Repository** window, click **Archive**, navigate to the local directory in which you unzipped the p2 install repository in step "1.e" on page 109, and click **OK**.
5. Ensure that **Group items by category** is selected, and then select **Rational Team Concert Client (extend an Eclipse installation)**.
6. Click **Next**, then **Next** again in the **Install Details** window.
7. Accept the terms of the license agreement and click **Finish**.
   A security warning window opens during the installation because the Rational Team Concert client bundles and features are not signed.
8. Click **OK** to complete the installation.
9. Click **Restart Now** when prompted to restart the IBM App Connect Enterprise Toolkit.

What to do next

To work with Rational Team Concert source control:

1. Start the IBM App Connect Enterprise Toolkit.
2. Open the Work Items perspective and click **Window** > **Open Perspective** > **Other** > **Work Items**.
3. Click the **Create Repository Connection** link in the Team Artifacts view.
4. Follow the dialog and enter the information given to you by your Jazz administrator.
5. To add your project to the repository, right-click the project and select **Team** > **Share Project**.
6. In the Share Project window, select Jazz Source Control as the repository type.

See Getting started in your Rational Team Concert® source control workspace for more details about the Rational Team Concert source control operations.

You can also use the Jazz Team Build as your build engine for the IBM App Connect Enterprise Toolkit; see Building with Jazz Team Build for more information.

Configuring App Connect Enterprise to run on premises (on a physical or virtual machine)

You can create one or more integration nodes on one or more computers, and configure them on your test and production systems to process messages that contain your business data.

About this task

On Linux and Windows systems, you can install IBM App Connect Enterprise and the IBM App Connect Enterprise Toolkit, and start developing your applications. You can also configure an environment for more advanced application development and unit test, as described in “Configuring the IBM App Connect Enterprise Toolkit” on page 103.

Use the information in this section to plan and configure the resources that you need to run on premises. Alternatively, you can configure App Connect Enterprise to run in a container or in Docker.

Procedure

1. Plan your system; see “Planning an IBM App Connect Enterprise environment” on page 8.
2. Ensure that you have the correct authorization and permissions to create and access components.

   For more information, see “Authorization for configuration tasks” on page 2492 and “Security for runtime components” on page 2632.
3. Create the components, as described in “Configuring integration nodes” on page 113 and “Configuring integration servers” on page 167.
4. If you want to ensure that you are using the correct operation mode for your license, see “Checking the operation mode” on page 87 and “Changing the operation mode” on page 86.
5. Create and configure the databases.
6. If you want to ensure the data integrity of transactions, Configure global coordination of transactions.
7. If you want to connect to external resources such as Enterprise Information Systems, IMS, or JMS, Configure properties to connect to external resources.
8. If you want to configure the storage of events for aggregation, Collector, resequence, or timeout nodes, or configure monitoring event sources, Configure internal resources that are required by message flows.
9. If you want to view objects in a different language or code page, Change the locale.
10. If you want to operate your IBM App Connect Enterprise instances in a highly available configuration; see “Configuring integration nodes for high availability” on page 120.
11. If you want to operate your integration node as an IBM MQ service; see “Configuring an integration node as an IBM MQ service” on page 166.

Configuring App Connect Enterprise to run in a container

You can configure one or more integration servers and deploy them to run in a container, where they will process messages that contain your business data.

About this task

On Linux and Windows systems, you can install IBM App Connect Enterprise and the IBM App Connect Enterprise Toolkit, and start developing your applications. You can also configure an environment for more advanced application development and unit test, as described in "Configuring the IBM App Connect Enterprise Toolkit" on page 103.

Use the information in this section to plan and configure the resources that you need to run in a container. Alternatively, you can configure App Connect Enterprise to run on premises or in Docker.

If you are intending to run App Connect Enterprise in a container, you can develop and deploy your applications to an independent integration server quickly and easily, without the need to create and configure an integration node.

Procedure

Configure App Connect Enterprise to run in a container by following these steps:

1. Plan your system; see "Planning an IBM App Connect Enterprise environment" on page 8.
2. Configure security for the integration server, as described in "Configuring HTTP basic authentication for an integration node or server" on page 2548 and "Configuring SSL or TLS for an integration node or server" on page 2548.
3. Create and configure your integration servers, as described in "Configuring integration servers" on page 167.
4. If you want to ensure that you are using the correct operation mode for your license, see "Checking the operation mode" on page 87 and "Changing the operation mode" on page 86.
5. Create and configure the databases.
6. If you want to connect to external resources such as Enterprise Information Systems, IMS, or JMS, Configure properties to connect to external resources.
7. If you want to configure the storage of events for aggregation, Collector, resequence, or timeout nodes, or configure monitoring event sources, Configure internal resources that are required by message flows.
8. If you want to view objects in a different language or code page, Change the locale.

Configuring App Connect Enterprise to run in Docker

You can configure IBM App Connect Enterprise to run in a Docker container on AIX, Linux, and Windows systems, and in IBM z/OS Container Extensions (zCX).

About this task

You can use Docker to package an integration server into a standardized unit for software development. Changes to your IBM App Connect Enterprise environment can then be deployed to test and staging systems quickly and easily, which can be a major benefit to continuous delivery in your enterprise. You can choose to build specific configurations into your IBM App Connect Enterprise Docker images, such as integration servers where particular applications are deployed. Or you can choose to start a Docker container from the image, then deploy changes to the running integration server.

You can create your own Docker images by using the supplied files on ot4i (at https://github.com/ot4i/ace-docker). Alternatively, you can download a pre-built image of the IBM App Connect Enterprise for Developers edition (on selected platforms) to run in a Docker container. For more information, see Obtaining the IBM App Connect Enterprise server image from the IBM Cloud Container Registry. A pre-built image is not currently available for download for IBM z/OS Container Extensions (zCX).

Procedure

Use the information in the following topics to help you plan, install, and configure IBM App Connect Enterprise to run in Docker:

- "Docker support on Linux systems" on page 112
- "Stopping an IBM App Connect Enterprise Docker container" on page 112
- "Building a sample IBM App Connect Enterprise image using Docker" on page 113

What to do next

For more information about using Docker with IBM App Connect Enterprise, see Running IBM App Connect Enterprise in a Docker container.

Docker support on Linux systems

IBM App Connect Enterprise supports the use of Docker for hosting production servers, and for development and test environments. You can configure IBM App Connect Enterprise to run in a Docker container on AIX, Linux, and Windows systems, and in IBM z/OS Container Extensions (zCX).

About this task

For the latest information about version numbers and supported environments, see the system requirements information on the IBM Support web pages.

When you are running IBM App Connect Enterprise in a Docker container, you can build your own Docker images or you can use the samples that are provided. Note the following requirements:

- You must use Docker v1.7 or higher.
- The Docker guest must be an IBM App Connect Enterprise supported operating system.
- The host on which the Docker container is running must use a Linux kernel at level 3.10 or later.
- IBM App Connect Enterprise has no specific requirements for kernel configuration parameters, but other supporting products such as IBM MQ might have additional requirements.
- As advised in the Docker documentation, if you want data that is related to IBM App Connect Enterprise to be persisted independently of the container lifecycle, you must ensure that it is stored on a Docker volume. For more information, see https://docs.docker.com/engine/tutorials/dockervolumes/.
- To receive IBM support, you must have the following:
  - A means of capturing syslog messages.
  - A means of running commands against the running node; for example, by using `docker exec bash -c mqsilist` with the mqsiprofile set on login, or through `ssh`.
  - Access to the workpath directories, for diagnostic purposes.

For more information about Linux support, see IBM App Connect Enterprise system requirements for Linux systems:

Stopping an IBM App Connect Enterprise Docker container

You can stop your IBM App Connect Enterprise Docker container by running the `docker stop` command or by pressing `Ctrl-C`. You can configure IBM App Connect Enterprise to run in a Docker container on AIX, Linux, and Windows systems, and in IBM z/OS Container Extensions (zCX).

About this task

You can stop a Docker container by using one of the following methods:

- If the container is running with a pseudo-TTY allocated (by specifying the **-t** flag on the `docker run` command), you can stop it by pressing `Ctrl-C`. The signal is caught by the integration server, which shuts down gracefully.
- Run the `docker stop` command against the running container, as shown in the following example:

```
docker stop myAce
```

Building a sample IBM App Connect Enterprise image using Docker

You can build a sample IBM App Connect Enterprise Docker image. You can configure IBM App Connect Enterprise to run in a Docker container on AIX, Linux, and Windows systems, and in IBM z/OS Container Extensions (zCX).

About this task

To run IBM App Connect Enterprise in a Docker container, you must first build a base image containing an installation of IBM App Connect Enterprise. Instructions are available in the IBM App Connect Enterprise GitHub repository, at https://github.com/ot4i/ace-docker. Alternatively, you can download an image of the IBM App Connect Enterprise for Developers edition (for selected platforms) from https://hub.docker.com/r/ibmcom/ace/ and use this to run a Docker container.

If you plan to use IBM z/OS Container Extensions (zCX), ensure that you have installed the Linux on zSeries package. Until APAR OA59111 is available, you can build an image on IBM z/OS Container Extensions (zCX) only by using the experimental Ubuntu Dockerfiles. A pre-built image is not currently available for download for IBM z/OS Container Extensions (zCX).

A Dockerfile is a set of instructions for building a Docker image. Images can be stored in local or remote registries, and are used to create a running Docker container. To build the image, Docker executes the instructions in the Dockerfile. Each instruction causes a new image layer to be created. Docker best practice guidelines recommend that you keep the number of Dockerfile instructions to a minimum, because the number of layers in an image might be limited. The guidelines, which are available at https://docs.docker.com/engine/userguide/eng-image/dockerfile_best-practices, suggest that you “find the balance between readability (and thus long-term maintainability) of the Dockerfile and minimizing the number of layers it uses. Be strategic and cautious about the number of layers you use.”

The following GitHub repository contains a Dockerfile and some additional files that show how you can build an IBM App Connect Enterprise Docker image: https://github.com/ot4i/ace-docker.

If you do not have access to the GitHub CLI (which is not currently available on IBM z/OS Container Extensions (zCX)), you can obtain the contents of the repository by running the following curl command:

```
curl -Lk https://github.com/ot4i/ace-docker/tarball/master | tar xz
```

Configuring integration nodes

Create and configure the integration node that you want on the operating system of your choice.

Before you begin

Ensure that the following requirements are met:

- Your user ID has the correct authorizations to perform the task. The authorizations are defined in Security requirements for administrative tasks.
- Windows On Windows: you have created a user ID to be used as the service user ID. You specify this ID when you create the integration node; it is used to run the integration node.

  For more information about user ID authorization and creation, refer to “Planning for security” on page 17.

- You have initialized the command environment on distributed systems; see “Setting up a command environment” on page 64.

About this task

When you have created your physical components, you can administer your test and production environments programmatically by using the IBM Integration API.

This collection of tasks uses specific resource names and user IDs. These names are examples only; you can use your own names. Follow existing naming conventions for IBM MQ and other resources.

Procedure

- Create an integration node by following in the instructions in “Creating an integration node” on page 114.
- Verify that the integration node is created by following the instructions in “Verifying an integration node” on page 120.
- Modify the integration node by following the instructions in “Configuring an integration node by modifying the node.conf.yaml file” on page 118.
- (Optional) If you are developing message flows that include resources such as the WebSphere Adapters nodes, IMS nodes, or the CICSRequest node, you must set up your environment to support these applications. Details of the setup that you require is in “Configuring the environment to access external applications and resources” on page 182.
- (Optional) If you are working with web services message flows and want to ensure reliable messaging, you can configure WS-RM using policy sets. See “Web Services Reliable Messaging” on page 818.
- (Optional) You can use WS-Security with your web services message flows to provide quality of protection through message integrity, message confidentiality, and single message authentication. See “WS-Security” on page 2650.

Creating an integration node

You can create integration nodes on every software platform that is supported by IBM App Connect Enterprise.

Before you begin

Complete the following tasks:

- Ensure that your user ID has the correct authorizations to perform the task. Refer to Security requirements for administrative tasks.
- On distributed systems, you must set up your command line environment before you create an integration node by running the product profile or console; refer to “Setting up a command environment” on page 64.

About this task

Create an integration node by using the command line on the computer on which you installed IBM App Connect Enterprise.

You must give the integration node a name that is unique on the local computer. Integration node names are case-sensitive on all supported platforms except Windows.

Optionally, on all distributed systems you can specify a queue manager to be associated with the integration node. This queue manager is used by default for IBM MQ processing in the message flow if no queue manager has been specified explicitly on the MQ node. Some message flow nodes such as CD and FTE nodes, and event-driven processing nodes used for aggregation, timeout, message collections, and message sequences, require a queue manager to be specified for the integration node. These nodes use system queues, which are owned by the queue manager, to store information about in-flight messages.

For information about creating the system queues, see “Creating the default system queues on an IBM MQ queue manager” on page 99.

Queues that are specified on event-driven processing nodes are created automatically when the flow is deployed, provided that the integration node has the required permissions to create the queues. If the queues are not created automatically, you can create them manually; see “Creating the default system queues on an IBM MQ queue manager” on page 99. For more information about using IBM MQ with IBM App Connect Enterprise, see “Installing IBM MQ” on page 96 and “Enhanced flexibility in interactions with IBM MQ ” on page 26.

Multiple integration nodes can specify the same queue manager. You can also specify a queue manager to be used by an existing integration node, by modifying the `node.conf.yaml` configuration file for the integration node. You must then restart the integration node for the changes to take effect.

The mode in which IBM App Connect Enterprise is running can affect the number of integration servers and message flows that you can deploy. For more information, see “Restrictions that apply in each operation mode” on page 5.

To create an integration node, complete the steps in “Creating an integration node by using the command line” on page 115.

If you want to configure the integration node as an IBM MQ trusted application, see “Using IBM MQ trusted applications” on page 117.

Creating an integration node by using the command line

On Linux, UNIX and Windows, you can create integration nodes on the command line.

Before you begin

- If you want to configure the integration node as an IBM MQ trusted application, see “Using IBM MQ trusted applications” on page 117.
- Read “Controlling access to IBM App Connect Enterprise” on page 2633.
- Check which operation mode you are licensed to use. If you do not set a mode, the automatic default is `advanced` mode; see “Operation modes” on page 3.

About this task

When you create an integration node, you can optionally specify a queue manager for the integration node. If you do not specify a queue manager, features that require access to IBM MQ will be unavailable. For more information about using IBM MQ with IBM App Connect Enterprise, see “Enhanced flexibility in interactions with IBM MQ ” on page 26 and “Installing IBM MQ” on page 96.

When you create an integration node, a subdirectory is created to store files for the integration node (and its integration servers and the resources deployed to those servers). These files include the integration node's configuration file, `node.conf.yaml`. By default, the node's subdirectory is created under the IBM App Connect Enterprise working directory, which was set when the product was installed. On the **`mqsicreatebroker`** command you can optionally use the **`-w`** *workPath* parameter to specify your own choice of working directory.

For example, for the integration node *node_name*, the default working directory on Windows is `C:\ProgramData\IBM\MQSI\components\`*node_name*, which has the following structure:

```
C:\ProgramData\IBM\MQSI\components\node_name
C:\ProgramData\IBM\MQSI\components\node_name\node.conf.yaml
...
C:\ProgramData\IBM\MQSI\components\node_name\servers
```

The *node_name*`\servers` directory is created when you later create an integration server for the integration node, and a subdirectory is created under *node_name*`\servers` to store files for each integration server. These files include the server's configuration file, `server.conf.yaml`. For example, two integration servers created under the integration node `NODEIPL102`:

```
C:\ProgramData\IBM\MQSI\components\NODEIPL102\servers\N101ISAA
```

```
C:\ProgramData\IBM\MQSI\components\NODEIPL102\servers\N102ISAB
```

When you create an integration node by running the **mqsicreatebroker** command, an overrides subdirectory is also created under the working directory for the integration node. This overrides directory contains an additional `node.conf.yaml` configuration file, which contains property values that are set by IBM App Connect Enterprise commands, including the **mqsicreatebroker** command. These values override any values that are set for the same properties in the integration node's base `node.conf.yaml` file.

When you have created the integration node, you can configure it by modifying properties in its `node.conf.yaml` configuration file (for example, `C:\ProgramData\IBM\MQSI\components\acev11node\node.conf.yaml`). If any commands are run subsequently, which modify settings for the integration node, those modified settings are saved in a `node.conf.yaml` file in the overrides directory (for example, `C:\ProgramData\IBM\MQSI\components\acev11node\overrides\node.conf.yaml`).

If a property has been set in the integration node's base `node.conf.yaml` file, and also in the overrides directory (`\overrides\node.conf.yaml`), the property value that has been set in the overrides directory is used. Therefore, if an integration node does not appear to be using the settings that you would expect, check the `node.conf.yaml` file in the overrides directory to see if your expected property value has been overridden by a command. If you want to manually override the settings that have resulted from a command, you can either edit the property in the `node.conf.yaml` file in the overrides directory, or you can remove the entry from the overrides directory and modify the base `node.conf.yaml` file instead.

To create an integration node by using the command line, complete the following steps:

Procedure

1. Ensure that you have the authority to create an integration node by following the steps for your operating system:
   - Linux UNIX On Linux and UNIX, ensure that you are logged in using a user ID that has authority to run the **mqsicreatebroker** command.

     Run the **mqsiprofile** script to set up the command environment for the integration node:

     ```
     install_dir/server/bin/mqsiprofile
     ```

     You must run this script before you can run the IBM App Connect Enterprise commands.

     For more information, see “Setting up a command environment” on page 64.
   - Windows On Windows, open an IBM App Connect Enterprise command prompt for the runtime installation in which you want to create the integration node. For more information about initializing the runtime environment, see “Setting up a command environment” on page 64.

     On Windows systems, you must open a command console with elevated privileges. To open a command console with elevated privileges, use the **mqsicommandconsole** command. For more information, see command.
2. Use the **mqsicreatebroker** command to create the integration node.

   For example, if you want to create an integration node that is called INODE with a queue manager that is called ACEQMGR, enter the following command:

   ```
   mqsicreatebroker INODE -i wbrkuid -a wbrkpw -q ACEQMGR
   ```

   Where wbrkuid and wbrkpw are the user name and password under which the integration node runs.

   Note: You can specify a queue manager name that does not exist, but the specified queue manager must be running before you start your integration node.

   When you create your first integration node, the web user interface uses the default port 4414, and for each integration node created after the port number increments automatically by one. You can

change the port number to be used by editing the integration node's `node.conf.yaml` file. You can also change the port number or disable the web user interface by using the **mqsichangeproperties** command. If administration security is not enabled, web users can access the web user interface as a default user with unrestricted access to data and integration node resources.

For more information about the command parameters, see command.

Results

You have created an integration node.

What to do next

(Optional) If you want to configure properties of the integration node, edit its `node.conf.yaml` file. For example, you can set a REST administration port and an HTTPS port, you can enable administration security, and you can configure the trace level, activity logging, JVM, and the reporting of statistics and accounting data. For more information, see "Configuring an integration node by modifying the node.conf.yaml file" on page 118.

Start the integration node by using the **mqsistart** *node_name* command. See "Starting and stopping an integration node on Windows, Linux, and UNIX systems" on page 247.

1. If you want to work with the integration node in the IBM App Connect Enterprise Toolkit (or a custom integration application), connect the toolkit to the integration node. For example, connect to the integration node before you can use the Enterprise Toolkit to start the node's web user interface or create integration servers associated with the integration node. See "Connecting to an integration node by using the Toolkit" on page 245.
2. If you want to use the web user interface to manage the integration node's integration servers and their resources, start the web user interface using the administration URI (hostname and port) configured for the integration node. The hostname and port are reported by the **mqsilist** command; for example:

   ```
   mqsilist
   ...
   BIP1325I: Integration node 'NODEIPL101' with administration URI 'http://<host>:4417' is
    running.
   ```

   For more information about using the web user interface to manage integration servers and their resources, see "Managing integration servers" on page 249 and "Managing deployed resources" on page 316.
3. Create integration servers under the integration node; for example, by using the Enterprise Toolkit or the web user interface. For more information, see "Creating an integration server" on page 168.

When you have completed these tasks, you can create the resources that you want to associate with the integration node; for example message flows. You can create and work with resources by using either the IBM App Connect Enterprise Toolkit or the IBM Integration API.

Using IBM MQ trusted applications

Configure an integration node to run as an IBM MQ trusted application.

Before you begin

You must complete the following tasks:

- Ensure that your user ID is a member of the mqm group. On UNIX and Linux, specify the user ID mqm as the service user ID when you create the integration node. On Windows, use any service user ID that is a member of mqm. Refer to Security requirements for administrative tasks.
- Review the restrictions that IBM MQ places on trusted applications that apply to your environment. See Connecting to a queue manager using the MQCONNX call in the IBM MQ product documentation online.

About this task

You can configure an integration node to run as a trusted (fastpath) application on all supported platforms . If the integration node is configured as a trusted application, it runs in the same process as the IBM MQ queue manager agent, and all integration node processes benefit from an improvement in the overall system performance.

An integration node does not run as a trusted application by default; therefore, you must create a trusted application by using the command.

Configuring an integration node as a trusted application does not affect the operation of IBM MQ channel agents or listeners. For more information about running these as trusted applications, see Running channels and listeners as trusted applications in theIBM MQ product documentation online.

Take care when deploying user-defined message flow nodes or parsers. Because a trusted application (the integration node) runs in the same operating system process as the queue manager, a user-defined message flow node or parser might compromise the integrity of the queue manager. Consider fully the restrictions that apply to your environment and test user-defined nodes and parsers in a non-trusted environment before deploying them in a trusted integration node.

You can configure an integration node to run as a trusted application when you create it.

Procedure

- To create an integration node on a command line, run the **mqsicreatebroker** command with the `-t` flag, which specifies that the integration node is created as a trusted application.

  For example, enter the following command to create an integration node called INODE as a trusted application:

  ```
  mqsicreatebroker INODE -q ACEQMGR -i mqm -t
  ```

  See “Creating an integration node” on page 114 for more detailed information about how to create an integration node for your platform.

Configuring an integration node by modifying the node.conf.yaml file

You can configure an integration node by setting properties in the `node.conf.yaml` configuration file for the integration node.

Before you begin

You must have completed the following tasks:

- Ensure that your user ID has the correct authorizations to perform the task; see Security requirements for administrative tasks.
- Create an integration node.

About this task

When you create an integration node, a default `node.conf.yaml` configuration file is created automatically for the integration node and stored in the working directory for the integration node; for example: `C:\ProgramData\IBM\MQSI\components\`*`acev11node`*`\node.conf.yaml`. You can then configure the operation of the integration node and associated resources, by modifying properties in the `node.conf.yaml` file. For example, you can set a REST administration port and an HTTPS port, you can enable administration security, and you can configure the trace level, activity logging, JVM, and the reporting of statistics and accounting data.

When you create an integration node, an overrides subdirectory is also created under the integration node's working directory. This overrides directory contains an additional `node.conf.yaml` configuration file, which contains property values that are set by IBM App Connect Enterprise commands, including the

mqsicreatebroker command. These values override any values that are set for the same properties in the integration node's base `node.conf.yaml` file.

When commands are run that modify settings for the integration node, those modified settings are saved in a `node.conf.yaml` file in the overrides directory (for example, `C:\ProgramData\IBM\MQSI\components\`*`ace11node`*`\overrides\node.conf.yaml`).

If a property has been set in the integration node's base `node.conf.yaml` file, and also in the overrides directory (`\overrides\node.conf.yaml`), the property value that has been set in the overrides directory is used. Therefore, if an integration node does not appear to be using the settings that you would expect, check the `node.conf.yaml` file in the overrides directory to see if your expected property value has been overridden by a command. If you want to manually override the settings that have resulted from a command, you can either edit the property in the `node.conf.yaml` file in the overrides directory, or you can remove the entry from the overrides directory and modify the base `node.conf.yaml` file instead.

When you create integration servers that are owned by the integration node, a default `server.conf.yaml` configuration file is created for each of the integration servers, and they are stored in the file system in subdirectories below the integration node directory. Any properties that you set for the integration node, in the `node.conf.yaml` file, are inherited by the integration servers that it owns. However, you can change any of the integration server properties by modifying them in the appropriate `server.conf.yaml` file. For more information about configuring integration servers that are managed by an integration node, see “Configuring an integration server by modifying the server.conf.yaml file” on page 172.

Procedure

Change the properties of an integration node, by following these steps:

1. Use a YAML editor to open the `node.conf.yaml` file for the integration node that you want to modify.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, which are not accepted in YAML and will cause your integration node configuration to fail. If you choose to use a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

   For more information about working with YAML, see http://www.yaml.org/start.html.
2. Modify the properties that you want to change:
   a) Set the administration REST API port for the App Connect Enterprise web user interface and the App Connect Enterprise Toolkit, by setting a value for the **port** property. You can leave this property set to the default value of 4414.
   b) Specify a value for the **host** property.
   c) Enable authentication for the integration node, by setting the **basicAuth** property to `true`:

   ```
   basicAuth: true
   ```

   d) Enable administration security and specify an authorization mode, by setting the **authorizationEnabled** and **authorizationMode** properties.
   For example:

   ```
   authorizationEnabled: true
   authorizationMode: 'file'
   ```

   e) You can also modify properties to enable the integration node listener, to configure the MQTT server, and to specify a default queue manager.
3. Specify the security credentials to be used by the integration node when connecting to a secured resource (such as a database) by using the **mqsisetdbparms** command. When you run this command, the user ID and password are stored securely in the IBM App Connect Enterprise credentials store. For more information about using this command, see command.

4. Restart the integration node.

   The properties that you set in the `node.conf.yaml` file take effect when the integration node is started. If you modify these properties again, you must start the integration node again for the latest changes to take effect. For more information, see "Starting and stopping an integration node" on page 247.

Verifying an integration node

Use the **mqsilist** command to display the status of integration nodes.

About this task

If you run the **mqsilist** command with no parameters, that command displays a one line summary for every integration node in the current version of IBM App Connect Enterprise. For example:

```
mqsilist
...
BIP1325I: Integration node 'ACE01NODE' with administration URI 'http://localhost:4414' is
 running.
BIP1326I: Integration node 'ACE02NODE' is stopped.
BIP8071I: Successful command completion.
```

You can request further details about all resources by specifying the parameter **-d 2** on the command. You can also specify the **-r** parameter so that the command recursively returns information about integration servers, and the message flows and files that you have deployed to those integration servers.

You can also use this command to display a list of integration nodes that you have created for all concurrent installations on this computer. For example, you might have installed both Version 10.0 and Version 12.0 for assessment and migration. For example:

```
mqsilist -a
...
BIP1325I: Integration node 'ACE01NODE' with administration URI 'http://localhost:4414' is
 running.
BIP1326I: Integration node 'ACE02NODE' is stopped.
BIP8221I: Broker: IB01NODE (Version 10.0)  -
BIP8071I: Successful command completion.
```

Configuring integration nodes for high availability

If you want to operate your IBM App Connect Enterprise instances in a highly available configuration, you can set up your integration nodes to work with IBM MQ multi-instance queue managers, a replicated data queue manager (RDQM), the HTTP proxy servlet, an existing Windows Cluster (Windows Server), or a high availability manager such as HACMP, HA/XD, or Veritas Cluster Server (VCS).

About this task

The following topics describe how to configure your integration node for high availability:

- "Configuring multi-instance integration nodes" on page 121
- "Configuring the HTTP proxy servlet" on page 149
- "Using an integration node with an RDQM configuration" on page 139
- "Using an integration node with an existing high availability manager" on page 130
- "Using an integration node with an existing Windows Cluster (Windows Server)" on page 138

High availability overview

An overview of the high availability configuration and topology options available in IBM App Connect Enterprise.

In IBM App Connect Enterprise, you can create a high availability solution by using any of the following methods:

Multi-instance integration nodes with IBM MQ
Use a multi-instance integration node so that the integration node is available in the same location as the IBM MQ multi-instance queue manager in a high availability IBM MQ configuration. The multi-instance integration node can either dynamically start in all locations where the multi-instance queue manager runs, or can be set as an MQ Service dependency.

For more information, see "Configuring multi-instance integration nodes" on page 121.

An existing high availability manager
Use an external high availability manager by mounting the external resources to the shared file system. Script files are provided for the common tasks that are required to create a multi-instance integration node.

For more information, see "Using an integration node with an existing high availability manager" on page 130.

An RDQM configuration
Configure an integration node to work with an IBM MQ replicated data queue manager (RDQM).

For more information, see "Using an integration node with an RDQM configuration" on page 139.

An existing Windows Cluster
Add an integration node to the nodes in a Windows Cluster.

For more information, see "Using an integration node with an existing Windows Cluster (Windows Server)" on page 138.

The HTTP proxy servlet
Use the HTTP proxy servlet in a servlet container so that you can support high availability, load distribution, access to the integration node from multiple IP addresses and ports, and a larger number of concurrent HTTP sessions.

For more information, see HTTP proxy servlet overview.

Configuring multi-instance integration nodes

Use IBM MQ to configure an integration node to run in multi-instance mode for high availability.

Before you begin

- Review the topic Multi-instance queue managers in the IBM MQ product documentation to understand the use of multi-instance queue managers.

About this task

The set of tasks that describe how to configure a multi-instance integration node assumes the following criteria:

- A file server is configured to host both the shared work path directory for the multi-instance integration node and the shared directories for the multi-instance queue manager.
- The file server is shared between two computers, each of which has a licensed copy of the IBM App Connect Enterprise and IBM MQ products installed.

The steps apply to all operating systems that are supported by IBM App Connect Enterprise and IBM MQ.

To configure an integration node to run in multi-instance mode, complete the following steps.

Procedure

1. Create a shared path directory on an NFS or NAS server.

   On Windows, you can use a shared UNC path. Follow the steps as described in the IBM MQ product documentation; see Creating a shared file system.

2. Create or configure the multi-instance queue manager. Follow the appropriate steps for your operating system as described in the IBM MQ product documentation; see Create a multi-instance queue manager.
3. Follow the steps to create the multi-instance integration node as described in "Creating a multi-instance integration node" on page 122.

What to do next

After you have created a multi-instance integration node, you can also optionally complete the following actions.

- Use the **mqsilist** command to view integration nodes, and which integration nodes are multi-instance.
- Delete a multi-instance integration node, as described in "Deleting a multi-instance integration node" on page 125.
- Delete a multi-instance queue manager, as described in the IBM MQ product documentation, Deleting a multi-instance queue manager.
- Verify shared file system locks, as described in the IBM MQ product documentation, Verifying shared file system behavior.
- Back up, and later restore a multi-instance integration node, as described in "Backing up and restoring a multi-instance integration node" on page 128
- Learn how to fail over multi-instance integration nodes, as described in "Failing over a multi-instance integration node and queue manager" on page 129.

Creating a multi-instance integration node

If you specify a multi-instance queue manager for an integration node, you must configure that integration node as multi-instance.

Before you begin

- Create the shared directories that you require for the multi-instance integration node, as described in the topic Create a multi-instance queue manager in the IBM MQ product documentation. The examples shown in this topic assume that you have created a shared directory called `MQHA`.
- Create the IBM MQ multi-instance queue manager. On Windows, the queue manager must be created with the `"-a"` or `"-ar"` flag on **crtmqm**, specifying a domain group that IBM MQ can use for securing shared files. If you have the choice, use the `"-ar"` flag. For more information, see Create a multi-instance queue manager in the IBM MQ product documentation.

About this task

You can use two configurations for a multi-instance integration node:

- Configure the multi-instance integration node with explicit instances where the queue manager can run. The multi-instance integration node runs in all the defined locations where the multi-instance queue manager is available, and is inactive in locations where the queue manager is not running.
- Configure the multi-instance integration node as an MQ Service dependency. When a multi-instance integration node depends on an MQ Service, whenever the multi-instance queue manager becomes unavailable, the integration node stops. When the queue manager starts, the integration node is also started on the same computer that the queue manager is running on.

To create a multi-instance integration node of either configuration, complete the following steps:

Procedure

1. On the computers that will run the instances of the integration node, configure the required users and groups so that they will have access to the directory for the shared file system:
   - Linux UNIX On Linux and UNIX, the uid and gid for the mqbrkrs group in `/etc/password` must be the same on each server. For more information, see Create a multi-instance queue manager in the IBM MQ product documentation.
   - Windows On Windows, create the following users and groups:
     a. A domain group that is a member of the local mqbrkrs group on both systems. For example, `ACE\Domain mqbrkrs`.
     b. A domain user that is a member of the Domain mqbrkrs and mqm groups. This ID is used for running the integration node.
     c. A domain user that is a member of the Domain mqbrkrs group and a member of the local Administrators group on both machines. This ID is used for creating the integration node. You can use the same ID for both creating and running the integration node, but you do not have to be an Administrator to run the integration node. For example, `WMB\mqsiuser-admin`. The listed user and groups are using the example domain name ACE.
2. Create a directory for the integration node shared files on the file server:
   - Linux On Linux and UNIX systems, create a subdirectory (such as `mqsi`) on the shared drive (`MQHA`); for example: `/MQHA/mqsi`. Ensure that this directory is owned by the mqbrkrs user and group, and has the access permissions `rwx`. The UID of the integration node user ID in `/etc/passwd` and the GID for mqbrkrs in `/etc/group` must be the same on each server.
   - Windows On Windows, update the security permissions of the folder:
     a. In Windows Explorer, right-click the shared directory that you created, and select **Properties.**
     b. Click the **Security** tab, then click **Advanced** > **Change Permissions...**
     c. Clear **include inheritable permissions from this objects parent**.
     d. In the **Permission entries** window, select the entries for individual users and then click **Remove**. Leave the entries for SYSTEM, Administrators, and CREATOR OWNER.
     e. Add `mqbrkrs` with **Full Control**. If this folder is also being used for multi-instance queue manager, then the domain group that is used to secure the queue manager must also be added with **Full Control** set.
     f. Add the global group domain `mqm`. Click **Check Names**, and then click **OK**. If this folder is also being used for multi-instance queue manager, then the domain group that is used to secure the queue manager must also be added with **Full Control** set.
     g. Remove the default **Everyone** user from the list.
3. Open the command console or command prompt by running one of the following commands:
   - Linux UNIX On Linux and UNIX systems, as a non-root user that is in the mqm and mqbrkrs groups, open a command prompt, navigate to the `bin` directory of the installation, and run the **`mqsiprofile`** command. For example:

     ```
     . /opt/ibm/ace-11.0.0.n/server/bin/mqsiprofile
     ```

   - Windows On Windows, as the user `mqsiuser-admin`, open a command prompt with elevated privileges by using the **`mqsicommandconsole`** command; see command

4. Create a multi-instance integration node on computer A, by running one of the following commands:

   - Linux On Linux and UNIX systems:

     ```
     mqsicreatebroker INODE -q QM1 -e /MQHA/mqsi
     ```

     where INODE is the name of the integration node and the **-e** parameter specifies the name of the shared directory created in step 2.

   - Windows On Windows:

     ```
     mqsicreatebroker INODE -i "WMB\mqsiuser" -a password -q QM1 -e \\MQHA\\mqsi -B "WMB\Domain
      mqbrkrs"
     ```

     where INODE is the name of the integration node, and *password* is the `mqsiuser-admin` password. The **-e** parameter specifies the name of the shared directory that was created in step 2, and `QM1` is the name of the multi-instance queue manager that was created previously.

   If you want to start the multi-instance integration node as an MQ Service dependency, specify **-d** as `defined` on the **mqsicreatebroker** command. For more information, see command.

   Note: You must be a member of the mqm group to run the **mqsicreatebroker** command with the **-d** parameter.

   You must ensure that the shared location exists, and that your user ID has access to the shared location before you run this command.

5. Add the details of integration node INODE onto computer B as an instance of that integration node.

   Use the **mqsiaddbrokerinstance** command, in the appropriate format for your operating system.

   - Linux On Linux and UNIX:

     ```
     mqsiaddbrokerinstance INODE -e /MQHA/mqsi
     ```

     where the **-e** parameter specifies the name of the shared directory created in step 2.

   - Windows On Windows:

     ```
     mqsiaddbrokerinstance INODE -i "WMB\mqsiuser" -a password -e \\MQHA\\mqsi
     ```

     where the **-e** parameter specifies the name of the shared directory created in step 2.

   For more information, see command.

   Repeat this step for every computer that the multi-instance queue manager runs on.

6. Start queue manager `QM1` so that it is active on computer A.

   See Starting and stopping a multi-instance queue manager in the IBM MQ product documentation.

7. Start integration node `INODE` on computer A.

   Use the **mqsistart** command:

   ```
   mqsistart INODE
   ```

8. Start integration node INODE on computer B.

   You can observe that integration node INODE is running in standby mode against the standby queue manager `QM1` by running the command **mqsilist**.

9. Optional: Optional: test that the integration node works as follows:
   a) Stop integration node INODE and queue manager QM1 on computer A.

      Observe on computer B that integration node INODE and queue manager QM1 change from standby to active mode.
   b) Restart queue manager QM1 and integration node INODE on computer A.

      Observe on computer A that queue manager QM1 and integration node INODE are in standby mode and, on computer B, queue manager QM1 and integration node INODE remain in active mode.

Results

You have configured a multi-instance integration node, and created an instance of that integration node. When integration node INODE and queue manager QM1 stop on computer A, the same integration node and queue manager on computer B become active, and return to standby when computer A becomes active again.

If you chose to define the multi-instance integration node as an MQ Service dependency, then the integration node stops whenever the multi-instance queue manager becomes unavailable. The integration node is started again when the queue manager starts.

Deleting a multi-instance integration node

Delete a multi-instance integration node without affecting the shared multi-instance configuration.

About this task

Important: The order of deletion of a multi-instance integration node and its associated instances affects the shared configuration. Take care to use the correct command for each step in the process.

You must remove the integration node instances by using the **mqsiremovebrokerinstance** command before you attempt to remove the integration node itself. This command removes all local references to the integration node instance, but does not affect the shared configuration for the multi-instance integration node on the shared work path. The **mqsiremovebrokerinstance** command cannot be run against the standby integration node instance when it is running; stop the integration node instance before you run this command.

If you unintentionally remove an integration node instance, it can be re-created by using the **mqsiaddbrokerinstance** command, providing that the **mqsideletebroker** command was not already used to delete the integration node.

If the multi-instance integration node was removed by using the **mqsideletebroker** command before the associated integration node instances were removed, it will not be possible to start the integration node instances. To recover from this situation, re-create the multi-instance integration node by using the **mqsicreatebroker** command with the **-e** parameter, specifying the original shared work path location.

The following procedure gives an overview of how to delete a multi-instance integration node:

Procedure

1. Stop the multi-instance integration node on computer A.
2. Stop the integration node instance on computer B.
3. Remove the integration node instance on computer B.

   Use the following command, where INODE represents the name of the integration node:

   ```
   mqsiremovebrokerinstance INODE
   ```

   For more information, see command.

   Repeat this step for all integration node instances.

4. Remove the multi-instance integration node on computer A.

   Use the following command:

   ```
   mqsideletebroker INODE
   ```

   This process removes all references to the integration node on both the local and shared work paths. For more information, see command.

Results

You have deleted the multi-instance integration node, and removed all of its instances.

Migrating an integration node to a multi-instance integration node

Migrate an integration node to a multi-instance integration node by moving the queue manager data to a shared directory, and reconfiguring the integration node on two other servers.

Before you begin

Multi-instance integration nodes require a multi-instance queue manager. You must first check the prerequisites for running a multi-instance queue manager, and migrate your queue manager if it is single-instance. For more information, see Migrating from a single instance to a multi-instance queue manager in the IBM MQ product documentation.

For the latest information about tested environments, see Testing statement for IBM MQ multi-instance queue manager file systems. This support statement contains detailed version and prerequisite information for each environment. A test tool is provided with IBM MQ to assist you in testing unsupported environments.

You must provide three servers to run a multi-instance integration node, which provide the following functions:

- A shared file system to store the integration node data and logs.
- Active instances of the integration node.
- Standby instances of the integration node

For more information, see Create a multi-instance queue manager in the IBM MQ product documentation.

Procedure

On the servers that will run the active and standby instances of the integration node, configure the required users and groups so that they have access to a shared directory on the network file system.

1. On Windows, create the following users and groups:
   a) A domain group that is a member of the local `mqbrkrs` group on both servers. For example, `WMB\Domain mqbrkrs`
   b) A domain group that is a member of the local `mqm` group on both servers. For example, `WMB\Domain mqm`
   c) A domain user that is a member of the domain `mqbrkrs` and `mqm` groups. This ID is used for running the integration node. For example, `WMB\mqsiuser`
   d) A domain user that is a member of the domain `mqbrkrs` group and a member of the local administrators group on both machines. For example, `WMB\mqsiuser-admin`. This ID is used for creating the integration node. It can be the same as the previous ID, but you do not have to run the integration node as an administrator.
2. On UNIX and Linux, the uid and gid for `mqbrkrs` in `/etc/password` must be the same on each server. For more information, see Creating a shared file system in the IBM MQ product documentation.

Create a shared directory on the network file system with the correct access permissions. A typical configuration consists of a single shared directory that contains all data for all integration nodes that use the shared file system. Each integration node creates its own data directories under the shared directory.

3. On Windows, create a directory on the file server for the files shared by the integration node, for example, `C:\mqsishare`. Update the security permissions of the directory by completing the following steps:
   a) In Windows Explorer, right-click the shared directory that you have just created and select **Properties.**
   b) Click the **Security** tab, then click **Advanced** > **Change Permissions...**
   c) Clear the "Include inheritable permissions from this object's parent" checkbox.
   d) In the Permission entries window, select the entries for individual users and click **Remove**. Leave the entries for SYSTEM, Administrators, and CREATOR OWNER.
   e) Click **Add...**, and then enter the name of the global group domain `mqm`. Click **Check Names** and click **OK**.
   f) In the **Permission Entry** window, select the **Allow** checkbox for the **Full Control** entry.
   g) Repeat the previous two steps for the global group domain `mqbrkrs`.
   h) In the **Properties** window, click the **Sharing** tab and then click **Advanced Sharing**. Select the **Share this folder** checkbox, and leave the share name as `mqsishare`. Click **Permissions.**
   i) Click **Add**, and enter the name of the global group domain `mqbrkrs`. Click **Check Names**.
   j) In the **Group or user names** panel, select the domain `mqbrkrs`. Select the **Allow** checkbox for the **Full Control** entry, and then click **Apply**.
   k) Repeat the previous two steps for the global group `Administrators`.
   l) In the **Group or user names** panel, remove the group `Everyone`.
4. On Linux and UNIX, complete the following steps:
   a) Create `/HA/mqsi` on the shared drive.

      Ensure that `/HA/mqsi` is owned by the user and group `mqbrkrs`, and has the access permissions `rwx`.
   b) If you are using an NFS v4 file server, add the following line to the `/etc/exports` file:

      ```
      /IBHA * rw,sync,no_wdelay,fsid=0)
      ```

      Start the NFS daemon by using the following command:

      ```
      /etc/init.d/nfs start
      ```

Copying the integration node data to the share is a manual procedure. Before you continue, ensure that you have backed up your integration node. For more information, see “Backing up the integration node” on page 477.

5. Stop the integration node.

Move the IBM App Connect Enterprise configuration directories.

6. On Windows, run the following commands:
   a) **mkdir** *<server_name>*\mqsishare\mqsi\

      where *<server_name>* is the name of your server.
   b) **xcopy** /e /i /q /z C:\ProgramData\IBM\MQSI\components*<int_node_name>* \
      <server_name>\mqsishare\mqsi\components*<int_node_name>*

      where *<int_node_name>* is the name of your integration node.
   c) **xcopy** /e /i /q /z C:\ProgramData\IBM\MQSI\registry*<int_node_name>* \
      <server_name>\mqsishare\mqsi\registry*<int_node_name>*
   d) **rmdir** C:\ProgramData\IBM\MQSI\components*<int_node_name>* /q /s
   e) **rmdir** C:\ProgramData\IBM\MQSI\registry*<int_node_name>* /q /s

7. On Linux and UNIX, run the following commands:
   a) **mkdir** -p /HA/mqsi/components/
   b) **mkdir** -p /HA/mqsi/registry/
   c) **mv** /var/mqsi/components/*<int_node_name>*\ /HA/mqsi/components/
   d) **mv** /var/mqsi/registry/*<int_node_name>*\ /HA/mqsi/registry/

Create a file called HASharedWorkPath that contains the location of the new shared directory and place it with the integration nodes registry directory. The file must not contain any newline characters.

8. On Windows, run the following commands:
   a) **mkdir** C:\ProgramData\IBM\MQSI\registry*<int_node_name>*
   b) <nul set /p =*<server_name>*\mqsishare\mqsi> C:\ProgramData\IBM\MQSI \registry*<int_node_name>*\HASharedWorkPath.dat
9. On Linux and UNIX, run the following commands:
   a) **mkdir** /var/mqsi/registry/*<int_node_name>*
   b) **chmod** 770 /var/mqsi/registry/*<int_node_name>*
   c) **echo** –n /HA/mqsi> /var/mqsi/registry/*<int_node_name>*/HASharedWorkPath

On the standby server, add the standby instance using **mqsiaddbrokerinstance**. For more information, see command.

10. Configure the standby integration node:
    a) On Windows, run the following command: **mqsiaddbrokerinstance** *<int_node_name>* -i *<user_name>* -a *<password>* -e *<server_name>*\mqsishare
    b) On Linux and UNIX, run the following command: **mqsiaddbrokerinstance** *<int_node_name>* -e /HA/
11. On the active server, run the following command: **mqsistart** *<int_node_name>*
12. On the standby server, run the following command: **mqsistart** *<int_node_name>*

Results

Your single-instance integration node has been converted to a multi-instance integration node. You can verify this by using the **mqsilist** command. See command.

Backing up and restoring a multi-instance integration node

Back up the registry and configuration of the multi-instance integration node and its associated resources, and re-create that integration node from the backup.

Before you begin

To ensure that the backup is complete and correct, back up the integration node when the integration node is stopped, or when it is not processing a configuration change (such as a deployment or property change).

About this task

When you back up a multi-instance integration node, you back up the registry and configuration from the shared work path of the integration node and its associated instances. Therefore, the backup procedure that is described in this topic applies to the multi-instance integration node only. No additional steps exist for backing up the associated instances of the integration node.

When you restore a multi-instance integration node, you re-create associated instances by using the **mqsiaddbrokerinstance** command.

Procedure

1. Back up a multi-instance integration node by using the **mqsibackupbroker** command.
   For example:

   ```
   mqsibackupbroker INODE -d /BackupDirectory/ACE
   ```

   where:

   - INODE is the name of the integration node.
   - /BackupDirectory/ACE is the directory in which the backup file is created.

   The command detects a multi-instance integration node and backs up the registry and configuration from the shared work path of the integration node.
2. Restore a multi-instance integration node by using the **mqsirestorebroker** command.

   ```
   mqsirestorebroker INODE -d /BackupDirectory/ACE -a 20091009.zip
   ```

   where:

   - INODE is the name of the integration node.
   - /BackupDirectory/ACE is the directory in which the backup file is stored.
   - 20091009.zip is the name of the backup (archive) file.

   The command detects a multi-instance integration node and restores the registry and configuration to the shared work path of the integration node.
3. Re-create associated instances of the multi-instance integration node by using the **mqsiaddbrokerinstance** command.

   For more information, see the command.

Failing over a multi-instance integration node and queue manager

An active integration node instance fails over when its associated active multi-instance queue manager either terminates unexpectedly, or stops in a controlled manner. The action of stopping an active integration node instance on an active multi-instance queue manager does not by itself cause a standby integration node instance to become active.

About this task

The following examples list the 3 failover scenarios, and how to failover:

Procedure

- Controlled failover.
  - Switch over to a standby instance by stopping an active queue manager with the **endmqm** command:

    ```
    endmqm -s QueueManager
    ```

    where *QueueManager* is the name of the queue manager that you are stopping. As the active instance of the queue managers goes down, the standby instance starts.
- Immediate failover.
  - Stop an active queue manager process with the **kill** command on Linux and UNIX, or end the process with the Windows task manager on Windows:

    ```
    kill -9 amqzxma0 ProcessID
    ```

    where *ProcessID* is the process ID of the amqzxma0 process that you need to kill. The standby instance of the queue manager becomes active.

- Shutting down the server.
  - Restart the server that the active instance of the queue manager is running on. The standby instance of the queue manager becomes active.

Results

If the multi-instance integration node was configured as dependent on an MQ Service, when the multi-instance queue manager restarts, the integration node instance will also start on the computer on which the queue manager is running. Otherwise, the integration node that is in standby node becomes active.

Using an integration node with an existing high availability manager

You can use IBM App Connect Enterprise with an existing high availability manager, for example HACMP, HA/XD, Veritas Cluster Server (VCS), or HP-UX Serviceguard.

About this task

The provision of multi-instance nodes facilitates the configuration of IBM App Connect Enterprise with a high availability (HA) manager.

This topic summarizes how to complete the following tasks:

1. Create an integration node.
2. Add an integration node instance.
3. Start an integration node.
4. Stop an integration node.
5. Monitor an integration node.
6. Delete an integration node.

Procedure

1. To create an integration node, mount the shared resource onto your primary node and use the following **mqsicreatebroker** command with the **-e** parameter to specify your shared resource location.

   ```
   mqsicreatebroker INODE -e /MQHA/MyIntNode/
   ```

   where:

   - INODE is the name of the integration node.
   - /MQHA/INODE/ is the directory for your shared resource.
2. To add another integration node instance, mount the shared resource onto your secondary nodes and use the following **mqsiaddbrokerinstance** command.

   ```
   mqsiaddbrokerinstance INODE -e /MQHA/MyIntNode/
   ```

   where:

   - INODE is the name of the integration node.
   - /MQHA/INODE/ is the directory for your shared resource.
3. To start an integration node, you can use one of the following script files:

   hamqsi_start_broker

   ```
   #!/bin/ksh
   # Module:
   #   hamqsi_start_broker
   #
   # Args:
   #   BROKER = name of integration node to start
   #
   ```

```
# Description:
#   This script attempts to start the MQSI integration node
#
#   Runs as the userid which runs integration node, and must have
#   the user's environment (i.e. invoke from "su - $MQUSER ..")
#

BROKER=$1

if [ -z "$BROKER" ]
then
  echo "hamqsi_start_broker: ERROR! No integration node name supplied"
  echo "   Usage: hamqsi_start_broker <BROKER>"
  exit 1
fi

# Ensure that the integration node is not already running. In this test
# we look for any integration node-related processes, which might have
# been left around after a previous failure. Any that remain
# must now be terminated. This is a severe method of cleaning
# up integration node processes.
# We stop the processes in the following order:
#   bipservice       - first so it cannot issue restarts
#   bipbroker        - next for same reason
#   biphttplistener
#   bipMQTT
#   startDataFlowEngine
#  DataFlowEngine  - last
#

hamqsi_start_broker_as

```
#
#!/bin/ksh
# Module:
#   hamqsi_start_broker_as
#
# Args:
#   integration node = integration node name
#   qm     = name of integration node queue manager
#   mquser = user account under which QM and Integration node are run
#
# Description:
#   Starting an MQSI integration node requires the following services:
#   (1) The MQSeries Queue Manager which supports the integration node
#   (2) The MQSI integration node service
#   This script provides a single source to initiate the required
#   services in sequence.
#
#   Queue Manager:
#   This script uses the strmqm script supplied by MQSeries V7
#
#   Integration node:
#   This script then invokes the hamqsi_start_broker script which
#   checks that the integration node is fully stopped and then starts it.
#
#   The hamqsi_start_broker_as script should be run as root.

# Check running as root
if [ `id -u`  -ne 0 ]
then
  echo "Must be running as root"
  exit 1
fi

BROKER=$1
QM=$2
MQUSER=$3

# Check all parameters exist

if [ -z "$BROKER" ]
then
  echo "hamqsi_start_broker_as: ERROR! No integration node name supplied"
  echo "  Usage: hamqsi_start_broker_as <BROKER> <QM> <MQUSER>"
  exit 1
fi

if [ -z "$QM" ]

5. To monitor an integration node, you can use the following script file that checks only for the existence of the main integration node processes and provides a successful return code if they are found:

   hamqsi_monitor_broker_as

```
#!/bin/ksh
# Module:
#   hamqsi_monitor_broker_as
```

```
#
# Args:
#   BROKER = name of integration node in AppServer
#   QM     = name of queue manager in AppServer
#   MQUSER = userid under which queue manager and integration node run
#
# Description:
#   This is the application monitor script used with HACMP/ES. It
#   needs to be invoked by a parameter-less wrapper script because
#   HACMP does not allow parameters to be passed to application
#   monitor scripts.
#
#   This hamqsi_monitor_broker_as script is run as root, and uses
#   su as needed to monitor the 3 components of the application server.
#
#   This script is tolerant of a queue manager that is still in
#   startup. If the queue manager is still starting this application
#   monitor script will exit with 0 - which indicates
#   to HACMP that there's nothing wrong. This is to allow for
#   startup time for the queue manager which might exceed the
#   Stabilisation Interval set for the Application Monitor in HACMP/ES.
#
#
# Exit codes:
#   0  => Integration node & QM are all running OK or starting
#   >0 => One or more components are not responding.
#

# Check running as root
if [ `id -u`  -ne 0 ]
then
  echo "Must be running as root"
  exit 1
fi

BROKER=$1
QM=$2
MQUSER=$3

# Check the parameters

if [ -z "$BROKER" ]
then
  echo "hamqsi_monitor_broker_as: ERROR! No integration node name supplied"
  exit 1
fi

if [ -z "$QM" ]
then
  echo "hamqsi_monitor_broker_as: ERROR! No queue manager name supplied"
  exit 1
fi

if [ -z "$MQUSER" ]
then
  echo "hamqsi_monitor_broker_as: ERROR! No mquser supplied"
  exit 1
fi

# Use a state variable to reflect the state of components as they
# are tested. Valid values are "stopped", "starting" and "started"
# Initialise it to "stopped" for safety.
STATE="stopped"

# ------------------------------------------------------------------
# Check that the queue manager is running or starting.
#
su - $MQUSER -c "echo 'ping qmgr' | runmqsc ${QM}" > /dev/null 2>&1
pingresult=$?
# pingresult will be 0 on success; non-zero on error (man runmqsc)

    continue
    ;;
esac

# ------------------------------------------------------------------
# Check the MQSI integration node is running
#
# Re-initialise STATE for safety
STATE="stopped"
#
# The integration node runs as a process called bipservice which is responsible
# for starting and re-starting the admin agent process (bipbroker).
# The bipbroker is responsible for starting any DataFlowEngines. The
# bipbroker starts the DataFlowEngines using the wrapper script
# startDataFlowEngine. If no integration servers have been assigned to
# the integration node there will be no DataFlowEngine processes. There should
# always be a bipservice and bipbroker process pair. This monitor
# script only tests for bipservice, because bipservice should restart
# bipbroker if necessary - the monitor script should not attempt to
# restart bipbroker and it might be premature to report an absence
# of a bipbroker as a failure.
#
cnt=`ps -ef | grep "bipservice $BROKER" | grep -v grep | wc -l`
if [ $cnt -eq 0 ]
then
  echo "hamqsi_monitor_broker_as: MQSI integration node $BROKER is not running"
  STATE="stopped"
else
  echo "hamqsi_monitor_broker_as: MQSI integration node $BROKER is running"
  STATE="started"
fi

# Decide how to exit
case $STATE in
  stopped)
    echo "hamqsi_monitor_broker_as: Integration node ($BROKER) is not running correctly"
    exit 1
    ;;
  started)
    echo "hamqsi_monitor_broker_as: Integration node ($BROKER) is running"
    exit 0
   ;;
esac
```

If you require more information than that supplied by the preceding example, you can code your monitor to do the following actions:

- Subscribe to IBM App Connect Enterprise accounting and statistics, and analyze the results.
- Put a dummy message through the integration node and analyze the results.

6. Before you delete the integration node on the primary node, you must delete any integration nodes on the standby nodes. For more information, see “Deleting an integration node” on page 165.

Using an integration node with an existing Windows Cluster (Windows Server)

You can use IBM App Connect Enterprise with the existing high availability manager for Windows Server (Failover Cluster Manager).

About this task

For more information about the versions of Windows Server that are supported by IBM App Connect Enterprise, see the IBM App Connect Enterprise system requirements web page.

This topic summarizes how to complete the following tasks:

1. Complete the prerequisite setup.
2. Configure a local group.
3. Create an integration node.
4. Add integration node instances to the additional nodes.
5. Add the integration node service to the cluster configuration
6. Start and stop an integration node.
7. Delete an integration node.

Procedure

1. To complete the prerequisite setup, complete the following steps:
   a) Validate your Failover Cluster Manager configuration.
   b) Complete all of the steps documented in 'Supporting the Microsoft Cluster Service' of the IBM MQ documentation to create a cluster configuration that contains the queue manager on which you want the integration node to run.
   c) Note the `haregtyp.exe` command as a prerequisite for creating IBM MQ resources in the cluster.
2. To configure a local group, ensure that the domain user under which you want the integration node to run exists in the local `mqbrkrs` group on all nodes on which you want the integration node to run.
3. To create an integration node, use the following **mqsicreatebroker** command on the node on which your cluster is currently running.

   ```
   mqsicreatebroker INODE -q MQ1 -e E:\ACE\Workspace
   ```

   where:

   - INODE is the name of the integration node.
   - MQ1 is the name of the queue manager.
   - E:\ACE\Workspace is the directory of a shared disk (nonquorum) in your cluster configuration.
4. To add this integration node instance to the other nodes in your cluster, switch your cluster to each node in turn. When a node is active, use the following **mqsiaddbrokerinstance** command.

   ```
   mqsiaddbrokerinstance INODE -e E:\ACE\Workspace
   ```

   where:

   - INODE is the name of the integration node.
   - E:\ACE\Workspace is the directory of a shared disk (nonquorum) in your cluster configuration.

5. To add an integration node generic service resource to the cluster which contains the integration node queue manager, complete the following steps:
   a) Select the IBM App Connect Enterprise component `integration_node` service when asked. All other settings can be left unchanged.
   b) Add a dependency on the IBM MQ resource, to ensure that the queue manager is started before the integration node.
6. To start and stop the integration node resource, use Failover Cluster Manager.
7. To delete an integration node resource from the Failover Cluster Manager, take the following steps:
   a) Delete the integration node generic service from the cluster configuration.
   b) Use the **mqsiremovebrokerinstance** command on all nodes but one, moving the cluster between nodes before running each command.
   c) On the final node, use the **mqsideletebroker** command to completely remove the integration node configuration.

Results

For further information about configuring IBM MQ with a high availability manager for Windows Server, see the IBM MQ product documentation online.

See the following topics:

- Introducing MSCS clusters
- Supporting the Microsoft Cluster Service (MSCS)
- Setting up IBM MQ for MSCS clustering

Using an integration node with an RDQM configuration

You can use IBM App Connect Enterprise with an IBM MQ replicated data queue manager (RDQM), to provide a high availability (HA) solution.

About this task

An RDQM configuration consists of three servers configured in a high availability (HA) group, each with an instance of the queue manager. One instance is the running queue manager, which synchronously replicates its data to the other two instances. If the server running this queue manager fails, another instance of the queue manager starts and has current data to work with. The three instances of the queue manager share a floating IP address, so clients need to be configured with only a single IP address. Only one instance of the queue manager can run at any one time, even if the HA group becomes partitioned due to network problems. The server running the queue manager is known as the primary, and each of the other two servers is known as a secondary.

For more information about RDQM, see the IBM MQ product documentation online.

You can configure an integration node to work with an RDQM high availability solution, by completing the following steps:

Procedure

1. Install IBM App Connect Enterprise on all hosts that are part of the RDQM cluster.
2. On all hosts, add the `mqm` user ID and your login user ID to the **mqbrkrs** group.
3. Restart the queue manager to ensure that it gains the **mqbrkrs** group membership.
4. Create a directory in the queue manager `vols` directory for the integration node, as shown in the following example:

```
# mkdir /var/mqm/vols/ha1/userdata/ace
# chown mqm:mqbrkrs /var/mqm/vols/ha1/userdata/ace
```

```
# chmod 775 /var/mqm/vols/ha1/userdata/ace
```

5. Use the **mqsicreatebroker** command to create an integration node called ACEHA1, set the new data directory, and specify that the integration node is to be started and stopped as an MQ service when the queue manager starts and stops:

```
# mqsicreatebroker -e /var/mqm/vols/ha1/userdata/ace -d defined -q HA1 ACE1HA1
```

6. Configure the integration node by editing its `node.conf.yaml` configuration file:

```
# vi /var/mqm/vols/ha1/userdata/ace/mqsi/components/ACEHA1/node.conf.yaml
```

   If your system has a limited amount of memory, consider reducing the amount of memory required by IBM App Connect Enterprise by setting the **startListener** property in the **NodeHttpListener** section to `false` to turn off the biphttplistener process:

```
NodeHttpListener:
  startListener: false
```

7. Start the integration node by running the **mqsistart** command:

```
# mqsistart ACEHA1
```

8. Verify that the integration node is running by using the **mqsilist** command:

```
 # mqsilist
```

   A response similar to the following message confirms that the integration node is running:

```
BIP1376I: Integration node 'ACEHA1' is an active multi-instance or High Availability
 integration node that is running on queue manager 'HA1'.
The administration URI is 'http://admin.myloc.company.com:4414'
BIP8071I: Successful command completion.
```

   If the integration node does not start, check for FDC files in the `/var/mqm/errors` directory and the contents on the queue manager error log. Also check the contents of the service log file:

```
/var/mqsi/common/log/ACEHA1.mqservice.log
```

9. Create an integration server on integration node ACEHA1:

```
# mqsicreateexecutiongroup -e default ACEHA1
```

10. Create the instances on the other nodes by using the **mqsiaddbrokerinstance** command. This command cannot be run unless the `/var/mqm/vols/ha1` filesystem exists, so you must fail over to each node in turn by using the IBM MQ **rdqmadm** command and then add the broker instance by using the **mqsiaddbrokerinstance** command.

    For each node, complete the following steps:

    a) Run the IBM MQ command **rdqmadm**, specifying the name of the queue manager (for example, HA1):

```
# rdqmadm -p -m HA1
```

    b) Run the IBM App Connect Enterprise command **mqsiaddbrokerinstance**, specifying the integration node name (for example, ACEHA1) and the filesystem to be used:

```
# mqsiaddbrokerinstance ACEHA1 -e /var/mqm/vols/ha1/userdata/ace
```

11. You have now configured an RDQM solution.

HTTP proxy servlet overview

By using the HTTP proxy servlet in a servlet container, you can support high availability, load distribution, access to the integration node from multiple IP addresses and ports, and a larger number of concurrent HTTP sessions.

The HTTP proxy servlet is a Java servlet that you can use in a servlet container, such as WebSphere Application Server Liberty Profile or Apache Tomcat, or in an application server such as IBM WebSphere Application Server. The HTTP proxy servlet receives HTTP requests from web services client applications and replaces the support that is provided by the integration node and embedded (integration server) HTTP listeners.

The HTTP proxy servlet supports SSL (HTTPS) secure protocol when it is deployed in a servlet container that is configured to support SSL.

If you are deploying a web browser-based JavaScript application that uses the JavaScript client API to call an IBM App Connect Enterprise integration service, then you must deploy the proxy servlet on the same web application server as your JavaScript application. For more information about the JavaScript client API, see “Integration service JavaScript client API ” on page 1995.

You cannot use the HTTP proxy servlet if you configure your integration node environment to use multi-instance IBM MQ queue managers, because the HTTP proxy servlet cannot connect to the standby queue manager when it becomes active.

For a detailed description of the HTTP proxy servlet, see “HTTP proxy servlet operation” on page 141.

Before you install and test the HTTP proxy servlet, ensure that you understand the following concepts:

- “Working with HTTP flows” on page 792
- “HTTP listeners” on page 795
- “HTTP proxy servlet operation” on page 141
- “Importance of the context root when you configure the HTTP proxy servlet” on page 147

When you have gained an understanding of the HTTP proxy servlet concepts, read the following topics to help you configure, install, and test the HTTP proxy servlet:

- “Configuring the HTTP proxy servlet” on page 149
- “Deploying the HTTP proxy servlet on a servlet container” on page 159
- “Testing the HTTP proxy servlet” on page 164

HTTP proxy servlet operation

Before you deploy the HTTP proxy servlet, ensure that you understand how the HTTP proxy servlet manages the communication between IBM App Connect Enterprise applications and web services clients in a number of supported configurations.

The HTTP proxy servlet is a Java Web Application Archive (`.war`) file that is part of the runtime environment, and can be found in the following directory:

install_dir`/tools`

where *install_dir* is the name of your App Connect Enterprise runtime installation directory.

The HTTP proxy servlet is a Java servlet that receives HTTP requests. The HTTP proxy servlet matches the received web address with the web address that the HTTP or SOAP input nodes are monitoring, then passes the HTTP request message to the correct HTTP or SOAP input node flow by using IBM MQ.

The HTTP proxy servlet receives response messages from the HTTP or SOAP reply nodes and sends them back to the client applications over HTTP or HTTPS. The integration node has several internal IBM MQ queues (SYSTEM.BROKER.WS.* queues), which are used for the communication between the HTTP proxy servlet and the HTTP or SOAP input and reply nodes.

The HTTP proxy servlet is deployed in a *servlet container*. A servlet container (or web container) is the runtime environment for servlets and Java Server Pages (JSP). Apache Tomcat is an example of a servlet container. WebSphere Application Server is an example of an application server, which includes the

functions of a servlet container. The HTTP proxy servlet can be deployed in a local servlet container that is running on the same machine as IBM App Connect Enterprise or on a remote servlet container that is running on a different machine to IBM App Connect Enterprise. The servlet container must allow the HTTP proxy servlet to configure and call the IBM MQ classes for Java.

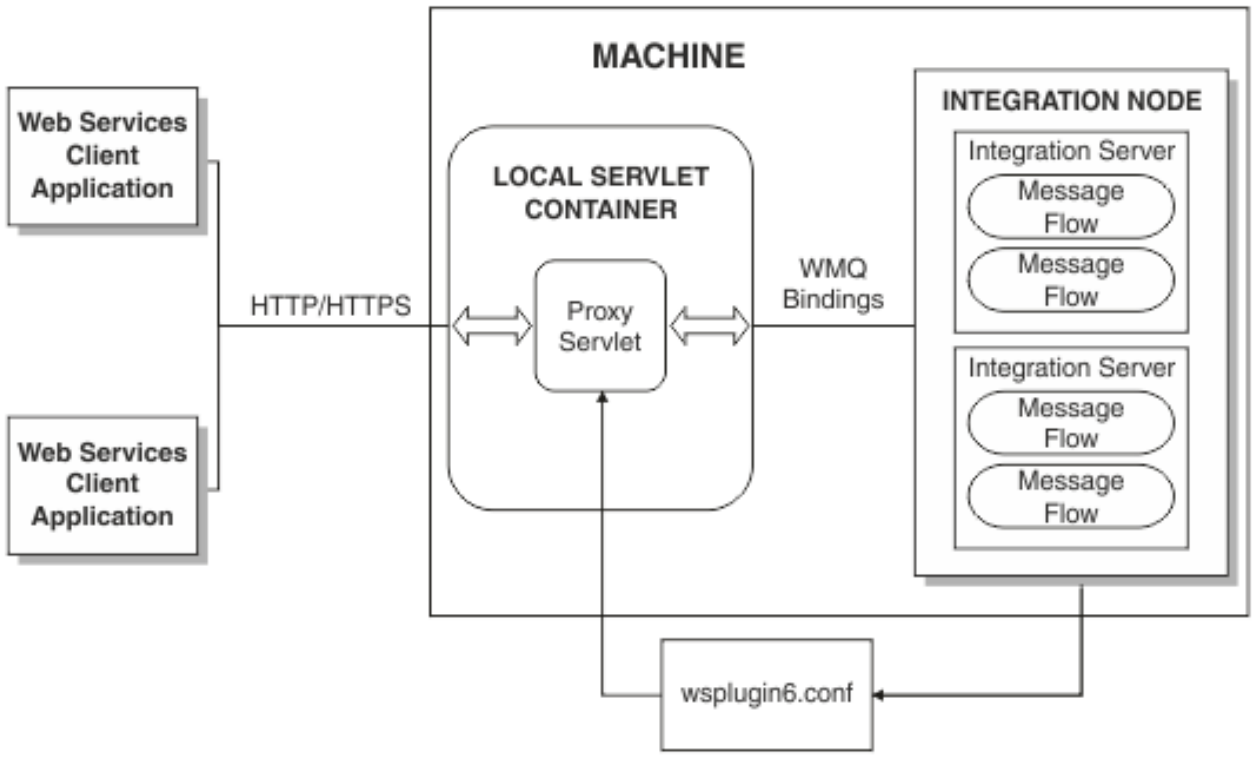
After the HTTP proxy servlet is deployed and running on the servlet container, it uses the HTTP listener of the servlet container to receive HTTP requests. If the servlet container is configured to support SSL (HTTPS), web services requests are received by the message flows by using SSL.

The following topics describe some common scenarios that are based on typical IBM App Connect Enterprise deployments, and the HTTP proxy servlet configuration parameters that are required:

- The HTTP proxy servlet is on the same machine as IBM App Connect Enterprise
- The HTTP proxy servlet is on a different machine to IBM App Connect Enterprise
- The HTTP proxy servlet is on a machine with its own queue manager
- The HTTP proxy servlet is deployed in an environment with a network local-balancer

HTTP proxy servlet is deployed to a servlet container on the same machine as IBM App Connect Enterprise
You can configure the HTTP proxy servlet for a deployment where the HTTP proxy servlet is deployed to a servlet container on the same machine as IBM App Connect Enterprise.

In the following figure, the HTTP proxy servlet is running on the same machine as the integration node. The HTTP proxy servlet connects to the integration node queue manager by using bindings mode (local connection).



In this configuration example, you must configure the following HTTP proxy servlet configuration parameters. For information about configuring the HTTP proxy servlet, see “Configuring the HTTP proxy servlet” on page 149.

- Set **useClientMode** to `false`.
- Set **useQueueManagerDataInsteadOfConfigFile** to "".
- Set **configFile** to the location of the configuration file, for example, `C:\ProgramData\IBM\MQSI\components\`*`my_node`*`\config\wsplugin6.conf`.

where *my_node* is the name of your integration node.

Before you configure, deploy, and test the HTTP proxy servlet, ensure that you understand the following concepts:

- “Working with HTTP flows” on page 792
- “HTTP listeners” on page 795
- “HTTP proxy servlet operation” on page 141
- “Importance of the context root when you configure the HTTP proxy servlet” on page 147

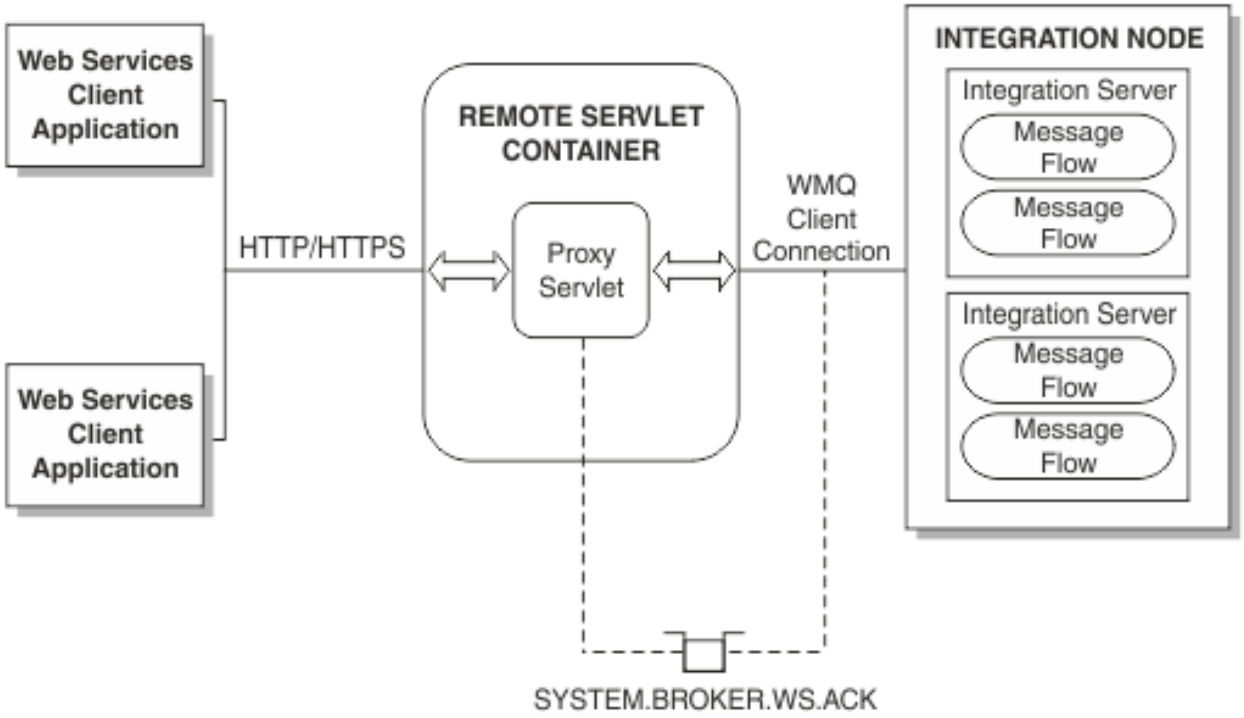
When you have gained an understanding of the HTTP proxy servlet concepts, read the following topics to help you configure, deploy, and test the HTTP proxy servlet:

- “Configuring the HTTP proxy servlet” on page 149
- “Deploying the HTTP proxy servlet on a servlet container” on page 159
- “Testing the HTTP proxy servlet” on page 164

HTTP proxy servlet is deployed to a servlet container that is on a different machine to IBM App Connect Enterprise

You can configure the HTTP proxy servlet for a deployment where the HTTP proxy servlet is deployed to a servlet container on a different machine to IBM App Connect Enterprise, with an IBM MQ client link to the integration node queue manager.

In the following figure, the HTTP proxy servlet is running on a remote machine to the integration node. The HTTP proxy servlet connects to the integration node queue manager by using an IBM MQ client connection, the HTTP proxy servlet can be configured to access HTTP or SOAP nodes, and the HTTP or SOAP node configuration is retrieved from the SYSTEM.BROKER.WS.ACK queue.



In this configuration example, you must configure the following HTTP proxy servlet configuration parameters. For information about configuring the HTTP proxy servlet, see “Configuring the HTTP proxy servlet” on page 149.

- Set **useClientMode** to `true`.

- Set **useQueueManagerDataInsteadOfConfigFile** to * or the integration node queue manager name.
- Set **clientModeHostname**, **clientModeChannelName**, and **clientModePortNumber** to the correct values as detailed in "HTTP proxy servlet configuration parameters" on page 151.

The HTTP proxy servlet attempts to connect to the remote queue manager for the integration node by reading the required configuration data from the IBM MQ client connection. For the client connection to succeed, you must start the SYSTEM.DEFAULT.LISTENER.TCP listener in the queue manager. For more information, search for *START LISTENER* in the IBM MQ product documentation.

Before you configure, deploy, and test the HTTP proxy servlet, ensure that you understand the following concepts:

- "Working with HTTP flows" on page 792
- "HTTP listeners" on page 795
- "HTTP proxy servlet operation" on page 141
- "Importance of the context root when you configure the HTTP proxy servlet" on page 147

When you have gained an understanding of the HTTP proxy servlet concepts, read the following topics to help you configure, deploy, and test the HTTP proxy servlet:

- "Configuring the HTTP proxy servlet" on page 149
- "Deploying the HTTP proxy servlet on a servlet container" on page 159
- "Testing the HTTP proxy servlet" on page 164

HTTP proxy servlet is deployed to a servlet container on a machine with its own queue manager
You can configure the HTTP proxy servlet for a deployment where the HTTP proxy servlet is deployed to a servlet container that is on a machine with its own queue manager and an IBM MQ channel link to the integration node queue manager.

In this configuration example, you must configure the following HTTP proxy servlet configuration parameters. For information about configuring the HTTP proxy servlet, see "Configuring the HTTP proxy servlet" on page 149.

- Set **useClusterMode** to `true`.
- Set **clusterModeQueueManagerName** to the queue manager of the Web servlet container.
- Set **clusterModeReplyToQ** to a queue that exists on that queue manager.

The HTTP proxy servlet attempts to open the queue SYSTEM.BROKER.WS.INPUT on the specified queue manager by using the queue manager name from the configuration file. Therefore, you must set up channels and transmit queues beforehand to ensure that the messages arrive on the queue manager of the integration node.

You must copy the configuration files from the integration node machine in this scenario.

Before you configure, deploy, and test the HTTP proxy servlet, ensure that you understand the following concepts:

- "Working with HTTP flows" on page 792
- "HTTP listeners" on page 795
- "HTTP proxy servlet operation" on page 141
- "Importance of the context root when you configure the HTTP proxy servlet" on page 147

When you have gained an understanding of the HTTP proxy servlet concepts, read the following topics to help you configure, deploy, and test the HTTP proxy servlet:

- "Configuring the HTTP proxy servlet" on page 149
- "Deploying the HTTP proxy servlet on a servlet container" on page 159
- "Testing the HTTP proxy servlet" on page 164

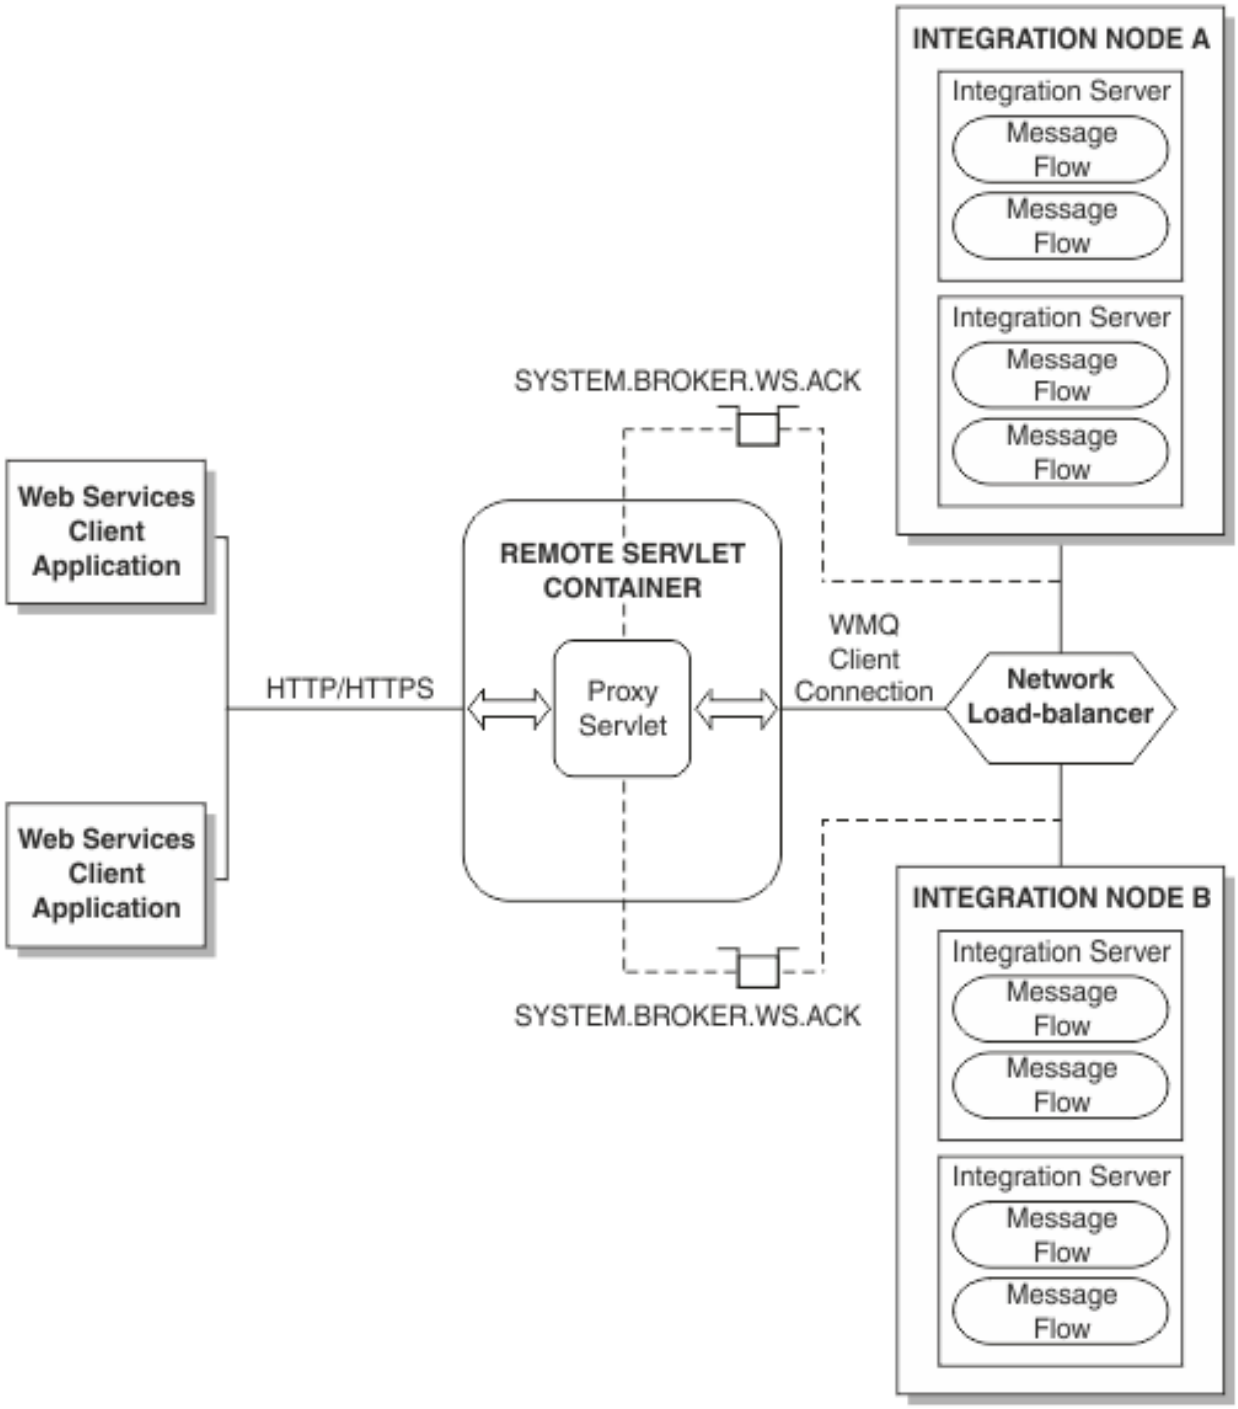
HTTP proxy servlet is deployed to a servlet container that is on a different machine to IBM App Connect Enterprise with a network load-balancer for distributing work to several integration nodes

You can configure the HTTP proxy servlet for a deployment where the HTTP proxy servlet is deployed to a servlet container that is on a different machine to IBM App Connect Enterprise, and the servlet container has an IBM MQ client link to the integration node queue manager. In this configuration, a network load-balancer is used to distribute work to several integration nodes.

In the following figure the HTTP proxy servlet is configured to load balance IBM MQ connections across multiple integration nodes. A network load balancer is required for this configuration.

When the HTTP proxy servlet is configured to connect to multiple integration nodes, the integration nodes must be identical clones of each other, which means that the same HTTP and SOAP flows are deployed with the same web addresses.

The HTTP proxy servlet sends the HTTP requests over the IBM MQ connections to distribute the load between the active integration node connections.



The configuration is the same as that described in "HTTP proxy servlet is deployed to a servlet container that is on a different machine to IBM App Connect Enterprise" on page 143, but the network load-balancer replaces the integration node machine. Configuration files cannot be used because there are several integration nodes behind one virtual IP address, and each one has a different configuration file. The HTTP proxy servlet loads information for each connection, and uses the relevant configuration information for each integration node.

In this configuration example, you must configure the following HTTP proxy servlet configuration parameters. For information about configuring the HTTP proxy servlet, see "Configuring the HTTP proxy servlet" on page 149.

- Set **useClientMode** to `true`.

- Set **useQueueManagerDataInsteadOfConfigFile** to * or the integration node queue manager name.
- Set **clientModeHostname**, **clientModeChannelName**, and **clientModePortNumber** to the correct values as detailed in "HTTP proxy servlet configuration parameters" on page 151.

If failover is one of the reasons for deploying this configuration, it is recommended that you configure the following additional HTTP proxy servlet configuration parameters:

- Set **clientModeConnectRetryCount** to a value equal or higher than the number of integration nodes. This setting ensures that a single failed server does not cause intermittent errors, even if the load-balancer does simple round-robin scheduling. The HTTP proxy servlet uses the first available integration node.
- Set **reconnectActiveLinksAge** to a value less than the firewall timeout. This setting prevents the reuse of old connections that might have been discarded by firewalls between the HTTP proxy servlet and the load-balancer (or between the load-balancer and the integration nodes).

You can set **testConnectionBeforeReuse** to `true` as an alternative way to manage dropped IBM MQ connections between the HTTP proxy servlet and integration node queue managers. However, this option causes an MQINQ call to be performed before any attempt to send data to the integration node. If the MQINQ call fails, a new connection is established, and the data is sent over the new connection. Because the configuration adds another operation to the MQPUT and MQGET calls, it results in significant processing for every message; use this option only if no alternative options are available. For information about MQINQ, MQPUT, and MQGET calls, search for *Function calls* in the IBM MQ product documentation.

Before you configure, deploy, and test the HTTP proxy servlet, ensure that you understand the following concepts:

- "Working with HTTP flows" on page 792
- "HTTP listeners" on page 795
- "HTTP proxy servlet operation" on page 141
- "Importance of the context root when you configure the HTTP proxy servlet" on page 147

When you have gained an understanding of the HTTP proxy servlet concepts, read the following topics to help you configure, deploy, and test the HTTP proxy servlet:

- "Configuring the HTTP proxy servlet" on page 149
- "Deploying the HTTP proxy servlet on a servlet container" on page 159
- "Testing the HTTP proxy servlet" on page 164

Importance of the context root when you configure the HTTP proxy servlet

You must assign a context root to the HTTP proxy servlet when you deploy the HTTP proxy servlet to a servlet container. The choice of context root determines the message flow nodes or integration service URLs with which the HTTP proxy servlet can communicate.

Web addresses, or Universal Resource Locators (URLs), have an important role when HTTP or SSL (HTTPS) protocols are used.

The HTTP proxy servlet passes the requests from the servlet container to the integration node and vice versa.

Each HTTP or SOAP input node expects to receive requests from a specific web address (or web addresses when wildcard characters are used). The servlet container also uses the web address to locate the servlets that are going to process the HTTP or HTTPS requests that the servlet container receives on behalf of the integration node.

The web address is structured in the following way:

```
schema://host_name:port/url_path
```

where:

schema
Specifies the protocol (HTTP or HTTPS).

host_name
Specifies the host name or IP address of the server where the servlet container is running.

port
Specifies the port number on which the servlet container is listening.

url_path
Specifies the URL path; a series of tokens (separated by slashes /) that identify both the HTTP proxy servlet, and the HTTP or SOAP input nodes.

When you use the HTTP proxy servlet, the URL path is partitioned as follows:

```
context_root/node_url_path
```

where:

context_root
Specifies the part of the URL path (context root) that is allocated to the proxy servlet by the servlet container when the proxy servlet is deployed.

node_url_path
Specifies the part of the URL path that makes the web address unique to a specific HTTP or SOAP input node.

Note: You can set *context_root* to / in which case *url_path* and *node_url_path* are the same.

The entire URL path must be configured in the properties of the HTTPInput or SOAPInput node. For more information, see node and node.

For example, you might have HTTPInput nodes that are configured to receive requests for the following web addresses:

- Node1: `http://myhost.com/app1`
- Node2: `http://myhost.com/public/app2`
- Node3: `http://myhost.com/public/app3`
- Node4: `http://myhost.com/private/app4`

If you set the context root for your HTTP proxy servlet to `/public`, then you can communicate with Node2 and Node3 via the HTTP proxy servlet.

If you set the context root for your HTTP proxy servlet to `/private`, then you can communicate with Node4 via the HTTP proxy servlet.

If you set the context root for your HTTP proxy servlet to `/`, then you can communicate with all of the HTTPInput nodes via the HTTP proxy servlet.

Choosing a context root for the HTTP proxy servlet

- If you have many existing applications that you want to access with the HTTP proxy servlet, and the input nodes or integration services do not use URLs with a common root, you might want to set the context root for the HTTP proxy servlet to `/`. Then you do not need to modify the URLs used by your input nodes or integration services. However, if you set the context root for the HTTP proxy servlet to `/`, then the HTTP proxy servlet becomes the default application for the servlet container, and the HTTP proxy servlet attempts to process all requests that do not match the context root of any other applications that are hosted by the servlet container.
- If you want to access a subset of your existing applications with the HTTP proxy servlet, you might configure the URLs for the input nodes or integration services to start with a consistent value, for example `/public`. Then you must set the context root of the HTTP proxy servlet to the same value.
- If you are building applications from scratch, then consider the requirements of the HTTP proxy servlet when you plan the structure of the URLs you configure for your input nodes or integration services.

Before you install and test the HTTP proxy servlet, ensure that you understand the following concepts:

- “Working with HTTP flows” on page 792
- “HTTP listeners” on page 795
- “HTTP proxy servlet operation” on page 141

When you have gained an understanding of the HTTP proxy servlet concepts, read the following topics to help you configure, install, and test the HTTP proxy servlet:

- “Configuring the HTTP proxy servlet” on page 149
- “Deploying the HTTP proxy servlet on a servlet container” on page 159
- “Testing the HTTP proxy servlet” on page 164

Configuring the HTTP proxy servlet

Configure the HTTP proxy servlet with the details of the integration node environment to which the HTTP proxy servlet connects. The HTTP proxy servlet must be configured before you deploy the HTTP proxy servlet to a servlet container.

Before you begin

In order that the HTTP proxy servlet can access the SOAPInput and SOAPReply nodes, you must enable the integration node listener for each integration server where message flows with SOAP nodes are deployed. See “HTTP listeners” on page 795 and “Switching from embedded listeners to an integration node listener” on page 798.

About this task

The HTTP proxy servlet `proxyservlet.war` file is part of the runtime environment, and can be found in the following directory:

install_dir`/server/tools`

where *install_dir* specifies the name of your runtime installation directory.

Complete the following steps to configure the web deployment descriptor (`web.xml`) for the HTTP proxy servlet by using the IBM App Connect Enterprise Toolkit.

Procedure

1. To import and configure a `.war` file, you must have the Eclipse Java EE developer Tools feature installed in the IBM App Connect Enterprise Toolkit. This feature is not included in the IBM App Connect Enterprise Toolkit by default but can be installed by completing the following instructions:
   a) From the IBM App Connect Enterprise Toolkit menu, click **Help** > **Install New Software**.
   b) Enter the following URL in the "Work with" field:
      `http://download.eclipse.org/releases/juno`
   c) Click **Add** and enter a name for the site.
      For example, `Eclipse Juno downloads`.
   d) Click **OK** and wait until the available features are listed.
   e) Expand the **Web, XML, Java EE and OSGi Enterprise Development** category, select the **Eclipse Java EE Developer Tools** feature and click **Next**.
      The **Install Details** dialog is displayed.
   f) Click **Next**, accept the license, and then click **Finish**.
      The feature is installed.
   g) Click **Yes** when you are prompted to restart the IBM App Connect Enterprise Toolkit.

   The **Eclipse Java EE Developer Tools** feature is now available in the IBM App Connect Enterprise Toolkit.
2. From the IBM App Connect Enterprise Toolkit menu, switch to the Java EE perspective by clicking **Window** > **Open Perspective** > **Other** and clicking **Java EE**.
3. Click **File** > **Import**, expand the **Web** section, select **WAR file** in the list, and click **Next**.
4. Click **Browse** to find the `proxyservlet.war` file in *`install_dir`*`\server\tools`, where *install_dir* specifies the name of your IBM App Connect Enterprise installation directory (for example, `C:\Program Files\IBM\ACE\12.0.`*`n`*`.0\server\tools\proxyservlet.war`), and click **Open**.
5. Set the name of the Web project to `proxyservlet` and click **Finish**.
   The HTTP proxy servlet is now ready for configuring by using the Java EE perspective.
6. In the **Project Explorer** view, expand **proxyservlet** and double-click **Deployment Descriptor** to view the web deployment descriptor.
7. Find the **Servlets and JSPs** section in the Web Deployment Descriptor, and click the servlet link called **WBIMBServlet** to display the servlet web address mappings and initialization parameters.
   The same parameters in the `web.xml` file can be configured through JNDI in WebSphere Application Server. This alternative method means that you set up at the application server side only once for any future deployment of the proxy servlet. This operation is possible because the JNDI configuration parameters take precedence over the initialization parameters in the `web.xml` file. For more information about setting up the JNDI interface for the proxy servlet, see "Setting up the JNDI interface for the proxy servlet" on page 156.
8. Click the **Source** tab, which is found at the bottom of the **Deployment Descriptor** view.
   The source of the web deployment descriptor (`web.xml`) displays the HTTP proxy servlet parameters.
9. Edit the HTTP proxy servlet parameters as required; see "HTTP proxy servlet configuration parameters" on page 151.
10. When the configuration is complete, save the changes to the `web.xml` file by pressing **Ctrl+S**.

11. Export the configured HTTP proxy servlet ready for deployment to a servlet container by completing the following steps:
    a) In the **Project Explorer** view, right-click the **Deployment Descriptor** for the proxyservlet Web project, and click **Export** > **WAR file**.

       The **WAR Export** dialog window is displayed.
    b) Click **Browse** and specify a location and a name for the configured WAR file. For example, `myproxyserlet.war`.
    c) Click **Save** and then click **Finish**.

Results

You have now configured the HTTP proxy servlet with the initialization parameters.

What to do next

Deploy and configure the HTTP proxy servlet on the web application server that will host the JavaScript application, see “Deploying the HTTP proxy servlet on a servlet container” on page 159.

HTTP proxy servlet configuration parameters
Before you can deploy the HTTP proxy servlet to the servlet container, you must configure it with the following initialization parameters for the integration node environment to which the HTTP proxy servlet connects.

The parameters that you can configure for the HTTP proxy servlet are detailed in the following sections. For information about how to configure the HTTP proxy servlet, see “Configuring the HTTP proxy servlet” on page 149.

- “General options” on page 152
- “Information options” on page 153
- “ReplyToQ and QMgr options” on page 153
- “SSL connection options” on page 153
- “MQ connection options” on page 154

The following topics describe some common scenarios and the HTTP proxy servlet configuration parameters that are required.

- “HTTP proxy servlet is deployed to a servlet container on the same machine as IBM App Connect Enterprise” on page 142
- “HTTP proxy servlet is deployed to a servlet container that is on a different machine to IBM App Connect Enterprise” on page 143
- “HTTP proxy servlet is deployed to a servlet container on a machine with its own queue manager” on page 144
- “HTTP proxy servlet is deployed to a servlet container that is on a different machine to IBM App Connect Enterprise with a network load-balancer for distributing work to several integration nodes” on page 145

General options

Parameter name	Default value	Description
brokerName	*	Set to * or the name of your integration node. Use this parameter to specify the name that is used for error messages; the value is auto-detected if set to "*". Specify a value if several integration nodes are being used by the HTTP proxy servlet, and a single name is required for error messages.
configFilePath	`/var/mqsi/components/INODE/config/wsplugin6.conf`	Specify the full path of the configuration file. If the integration node that is used by the HTTP proxy servlet is local, set this parameter to the `wsplugin6.conf` file. This value is used only when the parameter **useQueueManagerDataInsteadOfConfigFile** is set to blank. The configuration file is used only when the HTTP proxy servlet is running on the same server as the integration node, and it has access to the file. In Windows, the file is stored in `C:\`*`install_dir`*`\config\wsplugin.conf` or `C:\Documents and Settings\All Users\IBM\MQSI\components\`*`NodeName`*`\config\wsplugin6.conf` where *NodeName* is the name of your integration node. On Linux and UNIX, the file is stored in `/var/mqsi/config/wsplugin.conf` or in `/var/mqsi/components/`*`NodeName`*`/config/wsplugin6.conf` where *NodeName* is the name of your integration node.
useFastpathBindingsConnection	false	Specify `true` or `false`. Set the value to `true` to make the HTTP proxy servlet connect in fastpath mode if the HTTP proxy servlet is using a local queue manager.
traceFileName		Specify the full path of the trace file. If this parameter is not specified the trace is sent to stdout.
turnTraceOn	0	Set to `0`, `1`, or `2`. Set `0` for no trace, `1` for normal trace, or `2` for debug trace.

Information options

Parameter name	Default value	Description
enableStatusPage	false	Set to `true` or `false`. Set the value to `true`, to make the page accessible at `http://`*`HostName`*`:`*`Port`*`/`*`ContextRoot`*`/messagebroker/httpproxy/statuspage` where *HostName* is the name of your servlet container, *Port* is the port for your servlet container, and *ContextRoot* is the context root you have set for your HTTP proxy servlet. For more information about the context root, see "Importance of the context root when you configure the HTTP proxy servlet" on page 147.
enableInfoHeaders	false	Set to `true` or `false`. Set the value to `true` to make the HTTP proxy servlet add extra headers in the response message. These headers are: • X-WMB-Broker-Name • X-WMB-QM-Name • X-WMB-MQ-URL-CorrelId The headers also contain details of the configuration that is used for the response message.

ReplyToQ and QMgr options

Parameter name	Default value	Description
useClusterMode	false	Set to `true` or `false`. Set to `true` if the HTTP proxy servlet is required to put reply-to queue and queue manager information in the MQMD of sent messages to enable the integration node to respond to the correct queue manager in a cluster.
clusterModeQueueManagerName	SOME_OTHER_QUEUE_MANAGER	Set to the queue manager name for initial MQCONN and ReplyToQMgr.
clusterModeReplyToQ	YOUR.REPLYTO.QUEUE	Set to the reply queue name on which to listen.

SSL connection options

Parameter name	Default value	Description
useSecuredChannel	false	Set to `true` or `false`. Set to `true` if SSL is configured on the MQ channel. If set to `true`, the proxy servlet attempts to establish a secured connection to the MQ channel by using the `keyStore`, `keyStorePassword`, `trustStore`, `trustStorePassword`, and `cipherSuite` parameter values.

Parameter name	Default value	Description
keyStore		Set to the full path of the keystore file. The fully qualified path to the keystore file, which is of type "JKS". For example, in Windows: `C:\\Program Files\ \IBM\\MQSI\\keystore.jks` On Linux and UNIX: `/var/mqsi/keystore.jks`
keyStorePassword	changeit	Set to the password of the keystore file.
trustStore		Set to the full path of the truststore file. The fully qualified path to the truststore file, which is of type "JKS". For example, on Windows: `C:\\Program Files\ \IBM\\MQSI\\truststore.jks` On Linux and UNIX: `/var/mqsi/truststore.jks` This field is mandatory if `useSecuredChannel` is set to `true`.
trustStorePassword	changeit	Set to the password of the truststore file.
cipherSuite		Set to the encryption type that is configured in the MQ channel. For example: `SSL_RSA_WITH_NULL_MD5` This field is mandatory if `useSecuredChannel` is set to `true`.

MQ connection options

Parameter name	Default value	Description
useClientMode	false	Set to `true` or `false`. Set the value to `true` to use the IBM MQ client or set the value to `false` to use the bindings connection. Normally, **useQueueManagerDataInsteadOfConfigFile** would also be set to the integration node queue manager if this parameter is set to `true`.
clientModeHostname	localhost	Set to the host name or the IP address for the queue manager.
clientModeChannelName	SYSTEM.DEF.SVRCONN	Set to the IBM MQ SVRCONN channel name
clientModePortNumber	1414	Set to the port number of the IBM MQ listener.

Parameter name	Default value	Description
clientModeConnectRetryCount	1	Specify the number of times to retry the IBM MQ connect call. Use this parameter in cases where a network dispatcher or load balancer is used to distribute work to a set of queue managers and one of the queue managers fails. A new connect call might fail the first time, but succeed the second time. The retry count must be set to a high number to provide the greatest chance of success.
useQueueManagerDataInsteadOfConfigFile		Set to the queue manager name, * (remote proxy), or leave blank (local proxy). Set this value to the queue manager name to make the HTTP proxy servlet retrieve web address data from a queue, and avoid the need for a configuration file to be accessible by the HTTP proxy servlet.
sleepBeforeGet	0	Set to the time (in seconds) to wait before the HTTP proxy servlet issues an MQGET call for a response message from the integration node.
disconnectBeforeSleep	true	Set to `true` or `false`. Set the value to `true` to release the IBM MQ handle while sleeping and minimize the number of simultaneous IBM MQ connections.
reconnectActiveLinksAge	-1	Set to a time (in seconds), `0`, or `-1` Set the value to a number greater than zero to force IBM MQ connections to be disconnected and reconnected if they have been inactive, because of low traffic volumes, for more than the specified number of seconds. Set the value to `-1` to prevent any reconnection. Set the value to `0` to force all connections to be used only one time. This parameter is useful if the connection to IBM MQ goes through a firewall that closes connections after a period of inactivity. Set the value to a value less than the firewall timeout to prevent clients from receiving IBM MQ 2009 (connection broken) error code responses.

Parameter name	Default value	Description
testConnectionBeforeReuse	false	Set to `true` or `false`. Set the value to `true`, to make the HTTP proxy servlet attempt an MQINQ before it does the MQPUT of the HTTP data message. All problems with a cached IBM MQ client connection are detected at that point, and a new connection is established for the MQPUT of the actual data (and MQGET of the response). This parameter causes significant extra network traffic, and must be used only if there are problems with dropped connections, which are usually seen as IBM MQ 2009 errors, indicating that the connection is broken.
maximumConnectionAge	-1	Set to a time (in seconds), `0`, or `-1` Set the value to a number greater than zero to disconnect and reconnect IBM MQ connections if they are older than the specified number of seconds. Set the value to `-1` to prevents any reconnections. Set the value to `0` to use all connections only one time. This parameter is of most use if the frequent changes to the IBM MQ connection parameters are expected due to redeployment of the IBM App Connect Enterprise flows, and you require the HTTP proxy servlet to reflect these changes within the specified number of seconds.

Setting up the JNDI interface for the proxy servlet
The JNDI interface for the proxy servlet requires a one time setup of the WebSphere Application Server full profile.

About this task

The proxy servlet initialization parameters must be configured for the integration node environment that the proxy servlet is connecting to each time the proxy servlet is deployed to the servlet container. It is now possible to configure the `web.xml` parameters only once through the JNDI in WebSphere Application Server, regardless of how many future deployments there might be of the proxy servlet. Because the JNDI configuration parameters take precedence over the initialization parameters in the `web.xml` file, using this method means that you need to set up at the application server side only once for any future deployments of the proxy servlet.

These setup tasks must all be completed in the WebSphere Application Server administrative console.

Creating a resource environment provider

About this task

Configure a resource environment provider, which encapsulates the referenceables that convert resource environment entry data into resource objects. These resource objects can then be accessed by applications.

Procedure

1. Select **Resources** > **Resource Environment** > **Resource Environment Providers**.

   The **Resource environment providers** wizard opens.
2. Click **New**.

   The **Configuration** panel opens so that you can configure a new resource environment provider.
3. Type a name for the resource environment provider in the **Name** filed. For example, `MyResourceEnvironmentProvider`. It is recommended that you enter a meaningful description in the **Description** field, but it is not required. Click **OK** to continue and then save the changes.

Results

The new resource environment provider is listed in the wizard.

Creating a referenceable object

About this task

Configure a new referenceable, which specifies the factory class that converts data in the Java Naming and Directory Interface (JNDI) name space into an object that represents your resource to WebSphere Application Server.

Procedure

1. Select **Resources** > **Resource Environment** > **Resource Environment Providers**.

   The **Resource environment providers** wizard opens.
2. From the **Resource environment providers** panel, select the provider that you created in the previous task: In this example, it is called *MyResourceEnvironmentProvider*.
3. Click **Referenceables**.

   The **Referenceables** panel opens.
4. Click **New**.

   The **Configuration** panel opens.
5. In the **Configuration** panel, type the following values:

   a) In the **Factory class name** field, type: `com.ibm.broker.httpproxy.MQResourceConnectionFactory`

   b) In the **Class name** field, type: `com.ibm.broker.httpproxy.MQResourceConnection`
6. Click **OK** and save the changes.

Creating resource environment entries

About this task

Configure resource environment entries, which are objects that contain information about a resource, and represent it in the JNDI name space.

Procedure

1. Select **Resources** > **Resource Environment** > **Resource Environment Providers** > ***MyResourceEnvironmentProvider***.

   The **Resource environment providers** wizard opens at the configuration panel for your provider.
2. Click **Resource environment entries**.

   The **Resource environment entries** panel opens.
3. Click **New**.

   The **Configuration** panel opens.

4. In the **Configuration** panel, type your values. In this example, the values are:
   a) In the **Name** field, type for example: `MQResourceReference`
   b) In the **JNDI name** field, type for example: `proxyservlet/reference/MQResourceReference`.
      This JNDI name is used during application deployment resource mapping.
   c) In the **Referenceables** drop-down list, ensure that `com.ibm.broker.httpproxy.MQResourceConnectionFactory` is selected.
5. Click **OK** and save the changes.

Creating custom properties or define the parameters to be configured

About this task

Specify custom properties that your enterprise information system (IES) requires for the resource providers and resource factories that you configure. For example, most database vendors require extra custom properties for data sources that access the database.

Procedure

1. Select **Resources** > **Resource Environment** > **Resource Environment Providers** > ***MyResourceEnvironmentProvider*** > **ResourceEnvironment Entries** > ***MQResourceReference***. where *MyResourceEnvironmentProvider* and *MQResourceReference* are your own specified values.
   The **Resource environment providers** wizard opens at the configuration panel for your entry.
2. Click **Custom properties**.
   The **Configuration** panel opens.
3. Click **New**.
4. In the **Configuration** panel, you must type your values for all the resources that are administered through the administrative console. For example: The integration node name, the configuration file path, the client mode channel name, and the client mode port number. For each resource, you must provide values for **Name**, **Value**, **Description**, and **Type**. The following example is for the integration node name:

Option	Description
Name	This field refers to the value in the "`<param-name> </param-name>`" tag in the `web.xml`. For example: `brokerName`
Value	This field refers to the value in the "`<param-value> </param-value>`" tag in the `web.xml`. For example: RRB
Description	Optional. It is recommended that you provide a meaningful description.
Type	Specify the type. For example: `java.lang.String`

5. Click **OK** to save the configuration.
6. Click **New** to create a new configuration for the remaining resources.

Results

You have a list of configured resources that is similar to the following table, but with the values that you specified:

Name	Value	Description	Required
brokerName	RRB	Integration node name	false

Name	Value	Description	Required
configFilePath	C:\\Documents and Settings\\All Users.WINDOWS\ \Application Data\\IBM\\MQSI\\components\\RRB\ \config\soapplugin6.conf	Configuration file path	false
clientModeChannelName	SYSTEM.DEF.SVR.CONN	Client mode channel name	false
clientModePortNumber	2908	Client mode port number	false

The WebSphere Application Server wizard does not provide an option to specify the **Required** attribute and so the default value is set to false. This attribute can be ignored.

What to do next

After you complete these tasks, you must deploy the `proxyservlet.war` file. During the deployment, you must provide the JNDI reference name for the **`Resource Environment`** reference that is defined in the `web.xml` file. For example: `proxyservlet/reference/MQResourceReference`.

After the deployment, proxyservlet gives precedence to the values configures in the Resource Environment Entries. If there is an environment change, the values must be modified in the custom properties of the Resource Environment Entries. After you modify a value, restart the `Proxyservlet` application in WebSphere Application Server for the new values to take effect.

Deploying the HTTP proxy servlet on a servlet container

Load and install the HTTP proxy servlet file on a servlet container, such as Apache Tomcat, WebSphere Application Server Liberty Profile, or an application server such as WebSphere Application Server.

Before you begin

Before you deploy the HTTP proxy servlet, you must complete the following tasks:

- Enable the integration node listener for each integration server where message flows with SOAP nodes are deployed. See "HTTP listeners" on page 795 and "Switching from embedded listeners to an integration node listener" on page 798.
- "Configuring the HTTP proxy servlet" on page 149

About this task

Supported operating systems

This documentation describes the installation on Windows, but the HTTP proxy servlet can be installed on any operating system that is supported by the servlet container.

Prerequisite components

In addition to IBM App Connect Enterprise, the HTTP proxy servlet requires the following components:

- A supported version of IBM MQ. For the latest details of all supported levels of hardware and software, see the IBM App Connect Enterprise system requirements website.
- A servlet container, such as WebSphere Application Server Liberty Profile or Apache Tomcat, or an application server, such as WebSphere Application Server.

The following topics describe how to deploy the HTTP proxy servlet onto WebSphere Application Server Liberty Profile, Apache Tomcat, and WebSphere Application Server; however, the process is similar for other servlet containers or web servers:

- "Deploying the HTTP proxy servlet on WebSphere Application Server Liberty Profile" on page 160
- "Deploying the HTTP proxy servlet on Apache Tomcat" on page 161
- "Deploying the HTTP proxy servlet on WebSphere Application Server" on page 163

Results

You have deployed the HTTP proxy servlet on a servlet container or web server

What to do next

Test the HTTP proxy servlet. For information about how to complete this task, see "Testing the HTTP proxy servlet" on page 164.

Deploying the HTTP proxy servlet on WebSphere Application Server Liberty Profile
Load and install the HTTP proxy servlet file on WebSphere Application Server Liberty Profile.

Before you begin

Before you deploy the HTTP proxy servlet, you must complete the following tasks:

- "Configuring the HTTP proxy servlet" on page 149
- Enabling the integration node listener for SOAP nodes

About this task

Install and customize a WebSphere Application Server Liberty Profile (Liberty) server, and then deploy the HTTP proxy servlet by completing the following steps. The instructions assume that IBM App Connect Enterprise is installed and running on the same machine as the Liberty server.

Procedure

To deploy the HTTP proxy servlet on the Liberty server, complete the following steps:

1. Follow the instructions on the WebSphere Application Server Liberty Profile download page to download and install a Liberty server.
2. Create the following sub directory in your Liberty server installation: *Liberty_installation_path*\wlp\usr\shared\resources\wmq.
3. Copy the following IBM MQ JAR files from *WebSphere_MQ_installation_path*\Java\lib to *Liberty_installation_path*\wlp\usr\shared\resources\wmq:
   - com.ibm.mq.commonservices.jar
   - com.ibm.mq.headers.jar
   - com.ibm.mq.jar
   - com.ibm.mq.jmqi.jar
   - com.ibm.mq.pcf.jar
   - connector.jar

   The HTTP proxy servlet uses IBM MQ to communicate with IBM App Connect Enterprise.
4. Copy the HTTP proxy servlet .war file that you exported from IBM App Connect Enterprise (for example, myproxyservlet.war) to *Liberty_installation_path*\wlp\usr\shared\apps.
5. In the Eclipse workspace for the Liberty server, click the **Servers** tab and open the server.xml file by double-clicking the **Server Configuration** entry.
6. Add the following lines to server.xml to define the shared library that contains the IBM MQ .jar files:

```
<library id="wmq" name="wmq">
     <fileset dir="${shared.resource.dir}/wmq" includes="*.jar"/>
</library>
```

7. Add the following lines to `server.xml` to set the context root for the HTTP proxy servlet and link the HTTP proxy servlet with the IBM MQ shared library. For information about the context root, see "Importance of the context root when you configure the HTTP proxy servlet" on page 147.

```
<application id="proxyservlet" location="servlet_file_name.war"
        name="proxyservlet" type="war" context-root="context_root">
        <classloader privateLibraryRef="wmq"/>
</application>
```

   where:

   servlet_file_name
   Specifies the name of the HTTP proxy servlet file that you exported from IBM App Connect Enterprise.

   context_root
   Specifies the context root you want to assign to the HTTP proxy servlet.

   Note: If you want the HTTP proxy servlet to use an empty context root set `context-root="/"`.

8. Save and close `server.xml`, and start the Liberty server.
9. To test if the HTTP proxy servlet is active, enter the following URL in a web browser:

```
http://host_name:port/context_root
```

   where:

   host_name
   Specifies the host name of your Liberty server.

   port
   Specifies the port number of your Liberty server.

   context_root
   Specifies the context root that you assigned to the HTTP proxy servlet.

   For example: `http://localhost:9080/`.

   If the HTTP proxy servlet can reach the integration node, then you should get an HTTP Status 404 response with the following error message:

   `URI / does not map to any message flow in integration node integration_node`

   where *integration_node* is the name of your integration node.

Results

The HTTP proxy servlet is deployed on the WebSphere Application Server Liberty Profile server.

What to do next

The HTTP proxy servlet is now ready to be tested with an integration node that receives HTTP (not HTTPS) requests and passes them to a message flow. For information about how to complete this task, see "Testing the HTTP proxy servlet" on page 164.

Deploying the HTTP proxy servlet on Apache Tomcat
Load and install the HTTP proxy servlet file on Apache Tomcat.

Before you begin

Before you deploy the HTTP proxy servlet, you must complete the following tasks:

- "Configuring the HTTP proxy servlet" on page 149
- Enabling the integration node listener for SOAP nodes

About this task

Install and customize Apache Tomcat, and then deploy the HTTP proxy servlet by completing the following steps. The instructions assume that IBM App Connect Enterprise is installed and running on the same machine as Apache Tomcat.

Procedure

1. Download Apache Tomcat from the Apache Tomcat 9 download page.
2. Run the Apache Tomcat installer and follow the instructions to complete the installation.

   Note: When prompted for the path to a Java virtual machine (JVM) you can use the JVM that is deployed with IBM App Connect Enterprise, for example `C:\Program Files\IBM\ACE\12.0.n.0\common\jdk\jre`.
3. Find the file `catalina.properties`.

   This can be found at the following location:

   Tomcat_installation_path`/conf/catalina.properties`

   where *Tomcat_installation_path* is the name of your Apache Tomcat installation directory.
4. Edit `catalina.properties` and locate the following line:

   ```
   shared.loader=
   ```
5. Edit the line so that it includes the following text:

   ```
   shared.loader=${catalina.home}/shared/lib,${catalina.home}/shared/lib/*.jar
   ```
6. Create the directory *Tomcat_installation_path*`/shared/lib`.
7. Copy the following IBM MQ JAR files from *WebSphere_MQ_installation_path*`\Java\lib` to *Tomcat_installation_path*`\shared\lib`:

   - `com.ibm.mq.commonservices.jar`
   - `com.ibm.mq.headers.jar`
   - `com.ibm.mq.jar`
   - `com.ibm.mq.jmqi.jar`
   - `com.ibm.mq.pcf.jar`
   - `connector.jar`

   The HTTP proxy servlet uses IBM MQ to communicate with IBM App Connect Enterprise.
8. Start the Apache Tomcat Windows service.
9. Open a web browser and enter the web address `http://localhost:`*port* where *port* is the HTTP port number you specified in the Apache Tomcat installation.

   The default value for the port is 8080.

   The Apache Tomcat home page is displayed.
10. Click **Tomcat Manager** and enter the admin user ID and password.
11. Scroll down to the section **WAR file to deploy** and click **Browse**.
12. Navigate to the HTTP proxy servlet file that you exported from IBM App Connect Enterprise. For example, `myproxyservlet.war`.

    Note: By default in Apache Tomcat, the context root that is used by the HTTP proxy servlet is the same as the `.war` file name. You can rename the `.war` file before you deploy the HTTP proxy servlet in order to assign a different context root to the HTTP proxy servlet. For information about the context root, see "Importance of the context root when you configure the HTTP proxy servlet" on page 147. If you want the HTTP proxy servlet to use an empty context root (`/`), then you must rename the `.war` file to `ROOT.war` and uninstall the current default web application (the Tomcat Welcome page).
13. Click **Deploy**.

14. To test if the HTTP proxy servlet is active, enter the following URL in a web browser:

    ```
    http://host_name:port/context_root
    ```

    where:

    host_name
    Specifies the host name of your Apache Tomcat server.

    port
    Specifies the port number of your Apache Tomcat server.

    context_root
    Specifies the context root that you assigned to the HTTP proxy servlet.

    For example: `http://localhost:8080/`.

    If the HTTP proxy servlet can reach the integration node, you should get an `HTTP Status 404` response with the following error message:

    `URI / does not map to any message flow in integration node integration_node`

    where *integration_node* is the name of your integration node.

Results

The proxy servlet is deployed on your Apache Tomcat server.

What to do next

The HTTP proxy servlet is now ready to be tested with an integration node that receives HTTP (not HTTPS) requests and passes them to a message flow. For information about how to complete this task, see “Testing the HTTP proxy servlet” on page 164.

Deploying the HTTP proxy servlet on WebSphere Application Server
Load and install the HTTP proxy servlet file on WebSphere Application Server.

Before you begin

Before you deploy the HTTP proxy servlet, you must complete the following tasks:

- Configure the HTTP proxy servlet, as described in “Configuring the HTTP proxy servlet” on page 149
- Enable the integration node listener, as described in Enabling the integration node listener for SOAP nodes
- Identify or install a WebSphere Application Server installation that can host the HTTP proxy servlet.

Procedure

To deploy the HTTP proxy servlet on WebSphere Application Server, complete the following steps:

1. Deploy the HTTP proxy servlet file that you exported from IBM App Connect Enterprise, by following the instructions for deploying a web application in the WebSphere Application Server Version 8.5 product documentation online.

   Ensure that you select the correct context root for your HTTP proxy servlet, as described in “Importance of the context root when you configure the HTTP proxy servlet” on page 147.

2. To test if the HTTP proxy servlet is active, enter the following URL in a web browser:

   ```
   http://host_name:port/context_root
   ```

   where:

   host_name
   Specifies the host name of your WebSphere Application Server

   port
   Specifies the port number of your WebSphere Application Server

   context_root
   Specifies the context root that you assigned to the HTTP proxy servlet

   For example: `http://localhost:9080/`.

   If the HTTP proxy servlet can reach the integration node, you will see an `HTTP Status 404` response with the following error message:

   `URI / does not map to any message flow in integration node` *integration_node*

   where *integration_node* is the name of your integration node.

Results

The HTTP proxy servlet is deployed on WebSphere Application Server.

What to do next

The HTTP proxy servlet is now ready to be tested with an integration node that receives HTTP (not HTTPS) requests and passes them to a message flow. For information about how to complete this task, see "Testing the HTTP proxy servlet" on page 164.

Testing the HTTP proxy servlet

Test the HTTP proxy servlet with an integration node that receives HTTP requests and passes them to a message flow.

Before you begin

To test the HTTP proxy servlet, use an existing web services client application or write your own SSL test client application by using Java.

Before you test the HTTP proxy servlet, you must have completed the following tasks:

- "Configuring the HTTP proxy servlet" on page 149
- Enabling the integration node listener for SOAP nodes for the proxy servlet to access
- "Deploying the HTTP proxy servlet on a servlet container" on page 159

Procedure

To test the HTTP proxy servlet, complete the following steps:

1. Install a client application that can send HTTP or SSL (HTTPS) requests.

   For example,:

   - An open source tool available from the OpenSSL downloads website that can be used to send HTTPS requests to the servlet container.
   - An integration node message flow that has an HTTPRequest or SOAPRequest node, which can generate and send HTTP requests to an HTTP listener.
   - A web browser, by using web pages or Java Server Pages (JSP), that can send HTTP POST requests. Most web browsers support HTTP and HTTPS.
   - A client application that sends requests by using HTTP, HTTPS, or both HHTP and HTTPS.

2. Configure a message flow with HTTP and SOAP input and reply nodes. The HTTPInput and SOAPInput nodes must be configured with a URL that matches the context root of the HTTP proxy servlet; for more information, see “Importance of the context root when you configure the HTTP proxy servlet” on page 147.

   The message flow receives the messages from the HTTP proxy servlet. If an HTTP or SOAP reply node is configured, responses are sent back to the HTTP proxy servlet.

Results

You have tested the HTTP proxy servlet.

Deleting an integration node

Delete an integration node by either using the command line on the system where IBM App Connect Enterprise is installed, or use the IBM App Connect Enterprise Toolkit.

Before you begin

Check that your user ID has the correct authorizations to delete the integration node; for details, see Security requirements for administrative tasks.

On Windows, Linux, and UNIX systems, you must set up your command-line environment before you delete an integration node, by running the product profile or console; see “Setting up a command environment” on page 64.

About this task

On Windows, Linux, and UNIX systems, you can delete an integration node by using the IBM App Connect Enterprise Toolkit.

You cannot delete a remote integration node by using the IBM App Connect Enterprise Toolkit, but you can remove the connection to the remote integration node from your workspace. To remove the connection to a remote integration node in the IBM App Connect Enterprise Toolkit, right-click the integration node in the Integration Explorer view, and click **Remove Connection**.

You can delete an integration node in the following ways:

- “Deleting an integration node by using the command line” on page 165
- “Deleting an integration node by using the IBM App Connect Enterprise Toolkit” on page 166.

Deleting an integration node by using the command line

Procedure

1. Stop the integration node by using the **mqsistop** command.
2. Delete the integration node by doing one of the following, dependent on your operating system:
   - Linux Windows UNIX Enter the following command to delete the integration node:

     ```
     mqsideletebroker INODE
     ```

     where INODE is the integration node name.
3. If you created integration server profiles for this integration node, delete these profiles if they are no longer required.
4. Any empty integration server `shared-classes` directories (under *workpath*/`config/`*<my_int_node_name>*`/`*<my_int_server_label>*) are automatically deleted. Otherwise, if no longer required, it is left to the user to manually delete the directories and contents.

5. If the integration node level `shared-classes` directory (under *workpath*`/config/`*<my_int_node_name>*) is empty, it is automatically deleted. Otherwise, if no longer required, it is left to the user to manually delete the directory and contents.

Results

On completion of this task:

- Linux UNIX On Linux, and UNIX, the integration node definition is removed.
- Windows Stopped and deleted the Windows service that runs the integration node.
- Removed any integration server profile scripts that are no longer needed.
- Removed any empty integration server `shared-classes` directories.
- Removed any empty integration node `shared-classes` directory.

Deleting an integration node by using the IBM App Connect Enterprise Toolkit

Procedure

1. Open the IBM App Connect Enterprise Toolkit, and switch to the Integration Development perspective.
2. In the Integration Explorer view, right-click the integration node, and click **Delete**.
   If the integration node is a remote integration node, the connection to the integration node is removed from your workspace.
   If the integration node is a local integration node, the **Delete Local Broker** wizard is displayed.
3. Click **Finish** to delete the integration node.
   If the integration node is running, the wizard stops the integration node.

Results

You have deleted the integration node.

Configuring an integration node as an IBM MQ service

Use these topics to make changes when your integration node is operating as an IBM MQ service.

About this task

The topics in this section describe how to configure your system for high availability.

- "Starting and stopping an integration node as an IBM MQ service" on page 166

Starting and stopping an integration node as an IBM MQ service

Configuring an integration node to start and stop as an IBM MQ service.

Before you begin

Ensure that you make the mqm user ID a member of the mqbrkrs group. On Windows systems, you must restart your workstation for the change to take effect.

Procedure

To configure an integration node to run as an IBM MQ service, complete the following steps.

1. Create an integration node to start as an IBM MQ service by using the **mqsicreatebroker** command with the **-d** parameter.

   Note: You must be a member of the mqm group to run the **mqsicreatebroker** command with the **-d** parameter.

   For example,

   ```
   mqsicreatebroker MyBroker -q MyQMGR -d defined
   ```

   where

   MyBroker
   Is the name of the integration node that you want to start and stop as an IBM MQ service.

   MyQMGR
   Is the name of the queue manager that is associated with the integration node.
2. Optional: If you want to create an App Connect Enterprise vault to hold the credentials that are used by the integration node when secured resources are accessed, use the **mqsivault** command.

   For example,

   ```
   mqsivault MyBroker --create --vault-key 12345678
   ```

   where

   MyBroker
   Is the name of the integration node that you want to start and stop as an IBM MQ service.
3. Optional: If you created an IBM App Connect Enterprise vault by running the **mqsivault** command at step “2” on page 167, you must configure your environment by running one of the following steps:
   a) Set the vault key as an environment variable. For example, on Windows:`set MQSI_VAULT_KEY=12345678`
   b) Add the vault key to an `.mqsivaultrc` file and copy the file into the home directory of the user who starts the IBM MQ queue manager.

      For more information about IBM App Connect Enterprise vaults and the `.mqsivaultrc` file, see command and command.
4. Stop the queue manager.

Results

When you configure an integration node to start and stop as an IBM MQ service:

- The integration node starts and stops automatically when its associated queue manager starts and stops. For a multi-instance integration node, this action can occur during failover of the active queue manager.
- A multi-instance integration node cannot be started in standby mode when its IBM MQ service is defined as active.
- You can stop the integration node manually by using the **mqsistop** command, but the integration node does not restart until the queue manager is stopped and started again.
- On UNIX and Linux systems, the integration node environment is inherited from IBM MQ. Set any required environment variables (such as ODBCINI) by using a script in the `work_path/common/profiles` directory. For more information, see “Setting up a command environment” on page 64.

Configuring integration servers

Create and configure the integration servers that you want to use on the operating system of your choice.

Before you begin

Ensure that the following requirements are met:

- Your user ID has the correct authorizations to perform the task. The authorizations are defined in Security requirements for administrative tasks.
- You have initialized the command environment on distributed systems; see "Setting up a command environment" on page 64.

About this task

You can create an integration server by using the IBM App Connect Enterprise Toolkit, the web user interface, or App Connect Enterprise commands, and you can then configure it by modifying the `server.conf.yaml` file.

When you have created and configured your integration servers, you can administer them and their resources by using the web user interface, the command line, or programmatically by using the App Connect Enterprise REST API. For more information, see "Managing integration servers" on page 249, "Managing resources by using the administration REST API" on page 334, and "Accessing the web user interface" on page 89.

Procedure

1. Create an integration server by following in the instructions in "Creating an integration server" on page 168.
2. Modify the integration server properties by following the instructions in "Configuring an integration server by modifying the server.conf.yaml file" on page 172.

   If you use any App Connect Enterprise commands that modify the integration server, an overrides directory is created under the working directory for the integration server. This overrides directory contains an additional `server.conf.yaml` configuration file, which includes property values that have been set by commands; for example, `<work_directory>/overrides/server.conf.yaml`. The values of properties in this `overrides/server.conf.yaml` file override any values that you have set in the integration server's `server.conf.yaml` file (`<work directory>/server.conf.yaml`).
3. Optional: Configure a default application for an integration server, by following the instructions in "Configuring a default application for an integration server" on page 181.
4. Optional: If you want to delete an integration server, follow the instructions in "Deleting an integration server" on page 175.

Creating an integration server

You can create integration servers by using the IBM App Connect Enterprise Toolkit, the web user interface, or commands.

About this task

You must create an integration server before you can deploy integration solutions and related resources.

You can create one or more independent integration servers, each with their own identity, and deploy them either to containers in the cloud or in an on-premises environment. If you are planning to run App Connect Enterprise directly on a physical machine or virtual machine image, you are advised to define integration servers under an integration node, which will manage its associated integration servers.

For information about why you might want to create multiple integration servers, see Integration servers and integration nodes.

The mode in which IBM App Connect Enterprise is running can affect the number of integration servers that you can use; see "Restrictions that apply in each operation mode" on page 5.

For an independent integration server, you create the server's work directory and then configure the server's properties, as described in "Creating an integration server work directory by using the mqsicreateworkdir command " on page 169.

You can also create and start a local independent integration server by using the IBM App Connect Enterprise Toolkit, as described in "Creating and starting a local, independent integration server by using the Toolkit" on page 170.

To create an integration server under an integration node, first start the integration node, and then use one of the following methods:

- "Creating an integration server that is managed by an integration node, by using the Toolkit" on page 171
- "Creating an integration server that is managed by an integration node, by using the web user interface" on page 171
- "Creating an integration server that is managed by an integration node, by using the mqsicreateexecutiongroup command" on page 172

You can also use the IBM Integration API to create integration servers on all platforms; see "Managing resources by using the IBM Integration API" on page 444.

Creating an integration server work directory by using the `mqsicreateworkdir` command

To create a work directory to be used by an independent integration server, use the **`mqsicreateworkdir`** command.

Procedure

1. Open a command window for your current installation.
2. Create a work directory for your independent integration server, by running the **`mqsicreateworkdir`** command, specifying the full path to the directory that you want to create.
   For example:

   ```
   mqsicreateworkdir c:\myaceworkdir\myserver
   ```

   This command creates the specified work directory, which contains a default configuration file called `server.conf.yaml`. This YAML file contains the default settings for your new integration server. The command also creates subdirectories, which will be used by the integration server when it is running. These include a `log` directory and a `run` directory. The `log` directory contains files of log messages, which can be used to review the status of your integration server. The `run` directory is where you can place your BAR files prior to starting your integration server, or while it is running. The resources from the BAR file are extracted and started by the integration server.

   If you have a BAR file with resources that contain graphical data maps, XML schemas, or DFDL schemas, these resources can be compiled using the command, prior to starting the integration server. This precompilation reduces the time that it takes for the deployed application to start processing messages.

   See the **`mqsicreateworkdir`** command for more information.
3. Configure your integration server by setting properties in the `server.conf.yaml` file, as described in "Configuring an integration server by modifying the server.conf.yaml file" on page 172.

Results

The integration server is created and the updated `server.conf.yaml` configuration file is stored in integration server's subdirectory in the file system.

What to do next

You can now start the integration server by running the command, as described in "Starting an integration server" on page 250.

You can deploy resources to your integration server, as described in Chapter 7, “Deploying integration solutions,” on page 2463.

Creating and starting a local, independent integration server by using the Toolkit

You can use the IBM App Connect Enterprise Toolkit to create and start a local, independent integration server.

About this task

You can create and start a local, independent integration server by using a wizard in the IBM App Connect Enterprise Toolkit. The wizard starts a process on the operating system for the independent integration server. The Toolkit does not manage the process for an independent integration server in the same way that an integration node manages the integration servers that are associated with it. When you stop the Toolkit, any independent integration server processes that were started from the Toolkit are stopped. However, if the Toolkit stops unexpectedly, or if its Eclipse process is stopped, the independent integration server processes continue to run on your operating system, and you will need to use an operating system process management tool to stop them.

Procedure

Create and start a local, independent integration server by completing the following steps:

1. In the Integration Explorer view, right-click **Integration servers** and then click **Create a local integration server**.
2. In the **Connection details** wizard, enter the following information:

   - **Name**

     Enter the name of the local independent integration server that you want to create and start. When you run the wizard for the first time, the default name for the integration server is TEST_SERVER. If you run the wizard again, the TEST_SERVER will already exist so you must specify an alternative name for the new integration server.

   - **REST Administration Port**

     Specify the port to be used for REST administration. By default, you can allow the wizard to find a port that is available to use. If you want to specify a different port, first ensure that it is not being used by another process, then deselect the checkbox and enter the required port number. The port that you specify cannot be used by the integration server if it is already in use by another process.

   - **HTTP Port**

     Specify the port that is used by the HTTPConnector resource manager when an HTTP-based message flow is deployed as part of an application. By default, you can allow the wizard to find a port that is available to use. If you want to specify a different port, first ensure that it is not being used by another process, then deselect the checkbox and enter the required port number. The port is then used when the message flow is deployed. The wizard finds an available port when the integration server is started. If the message flow is deployed at a much later date, the port might no longer be available, in which case an error message is shown at deployment time to indicate that the HTTP listener could not be started for that port. If this happens, specify the correct port used by the HTTPConnector in the `server.conf.yaml` file in the `overrides` directory, and then stop and start the integration server.

   - **JVM Debug Port**

     Specify the port to be used for debugging a message flow. By default, you can allow the wizard find a port that is available to use. If you want to specify a different port, first ensure that it is not being used by another process, then deselect the checkbox and enter the required port number. This sets the **`jvmDebugPort`** property in the `server.conf.yaml` file for the JVM resource manager to use.

If you do not want to debug a message flow, you can disable the JVM debug port by deselecting the checkbox and entering the value `0` in the field.

- Click **Finish**.

  A confirmation message shows that a configuration directory has been created in the workspace and that the integration server has been started using the details in the configuration directory. The configuration directory that is created in your workspace has the same name as the integration server that has been created and started. This is the same configuration directory that is created by the **`mqsicreateworkdir`** command. The configuration directory is shown under **Independent Resources** in your workspace. The wizard creates an override file for the `server.conf.yaml` that is used by the integration server. This override file contains the values of the ports that will be used by the integration server.

3. Optional: When you have created and started the integration server, you can deploy an application or library to it.
4. Optional: You can view the `console.log` file for the integration server. The location of the `console.log` file is under the main configuration directory.
5. Optional: You can stop the integration server by right-clicking it and then clicking **Stop**, which stops the integration server process. You can restart the integration server by right-clicking it and then clicking **Start** to start the integration server process.
6. Optional: You can remove the connection for the integration server when it has been stopped, but the configuration directory is not deleted from your workspace automatically; however, you can delete the directory manually.

   If you have previously stopped the integration server and removed the connection for it, you can create it again and it will use the configuration directory in your workspace, if it exists. In this case, a message informs you that the existing configuration directory in your workspace will be used.

Creating an integration server that is managed by an integration node, by using the Toolkit

Procedure

To create an integration server under an integration node, you can use the IBM App Connect Enterprise Toolkit:

1. Optional: If you are working with a remote integration node, connect to the integration node; see Connect to a remote integration node.
2. Make sure that the integration node is running.
3. In the Integration Explorer view, right-click the integration node, and then select **New Integration Server**.
4. In the **New Integration Server** dialog, enter the integration server name.
5. Click **OK** to create the integration server.

Results

The integration server is added to the selected integration node.

Creating an integration server that is managed by an integration node, by using the web user interface

Procedure

To create an integration server under an integration node, you can use the web user interface:

1. Make sure that the integration node is running.
2. Start the web user interface, as described in “Accessing the web user interface” on page 89.

3. Select the **Servers** tab, and then click **Create**.
4. In the **New Integration Server** dialog, enter the integration server name.
5. Click **OK** to add the integration server.
6. Optional: Configure your integration server by setting properties in the `server.conf.yaml` file, as described in "Configuring an integration server by modifying the server.conf.yaml file" on page 172.

Results

The integration server is created.

Creating an integration server that is managed by an integration node, by using the `mqsicreateexecutiongroup` command

To create integration server under an integration node, you can use the **mqsicreateexecutiongroup** command.

Procedure

1. If you are creating an integration server on Linux or Windows systems:
   a) Open a command window for your current installation.
   b) Enter the **mqsicreateexecutiongroup** command, and specify the parameters for the integration server that you want to create.
      - If the integration node is local, specify the integration node name. For example:

        ```
        mqsicreateexecutiongroup INODE -e IServer_2
        ```

      - If the integration node is remote, you can specify a configuration file. For example:

        ```
        mqsicreateexecutiongroup -n INODE.broker -e IServer_2
        ```

      - If the integration node is remote, you can alternatively specify the connection parameters **-i** and **-p**. For example:

        ```
        mqsicreateexecutiongroup -n INODE -e IServer_2 -p 4414 -i host
        ```

      See the **mqsicreateexecutiongroup** command description for more details about these options.
2. If you are creating an integration server on z/OS:
   a) Configure the BIPCREG job to specify the properties for the integration server that you want to create.
   b) Run the BIPCREG job.
3. Optional: Configure your integration server by setting properties in the `server.conf.yaml` file, as described in "Configuring an integration server by modifying the server.conf.yaml file" on page 172.

Results

The integration server has been created under the specified integration node.

What to do next

Deploy resources to your integration server; see Chapter 7, "Deploying integration solutions," on page 2463.

Configuring an integration server by modifying the server.conf.yaml file

You can configure your IBM App Connect Enterprise integration server by modifying properties in a `server.conf.yaml` configuration file. The location of the `server.conf.yaml` file that you need to

modify depends on whether you are configuring an independent integration server or an integration server that is managed by an integration node.

Before you begin

Ensure that you set up your command environment, as described in "Setting up a command environment" on page 64.

About this task

When you have created an integration server, you set properties in the `server.conf.yaml` file to configure the operation of the integration server and associated resources. For example, you can set a REST administration port and an HTTPS port, and you can configure the trace level, activity logging, JVM, and the reporting of statistics data for your integration server. You can also configure the integration server to record all messages that pass through a message flow, and then use these recorded messages to generate unit tests.

For an independent integration server, the `server.conf.yaml` configuration file is created for you automatically when you use the **`mqsicreateworkdir`** command to create an integration server work directory. The `server.conf.yaml` file is created in the root of the specified work directory: `<work directory>/server.conf.yaml`.

If you use any commands that modify the integration server, an overrides directory is created under the working directory for the integration server. This overrides directory contains an additional `server.conf.yaml` configuration file, which contains property values that are set by commands; for example, `<work directory>/overrides/server.conf.yaml`. The values of properties in this `overrides/server.conf.yaml` file override any values that you have set in the integration server's `server.conf.yaml` file (`<work directory>/server.conf.yaml`).

If a property has been set in the integration server's `server.conf.yaml` file, and also in the overrides directory (`/overrides/server.conf.yaml`), the property value that has been set in the overrides directory is used. Therefore, if an integration server does not appear to be using the settings that you would expect, check the `server.conf.yaml` file in the overrides directory to see if your expected property value has been overridden by a command. If you want to manually override the settings that have resulted from a command, you can either edit the property in the `server.conf.yaml` file in the overrides directory, or you can remove the entry from the overrides directory and modify the base `server.conf.yaml` file instead.

For integration servers that are managed by an integration node, each server has its own `server.conf.yaml` configuration file that overrides common settings from the integration node's `node.conf.yaml` configuration file. When you create an integration node, the `node.conf.yaml` file is located at: `$MQSI_WORKPATH/components/<Node name>/node.conf.yaml`.

If you use commands to modify the integration node, the changes are saved in the integration node's override `node.conf.yaml` file. This file is located at: `$MQSI_WORKPATH/components/<Node name>/overrides/node.conf.yaml`, as described in "Creating an integration node by using the command line" on page 115. When you create a managed integration server for an integration node, server-specific settings are created for it in its own `server.conf.yaml` file. The server-specific file is located at: `$MQSI_WORKPATH/components/<Node name>/servers/<Server name>/server.conf.yaml`.

If you use commands to modify this integration server, the changes are saved in: `$MQSI_WORKPATH/components/<Node name>/servers/<Server name>/overrides/server.conf.yaml`. The values of properties in this `overrides/server.conf.yaml` file override any values that you have set in the `<Node name>/servers/<Server name>/server.conf.yaml` file.

Procedure

1. If the integration server does not exist already, you can create it by following the instructions in "Creating an integration server" on page 168.

2. Use a YAML editor to open the `server.conf.yaml` file.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor. However, you must ensure that you do not include any tab characters, which are not accepted in YAML and would cause your integration server configuration to fail. If you choose to use a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

   For more information about working with YAML, see http://www.yaml.org/start.html.
3. Modify the properties that you want to change in the file.
   For example:

   - In the RestAdminListener section, set a value for the **Port** property to be used by the REST administration port, which is the primary method of communicating with the integration server. (Default value of 7600.)
   - In the ResourceManagers / HTTPConnector section, set a value for the **ListenerPort** so that you can send messages to a flow that is using a HTTPInput node. (Default value of 7800.)
   - In the ResourceManagers / JVM section, set a value for the **jvmDebugPort** so that you can use the Flow Debugger. For example, set this property to 6511.

   You can also configure the integration server to record all messages that pass through a message flow, by setting properties in the **RecordedMessageManager** section of the `server.conf.yaml` file. You can then use these recorded messages to generate unit tests for the flow, as described in "Generating tests from recorded messages in a message flow" on page 1908.
4. Save your changes to the `server.conf.yaml` file.

   If you run any commands that modify the integration server at any time after you set properties in the `server.conf.yaml` file, an overrides directory is created under the working directory for the integration server. This overrides directory contains another `server.conf.yaml` configuration file, which contains property values that are set by commands; for example, `<work directory>/overrides/server.conf.yaml`. The values of properties in this `overrides/server.conf.yaml` file override any values that you have set in the integration server's `server.conf.yaml` file (`<work directory>/server.conf.yaml`). If you want to manually override the settings that have resulted from a command, you can either edit the property in the `server.conf.yaml` file in the overrides directory, or you can remove the entry from the overrides directory and modify the base `server.conf.yaml` file instead.
5. Specify the security credentials to be used by the integration server when you connect to a secured resource (such as a database) by using the **mqsisetdbparms** command. Use the **-w** parameter to specify the integration server's work directory that you created in step 1:
   For example:

   ```
   mqsisetdbparms -w c:\myaceworkdir -n jdbc::secID -u iibuser -p password
   ```

   When you run this command, the user ID and password are stored securely in the IBM App Connect Enterprise credentials store. For more information about using the **mqsisetdbparms** command, see command.

   Alternatively, you can configure an independent integration server to connect to secured resources by using credentials that are stored in encrypted form in an App Connect Enterprise vault. You can configure security credentials by using the command or the administrative REST API. These encrypted credentials are stored in the integration server's vault, which you configure by using the command. For more information, see "Configuring encrypted security credentials" on page 177.
6. Optional: You can configure applications to run when the integration server starts, by pre-loading the BAR file into the `run` folder of the integration server's work directory. For information, see command.
7. Restart the integration server. The properties that you set in the `server.conf.yaml` file take effect when the integration server is started. If you modify these properties again, you must start the integration server again for the subsequent changes to take effect. For more information, see "Starting an integration server" on page 250.

   If the integration server fails to restart, check to see whether the failure was caused by a YAML parsing error. For an independent integration server, parsing errors are reported to the `stderr` log. For an

integration server that is managed by an integration node, YAML parsing errors are reported to the integration server's `console.txt` file. For more information, see Standard system logs.

Deleting an integration server

Delete integration servers by using IBM App Connect Enterprise Toolkit, the web user interface, or a command.

Before you begin

Check that the integration server is running; you cannot delete an integration server that is stopped.

About this task

Use one of the following methods to complete this task:

- "Deleting an integration server by using the IBM App Connect Enterprise Toolkit" on page 175
- "Deleting an integration server by using the web user interface" on page 175
- "Deleting an integration server by using the mqsideleteexecutiongroup command" on page 176

You can also use the IBM Integration API to delete integration servers on all platforms; see "Managing resources by using the IBM Integration API" on page 444.

Deleting an integration server by using the IBM App Connect Enterprise Toolkit

Procedure

Complete the following steps to delete an integration server:

1. Open the IBM App Connect Enterprise Toolkit, and switch to the Integration Development perspective.
2. In the Integration Explorer view, expand your integration node.
3. Right-click the integration server that you want to delete, and click **Delete** > **Integration Server**.

Results

Your integration server and all resources that are deployed to it are deleted.

- If you created any integration server profiles for this integration server, delete them manually if they are no longer required.
- If the `shared-classes` directory (under *workpath*`/config/`*<my_int_node_name>*`/`*<my_int_server_label>*) is empty, this directory is automatically deleted.

  Note: If the `shared-classes` directory is not empty but is no longer required, the directory can be deleted manually.

Deleting an integration server by using the web user interface

Procedure

Complete the following steps to delete an integration server:

1. Start the web user interface for your integration node; see "Accessing the web user interface" on page 89.

   The navigator is displayed on the left side of the pane, showing the servers (integration servers), message flows, and other resources that are owned by your integration node.
2. Expand the **Servers** folder, click the down arrow beside the integration server you want to delete to display the menu, and then click **Delete**.

3. Click **Yes** to confirm that you want to delete the integration server.

Results

Your integration server and all resources that are deployed to it are deleted.

- If you created any integration server profiles for this integration server, delete them manually if they are no longer required.
- If the `shared-classes` directory (under *workpath*`/config/`*<my_int_node_name>*`/`*<my_int_server_label>*) is empty, this directory is automatically deleted.

  Note: If the `shared-classes` directory is not empty but is no longer required, the directory can be deleted manually.

Deleting an integration server by using the `mqsideleteexecutiongroup` command

Procedure

Complete the following steps to delete an integration server:

1. If you are deleting an integration server on Linux, UNIX, and Windows systems:
   a) Open a command window for your installation.
   b) Enter the **mqsideleteexecutiongroup** command, and specify the parameters for the integration server that you want to delete.
      - If the integration node is local, specify the integration node name; for example:

        ```
        mqsideleteexecutiongroup -n INODE -e IServer_2
        ```

      - If the integration node is remote, you can specify a configuration file; for example:

        ```
        mqsideleteexecutiongroup -n INODE.broker -e EGroup_2
        ```

      - If the integration node is remote, you can alternatively specify the connection parameters **-i** and **-p**; for example:

        ```
        mqsideleteexecutiongroup -e IServer_2 -n INODE -e IServer_2 -p 4414 -i
        ```

      See the **mqsideleteexecutiongroup** command description for more details about these options.
2. If you are deleting an integration server on z/OS:
   a) Configure the BIPDLEG job to specify the properties for the integration server that you want to delete.
   b) Run the BIPDLEG job.

Results

Your integration server and all resources that are deployed to it are deleted.

- If you created any integration server profiles for this integration server, delete them manually if they are no longer required.
- If the `shared-classes` directory (under *workpath*`/config/`*<my_int_node_name>*`/`*<my_int_server_label>*) is empty, this directory is automatically deleted.

  Note: If the `shared-classes` directory is not empty but is no longer required, the directory can be deleted manually.

Configuring encrypted security credentials

You can configure integration nodes and integration servers to connect to secured resources by using credentials that are stored in encrypted form in an IBM App Connect Enterprise vault.

You can configure security credentials by using the command or the administrative REST API, and you can view credentials by using the web user interface. The encrypted credentials are stored in a vault, which you can configure by using the command, or by specifying a vault key on the command.

Alternatively, you can use the **mqsisetdbparms** command to associate credentials with resources that are accessed by an integration server or an integration node. For more information, see command.

Video: Storing encrypted security credentials in a vault using App Connect Enterprise

This video demonstrates create a vault in App Connect Enterprise and then store credentials in it in encrypted form.

Note:

This video was created for App Connect Enterprise 11.0, but also applies to App Connect Enterprise 12.0.

Creating a vault by using the `mqsivault` command

Before you can store encrypted credentials for an integration node or integration server, you must configure an App Connect Enterprise vault. You create a separate vault for each independent integration server, and for each integration node. Each independent integration server has its own vault, with its own vault key. Each integration node has its own vault, with its own vault key, which is shared by all the integration servers that it manages. Each integration server that is managed by an integration node has its own credentials stored in the vault, but all the credentials in the vault are accessed by the same vault key.

You can use the **mqsivault** command to create or destroy a vault, to change or verify a vault key, or to retrieve credentials from the vault. The vault stores the credentials (in encrypted form), and the integration node or server uses them to access secured resources.

For more information about how to use the command, see command.

Creating a vault by using the `mqsicreatebroker` command

If you create an integration node by running the **mqsicreatebroker** command, you can create a vault for that integration node by specifying either the **--vault-key** or **--vaultrc-location** parameter on the command. For more information about how to use the command, see command.

Configuring encrypted credentials by using the `mqsicredentials` command

You can use the **mqsicredentials** command to configure an integration node or integration server to use encrypted credentials for connecting to a secured resource.

You use the **mqsicredentials** command to create, update, report, and delete credentials for an independent integration server or for an integration node and the integration servers that it manages. You can use the command to create and report credentials when the integration server is running or stopped, but you must stop the integration server before you can update or delete credentials.

For information about how to use the command, see command.

Creating and viewing credentials by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to create or report security credentials for an integration node or server. For information about using the administration REST API, see REST API for administering integration servers.

Viewing credentials by using the web user interface

You can use the IBM App Connect Enterprise web user interface to view credentials for an integration node or server.

To display information about the credential, start the web user interface to view the relevant integration server, and then click the tile for the credential that you want to view. The properties for that credential are displayed, including the user name, authentication type, credentials provider, whether the credential is read-only, and whether a password has been set. For information about how to start the web user interface, see “Accessing the web user interface” on page 89.

Configuring security credentials for an independent integration server in the server.conf.yaml file

You can configure an independent integration server to connect to secured resources by using credentials that are defined in the integration server's `server.conf.yaml` configuration file.

You can configure credentials for each credential type by setting properties in the **`ServerCredentials`** section of the `server.conf.yaml` file. You can specify the credential type, name, and each of the properties that you want to set; for example:

```
ServerCredentials:
  odbc:
    USERDB:
      username: "user1"
      password: "pass"
    DATAFLOW:
      username: "usr2"
      password: "myLongPassword"
  salesforce:
    mysf1:
      username: "aName"
      password: "passw0rd"
      clientId: "clientEye"
      clientSecret: "worldsBiggestSecret"
  jdbc:
    db:
      username: "myusername"
```

If you want to change the credentials when they have been set, you must update the properties in the `server.conf.yaml` file and then restart the integration server. The credentials are read when the integration server starts, and can be used by the message flows that are running on the integration server.

The credentials are accessible through the web user interface, the REST API, and the **`mqsicredentials`** command (when the integration server is running). The **`credentialProvider`** field for credentials that are defined in this way is shown as `servercredentials`.

You can specify the following credential types and properties in the `server.conf.yaml` file:

- **cd**:

  Specify this type to set credentials for connecting an IBM Sterling Connect:Direct® CDOutput node to its Connect:Direct server.

  You can set the **`username`** and **`password`** properties for connecting to a Connect:Direct server.

- **cics**:

  Specify this type to set credentials for connecting a CICSRequest node to a CICS® Transaction Server for z/OS server.

  You can set the **`username`** and **`password`** properties for connecting to a CICS Transaction Server for z/OS server. Password is optional.

- **eis**:

  Specify this type to set credentials for connecting to an external Enterprise Information System (EIS), such as SAP, Siebel, JD Edwards, or PeopleSoft.

  You can set the **username** and **password** properties for connecting to an EIS.
- **email**:

  Specify this type to set credentials for connecting to an email server.

  You can set the **username** and **password** properties for connecting to an email server.
- **ftp**:

  Specify this type to set credentials for connecting to an FTP server.

  You can set the **username** and **password** properties for connecting to an FTP server.
- **http**:

  Specify this type to set credentials for static ID identity propagation with SOAP or HTTP request nodes when using basic authentication (basicAuth).

  You can set the **username** and **password** properties for SOAP or HTTP request nodes (SOAPRequest, SOAPAsyncRequest, HTTPRequest, and HTTPAsyncRequest nodes).
- **httpproxy**:

  Specify this type to set credentials for connecting to a secured HTTP proxy server.

  You can set the **username** and **password** properties for connecting to an HTTP server.
- **ims**:

  Specify this type to set credentials for connecting from an IMSRequest node to the IMS server.

  You can set the **username** and **password** properties for connecting to an IMS server.
- **jdbc**:

  Specify this type to set credentials for a JDBC type 4 connection.

  You can set the **username** and **password** properties for connecting to a JDBC resource.
- **jms**:

  Specify this type to set credentials for connecting to JMS resource.

  You can set the **username** and **password** properties for connecting to a JMS resource.
- **jndi**:

  Specify this type to set credentials for connecting to a JNDI resource.

  You can set the **username** and **password** properties for connecting to a JNDI resource.
- **kafka**:

  Specify this type to set credentials for connecting to a secured Kafka cluster.

  You can set the **username** and **password** properties for connecting to a Kafka cluster.
- **kerberos**:

  Specify this type to set credentials for connecting to the Kerberos Key Distribution Center (KDC).

  You can set the **username** and **password** properties for connecting to a Kerberos KDC.
- **keystore**:

  Specify this type to set credentials for opening the web user interface keystore.

  You can set the **password** property for opening the web user interface keystore.

- **keystorekey**:

  Specify this type to set credentials for opening a key inside the web user interface keystore.

  You can set the **password** property for opening the key inside the keystore (for use when the key inside the keystore is protected by a password that is different from the password used to open the keystore).
- **ldap**:

  Specify this type to set Lightweight Directory Access Protocol (LDAP) bind credentials.

  You can set the **username** and **password** properties for binding to an LDAP server.
- **loopback**:

  Specify this type to set credentials for a connection that is made through a LoopBack® connector.

  You can set either the **username** and **password** or the **username**, **password**, **clientId**, and **clientSecret** properties for connecting through a LoopBack connector.
- **mq**:

  Specify this type to set credentials for connecting to a secured IBM MQ queue manager.

  You can set the **username** and **password** properties for connecting to an IBM MQ queue manager.
- **mqtt**:

  Specify this type to set credentials for connecting to a secured external MQTT server, which the integration server uses to publish its event messages.

  You can set the **username** and **password** properties for connecting to an external MQTT server.
- **odbc**:

  Specify this type to set credentials for an Open Database Connectivity (ODBC) data source name (DSN) that is accessed from a message flow.

  You can set the **username** and **password** properties for accessing an ODBC DSN from a message flow.
- **odm**:

  Specify this type to set credentials for an Operational Decision Manager (ODM) Rule Execution Server that is accessed from a message flow.

  You can set the **username** and **password** properties for accessing an ODM Rule Execution Server from a message flow.
- **rest**:

  Specify this type to set credentials for authenticating a connection to an external REST API.

  You can set the following properties for connecting to an external REST API:

  - **apiKey**
  - **username** and **password**
  - **username**, **password**, and **apiKey**
- **salesforce**:

  Specify this type to set credentials for authenticating a connection to a Salesforce system.

  You can set the **username**, **password**, **clientId**, and **clientSecret** properties for accessing a Salesforce system.
- **sftp**:

  Specify this type to set credentials for authenticating a connection to an SFTP server.

  To access an SFTP server, you must specify either the **password** or **sshIdentityFile** property, but not both. If you specify an identity file, you can also specify a passphrase with the **passphrase** property.

- **smtp**:

  Specify this type to set credentials for authenticating a connection to an SMTP server.

  You can set the **username** and **password** properties for connecting to an SMTP server.
- **soap**:

  Specify this type to set credentials for static ID identity propagation with SOAP request and reply nodes when using WS-Security while connecting to or replying from a web service (SOAPRequest, SOAPAsyncRequest, and SOAPReply nodes).

  You can set the **username** and **password** properties to specify the credentials for these connections.
- **truststore**:

  Specify this type to set credentials for connecting to an integration server truststore.

  You can set the **password** property for connecting to a truststore.
- **truststorekey**:

  Specify this type to set credentials for opening a key inside the integration server truststore.

  You can set the **password** property for opening the key inside the truststore (for use when the key inside the truststore is protected by a password that is different from the password used to open the truststore).
- **wsrr**:

  Specify this type to set credentials for connecting to a WebSphere Service Registry and Repository

  You can set the **username** and **password** properties for accessing a WebSphere Service Registry and Repository.
- **wxs**:

  Specify this type to set credentials for connecting to a secure WebSphere eXtreme Scale grid.

  You can set the **username** and **password** properties for accessing a WebSphere eXtreme Scale grid.

For more information about configuring an integration server, see "Configuring an integration server by modifying the server.conf.yaml file" on page 172.

Configuring a default application for an integration server

You can configure a default application for an integration server by setting the application name in the integration server's `server.conf.yaml` configuration file.

Before you begin

- Create an integration server, as described in "Creating an integration server" on page 168.
- Configure the integration server, by following the instructions in "Configuring an integration server by modifying the server.conf.yaml file" on page 172.

About this task

All resources that are run by the IBM App Connect Enterprise run time must be located in an application. Any independent resources (located in an independent resource project), are automatically placed in the integration server's default application. You can specify the default application when you create the integration server, by specifying the **--default-application-name** parameter on the command. Alternatively, you can specify a default application for an existing integration server, by setting the **defaultApplication** property in the integration server's `server.conf.yaml` configuration file. When an integration server has been configured to use a default application, independent resources are placed under the specified default application so that they can be accessed.

Procedure

To configure a default application for an integration server, complete the following steps:

1. Use a YAML editor to open the `server.conf.yaml` file.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor. However, you must ensure that you do not include any tab characters, which are not accepted in YAML and would cause your integration server configuration to fail. If you choose to use a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

   For more information about working with YAML, see http://www.yaml.org/start.html.

2. Set the **`defaultApplication`** property in the `Defaults` section of the `server.conf.yaml` file, by removing the comment (*#*) from the start of the `defaultApplication` line and specifying a name for the default application that will be used by the integration server:

   ```
   Defaults:
     defaultApplication: 'myDefaultApp'   # Name a default application under which independent
    resources will be placed
   ```

3. Restart the integration server. The properties that you set in the `server.conf.yaml` file take effect when the integration server is started. If you modify these properties again, you must also start the integration server again for the subsequent changes to take effect. For more information, see "Starting an integration server" on page 250.

Configuring the environment to access external applications and resources

If you are developing message flows that access external resources such as databases, Enterprise Information Systems, IMS, or email servers, you must set up your environment to support these applications.

About this task

The topics in this section describe how to configure your environment to support specific applications.

Note: You can also use policies to control certain aspects of message flow and message flow node behavior at run time. For more information, see "Overriding properties at run time with policies" on page 324.

Configuring databases

Configure databases to hold application or business data that you can access from your message flows.

About this task

Databases that hold application or business data can be read from and written to by nodes within the message flows that you deploy to one or more integration nodes in your domain.

For more information about the requirement for, and set up of, databases, and the restrictions that apply, see "Databases overview" on page 1131.

To make databases available, complete the following steps:

Procedure

1. If you want to access databases from your deployed message flows, create and configure the databases and the connections to them.

2. On distributed platforms, create and configure connections to the databases that you have created:
   a) If your message flows use an ODBC connection to a database, enable an ODBC connection for that database.

      Repeat this step for each database that you want to access in this way.

      Note that you can use the **mqsicvp** command as an ODBC test tool; see "Enabling ODBC connections to the databases" on page 184 for further information.
   b) If your message flows use a JDBC connection to a database, enable a JDBC connection for that database.

      Repeat this step for each database that you want to access in this way.

Securing database connections

Set up security for a database connection, whether it is required by the database provider or optional.

Before you begin

- If you are using a JDBC provider, you must first set up the JDBC provider. See Set up your JDBC provider definition.
- If you are using an ODBC connection, you must first connect to the database. See "Enabling ODBC connections to the databases" on page 184.

About this task

Some databases require that all access is associated with a known user ID, for others this association is optional. For example, DB2 requires a data source login name and password on all connections.

Use the **mqsisetdbparms** command to specify a user ID and password that the integration node can use to access each database. If a user ID and password have not been specified for database access using the mqsisetdbparms command, default values for user ID and password are used which are platform specific:

1. Windows On Windows: The integration node service ID and password that you specified on the **mqsicreatebroker** command.
2. Linux UNIX On Linux and UNIX: The user ID `mqsiUser` and password `********` (these values are fixed).

Steps for setting up security are specific to the type of database connection that you are using. Choose your database connection type to see the steps:

- "ODBC connections" on page 183
- "JDBC connections" on page 184

ODBC connections

About this task

If your ODBC data source requires you to define secure access, or if you want to implement security where this is optional, complete the following steps:

Procedure

1. Identify the user IDs that you want to associate with the database connection, or create a user ID with a password, following the appropriate instructions for your operating system and database.
2. Define the user IDs and passwords that the integration node can use to access a particular data source.

3. Run the **mqsisetdbparms** command to create user IDs and passwords that can be used to access the data source from an integration node.

   Use the following format:

   ```
   mqsisetdbparms broker_name -n data_source_name -u database_userID -p database_userID_password
   ```

4. Optional: If you want to use the same user ID and password for more than one database as a default set of credentials, you can specify `dsn::`DSN in the **-n** parameter, as shown in the following example:

   ```
   mqsisetdbparms broker_name -n dsn::DSN -u default_userID -p default_password
   ```

Results

You have secured access to your ODBC data source.

JDBC connections

About this task

If your database requires you to define secure access, or if you want to implement security where this is optional, complete the following steps:

Procedure

1. Identify the user ID that you want to associate with the database connection, or create a user ID with a password, following the appropriate instructions for your operating system and database.
2. Define the user IDs and passwords that the integration node can use for the JDBC connections:
   - Use the following command format:

     ```
     mqsisetdbparms broker_name -n jdbc::security_identity -u userID -p password
     ```

     For example, if you want a user ID *myuserid* with a password of *secretpw* to access a database on integration node *INODE1*, run the following command:

     ```
     mqsisetdbparms INODE1 -n jdbc::mySecurityIdentity -u myuserid -p secretpw
     ```

     The `jdbc::` prefix indicates that the **security_identity** is to be used for JDBC connections.
   - If you want to use the same user ID and password for more than one database as a default set of credentials, you can specify `dsn::`DSN in the **-n** parameter, as shown in the following example:

     ```
     mqsisetdbparms INODE1 -n jdbc::JDBC -u default_userID -p default default_password
     ```

   - Update the corresponding `Security identity` property for the JDBC Providers policy to associate the connection with the security identity that you have defined (see JDBC Providers policy (JDBCProviders)).

Results

You have secured access to your JDBC databases. If you need to define user credentials that can be shared across a business area or account, you can reuse the same security identity that you defined in the previous steps in different JDBC Providers policies.

Enabling ODBC connections to the databases

Set up the resources and environment that the integration node requires for Open Database Connectivity (ODBC) connections to databases on distributed systems.

Before you begin

Read the following topic: “Configuring databases” on page 182.

Note: In IBM App Connect Enterprise, you do not need to install the IBM Integration ODBC Database Extender program to use database nodes in your applications. The program code is installed as part of the IBM App Connect Enterprise installation.

About this task

You can configure both ODBC and Java Database Connectivity (JDBC) connections for access to databases:

- To set up ODBC connections to databases, follow the instructions in this section.

  Optionally, after configuring the ODBC connection parameters, run the command to verify that the integration node can connect to the data source, and to provide useful information about the data source and its interface.On Linux and UNIX systems, this command also checks that the ODBC environment is set up correctly.
- On Linux and UNIX systems, IBM Integration ODBC Database Extender, which encapsulates unixODBC, is provided as the driver manager. IBM App Connect Enterprise provides DataDirect ODBC drivers for interfacing with Oracle, Sybase, and SQLServer databases. For other databases, you must provide the appropriate ODBC driver.

  On Windows, the ODBC driver manager is provided by the operating system. IBM App Connect Enterprise provides DataDirect ODBC drivers for interfacing with Oracle and Sybase. For other databases, you must provide the appropriate ODBC driver.
- To set up JDBC connections to databases, see "Enabling JDBC connections to the databases" on page 200.
- On Linux and UNIX systems, delete the ODBCINI64 environment variable if it exists; it is not required by IBM Integration Bus 10.0. For more information, see "Database connections" on page 1131. The sample `odbc.ini` and `odbcinst.ini` files that are supplied, and the information that is contained in these configuration topics, include all the connection parameters that are supported for connections to your databases. Any additional parameters that are provided by your chosen database drivers are not tested or supported in an IBM App Connect Enterprise environment; consider your requirements carefully before specifying other parameters in your tailored ODBC `.ini` files.

To enable connections on distributed systems:

Procedure

Define the ODBC DSNs according to your platform:

Windows **On Windows:**
Follow the instructions in "Connecting to a database from Windows systems" on page 185.

Linux UNIX **On Linux and UNIX systems:**
For all supported databases, follow the instructions in "Connecting to a database from Linux and UNIX systems by using the IBM Integration ODBC Database Extender" on page 189.

You have now configured the ODBC DSNs for your databases.

Results

You have now enabled the integration node to make connections to your databases.

Connecting to a database from Windows systems

To enable an integration node to connect to a database, define the ODBC data source name (DSN) for the database.

Before you begin

Check that you have set up your environment so that the integration node can connect to the database. Most database managers set up the required environment when you install, but others supply a database

profile that you must run. For information about environments and running database profiles, see "Running database setup scripts before starting an integration node" on page 83.

About this task

Configure an ODBC data source by using the ODBC Data Source Administrator:

1. Click **Start** > **Control Panel** > **Administrative Tools** > **Data Sources (ODBC)**.
2. Click the **System DSN** tab and click **Add**.
3. Complete the steps in the following sections for the databases that you are working with.

   If you need more information about a particular database product, see the product-specific documentation.

DB2 UDB

Define a data source for DB2 UDB:

1. Select the driver `IBM DB2 ODBC DRIVER`.
2. Enter the data source name (DSN) and description.
3. Select the correct database alias from the list.
4. Click **Finish** to save your definition.
5. Click **OK** to close the ODBC Data Source Administrator.
6. If you need to use Global Coordination with your database from IBM App Connect Enterprise on Windows systems, the next task is to set up the 32-bit environment that is needed by IBM MQ, see "Setting your environment to support access to databases" on page 200.

You must register the data source as a system data source.

If you prefer, you can use the Configuration Assistant instead of the ODBC Data Source Administrator:

1. Open the DB2 Configuration Assistant.
2. Right-click the database and select **Change Database**.
3. Select **Data Source**.
4. Select **Register this database for ODBC**. Select the system data source option.
5. Click **Finish**.
6. The **Test Connection** dialog opens automatically and you can test the various connections.

Informix® Dynamic Server

Define a data source for Informix Dynamic Server:

1. Select the driver `IBM INFORMIX ODBC DRIVER`.
2. On the **Connection** tab, specify:
   - The Informix server name.
   - The server host name.
   - The Informix network service name (as defined in the services file).
   - The network protocol (for example, `olsoctcp`).
   - The Informix data source name.
   - The user identifier to access the data source within.
   - The password for that user identifier.
3. Click **Apply**.
4. Click **Test Connection** to check your supplied values.
5. Click **OK** to close the ODBC Data Source Administrator.

Microsoft SQL Server

Define a data source for Microsoft SQL Server:

1. Select the driver for the version of SQL Server that you are using:
   - `SQL Native Client` 10.0 for SQL Server 2008.
   - `SQL Native Client` 11.0 for SQL Server 2012, 2014, and 2016.
2. Specify a name and description.
3. Select the correct server from the list.
4. To specify the authentication mode that is used by the server:
   a. Click **Next**.
   b. Select the authentication mode.
   c. Click **Back** to move back to the first panel.
5. Click **Finish** to save your definition.
6. Click **OK** to close the ODBC Data Source Administrator.

Oracle

Define a data source for Oracle:

1. • Select the driver `IBM App Connect Enterprise (10.0.0.`*n*`) DataDirect Technologies 64-BIT Oracle Wire Protocol` where *n* is the level of the installed fix pack.

   The **ODBC Oracle Driver Setup** dialog box opens.
2. On the **General** tab:
   a. Enter the DSN name, description, and host name of the machine where Oracle is running, the port number on which Oracle is listening, and the Oracle Service Name that you want to connect to.
3. On the **Advanced** tab:
   a. Select **Enable SQLDescribeParam**.
   b. Select **Procedure Returns Results**. The resultant ODBC definition in the Windows registry has a string value that is called **`ProcedureRetResults`** with the value 1.
   c. Select **Login Timeout** and set the value to `0`.
   d. Ensure that **Enable N-CHAR** is not selected.
   e. If you are using TIMESTAMP WITH TIMEZONE columns, select **Enable Timestamp With Timezone**.
   f. In **Extended Options**, enter:

```
WorkArounds=536870912;
```

Oracle using Secure Socket Layer (SSL) authentication

Complete the steps for Oracle above.

Then, complete these additional steps:

1. Reopen the **ODBC Oracle Driver Setup** dialog box, see Step 1 for Oracle above.

2. On the **Security** tab:
   a. In the **Authentication section**, set the **Authentication Method** to `Encrypt Password`.
   b. In the **Encryption Section**, set the **Encryption Method** to `SSL Auto`.
   c. Select the check box if you want to **validate the Server certificate**.
   d. Enter a fully qualified path for your **Trust Store**.
   e. Enter your **Trust Store Password**.
   f. Enter a fully qualified path for your **Key Store**.
   g. Enter your **Key Store Password**.
   h. Enter your **SSL Key Password**.
3. Click **OK** to close the ODBC Data Source Administrator.

Oracle using Advanced Security (OAS)

Complete the steps for Oracle above.

Then, complete these additional steps:

1. Reopen the **ODBC Oracle Driver Setup** dialog box, see Step 1 for Oracle above.
2. On the **Advanced Security** tab:
   a. Select the Encryption Level that you want to use. Choose from the following options:
      - 0 - Rejected. If rejected, or no match is found between the driver and server encryption types, data that is sent between the driver and the database server is not encrypted or decrypted. If the Oracle server has its **`sqlnet.encryption_server`** setting set to "REQUIRED" and this option is selected, then the connection to the Oracle database fails.
      - 1 - Accepted. Encryption is used on data that is sent between the driver and the database server if the database server requests or requires it.
      - 2 - Requested. Data that is sent between the driver and the database server is encrypted and decrypted if the database server permits it.
      - 3 - Required. Data that is sent between the driver and the database server must be encrypted and decrypted. If the Oracle server has its **`sqlnet.encryption_server`** setting set to "REJECTED" and this option is selected, then the connection to the Oracle database fails.
   b. Select the Encryption Types that you want to use.
   c. Select the Data Integrity Level you want to use. Choose from the following options:
      - 0 - Rejected. A data integrity check on data that is sent between the driver and the database server is refused. If the Oracle server has its **`sqlnet.crypto_checksum`** setting set to "REQUIRED" and this option is selected, then the connection to the Oracle database fails.
      - 1 - Accepted. A data integrity check can be made on data that is sent between the driver and the database server. Data integrity is used if the database server requests or requires it.
      - 2 - Requested. The driver enables a data integrity check on data that is sent between the driver and the database server if the database server permits it.
      - 3 - Required. A data integrity check must be performed on data that is sent between the driver and the database server. If the Oracle server has its **`sqlnet.crypto_checksum`** setting set to "REJECTED" and this option is selected, then the connection to the Oracle database fails.
   d. Select the Data Integrity Types that you want to use.
3. Click **OK** to close the ODBC Data Source Administrator.

Sybase Adaptive Server Enterprise

Define a data source for Sybase Adaptive Server Enterprise:

1. • Select the driver `IBM App Connect Enterprise (10.0.0.n) DataDirect Technologies 64-BIT Sybase Wire Protocol` where *n* is the level of the installed fix pack.
2. Enter the DSN name, description, and network address of the server, where the network address is made up of **`MyHostMachineName,MyHostMachinePortNumber`**.
3. On the **Advanced** tab:
   - Select **Enable Describe Parameter**.
   - Select **Login Timeout** and set the value to `0`.
   - In **Extended Options**, enter:

     ```
     TimestampTruncationBehavior=1;EnableSPColumnTypes=2;XAConnOptBehavior=3;
     ```
4. On the **Performance** tab:
   - Ensure that the **Prepare Method** setting is `1 - Partial`.

solidDB

Define a data source for solidDB:

1. Select the driver IBM solidDB - (Unicode) DRIVER.
2. Enter the description.
3. Enter the communication port in the network location field, for example, `tcp 2315`.
4. Click **Finish** to save your definition.
5. Click **OK** to close the ODBC Data Source Administrator.

Results

You have now configured your ODBC data source names on Windows.

Connecting to a database from Linux and UNIX systems by using the IBM Integration ODBC Database Extender

IBM Integration ODBC Database Extender encapsulates the unixODBC driver manager. You must set up and configure the integration node to use it.

Before you begin

The following information applies to all supported databases.

- Read the information about the unixODBC Project.
- Create the database.
- Ensure that your database is set up so that the integration node is authorized to access the database.
- Check that you have set up your environment so that the integration node can access the database. You might have to run a database profile that is supplied by the database vendor. For more information, see “Running database setup scripts before starting an integration node” on page 83.

You do not need to install the IBM Integration ODBC Database Extender program to use database nodes in your applications. The program code is installed as part of the IBM App Connect Enterprise installation.

Procedure

1. Copy the `odbc.ini` sample file that is supplied in the *`install_dir`*`/server/ODBC/unixodbc/` directory to a location of your choice.

   Each integration node service user ID on the system can therefore use its own data source name (DSN) definitions.

   Note: To prevent problems with the backup and restore procedures, store the copy of the sample file in the `/var/mqsi` directory, rather than the home directory for your user ID.

2. Ensure that your copy of the `odbc.ini` file is owned by the `mqbrkrs` group, and has 664 permissions.
3. Set the ODBCINI environment variable to point to your copy of the `odbc.ini` file, specifying a full path and file name. Ensure that you point to the copy of the file; do not point to the `odbc.ini` file in the installation directory.
4. Copy the `odbcinst.ini` sample file that is supplied in the *`install_dir`*`/server/ODBC/unixodbc/` directory to a location of your choice. See the **Note** in step 1.
5. Ensure that your copy of the `odbcinst.ini` file is owned by the `mqbrkrs` group and has 664 permissions.
6. Set the ODBCSYSINI environment variable to point to the directory that contains your copy of the `odbcinst.ini` file, specifying a full path name. Ensure that you point to the directory containing the copy; do not point to the directory containing the `odbcinst.ini` file in the installation directory.
7. If you are using the Data Server driver for ODBC that is supplied as part of App Connect Enterprise:
   a) Copy the `db2cli.ini` sample file that is supplied in the *`install_dir`*`/server/ODBC/unixodbc/` directory to a location of your choice.
   b) Ensure that your copy of the `db2cli.ini` file is owned by the `mqbrkrs` group, and that it has 664 permissions.
   c) Set the DB2CLIINIPATH environment variable to point to the directory that contains your copy of the `db2cli.ini file`, specifying a full path name. Ensure that you point to the directory containing the copy; do not point to the directory containing the `db2cli.ini` file in the installation directory.
8. If you are connecting directly to DB2 server, solidDB, or Informix databases, set the library search path environment variable to show the location of the libraries for the database manager that you are using. This step is not required if you are using the Data Server driver for ODBC that is supplied as part of App Connect Enterprise.

   For more information about the library search path, ask your database administrator (DBA), or see the documentation for your database manager.

   The library search path environment variable depends on your platform:

   - Linux On Linux, set `LD_LIBRARY_PATH`.
   - AIX On AIX, set `LIBPATH`.

   Updates to the library search path are not required for other supported databases.
9. If you are using a DB2 database instance that is installed on AIX, a single process can make a maximum of 10 connections that use shared memory to a DB2 database. Use TCP/IP mode to connect to the database instance.
10. Edit the final stanza in the `odbc.ini` file (the [ODBC] stanza), to specify the location of the installed DataDirect ODBC drivers.

    To ensure that you edit the correct `odbc.ini` file, you can open the file in the vi text editor by using the following command:

    ```
    vi $ODBCINI
    ```

    a) In the **`InstallDir`** field, add the IBM App Connect Enterprise installation location to complete the fully qualified path to the ODBC directory.

    Ensure that the path points to the ODBC directory in the IBM App Connect Enterprise installation location. If you do not specify this value correctly, the ODBC definition will not work.

    b) Accept the default values shown in the sample `odbc.ini` file for all the other entries in the stanza.

    For example, on AIX:

    ```
    ;##################################################
    ;###### Mandatory information stanza ######
    ```

```
;##############################################

[ODBC]
InstallDir=/usr/opt/IBM/mqsi/11.0.0.2/server/ODBC/drivers
UseCursorLib=0
IANAAppCodePage=4
UNICODE=UTF-8
```

11. Edit the first stanza in the `odbc.ini` file (the [ODBC Data Sources] stanza) to list the DSN of each database.

    For example, on AIX:

    ```
    ;##############################################
    ;###### List of data sources stanza #######
    ;##############################################
    [ODBC Data Sources]
    DB2DB=IBM DB2 ODBC Driver
    DB2DSDB=IBM DB2 using the Data Server driver included in ACE
    ORACLEDB=DataDirect ODBC Oracle Wire Protocol
    ORACLERACDB=DataDirect ODBC Oracle RAC Wire Protocol
    ORACLESSLDB=DataDirect ODBC Oracle SSL Wire Protocol
    SYBASEDB=DataDirect ODBC Sybase Wire Protocol
    SYBASEDBUTF8=DataDirect ODBC Sybase UTF8 Wire Protocol
    SQLSERVERDB=DataDirect ODBC SQL Server Wire Protocol
    INFORMIXDB=IBM Informix ODBC Driver
    SOLIDDB_DB=IBM Solid DB ODBC Driver
    ```

    List all your DSNs in your `odbc.ini` file, regardless of the database manager. You can define multiple DSNs to resolve to the same database; however, if you are using global coordination of transactions with an Oracle database, do not use this option because it might cause data integrity problems.

12. For each database that you listed in the [ODBC Data Sources] stanza in the `odbc.ini` file, create a data source stanza in the `odbc.ini` file. The entries in the stanza depend on the database manager.

    For a DB2 database instance:

    a. In the **Driver** field:

    - If you are directly connecting to a DB2 server, add the full path of your DB2 installation.
    - If you are using the Data Server driver for ODBC supplied with App Connect Enterprise, ensure that the path points to the driver file in the App Connect Enterprise installation location.

    b. In the **Description** field, type a meaningful description of the database. This field is for information only and does not affect the connection.

    c. In the **Database** field, type the DB2 alias. The data source name must be the same as the database alias name. If you are using a remote DB2 database, you must set up your client/server connection to resolve this alias to the correct database. For more information, see the DB2 documentation.

    If the requirement is to have multiple stanzas that refer to the same DB2 database, aliases must be created in DB2 by using the DB2 CATALOG command. These aliases can then have their own stanza in the `odbc.ini` file.

    The `odbc.ini` file cannot be used to set up aliases for DB2.

    For example, connecting directly to a DB2 server on AIX:

    ```
    ;# DB2 stanza
    [MYDB2DB]
    DRIVER=/opt/IBM/db2/V11.1/lib64/db2o.o
    Description=IBM DB2 ODBC Database
    Database=MYDB2DB
    ```

    Connecting directly to a DB2 server on Linux systems:

    ```
    ;# DB2 stanza
    [MYDB2DB]
    DRIVER=/opt/IBM/db2/V11.1/lib64/libdb2o.so
    Description=IBM DB2 ODBC Database
    ```

```
Database=MYDB2DB
```

Connecting to DB2 using the Data Server Driver on Linux Systems:

```
;# DB2 using DataServer driver included in ACE
[MYDB2DB]
DRIVER=/usr/opt/IBM/mqsi/11.0.0.11/server/ODBC/dsdriver/odbc_cli/clidriver/lib/
libdb2o.so
Description=IBM DB2 ODBC Database
Database=MYDB2DB
```

For an Oracle database:

For all platforms:

a. In the **Driver** field, ensure that the path points to the driver file in the IBM App Connect Enterprise installation location, as shown in the following example.

b. In the **Description** field, type a meaningful description of the database. This field is for information only and does not affect the connection.

c. In the **HostName** field, type the name or IP address of the machine that is hosting your Oracle system.

d. In the **PortNumber** field, type the number of the port on which your Oracle server is listening on the machine that you specified in the **HostName** field.

e. In the **ServiceName**field, type the Oracle service name that you want to connect to on the system you specified in the **HostName** field.

f. If you are using TIMESTAMP WITH TIMEZONE columns, uncomment the `EnableTimestampwithTimezone` setting.

g. Accept the default values shown in the sample `odbc.ini` file for all the other entries in the stanza.

For example, on AIX:

```
;# Oracle stanza
[MYORACLEDB]
Driver=/usr/opt/IBM/mqsi/11.0.0.2/server/ODBC/drivers/lib/UKora95.so
Description=DataDirect ODBC Oracle Wire Protocol
HostName=my-machine.hursley.ibm.com
PortNumber=1521
ServiceName=my-oracle-service
CatalogOptions=0
EnableStaticCursorsForLongData=0
ApplicationUsingThreads=1
EnableDescribeParam=1
OptimizePrepare=1
WorkArounds=536870912
ProcedureRetResults=1
ColumnSizeAsCharacter=1
LoginTimeout=0
EnableNcharSupport=0
;# Un-comment the next setting if you wish to use Oracle TIMESTAMP WITH TIMEZONE
 columns
```

```
;# EnableTimestampwithTimezone=1
```

For an Oracle database that uses Real Application Clusters:

For all platforms:

a. In the **Driver** field, ensure that the path points to the driver file in the IBM App Connect Enterprise installation location, as shown in the following example.

b. In the **Description** field, type a meaningful description of the database. This field is for information only and does not affect the connection.

c. In the **HostName** field, type the name or IP address of the machine that is hosting your primary (preferred) Oracle instance.

d. In the **PortNumber** field, type the number of the port on which your Oracle server is listening on the machine that you specified in the **HostName** field.

e. In the **ServiceName** field, type the Oracle Real Application Cluster service name that you want to connect to on the system that you specified in the **HostName** field.

f. If you are using TIMESTAMP WITH TIMEZONE columns, uncomment the `EnableTimestampwithTimezone` setting.

g. In the **AlternateServers** field, provide a list of alternative locations for this service for situations when the primary location, which is defined in **HostName**, is unavailable. Each location specification consists of three parts, which are separated by colons. Enter these values as one continuous string; the text in this example has been split to improve readability.

```
HostName=<Alternative host name>
:PortNumber=<Oracle listner port on alternative server>
:ServiceName=<Service name on the alternative server>
```

If you want to specify more than one AlternateServer, separate each additional location specification with a comma. Whenever a new database connection is required, for example after an Oracle instance failover, the primary location will be tried first. However, if the primary location is unavailable, the driver will try the list of alternative locations in turn.

h. Accept the default values shown in the sample `odbc.ini` file for all the other entries in the stanza.

For example, on AIX:

```
;# Oracle Real Application Clusters stanza
[MYORACLERACDB]
Driver=/usr/opt/IBM/mqsi/11.0.0.2/server/ODBC/drivers/lib/UKora95.so
Description=DataDirect ODBC Oracle RAC Wire Protocol
HostName=my-primary-machine.hursley.ibm.com
PortNumber=1521
ServiceName=my-oracle-rac-service
;#This shows one alternate server definition. Add extra ones using a ',' to seperate
 each definition.
AlternateServers=(HostName=my-first-backup-
machine.hursley.ibm.com:PortNumber=1521:ServiceName=my-
oracle-rac-first-backup-service,HostName=my-second-backup-
machine.hursley.ibm.com:PortNumber=1521:ServiceName=my-oracle-rac-second-backup-
service)
CatalogOptions=0
EnableStaticCursorsForLongData=0
ApplicationUsingThreads=1
EnableDescribeParam=1
OptimizePrepare=1
WorkArounds=536870912
ProcedureRetResults=1
ColumnSizeAsCharacter=1
LoginTimeout=0
EnableNcharSupport=0
;# Un-comment the next setting if you wish to use Oracle TIMESTAMP WITH TIMEZONE
 columns
```

```
;# EnableTimestampwithTimezone=1
```

For an Oracle database that uses Secure Socket Layer (SSL):

For all platforms:

a. In the **Driver** field, ensure that the path points to the driver file in the IBM App Connect Enterprise installation location, as shown in the following example.

b. In the **Description** field, type a meaningful description of the database. This field is for information only and does not affect the connection.

c. In the **HostName** field, type the name or IP address of the machine that is hosting your primary (preferred) Oracle instance.

d. In the **PortNumber** field, type the number of the port on which your Oracle server is listening for SSL connections on the machine you specified in **HostName**.

e. In the **ServiceName** field, type the Oracle SSL service name that you want to connect to on the system you specified in the **HostName** field.

f. If you are using TIMESTAMP WITH TIMEZONE columns, uncomment the `EnableTimestampwithTimezone` setting.

g. In the **KeyPassword** field, type your SSL key password.

h. In the **KeyStore** field, type the fully qualified name of your SSL key store.

i. In the **KeyStorePassword** field, type your SSL key store password.

j. In the **TrustStore** field, type the fully qualified name of your SSL trust store.

k. In the **TrustStorePassword** field, type your SSL trust store password.

l. In the **EncryptionMethod** field, type the method to use to encrypt data sent between the driver and the database server. Valid values are as follows:

- **0** No encryption. This value is the default.
- **1** SSL. If the server supports protocol negotiation, the driver and server negotiate the use of the SSL protocols specified in the **CryptoProtocolVersion** connection option.
- **3** SSL3.
- **4** SSL2.
- **5** TLS1.

m. If the **EncryptionMethod** has been set to 1, use **CryptoProtocolVersion** to specify a comma-separated list of the cryptographic protocols to use. Valid protocols are TLSv1.2, TLSv1.1, TLSv1, SSLv3 and SSLv2. When multiple protocols are specified, the driver uses the highest version supported by the server. The default value is `TLSv1.2, TLSv1.1, TLSv1`.

n. In the **ValidateServerCertificate** field, type 1 to enable validation of the certificate that is sent by the database server when SSL encryption is enabled.

o. Accept the default values shown in the sample `odbc.ini` file for all the other entries in the stanza.

For example, on AIX:

```
;# Oracle using SSL stanza
[MYORACLESSLDB]
Driver=/usr/opt/IBM/mqsi/11.0.0.2/server/ODBC/drivers/lib/UKora95.so
Description=DataDirect ODBC Oracle Wire Protocol
HostName=my-machine.hursley.ibm.com
PortNumber=2484
ServiceName=my-oracle-ssl-service
CatalogOptions=0
EnableStaticCursorsForLongData=0
ApplicationUsingThreads=1
EnableDescribeParam=1
OptimizePrepare=1
WorkArounds=536870912
ProcedureRetResults=1
ColumnSizeAsCharacter=1
LoginTimeout=0
```

```
AuthenticationMethod=1
KeyPassword=my-password
KeyStore=/Development/ssl/my-store.p12
KeyStorePassword=my-password
TrustStore=/Development/ssl/my-store.p12
TrustStorePassword=my-password
EncryptionMethod=1
CryptoProtocolVersion=TLSv1.2
ValidateServerCertificate=1
EnableNcharSupport=0
;# Un-comment the next setting if you wish to use Oracle TIMESTAMP WITH TIMEZONE
 columns
;# EnableTimestampwithTimezone=1
```

For an Oracle database that uses Advanced Security (OAS):

For all platforms:

a. In the **Driver** field, ensure that the path points to the driver file in the IBM App Connect Enterprise installation location, as shown in the following example.

b. In the **Description** field, type a meaningful description of the database. This field is for information only and does not affect the connection.

c. In the **HostName** field, type the name or IP address of the machine that is hosting your Oracle system.

d. In the **PortNumber** field, type the number of the port on which your Oracle server is listening on the machine you specified in **HostName**.

e. In the **ServiceName** field, type the Oracle service name that you want to connect to on the system that you specified in the **HostName** field.

f. If you are using TIMESTAMP WITH TIMEZONE columns, uncomment the `EnableTimestampwithTimezone` setting.

g. In the **EncryptionLevel** field, enter the level of encryption that you are using. Choose one value from the following options:

- 0 - Rejected. If rejected, or no match is found between the driver and server encryption types, data that is sent between the driver and the database server is not encrypted or decrypted. If the Oracle server has its **sqlnet.encryption_server** setting set to "REQUIRED" and this option is selected, then the connection to the Oracle database fails.
- 1 - Accepted. Encryption is used on data that is sent between the driver and the database server if the database server requests or requires it.
- 2 - Requested. Data that is sent between the driver and the database server is encrypted and decrypted if the database server permits it.
- 3 - Required. Data that is sent between the driver and the database server must be encrypted and decrypted. If the Oracle server has its **sqlnet.encryption_server** setting set to "REJECTED" and this option is selected, then the connection to the Oracle database fails.

h. In the **DataIntegrityLevel** field, choose one value from the following options:

- 0 - Rejected. A data integrity check on data that is sent between the driver and the database server is refused. If the Oracle server has its **sqlnet.crypto_checksum** setting set to "REQUIRED" and this option is selected, then the connection to the Oracle database fails.
- 1 - Accepted. A data integrity check can be made on data that is sent between the driver and the database server. Data integrity is used if the database server requests or requires it.
- 2 - Requested. The driver enables a data integrity check on data that is sent between the driver and the database server if the database server permits it.
- 3 - Required. A data integrity check must be performed on data that is sent between the driver and the database server. If the Oracle server has its **sqlnet.crypto_checksum**

setting set to "REJECTED" and this option is selected, then the connection to the Oracle database fails.

i. Accept the default values shown in the sample odbc.ini file for all the other entries in the stanza.

For example, on AIX:

```
;# Oracle using SSL stanza
[MYORACLEOASDB]
Driver=/usr/opt/IBM/mqsi/11.0.0.2/server/ODBC/drivers/lib/UKora95.so
Description=DataDirect ODBC Oracle Wire Protocol
HostName=my-machine.hursley.ibm.com
PortNumber=1586
ServiceName=my-oracle-oas-service
CatalogOptions=0
EnableStaticCursorsForLongData=0
ApplicationUsingThreads=1
EnableDescribeParam=1
OptimizePrepare=1
WorkArounds=536870912
ProcedureRetResults=1
ColumnSizeAsCharacter=1
LoginTimeout=0
EncryptionTypes=AES128,AES192,AES256,RC4_40,RC4_56,RC4_128,RC4_256,DES,3DES112,3DES168
EncryptionLevel=3
DataIntegrityTypes=SHA1,MD5
DataIntegrityLevel=3
EnableNcharSupport=0
;# Un-comment the next setting if you wish to use Oracle TIMESTAMP WITH TIMEZONE
 columns
;# EnableTimestampwithTimezone=1
```

For a Sybase database:

For all platforms except Linux on Z:

a. In the **Driver** field, ensure that the path points to the driver file in the IBM App Connect Enterprise installation location, as shown in the following example.

b. In the **Description** field, type a meaningful description of the database. This field is for information only and does not affect the connection.

c. In the **Database** field, type the name of the database to which you want to connect by default. If you do not specify a value, the default value is the database that is defined by your system administrator for each user.

d. In the **NetworkAddress** field, type the network address of your Sybase ASE server (this address is required for local and remote databases). Specify an IP address or server name, in the following format:

```
Your Sybase server name or IP address,Your Sybase port number
```

For example:

```
Sybaseserver,5000
```

You can also specify the IP address directly; for example:

```
199.226.224.34,5000
```

You can find the port number in the Sybase interfaces file, which is named interfaces.

e. Accept the default values shown in the sample odbc.ini file for all the other entries in the stanza.

For example, on AIX:

```
;# Sybase Stanza
[MYSYBASEDB]
Driver=/usr/opt/IBM/mqsi/11.0.0.2/server/ODBC/drivers/lib/UKase95.so
Description=DataDirect ODBC Sybase Wire Protocol
Database=SYBASEDB1
ApplicationUsingThreads=1
```

```
EnableDescribeParam=1
OptimizePrepare=1
SelectMethod=0
NetworkAddress=my-machine.hursley.ibm.com:4100
SelectUserName=1
ColumnSizeAsCharacter=1
EnableSPColumnTypes=2
LoginTimeout=0
TimestampTruncationBehavior=1
XAConnOptBehavior=3
```

If you want to use a UNICODE UTF8 Sybase data source, add the following line to the end of your Sybase stanza:

```
Charset=UTF8
```

For remote access to an SQL Server database

For all platforms:

a. In the **Driver** field, add the IBM App Connect Enterprise installation location to complete the fully qualified path to the driver shown in the sample odbc.ini file.

b. In the **Description** field, type a meaningful description of the database. This field is for information only and does not affect the connection.

c. In the **Database** field, type the name of the database to which you want to connect by default. If you do not specify a value, the default value is the database that is defined by your system administrator for each user.

d. In the **HostName** field, type the name or IP address of the server to which you want to connect.

e. In the **PortNumber** field, type the number of the port of the server listener.

f. To specify a named instance of SQL Server, replace the **HostName** and **PortNumber** lines with HostName=*Your SQLServer Machine Name**Your SQLServer Instance Name*

g. Accept the default values shown in the sample odbc.ini file for all the other entries in the stanza.

For example, on AIX:

```
;# UNIX to SQLServer stanza
[MYSQLSERVERDB]
Driver=/usr/opt/IBM/mqsi/11.0.0.2/server/ODBC/drivers/lib/UKsqls95.so
Description=DataDirect ODBC SQL Server Wire Protocol
Database=SQLSERVERDB
HostName=my-machine.hursley.ibm.com
PortNumber=1433
AnsiNPW=1
LoginTimeout=0
QueryTimeout=0
;# To specify a named instance of SQL Server replace the HostName and PortNumber
 lines with
;# HostName=<Your SQLServer Machine Name>\<Your SQLServer Instance Name>

;# To use Integrated Windows Authentication, reinstate the following line:
;# AuthenticationMethod=9
```

```
;# Domain=<Your Windows Domain Name>
```

h. If you want to use Integrated Windows Authentication (IWA) for access to the remote SQL Server database, reinstate and complete the lines at the end of the stanza.

For an Informix database:

a. In the **Driver** field, add the full path of your Informix Client library.

b. In the **Description** field, type a meaningful description of the database. This field is for information only and does not affect the connection.

c. In the **ServerName** field, type the name of the Informix IDS server.

d. In the **Database** field, type the name of the database to which you want to connect by default. If you do not specify a value, the default value is the database that is defined by your system administrator for each user.

For example, on AIX:

```
;# Informix Stanza
[MYINFORMIXDB]
Driver=/opt/IBM/informix/lib/cli/iclit09b.so
Description=IBM Informix ODBC Database
ServerName=my-machine
Database=MYDB
```

For a solidDB database:

For all platforms except Linux on POWER and Linux on Z:

Client side

odbc.ini file

a. In **Driver**, add the full path of your solidDB Client library.

b. In **Description**, type a meaningful description of the database. This field is for information only and does not affect the connection.

c. In **Database**, type the name of the database to which you want to connect by default. If you do not specify a value, the default value is the database that is defined by your system administrator for each user.

For example, on AIX:

```
;# SolidDB Stanza
[SOLID_DB]
Driver=/opt/solidDB/bin/soca5x6465.so
Description=IBM Solid DB ODBC database
```

```
Database=SOLIDDB_DB
```

Note: all additional information is ignored.

`solid.ini` file

a. This configuration file is located in the directory that is referenced by the environment variable SOLIDDIR.

b. The `solid.ini` mapping is from the data source name (as defined in `ODBCINI`) to the solidDB connection string.

c. The connection string takes the form <logical name of the driver> = <physical solidDB connect string>.

d. The Physical connection string specifies the:

- Protocol
- Machine name or IP address
- Port number to use

For example, on AIX:

```
[Data Sources]
SOLIDDB_DB=tcp my_aix_system 1964
```

Server side

`solid.ini` file

a. This configuration file is located in the installation directory for solidDB.

b. Set the Data Source as for the Client side `solid.ini` file.

c. Set **`Listen`** to where the listener for the server is located.

d. Set **`CharPadding=yes`** and **`NumericPadding=yes`** to turn on padding.

For example, on AIX:

```
[Data Sources]
SOLIDDB_DB=tcp my_aix_system 1964

[COM]
Listen=tcpip 1964

[SQL]
CharPadding=yes
NumericPadding=yes
```

13. Ensure that you have edited all necessary parts of all of the relevant `.ini` files:

- The [ODBC Data Source] stanza at the top of the `odbc.ini` file.
- A stanza for each data source in the `odbc.ini` file.
- The [ODBC] stanza at the end of the `odbc.ini` file.
- Additionally, for solidDB, both the client and server-side `solid.ini` files.

If you do not configure all parts correctly, the ODBC DSNs do not work and the integration node is unable to connect to the database.

14. Optional: On AIX, database connect times can sometimes take marginally longer than on Linux platforms due to the IBM Integration ODBC Database Extender searching for unicode conversion libraries that do not typically exist on AIX. To prevent this automatic search, you can set the following property in the `[ODBC]` stanza of the `odbcinst.ini` file:

```
IconvEncoding=UCS-2
```

Results

You have now configured database connections on Linux and AIX. You can check that the ODBC environment is configured correctly by running the **mqsicvp** command. For more information, see command.

Setting your environment to support access to databases

When you have configured your ODBC data source names (DSNs), you must also configure the environment so that you can issue console commands, and the integration node that you start can access the required database libraries. For example, if you have a DB2 database, you must add the DB2 client libraries to your library search path.

About this task

Windows

1. On Windows platforms, the environment is typically set up for you when you install the database product, and no further action is required. However, some database managers provide a database profile that you must run to enable the connection from the integration node; for further information, see “Running database setup scripts before starting an integration node” on page 83.

Linux UNIX

1. On Linux and UNIX systems, run a profile for each database you want to access. For example, on DB2 you must run `db2profile`; other database vendors have similar profiles. For further information, see “Running database setup scripts before starting an integration node” on page 83.

Enabling JDBC connections to the databases

Configure connections to a database through a JDBC Providers policy.

About this task

Use a JDBC connection from Java programs that are associated with a JavaCompute node or a user-defined node that is written in Java.

You must also set up JDBC connections if your message flows include graphical data maps with one or more database transforms to be run from a Mapping node, or if they include DatabaseRetrieve or DatabaseRoute nodes.

If you configure a JDBC type 4 connection from an application running on a Linux, UNIX, or Windows system, you can configure your integration node and queue manager to include interactions with the databases in globally-coordinated transactions. On z/OS, JDBC connections can be coordinated only by the integration node.

The information provided in this section is independent of whether your operating systems, integration nodes, integration servers, queue managers, and databases operate in 32-bit or 64-bit mode, except where stated.

When you write Java classes for a JavaCompute node or a user-defined node, your code must comply with the following restrictions:

- Do not include any code that performs a COMMIT or a ROLLBACK function.
- Do not close the connection to the database. The integration node manages all connections, and closes a connection if it is idle for approximately one minute, or if the message flow completes.

To configure JDBC type 4 connections:

Procedure

1. Set up your JDBC provider definition.
2. Optional: Set up security.

3. Optional: If your integration node is running on a Windows system, authorize access to JDBCProvider resources.

What to do next

If you have been following the instructions in "Working with databases" on page 1130 or Mapping database content, the next task is "Setting up a JDBC provider for type 4 connections" on page 201.

When you have completed configuration of the databases, add or modify Java code in your JavaCompute or user-defined nodes to access the database that is identified in the JDBC Providers policy.

Setting up a JDBC provider for type 4 connections

Use a JDBC Providers policy to configure a JDBC provider service.

Before you begin

- See the following information: "Creating an integration node" on page 114.
- Create the database by following the database documentation.

About this task

When you include a DatabaseRetrieve, DatabaseRoute, JavaCompute, Mapping, or Java user-defined node in a message flow, and interact with a database in that node, the integration server must establish a connection with the database to fulfill the operations that are performed by the node. You must define a JDBC Providers policy to provide the integration server with the information that it needs to complete the connection.

Important: When naming your JDBC Providers policy, consider the following requirements:

- If you want to use your JDBC Providers policy with a JavaCompute node, or with a Java user-defined node, the name of your policy must match the *datasourceName* parameter in the `getJDBCType4Connection()`, provided that the policy is in the default policy project. If the policy is not in the default policy project, you must specify the policy and policy project name in the format `{`*`policyProjectName`*`}:`*`PolicyName`*.
- If you want to use your JDBC Providers policy with a Mapping node, the name of your policy must match the database name that is used by the database transforms in your Graphical Data Map. For each database transform, the database name is determined by the database definition (`.dbm` file) in the Data Design project that was used to create the map. The JDBC Providers policy must be deployed in the default policy project; for more information, see "Configuring a default policy project" on page 329.
- If you want to use your JDBC Providers policy with a DatabaseRetrieve node, or with a DatabaseRoute node, the name of your policy must match the value of the *Data source name* property of the node. The JDBC Providers policy must be deployed in the default policy project; for more information, see "Configuring a default policy project" on page 329.

A JDBC Providers policy supports connections to one database only; you must create a policy for each database that your nodes or Java applications connect to.

To set up a JDBC provider for type 4 connections, complete the following steps.

Procedure

1. Identify the type of database for which you require a JDBC Providers policy.

   Supported JDBC drivers and databases are shown in IBM App Connect Enterprise system requirements; support for globally coordinated (XA) transactions is restricted on some platforms and for some databases.
2. Use the Policy editor in the IBM App Connect Enterprise Toolkit to create a JDBC Providers policy and choose the template for your chosen database type (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).

3. The template provides some default values, but you must change some of them to create a viable definition.
   For example, the `Database name` property is mandatory, but is initially empty (see JDBC Providers policy (JDBCProviders)).

   The following values and order of preference are used by the integration server to substitute the user ID and password in the pattern:

   a. First, on all platforms: The user ID and password that you have set for the specific database, by using the **mqsisetdbparms** and specifying the database in the **-n** parameter.

   b. Second, on all platforms: The user ID and password that you have set for all other databases, by using the **mqsisetdbparms** and specifying `jdbc::JDBC` in the **-n** parameter.

   c. Third, the values are platform-specific:

      i) Windows On Windows: The integration node service ID and password that you specified on the **mqsicreatebroker** command.

      ii) Linux UNIX On Linux and UNIX: The user ID `mqsiUser` and password `********` (these values are fixed).

4. When you have created your JDBC Providers policy, you must deploy it to any integration server where you will deploy the message flows that will use this policy. You can deploy the policy project directly to an integration server.

What to do next

If required, set up security for the JDBC connection, set up the environment to include the JDBC Providers policy in globally coordinated transactions, or both.

Configuring a JDBC type 4 connection for globally coordinated transactions

If you want the database that you access through a JDBC type 4 connection to participate in globally coordinated transactions, set up the appropriate environment.

Before you begin

Set up your JDBC provider definition.

About this task

On distributed systems, an IBM MQ queue manager associated with the integration node performs the transaction manager role, which means that IBM App Connect Enterprise requires access to IBM MQ when processing messages. For more information about using IBM MQ with IBM App Connect Enterprise, see “Installing IBM MQ” on page 96.

Updates that you make to a database across a JDBC type 4 connection can be coordinated with other actions taken within the message flow, if you set up the resources to support coordination.

Complete the following steps:

Procedure

1. Check that the definition of your JDBC Providers policy is appropriate for coordinated transactions.

   For example, to set up the required JDBC classes:

   - For DB2, set **JDBC type 4 data source class name** to `com.ibm.db2.jcc.DB2XADataSource` and **JDBC driver class name** to `com.ibm.db2.jcc.DB2Driver`.
   - For Oracle, set **JDBC type 4 data source class name** to `oracle.jdbc.xa.client.OracleXADataSource` and **JDBC driver class name** to `oracle.jdbc.OracleDriver`.

   Consult your database administrator or the documentation provided by your database supplier, to confirm that all the JDBC Providers policy properties are set appropriately. For example, a database supplier might require secure access if it is participating in coordinated transactions.

2. Define the switch file and the database properties:

   a) The JDBC switch file is supplied by IBM App Connect Enterprise, and uses static XA registration (see "Configuring databases for global coordination of transactions" on page 704).

   b) Linux

   On Linux and UNIX systems, open the `qm.ini` file for the integration node queue manager with a text editor. Add the following stanza for each database:

   ```
   XAResourceManager:
          Name=Database_Name
          SwitchFile=JDBCSwitch
          XAOpenString=JDBC_DataSource
          ThreadOfControl=THREAD
   ```

   Database_Name is the database name (DSN) of the database defined to the JDBC Providers policy.

   `JDBCSwitch` is a fixed generic name that represents the switch file for XA coordination. Use this value, or another single fixed value, in each stanza; the specific switch file that the queue manager uses is defined by the symbolic links you create in the next step.

   JDBC_DataSource is the identifier of the JDBC Providers policy.

   Define a stanza for each database (DSN) that you connect to from this integration server. You must create separate definitions even if the DSNs resolve to the same physical database. Therefore, you must have a stanza for each JDBC Providers policy that you have defined, because each service can define the properties for a single database.

   c) Windows

   On Windows, open IBM MQ Explorer and select the queue manager, for example BROKERQM.

   Open the **XA resource manager** page, and modify the attributes to create the definition of the database. The attributes are the same as those shown for Linux and UNIX; **Name**, **SwitchFile**, **XAOpenString**, and **ThreadofControl**. Leave the additional attribute, **XACloseString**, blank.

   Enter *JDBCSwitch* in **SwitchFile**.

3. Set up queue manager access to the switch file:

   a) Linux

   On Linux and UNIX systems, create a symbolic link to the switch files that are supplied in your *install_dir*`/server/lib` directory.

   install_dir is the directory to which you installed IBM App Connect Enterprise. The default location for this directory is *install_dir*`/ace-12.0.`*n*`.0/server` on Linux, or `/opt/IBM/`

`mqsi/12.0.n.0/server` on UNIX systems. The default directory includes the version, release, modification, and fix of the product, in the format v.r.m.f (version.release.modification.fix).

Set up links in the `/var/mqm/exits64` directory. The file name for all platforms is `libJDBCSwitch.so`.

Specify the same name of the switch file, `JDBCSwitch` or your own value, in the `/exits64` directory. For example, on AIX:

```
ln -s install_dir/server/lib/libJDBCSwitch.so /var/mqm/exits64/JDBCSwitch
```

b) Windows

On Windows, copy the `JDBCSwitch32.dll` file from the *install_dir*`\server\bin` directory to the `\exits` subdirectory in the IBM MQ installation directory, and rename the file to `JDBCSwitch.dll`. Then, copy the `JDBCSwitch.dll` file from the *install_dir*`\server\bin` directory to the `\exits64` subdirectory in the IBM MQ installation directory.

4. Configure the message flow that includes one or more nodes that access databases that are to participate in a globally coordinated transaction.
   a) Open an IBM App Connect Enterprise Toolkit session.
   b) Switch to the Integration Development perspective.
   c) Add the message flow that includes the node or nodes that connect to the database that is to participate in a globally coordinated transaction to a new or existing BAR file.
   d) Build the BAR file.
   e) Click the **Configure** tab, select the message flow that you have added, and select the **Coordinated Transaction** check box.

What to do next

If your integration node is running on Windows, authorize the queue manager to access resources that are associated with the JDBC Providers policy (see "Authorizing access to JDBC type 4 JDBCProvider resources on Windows" on page 204).

If you have been following the instructions in "Working with databases" on page 1130, the next task is "Configuring ODBC connections for globally coordinated transactions" on page 708 (optional).

Authorizing access to JDBC type 4 JDBCProvider resources on Windows

Authorize the integration node and queue manager to access shared resources that are associated with the JDBCProvider. This task is required only if you want the database updates to be included in globally coordinated transactions on Windows systems.

Before you begin

Set up your JDBC provider definition.

About this task

On distributed systems, an IBM MQ queue manager provides the coordinated transaction support, which means that IBM App Connect Enterprise must have access to IBM MQ when it is processing the messages in the flow. For more information about using IBM MQ with IBM App Connect Enterprise, see "Installing IBM MQ" on page 96.

When the queue manager coordinates transactions, both queue manager and integration node access shared memory to control a connection to the databases with which the message flow interacts. Therefore, they require the same access control of the shared memory. One method to achieve this control is to use the same ID for the integration node service ID and the queue manager administrative ID.

If you specified an existing queue manager when you created the integration node, check that its administrative ID is the same ID as the one used for the service ID of the integration node. If the ID is not the same, change the queue manager ID to be the same as the integration node service ID.

Complete the following steps on the Windows system on which the integration node is running:

Procedure

1. Click **Start** > **Run** and enter dcomcnfg. The Component Services window opens.
2. In the left pane, expand **Component Services** > **Computers** > **My Computer** and click **DCOM Config**.
3. In the right pane, right-click the IBM MQ service labeled **IBM MQSeries Services**, and click **Properties**.
4. Click the **Identity** tab.
5. Select **This user** and enter the user ID and password for the integration node service ID to associate that ID with the queue manager.
6. Click **OK** to confirm the change.

Enabling data encryption for a JDBC connection

Encryption of JDBC connection is managed by parameters passed to the third party JDBC client jars that are supplied by the JDBC provider. You can use the IBM App Connect Enterprise JDBC Providers policy or a vendor-specific configuration file to pass the parameters.

About this task

Encryption parameters are specific to a JDBC provider. Refer to the documentation issued by your JDBC provider for the details of the Java encryption parameters that you require in your runtime environment.

To enable data encryption for a JDBC connection, follow the instructions in one of the following sections:

- "Using the IBM App Connect Enterprise JDBC Providers policy to enable data encryption for JDBC connections " on page 205
- "Using a vendor-specific configuration file to enable data encryption for JDBC connections " on page 206

Note: You can also use either method to apply extra environment parameters for a JDBC connection; for example, when you configure JDBC with SSL, or with a high availability and scalability feature such as Oracle RAC. SSL setup requires additional steps and these are described in "Setting up a public key infrastructure" on page 2635.

Using the IBM App Connect Enterprise JDBC Providers policy to enable data encryption for JDBC connections

About this task

For information about how policies are used to enable JDBC connections, see "Enabling JDBC connections to the databases" on page 200.

The encryption parameters are set in the **`environmentParms`** property of the JDBC Providers policy; the property applies extra parameters to the JDBC connection URL.

In the example described in this section, the Oracle JDBC thin client is used to explain how to configure IBM App Connect Enterprise to enable the encryption features in the JDBC client JARs. The following parameters are set to enable encryption of data between IBM App Connect Enterprise and an Oracle database:

- ORACLE.NET.ENCRYPTION_CLIENT=REQUIRED
- ORACLE.NET.ENCRYPTION_TYPES_CLIENT(AES256)
- ORACLE.NET.CRYPTO_CHECKSUM_CLIENT=REQUIRED
- ORACLE.NET.CRYPTO_CHECKSUM_TYPES_CLIENT=(SHA256,SHA1)

This configuration method is particularly suitable when there is a limited set of parameters, or when different parameters need to be customized for multiple JDBC Providers policies.

Procedure

Complete the following step:

- Set the encryption parameters as name-value pairs separated by a semicolon by issuing the **mqsichangeproperties** command. For example:

```
mqsichangeproperties integrationNodeName -c JDBCProviders -o Oracle -n environmentParms
-v
 oracle.net.encryption_client=REQUIRED;oracle.net.encryption_types_client=AES256;oracle.net.crypto_checksu
```

Using a vendor-specific configuration file to enable data encryption for JDBC connections

About this task

Alternatively, you can use a vendor-specific configuration file that contains the encryption parameters. The location of this file is specified by a JVM system property that is runtime environment of the integration server. Update the JDBC Providers policy to refer to the relevant part of the configuration file.

The encryption parameters can be set as stanzas in an Oracle configuration file called TNSNAMES.ORA. The location of the configuration file is made available to an integration server by using a Java system property.

Procedure

Complete the following steps:

- Make the location of the configuration file available and issue the **mqsichangeproperties** command to update **serverName**:
  a. Make available the location of the configuration file to the integration server by specifying a Java system property on the **mqsichangeproperties** command. For example:

```
mqsichangeproperties integrationNodeName -e integrationServerName  -o ComIbmJVMManager
-n jvmSystemProperty -v "-Doracle.net.tns_admin=Location of TNSNAMES.ORA file"
```

  b. Issue the **mqsichangeproperties** command to update the **serverName** property of the JDBC Providers policy to specify the name of the Oracle Net service in the TNSNAMES.ORA file. For example:

```
mqsichangeproperties integrationNodeName -c JDBCProviders -o Oracle -n serverName
-v Name of Oracle Net service
```

Support for Unicode and DBCS data in databases

You can manipulate Unicode Standard version 3.0 data in suitably configured databases, using ESQL, in nodes that access databases through ODBC. Support for the manipulation of Unicode data is not available for nodes that access databases through JDBC.

IBM App Connect Enterprise does not support DBCS-only columns in tables that are defined in databases; therefore, the following data types are not supported through ODBC or JDBC connections:

- NCHAR, NVARCHAR, NVARCHAR2, NCLOB (on Oracle)
- NCHAR, NVARCHAR, NTEXT, UNICHAR, UNIVARCHAR (on Sybase)
- NCHAR, NVARCHAR (on Informix)

GRAPHIC, VARGRAPHIC, LONGVARGRAPHIC, and DBCLOB data type support on DB2 is provided for App Connect Enterprise with the following limitations:

- Using the DB2 string functions with Unicode data can return unexpected results. For more information, see "Unicode string functions in DB2" on page 207.

Support for Unicode is available only for the generally-supported versions of the following database managers:

- IBM DB2 for Windows, Linux, UNIX, and z/OS operating systems.
- Oracle
- Microsoft SQL server
- Sybase Adaptive Server Enterprise (ASE)

For information about the versions of databases supported, see IBM App Connect Enterprise system requirements.

Support for the manipulation of Unicode data is not available for nodes that access databases that use JDBC; for example, DatabaseRetrieve and DatabaseRoute.

If you are using DB2:

- On Windows, Linux, and UNIX operating systems, your database must be created with code set `utf-8`.
- On all platforms, DB2 returns the lengths of strings in bytes, rather than characters; this response has implications for the behavior of string length-related ESQL functions.

  Some functions might fail, or function differently, when processed by the database. See "Unicode string functions in DB2" on page 207 for further information.

If you are using Oracle:

- Your database must be created with NLS_CHARACTERSET of AL32UTF8.
- Your ODBC data source definition must include the setting `ColumnSizeAsCharacter=1`.

  On UNIX and Linux platforms, this setting must be included in the appropriate stanza in the ODBC ini files.

  On Windows platforms, this string value must be added to the ODBC data source key in the registry.

  See "Enabling ODBC connections to the databases" on page 184 for further information.
- For 32-bit connections, you must set the variable NLS_LANG in the App Connect Enterprise environment to the value `<yourlanguage>_<yourterritory>.AL32UTF8`.

if you are using Microsoft SQL server:

- You must use NCHAR, NVARCHAR, and NTEXT data types for your column definitions.
- For App Connect Enterprise on UNIX and Linux platforms, your ODBC data source definition must include the setting `ColumnSizeAsCharacter=1`; this setting must be included in the appropriate stanza in the ODBC `.ini` files.

If you are using Sybase ASE:

- The default character set of your ASE server must be `UTF-8`.
- Your ODBC data source definition must include the settings `ColumnSizeAsCharacter=1` and `CharSet=UTF8`.

  On UNIX and Linux platforms, this setting must be included in the appropriate stanza in the ODBC `.ini` files.

  On Windows platforms, this string value must be added to the ODBC data source key in the registry.

  See "Enabling ODBC connections to the databases" on page 184 for further information.

Unicode string functions in DB2

When you use string functions in ESQL expressions, certain parameters refer to character positions or counts.

For example, with the SUBSTRING function, coding:

```
SUBSTRING('Hello World!' FROM 7 FOR 4)
```

results in the string `Worl` because 7 refers to the seventh character position, and 4 refers to four characters.

If the string `Hello World!` is represented in an ASCII code page, the seventh *byte* of that representation is the seventh character. However, in other code pages or encoding schemes (for example, some Unicode representations) the seventh character could start at byte 13, and 4 characters can occupy 8 bytes.

IBM App Connect Enterprise correctly handles this situation; that is, the numeric parameters and results of these string functions always refer to *characters* and not the bytes used to represent them.

In some situations, IBM App Connect Enterprise delegates expressions to a database engine for processing. For example, if there is a WHERE clause, in a SELECT function, applied to a database data source, the database is passed the WHERE clause if it can interpret all the functions in the expression.

If there are functions that are not supported by the database, IBM App Connect Enterprise passes only those parts of the expression that can be interpreted, retrieves an unfiltered record set, and performs the remaining filtering itself.

DB2 string functions use *byte* indexing and not *character* indexing. Therefore, for Unicode data, the meaning of certain functions differs from the IBM App Connect Enterprise functions, even though they can be ‘interpreted'.

Characters in Unicode UTF8 representation, for example, can occupy from 1-4 bytes, so that the seventh character can start anywhere from byte 7 to byte 25.

The following string functions are affected:

- INSERT function
- LEFT function
- LENGTH function
- OVERLAY function
- POSITION function
- RIGHT function
- SPACE function
- SUBSTRING function

These functions either take numeric parameters, or return numeric results that refer to indexes, or counts, of characters in a string.

When expressions involving these functions are passed to the DB2 database, and Unicode string data is manipulated in the database, the results can be unexpected, or an error might occur.

This error might also occur if, for example, an expression of this type is passed directly to the database by using the PASSTHRU function. In this situation, you could modify each expression yourself, as necessary, for the target database.

It is not possible to systematically modify expressions to avoid this problem and IBM App Connect Enterprise does not attempt to do so.

If the Unicode strings do not use any characters that, in UTF8 representation, occupy more than 1 byte each, the functions perform correctly.

Configuring properties to connect to external resources

You can use policies to prepare the environment for external resources, or change connection details for external resources.

About this task

The following topics describe how to prepare your environment to connect to external resources.

Configuring for Enterprise Information Systems

You can use policies to enable the WebSphere Adapters nodes in the integration node runtime environment to connect with Enterprise Information Systems such as SAP, Siebel, and PeopleSoft.

About this task

The following topics describe how to prepare the environment to connect to Enterprise Information Systems, and how to change the connection details for adapters without the need to redeploy them.

Preparing the environment for WebSphere Adapters nodes

Before you can use the WebSphere Adapters nodes, you must set up the IBM App Connect Enterprise runtime environment so that you can access the Enterprise Information System (EIS).

Before you begin

Read "WebSphere Adapters nodes" on page 1050.

About this task

To enable the WebSphere Adapters nodes in the IBM App Connect Enterprise runtime environment, configure the integration server with the location of the EIS provider JAR files and native libraries. (On Windows, the location of the JAR files cannot be a mapped network drive on a remote Windows computer; the directory must be local or on a Storage Area Network (SAN) disk.)

The integration server configuration file (`server.conf.yaml`) contains a section for connector providers, which defines the location of the required JAR files and native libraries, as you can see in the following example:

```
ConnectorProviders:
  SAPConnectorProvider:
    jarsURL: default_Path     # Set to the absolute path containing the SAP JCo JARs
    nativeLibs: default_Path  # Set to the absolute path containing the SAP JCo libraries
```

By default, the location is set to `default_Path`, which indicates that the JAR files and libraries can be found in the integration server's shared-classes directory.

Procedure

To configure the integration server with the location of required JAR files and libraries, complete the following steps.

1. The WebSphere Adapters nodes require libraries from the EIS vendors. For more information on how to obtain and use these libraries, see "Developing message flows that use WebSphere Adapters" on page 1106.
2. Use a YAML editor to open the `server.conf.yaml` file, then find the `ConnectorProviders` section.

   For more information, see "Configuring an integration server by modifying the server.conf.yaml file" on page 172.
3. Set the `jarsURL` property to the absolute path where the JAR files are stored.
4. Set the `nativeLibs` property to the absolute path where the native libraries are stored.
5. Save the `server.conf.yaml` file.

What to do next

When you have set up the environment for the WebSphere Adapters nodes, you can perform the preparatory tasks that are listed in "Developing message flows that use WebSphere Adapters" on page 1106.

Changing connection details for SAP adapters

SAP nodes can get SAP connection details from either the adapter component or a policy. By using a policy, you can change the connection details for adapters without the need to redeploy the adapters. To

pick up new values when a policy is created or modified, you must restart the integration server where the adapter is deployed.

Before you begin

- Read "WebSphere Adapters nodes" on page 1050 and "Overriding properties at run time with policies" on page 324 for background information.

About this task

Use the SAP Connection policy to change connection details for an SAP adapter. The SAP node reads all connection properties from the adapter component that it is configured to use. If a SAP Connection policy exists with the same name as the node's **`Primary adapter component`** property, the node uses the values that are defined in that policy to override the corresponding properties from the adapter. If any properties on the policy are set to an empty string, the values that are configured in the `.inadapter` or `.outadapter` file are used. The properties of the SAP policy are described in SAP Connection policy (SAPConnection).

Procedure

To use a policy to change connection details at run time, complete the following steps:

1. Use the Policy editor in the IBM App Connect Enterprise Toolkit to create a policy and select **SAP Connection** as the policy type (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).
2. Ensure that the name of the policy is the same as the name that is specified by the `Primary adapter component` property on the SAPInput or SAPRequest node (without the `.inadapter` or `.outadapter` suffix).
3. Set the appropriate properties in the policy for the settings that you want to use at run time.

   The default value for most properties in the policy is an empty string, which indicates that behavior is controlled by the `.inadapter` or `.outadapter` file for those properties. For more information, see SAP Connection policy (SAPConnection).
4. Deploy this policy in the default policy project for the integration server before you start the associated message flow.

   For information about configuring a default policy project, see "Configuring a default policy project" on page 329.

Changing connection details for Siebel adapters

Siebel nodes can get Siebel connection details from either the adapter component or a policy. By using a policy, you can change the connection details for adapters without the need to redeploy the adapters. To pick up new values when a policy is created or modified, you must restart the integration server where the adapter is deployed.

Before you begin

- Read "WebSphere Adapters nodes" on page 1050 and "Overriding properties at run time with policies" on page 324 for background information.

About this task

Use the Siebel Connection policy to change connection details for a Siebel adapter. The Siebel node reads all connection properties from the adapter component that it is configured to use. If a Siebel Connection policy exists with the same name as the node's **`Primary adapter component`** property, the node uses the values that are defined in that policy to override the corresponding properties from the adapter. If any properties on the policy are set to an empty string, the values that are configured in the `.inadapter` or `.outadapter` file are used. The properties of the Siebel policy are described in Siebel Connection policy (SiebelConnection).

You can also connect to different versions of Siebel by creating an EIS Siebel Providers policy and setting the location of the appropriate library files (see "Connecting to different versions of Siebel" on page 1125).

Procedure

To use a policy to change connection details at run time, complete the following steps:

1. Use the Policy editor in the IBM App Connect Enterprise Toolkit to create a policy and select **Siebel Connection** as the policy type (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).
2. Ensure that the name of the policy is the same as the name that is specified by the `Primary adapter component` property on the SiebelInput or SiebelRequest node (without the `.inadapter` or `.outadapter` suffix).
3. Set the appropriate properties in the policy for the settings that you want to use at run time.

   The default value for most properties in the policy is an empty string, which indicates that behavior is controlled by the `.inadapter` or `.outadapter` file for those properties. For more information, see Siebel Connection policy (SiebelConnection).
4. Deploy this policy in the default policy project for the integration server before you start the associated message flow.

   For information about configuring a default policy project, see "Configuring a default policy project" on page 329.

Changing connection details for PeopleSoft adapters

PeopleSoft nodes can get PeopleSoft connection details from either the adapter component or a policy. By using a policy, you can change the connection details for adapters without the need to redeploy the adapters. To pick up new values when a policy is created or modified, you must restart the integration server where the adapter is deployed.

Before you begin

- Read "WebSphere Adapters nodes" on page 1050 and "Overriding properties at run time with policies" on page 324 for background information.

About this task

Use the PeopleSoft Connection policy to change connection details for a PeopleSoft adapter. The PeopleSoft node reads all connection properties from the adapter component that it is configured to use. If a PeopleSoft Connection policy exists with the same name as the node's **`Primary adapter component`** property, the node uses the values that are defined in that policy to override the corresponding properties from the adapter. If any properties on the policy are set to an empty string, the values that are configured in the `.inadapter` or `.outadapter` file are used. The properties of the PeopleSoft policy are described in PeopleSoft Connection policy (PeopleSoftConnection).

Procedure

To use a policy to change connection details at run time, complete the following steps:

1. Use the Policy editor in the IBM App Connect Enterprise Toolkit to create a policy and select **PeopleSoft Connection** as the policy type (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).
2. Ensure that the name of the policy is the same as the name that is specified by the `Primary adapter component` property on the PeopleSoftInput or PeopleSoftRequest node (without the `.inadapter` or `.outadapter` suffix).

3. Set the appropriate properties in the policy for the settings that you want to use at run time.

   The default value for most properties in the policy is an empty string, which indicates that behavior is controlled by the `.inadapter` or `.outadapter` file for those properties. For more information, see PeopleSoft Connection policy (PeopleSoftConnection).
4. Deploy this policy in the default policy project for the integration server before you start the associated message flow.

   For information about configuring a default policy project, see "Configuring a default policy project" on page 329.

Changing connection details for JD Edwards adapters

JDEdwards nodes can get JD Edwards EnterpriseOne connection details from either the adapter component or a policy. By using a policy, you can change the connection details for adapters without the need to redeploy the adapters. To pick up new values when a policy is created or modified, you must restart the integration server where the adapter is deployed.

Before you begin

- Read "WebSphere Adapters nodes" on page 1050 and "Overriding properties at run time with policies" on page 324 for background information.

About this task

Use the JDEdwards Connection policy to change connection details for a JD Edwards adapter. The JD Edwards node reads all connection properties from the adapter component that it is configured to use. If a JDEdwards Connection policy exists with the same name as the node's **`Primary adapter component`** property, the node uses the values that are defined in that policy to override the corresponding properties from the adapter. If any properties on the policy are set to an empty string, the values that are configured in the `.inadapter` or `.outadapter` file are used. The properties of the JD Edwards policy are described in JDEdwards Connection policy (JDEdwardsConnection).

Procedure

To use a policy to change connection details at run time, complete the following steps:

1. Use the Policy editor in the IBM App Connect Enterprise Toolkit to create a policy and select **JD Edwards Connection** as the policy type (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).
2. Ensure that the name of the policy is the same as the name that is specified by the `Primary adapter component` property on the JDEdwardsInput or JDEdwardsRequest node (without the `.inadapter` or `.outadapter` suffix).
3. Set the appropriate properties in the policy for the settings that you want to use at run time.

   The default value for most properties in the policy is an empty string, which indicates that behavior is controlled by the `.inadapter` or `.outadapter` file for those properties. For more information, see JDEdwards Connection policy (JDEdwardsConnection).
4. Deploy this policy in the default policy project for the integration server before you start the associated message flow.

   For information about configuring a default policy project, see "Configuring a default policy project" on page 329.

Configuring EIS connections to expire after a specified time

You can configure connections to SAP, Siebel, and PeopleSoft to expire after a specified time by using a policy.

About this task

You can use the `Connection idle timeout` property on a policy to control the number of connections to SAP, Siebel and PeopleSoft by closing connections that have not been used for a specified time.

Procedure

1. Use the Policy editor in the IBM App Connect Enterprise Toolkit to create a policy and select an appropriate policy type, such as **SAP Connection** (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).
2. Ensure that the name of the policy is the same as the name that is specified by the `Primary adapter component` property on the message flow node that you want to override.

   Specify the name of the policy project and the policy on the message flow node in the format {*policyProjectName*}:*PolicyName*.
3. Set the `Connection idle timeout` property on the policy to the number of seconds for which the connection can be idle before it is closed.

   The default value for this property is 0 (zero) seconds, indicating that no timeout occurs. Note that new connections to SAP are opened with different user IDs; therefore do not set this property to zero if you are using identity propagation.
4. Deploy this policy before you start the associated message flow.

Advanced configuration properties when using IBM Sterling Connect:Direct nodes

CDInput and CDOutput nodes can get connection details and staging directories in conjunction with a policy.

Before you begin

- Read "IBM Sterling Connect:Direct overview and concepts" on page 953 for background information.

About this task

Use the Connect:Direct Server policy to change connection details for an IBM Sterling Connect:Direct node (see Connect:Direct Server policy (CDServer)).

Use the following scenarios as examples of how you use the staging directories.

Procedure

- **What should I do if I have IBM App Connect Enterprise and IBM Sterling Connect:Direct on the same machine, and want the files to be staged for output within the IBM App Connect Enterprise work path?**

  You need not set any of the properties; the default settings allow this to happen.
- **Output**
  a) **What should I do if I have IBM App Connect Enterprise and IBM Sterling Connect:Direct on the same machine but want to use a specified location to create files for output?**

  Set the `Integration node path to staging directory` property on the policy to the location that you want. You do not need to set the `Connect:Direct path to staging`

`directory` property, because IBM App Connect Enterprise assumes this to be the same as the `Integration node path to staging directory`.

b) **Can I have IBM App Connect Enterprise and IBM Sterling Connect:Direct on separate machines?**

You can, but you must ensure that both machines have:

– Access to the same shared file system.

– The same timezone setting.

As IBM Sterling Connect:Direct does not support NFS file systems on z/OS, this configuration does not work on z/OS

c) **Can I have this shared file system mounted at different places on my IBM App Connect Enterprise and IBM Sterling Connect:Direct machines for platforms other than Windows?**

Set the `Integration node path to staging directory` property to be the location where it is mounted on the IBM App Connect Enterprise machine, and the `Connect:Direct path to staging directory` property to where it is mounted on the IBM Sterling Connect:Direct machine.

d) **Can I have this shared file system mounted at different places on my IBM App Connect Enterprise and IBM Sterling Connect:Direct machines for Windows platforms?**

You must use the `\\hostname\directory` path syntax to the shared drive, rather than a mapped drive letter. In addition, the user ID that is accessing the `\\hostname\directory` path (the IBM App Connect Enterprise or IBM Sterling Connect:Direct user ID, depending on which one is running on Windows), must have full (write) access to the file system, using the same password.

Set the `Integration node path to staging directory` to be the location where it is mounted on the IBM App Connect Enterprise machine, and the `Connect:Direct path to staging directory` to where it is mounted on the IBM Sterling Connect:Direct machine.

- **Input**

a) **Can I process files in the CDInput node if the IBM App Connect Enterprise and receiving Connect:Direct server are on different machines?**

You can, but you must ensure that both machines have access to the same shared file system and the same time zone setting.

As IBM Sterling Connect:Direct does not support NFS file systems on z/OS, this configuration does not work on z/OS

b) **Can I have this shared file system mounted at different places on my IBM App Connect Enterprise and IBM Sterling Connect:Direct machines for platforms other than Windows?**

Set the `Integration node path to input directory` property to be the location where it is mounted on the IBM App Connect Enterprise machine, and the `Connect:Direct path to input directory` property to where it is mounted on the IBM Sterling Connect:Direct machine.

c) **Can I have this shared file system mounted at different places on my IBM App Connect Enterprise and IBM Sterling Connect:Direct machines for Windows platforms?**

You must use the UNC path syntax to the shared drive, rather than a mapped drive letter. In addition, the user ID that is accessing the UNC path (the IBM App Connect Enterprise or IBM Sterling Connect:Direct user ID, depending on which one is running on Windows), must have full (write) access to the file system, using the same password.

Set the `Integration node path to input directory` property to be the location where it is mounted on the IBM App Connect Enterprise machine, and the `Connect:Direct path to input directory` property to where it is mounted on the IBM Sterling Connect:Direct machine.

Configuring for IMS

You can enable the IMS nodes in the integration node runtime environment to connect with the IMS system.

About this task

The following topics describe how to prepare the environment to connect to the IMS system, and how to change the connection details without the need to redeploy your message flow.

Preparing the environment for IMS nodes

Before you can use the IMS nodes, you must set up the runtime environment so that you can access the IMS system.

Before you begin

Read "IBM Information Management System (IMS)" on page 1146.

About this task

Complete the following steps to ensure that IBM App Connect Enterprise can connect to the IMS system.

Procedure

1. Ensure that IMS Connect is installed and started on the IMS system.
2. Use the **mqsisetdbparms** command to set security details in the integration server store.

   For example, to associate a user ID and password pair with an IMS Connect connection, run the **mqsisetdbparms** command as shown:

```
mqsisetdbparms -w c:\workdir\ACEServ1 -n ims::mySecurityIdentity -u myuserid -p mypassword
```

Preparing the environment for IBM MQ File Transfer Edition nodes

Prepare the file system and queue managers, and determine the name of the integration node agent.

About this task

Information about file transfers is held on storage queues that are controlled by IBM MQ, so you must install IBM MQ on the same computer as your integration node if you want to use the capabilities provided by the FTEInput and FTEOutput nodes. For information about installing and using IBM MQ with IBM App Connect Enterprise, see "Installing IBM MQ" on page 96.

- "Preparing the file system" on page 215
- "Preparing the queue manager" on page 216
- "Setting the coordination queue manager" on page 216
- "Naming integration servers" on page 217
- "Determining the agent name" on page 218

Preparing the file system

IBM App Connect Enterprise uses a location in its work path to store transfers to remote agents. It uses another location as the default directory for received files. The high-level directory path for both locations is:

- *workpath*/common/FTE

Ensure that enough space is available here for files that you will transfer to and from the integration node by IBM MQ File Transfer Edition.

Preparing the queue manager

Storage queues that hold file transfer information are owned by the queue manager that is specified on the integration node, and you specify this queue manager by using the **-q** property of the **mqsicreatebroker** command; see “Creating an integration node” on page 114 and command.

You must also create the system queues required by the FTEInput and FTEOutput nodes; see “Creating the default system queues on an IBM MQ queue manager” on page 99. A set of IBM MQ script (MQSC) commands is also provided, to enable you to create artifacts that are required by the agent and coordination manager; for more information, see “Scripts to create artifacts required for IBM MQ File Transfer Edition” on page 218.

Setting the coordination queue manager

When a message flow that contains a IBM MQ File Transfer Edition node is deployed to an integration server, an agent is automatically created and started in that integration server. By default, the agent uses the queue manager that is specified on the integration node as the coordination queue manager.

- If the queue manager specified on the integration node is being used as the coordination queue manager, the integration node configures it as a coordination queue manager.
- If you are using a different queue manager as the coordination queue manager, refer to the WebSphere File Transfer Edition product documentation for information about how to configure it as a coordination queue manager.

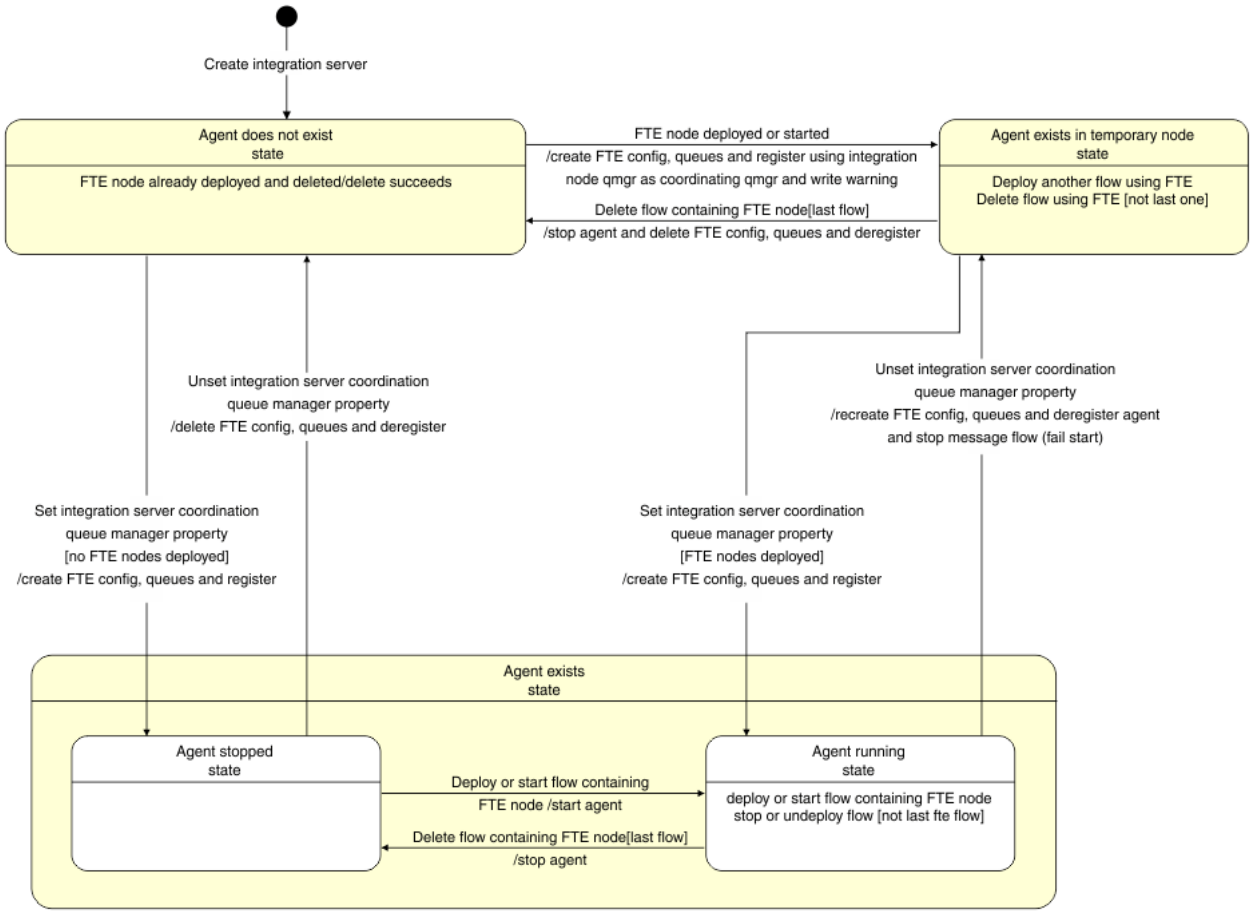
Unless you have previously defined the coordination queue manager, the agent is temporary; it is deleted when the flow is undeployed or the integration node is stopped. This behavior is acceptable in a test environment. However, for production, the administrator must specify the coordination queue manager for the integration server. Specifying a coordination queue manager has the following effects:

Ensures that the correct queue manager is used when the agent is created.

Makes the agent permanent. If a coordination queue manager has been defined, the agent is deleted only after you undefine the coordination queue manager (for example, by setting it to an empty string), and restart the integration server.

A warning is written to the log if the coordination queue manager is not changed from the default.

The following state diagram illustrates how the presence of nodes and a defined coordination queue manager affect the state of the agent.



About this task

Use one of the following methods to set the coordination queue manager.

Naming integration servers

About this task

The integration server name is used to form the queue name for IBM MQ File Transfer Edition queues. Consequently, the names of your integration servers must conform to the rules for naming IBM MQ objects. You cannot deploy a flow that contains a IBM MQ File Transfer Edition node unless this requirement is met. Permitted characters are:

- Uppercase A-Z
- Lowercase a-z (but there are restrictions on the use of lowercase letters for z/OS console support)

  On systems using EBCDIC Katakana you cannot use lowercase characters.
- Numerics 0-9
- Period (.)
- Forward slash (/)
- Underscore (_)
- Percent sign (%)

See the IBM MQ product documentation online for full details of naming requirements.

Determining the agent name

About this task

To send a file to a given integration server, users need to know the name of the agent that the integration node creates. The agent name is derived from *IntegrationNode*.*IntegrationServer*, and is not configurable. The total name length is limited to 28 characters, with a maximum 12 characters for the integration node name, and 15 characters for the integration server. Integration node and integration server names longer than these limits are truncated to form the agent name. The name must be a valid format for generating MQ Series queue name. Ensure that:

- The integration node name is 12 characters or fewer (or at least unique in the first 12 characters).
- The integration server names are 15 characters or fewer (or at least unique in the first 15 characters).
- The integration node and integration servers do not contain any characters that are invalid for queue names.
- The *integrationnode*.*integrationserver* tuples are all unique, even if case is ignored.

The value used is written to the event log in message BIP3358. Use one of the following methods to determine the agent name.

Procedure

Optional: Use the **mqsireportproperties** command.

For example, to display the FTE agent name for integration server FTESAMPLE in integration node INODE:

```
mqsireportproperties INODE -e FTESAMPLE -o FTEAgent -n agentName
```

If the agent has been created, the command returns the agent name. If the agent has not been created, the command returns an empty string.

Scripts to create artifacts required for IBM MQ File Transfer Edition

IBM MQ script (MQSC) commands for use if IBM App Connect Enterprise cannot create all the required artifacts, or you want to create them yourself.

Queues for the FTE agent

Before running the following command, replace *Agent name* with the name of your FTE agent; see "Determining the agent name" on page 218.

```

Preparing the environment for callable flows

To split message flow processing between different locations, you must set up secure data routing.

Before you begin

Read the concept information in “Callable message flows” on page 491.

About this task

You can split message flows so that you do processing in different locations, such as IBM App Connect Enterprise and IBM App Connect on IBM Cloud, which can improve performance and promote reuse.

If you are splitting processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, your flows communicate by using a Switch server and connectivity agents. The Switch server is a special kind of integration server that routes data. The connectivity agents contain the certificates that your flows require to communicate securely with the Switch server. The connectivity agents must be running in both the integration servers that are running on the integration node where you have deployed your flow.

The steps that you need to take to prepare your environment differ depending on whether you are splitting processing between different integration servers, or between IBM App Connect Enterprise and IBM Integration Bus on Cloud or IBM App Connect on IBM Cloud. For more information, see the following tasks.

Procedure

To prepare the environment for callable flows, complete one of the following tasks.

- “Preparing the environment to split processing between different integration servers” on page 222
- “Preparing the environment to split processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud” on page 225

Preparing the environment to split processing between different integration servers

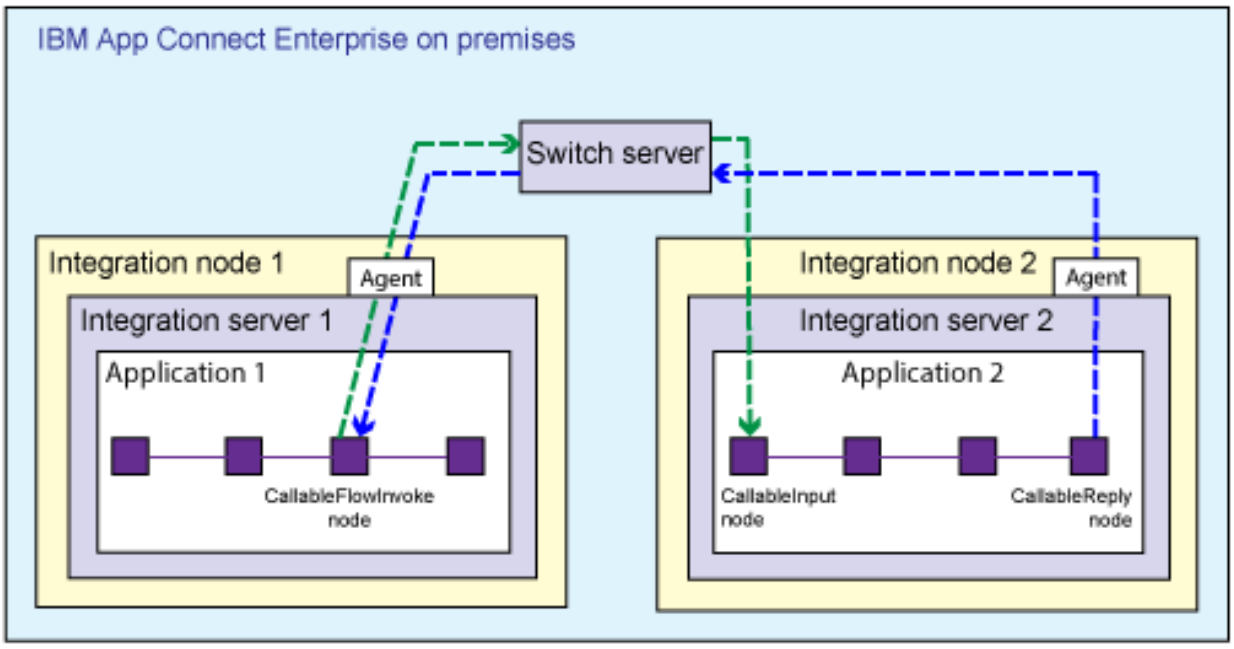
When you split message flow processing between different integration servers, you must configure a data router and a connectivity agent. The integration servers can be running on different integration nodes.

Before you begin

Read the concept information in “Callable message flows” on page 491.

About this task

When you split processing between different integration servers, your flows communicate securely by using a Switch server and connectivity agents. The Switch server is a special kind of integration server that routes data. The connectivity agents contain the certificates that your flows require to communicate securely with the Switch server. A connectivity agent must be running in each integration server where you have deployed message flows.



If your callable flows and the flows that call them are ***all*** deployed on premises, you must create and configure the Switch server on premises. You must run a command that creates some configuration files. You use one of the configuration files to create the Switch server, and the other file to configure connectivity agents for each integration server where you have deployed callable flows or flows that call them. The steps for this procedure are given in this topic.

This on-premises scenario is supported on Windows and Linux only.

If you are splitting processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, the Switch server is created and managed for you in the cloud. You must download an agent configuration file from the cloud, and use it to configure the on-premises connectivity agent for each integration server. For more information about configuring connectivity agents for use with IBM App Connect on IBM Cloud, see "Preparing the environment to split processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud" on page 225.

Procedure

To prepare the environment to split processing between integration servers on premises, complete the following steps.

1. Start an IBM App Connect Enterprise command environment.
2. Create the required configuration files, by running the **iibcreateswitchcfg** command.
   You need to run the command in a directory for which you have permission to write. Alternatively, you can specify an output directory. For example, the following command creates the configuration files and saves them in the `temp` directory.

   Windows On Windows:

   ```
   iibcreateswitchcfg /output c:\temp
   ```

   Linux On Linux:

   ```
   iibcreateswitchcfg -output /temp
   ```

   If this command is successful, you see the following responses:

   ```
   Generated self signed certificate file 'c:\temp\adminClient.p12'
   Generated switch configuration file 'c:\temp\switch.json'
   ```

```
Generated agentx configuration file 'c:\temp\agentx.json'
```

This command creates two JSON configuration files, and a certificate, which is reserved for future use. One file (`switch.json`) is used to create the Switch server. The other file (`agentx.json`) is used to configure the agent for each integration server where your flows are deployed.

3. Create the Switch server, by running the **iibswitch** command to use the configuration file (`switch.json`) that you created in step 2.

   Windows For example, on Windows:

   ```
   iibswitch create switch /config c:\temp\switch.json
   ```

   Linux On Linux:

   ```
   iibswitch create switch -c /temp/switch.json
   ```

   If the command is successful, you see a "Successful command completion" response. The Switch server is created in a special integration node called ACESWITCH_NODE_V11.

4. Optional: To test that the Switch server is created and running, run the following command: **mqsilist** ACESWITCH_NODE_V11.

   If the Switch server is running, you see the following response:

   ```
   BIP1286I: Integration server 'IIBSWITCH_SERVER' on integration node 'ACESWITCH_NODE_V11' is
    running.
   ```

5. Configure a connectivity agent for each integration server where you have deployed callable flows or flows that call them.

   You can configure the agent by copying the configuration file, `agentx.json` (that you created in step 2), to the server's `iibswitch/agentx` directory.

   - For an independent integration server: *work directory*`/config/iibswitch/agentx`
   - For an integration server under an integration node: *$MQSI_WORKPATH*`/config/`*Node_name*`/`*Server_name*`/iibswitch/agentx`

   For each affected integration server, the agent should automatically establish a connection to the Switch server. For example, in the App Connect Enterprise console for an independent integration server you should see the following messages:

   ```
   The connection agent for remote callable flows has established a connection to the Switch
    server with URL 'wss://localhost:9011'.
   The integration server component 'agentx' has been started.
   ```

   Similarly, in the Windows Application log, you should see the following messages for an integration server (N101ISAA) under an integration node (NODEIPL01):

   ```
   ( NODEIPL01.N101ISAA ) The connection agent for remote callable flows has established a
    connection to the Switch server with URL ''wss://localhost:9011''.

   A connection agent for remote callable flows has been configured on this integration server.
    The connection agent has successfully connected to the Switch server.

   No response required.
   ----------------------------------------------------------------------------------------------
   ( NODEIPL01.N101ISAA ) The integration server component ''agentx'' has been started.

   The specified component has been started and is available for use.

   No response required.
   ```

Results

A message flow that is deployed to one configured integration server can now communicate securely with a message flow on another configured integration server. For more information about developing these message flows, see “Developing synchronously callable message flows” on page 600.

Preparing the environment to split processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud

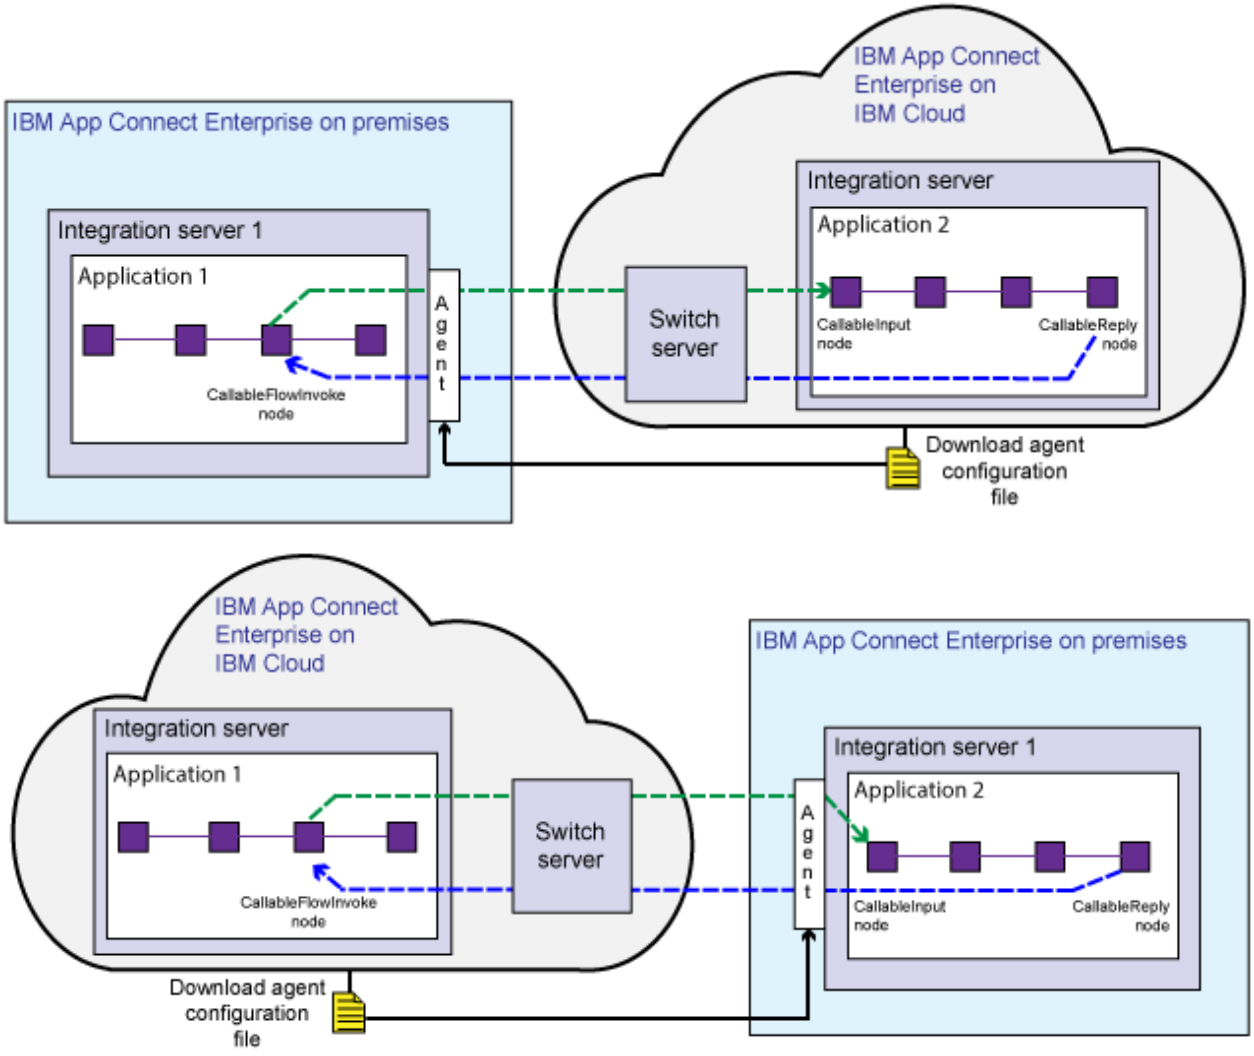
When you split message flow processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, you must configure a connectivity agent.

Before you begin

These instructions assume that you have IBM App Connect Enterprise installed on premises, and that you have created an App Connect service in IBM Cloud.

About this task

When you split processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, your flows communicate by using a Switch server and connectivity agent. The Switch server, which routes data, is managed for you by IBM App Connect on IBM Cloud. The connectivity agent contains the certificates that your flows require to communicate securely with the Switch server. A connectivity agent must be running in the IBM App Connect Enterprise integration server where you have deployed your on-premises message flows.



The Switch server is already created in IBM App Connect on IBM Cloud. You must download an agent configuration file from the cloud, and use it to configure the on-premises connectivity agent. Your callable flows use this agent to communicate with each other securely, through the Switch server.

Procedure

To prepare the environment to split processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, complete the following steps.

1. In IBM App Connect on IBM Cloud, click **Callable flows**  .

   If you have not configured callable flows before, the list will be empty.
2. Click **Connect callable flows**.

   A dialog box opens to set up your agent.
3. Click **Download the configuration** and save the agent configuration file (`agentx.json`) to convenient location, and then use it to configure the on-premises integration servers.

   Copying the `agentx.json` file, to the on-premises server's `iibswitch/agentx` directory.

   - For an independent integration server: *work directory*`/config/iibswitch/agentx`
   - For an integration server under an integration node: *$MQSI_WORKPATH*`/config/`*Node_name*`/`*Server_name*`/iibswitch/agentx`

   For each affected integration server, the agent should automatically establish a connection to the Switch server. For example, in the App Connect Enterprise console for an independent integration server you should see the following messages:

   ```
   The connection agent for remote callable flows has established a connection to the Switch
    server with URL 'wss://ibm-sw-lfcxnlolwumbamsnq.eu-gb.ace.ibm.com:443/'.
   The integration server component 'agentx' has been started.
   ```

   Similarly, in the Windows Application log, you should see the following messages for an integration server (N101ISAA) under an integration node (NODEIPL01):

   ```
   ( NODEIPL01.N101ISAA ) The connection agent for remote callable flows has established
    a connection to the Switch server with URL ''wss://ibm-sw-lfcxnlolwumbamsnq.eu-
   gb.ace.ibm.com:443/''.

   A connection agent for remote callable flows has been configured on this integration server.
    The connection agent has successfully connected to the Switch server.

   No response required.
   ----------------------------------------------------------------------------------------------
   ( NODEIPL01.N101ISAA ) The integration server component ''agentx'' has been started.

   The specified component has been started and is available for use.

   No response required.
   ```

   Note: If a message flow on one on-premises integration server calls a message flow on other on-premises integration servers, and one of those integration servers also uses the callable flows technique to interact with flows in IBM App Connect on IBM Cloud, you need to copy the downloaded `agentx.json` file to all those on-premises integration servers (so that they all continue to use the same Switch server, now on cloud). For example, consider the initial on-premises scenario where a flow on server A calls a flow on server B, with both servers configured with the local `agentx.json` (to use the on-premises Switch server). Later, a flow in IBM App Connect on IBM Cloud is added to call the flow on server B, so server B needs to be configured with the `agentx.json` downloaded from the cloud (to use the on-cloud Switch server). Also, to continue to use the same Switch server as server B, server A needs to be configured with the `agentx.json` downloaded from the cloud (to use the on-cloud Switch server)

4. In IBM App Connect on IBM Cloud, you can check that the on-premises agent can connect to the Switch server in the cloud.

   You can perform the following checks:

   - Refresh the Callable flows page. This should list all the callable and calling flows on premises and on cloud; for example:
   - In the **Connect callable flows** dialog, click **Test your agent**. This should return the number of on-premises agents found.

   If the test is successful, close the dialog box.

Results

The callable flows technique can be used between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, and between integration servers in IBM App Connect Enterprise configured to use the on-cloud Switch server.

For more information about developing these message flows, see "Developing synchronously callable message flows" on page 600.

Configuring for JMS

You can use policies to configure IBM App Connect Enterprise for JMS.

About this task

The following topics describe how to configure IBM App Connect Enterprise for JMS.

Enabling a JMS provider's proprietary API

Some JMS providers provide an alternative interface to the standard JMS specification for particular JMS API calls. In these cases, IBM supplies a Java class to interface with that proprietary API.

About this task

For example, BEA WebLogic uses a component called a *Client Interposed Transaction Manager* to allow a JMS client to obtain a reference to the XAResource that is associated with a user transaction.

If the WebSphere IBM Integration JMS nodes use BEA WebLogic as the JMS provider, and the nodes must participate in a globally coordinated message flow, you must modify the policy properties that are associated with that vendor (see JMS Providers policy (JMSProviders)). The following table shows the properties that have been added to the policy for BEA WebLogic.

JMS provider	Property	Purpose	Default value
BEA_WebLogic	`Proprietary API handler`	The name of the IBM supplied Java class to interface with a JMS provider's proprietary API.	`com.ibm.broker.apihandler.BEAWebLogicAPIHandler`
	`Proprietary API attribute 1`	The Initial Context Factory class name for the vendor	`weblogic.jndi.WLInitialContextFactory`
	`Proprietary API attribute 2`	The URL of the WebLogic bindings	*URL JNDI bindings*
	`Proprietary API attribute 3`	The DNS name of the JMS server	*Server name*

In the list of JMS provider policy templates, the name of the IBM supplied Java class is set to the default value for the `Proprietary API handler` property. Typically, you do not need to change this value, unless you are instructed to do so by an IBM Service team representative.

Procedure

- Use the Policy editor to modify values of the properties for this JMS provider.
- If you have defined a JMS provider policy, set the value for the `Proprietary API handler` property manually.

Connecting to different versions of the same JMS provider

To use different versions of the same JMS provider, create a policy for the JMS provider, and set the location of the JAR files to a unique path.

Procedure

To connect to two versions of the same JMS provider (for example, JBoss), complete the following steps.

1. Create a separate JMS Providers policy for each version of the JMS provider.

   For more information, see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327.
2. Set the **`Type 4 driver class JARs URL`** property of the JMS Providers policy to a unique path.

   For a description of the properties of the JMS Providers policy, see JMS Providers policy (JMSProviders).

Configuring the JMSInput node for batch message processing

Configure JMS message flows to send a batch acknowledgment for receipt of non-transactional JMS messages.

About this task

When the JMSInput node works in non-transactional mode, receipt and acknowledgment of messages take place in one step, followed by the message processing. In some scenarios, this acknowledgment response to the JMS server for each message might create an unacceptable level of network traffic. For example, using this messaging model to receive JMS messages across a wide area network that is already handling large volumes of traffic might result in non-optimal throughput rates for JMS messages.

The JMSInput node can acknowledge message receipt in batches rather than individually for non-transactional messages. Batch acknowledgment is enabled by using the JMS Providers policy properties **`clientAckBatchSize`** and **`clientAckBatchTime`**. You can set these properties separately, or use them together, to tune the number of messages that are received and processed by the node before an acknowledgment response is returned to the source JMS server.

clientAckBatchSize
: This an integer value that represents the threshold number of messages received before the batch acknowledgment is sent.

clientAckBatchTime
: This is an integer value that represents the length, in milliseconds, of a repeating interval. At the end of each interval a batch acknowledgment is sent for all unacknowledged non-transactional JMS messages that were received during the preceding interval.

A batch acknowledgment is also sent when:

- There are no more input messages on the JMS server
- An error occurs during message processing. In this case, all previous messages in the batch that were successfully processed are first acknowledged, before handling the error.
- The message flow stops.

To disable batch acknowledgment, set both **`clientAckBatchSize`** and **`clientAckBatchTime`** to `0`.

Configuring for email

You can use policies to enable the EmailOutput node and EmailInput node in the IBM App Connect Enterprise runtime environment to connect with email servers.

About this task

The following topics describe how to prepare the environment to connect to email servers, and how to change the connection details without the need to redeploy your message flow.

- "Changing connection information for the EmailOutput node" on page 946
- "Changing connection information for the EmailInput node" on page 951

Configuring properties for TCP/IP

If you are deploying message flows that contain TCP/IP nodes, and those nodes use a policy, create and deploy your TCPIPClient or Server policies before the message flows are deployed.

Before you begin

For background information about the TCP/IP transport, see "TCP/IP data transfer" on page 911 and "Connection management" on page 917.

Procedure

- Create a TCPIPClient or TCPIPServer policy by using the Policy editor in the IBM App Connect Enterprise Toolkit, as described in "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327.

  For more information about these policies, see TCPIP Client policy (TCPIPClient) and TCPIP Server policy (TCPIPServer).

Configuring internal resources required by message flows

You can use policies to configure the internal resources that are required by some message flows.

About this task

The following topics describe how to configure the storage of events for certain message flow nodes.

Configuring the storage of events for aggregation nodes

You can use an Aggregation policy to control the storage of events for AggregateControl and AggregateReply nodes.

About this task

Information about the state of in-flight messages is held on storage queues that are controlled by IBM MQ. The storage queues that hold the state information are owned by the queue manager that is associated with the integration server.

If you are using aggregation on an integration server that is managed by an integration node, you must install IBM MQ on the same computer as your integration node in order to use the capabilities that are provided by the aggregation nodes. If you are using aggregation on an independent integration server, you can use a remote default queue manager to control the system queues, without the need to install IBM MQ on the same machine as the integration server. Interactions between an independent integration server and IBM MQ can use a client connection to a remote queue manager, by using a default policy setting. For more information about using a remote default queue manager, see "Using a remote default queue manager" on page 750 and "Configuring an integration server to use a remote default queue manager" on page 751.

If the integration server has the necessary permissions to create the default system queues, they are created automatically when a flow containing aggregation nodes is deployed. If the default queues are not created automatically, you can create them manually by running the **iib_createqueues** command, as described in "Creating the default system queues on an IBM MQ queue manager" on page 99.

By default, the storage queues used by all aggregation nodes are:

- SYSTEM.BROKER.AGGR.CONTROL
- SYSTEM.BROKER.AGGR.REPLY
- SYSTEM.BROKER.AGGR.REQUEST
- SYSTEM.BROKER.AGGR.UNKNOWN
- SYSTEM.BROKER.AGGR.TIMEOUT

However, you can control the queues that are used by different aggregation nodes by creating alternative queues containing a *QueuePrefix*, and using an Aggregation policy to specify the names of those queues for storing events.

Follow these steps to specify the queues that are used to store event states, and to set the expiry time of an aggregation:

Procedure

1. Create the storage queues to be used by the aggregation nodes.

   The following queues are required:

   - SYSTEM.BROKER.AGGR.*QueuePrefix*.CONTROL
   - SYSTEM.BROKER.AGGR.*QueuePrefix*.REPLY
   - SYSTEM.BROKER.AGGR.*QueuePrefix*.REQUEST
   - SYSTEM.BROKER.AGGR.*QueuePrefix*.UNKNOWN
   - SYSTEM.BROKER.AGGR.*QueuePrefix*.TIMEOUT

   The *QueuePrefix* variable can contain any characters that are valid in an IBM MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, SET1 and SET.1 are valid queue prefixes, but .SET1 and SET1. are invalid.

   If you do not create the storage queues, IBM App Connect Enterprise creates the set of queues when the node is deployed; these queues are based on the default queues. If the queues cannot be created, the message flow is not deployed.
2. Create an Aggregation policy (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).
   a) You can create a policy to be used with either a specific aggregation or with all aggregations in an integration server. If the policy is to be used with a specific aggregation, create the policy with the same name as the name that you specify in the `Aggregate name` property on the AggregateControl and AggregateReply nodes.

      To specify a default Aggregation policy for all message flows that are deployed to an integration server, set the **Aggregation** property in the `server.conf.yaml` file to the name of an Aggregation policy. For information about setting properties in the `server.conf.yaml` file, see "Configuring an integration server by modifying the server.conf.yaml file" on page 172. If the default policy is in the default policy project, you do not need to specify the name of the policy

project. If the default policy is in a non-default policy project, qualify the name of the policy with the name of the policy project in the format {*policyProjectName*}:*PolicyName*

b) Set the **Queue prefix** property of the Aggregation policy to the required value (see Aggregation policy).

c) Optional: Set the **Timeout** property of the Aggregation policy to control the expiry time of an aggregation.

If you delete the Aggregation policy, the storage queues are not deleted automatically when the policy is deleted, so you must delete them separately.

3. In the AggregateControl and AggregateReply nodes, ensure that the name of the Aggregation policy is the same as the name that is specified in the `Aggregate name` property on the **Basic** tab; for example, `myAggregation`.

   If there is no Aggregation policy with the same name as the `Aggregate name` node property value, and if there is a default Aggregation policy specified in the `server.conf.yaml` file, that Aggregation policy is used instead.

What to do next

The properties for the policy are not used by the integration server until you restart or redeploy the message flow, or restart the integration server.

Configuring the storage of events for Collector nodes

You can use a Collector policy to control the storage of events for Collector nodes.

About this task

Information about the state of in-flight messages is held on storage queues that are controlled by IBM MQ. The storage queues that hold the state information are owned by the queue manager that is associated with the integration server.

If you are using message collections on an integration server that is managed by an integration node, you must install IBM MQ on the same computer as your integration node in order to use the capabilities that are provided by the Collector node. If you are using message collections on an independent integration server, you can use a remote default queue manager to control the system queues, without the need to install IBM MQ on the same machine as the integration server. Interactions between an independent integration server and IBM MQ can use a client connection to a remote queue manager, by using a default policy setting. For more information about using a remote default queue manager, see "Using a remote default queue manager" on page 750 and "Configuring an integration server to use a remote default queue manager" on page 751.

If the integration server has the necessary permissions to create the default system queues, they are created automatically when a flow that contains Collector nodes is deployed. If the default queues are not created automatically, you can create them manually by running the **iib_createqueues** command, as described in "Creating the default system queues on an IBM MQ queue manager" on page 99.

By default, the storage queues used by all Collector nodes are:

- SYSTEM.BROKER.EDA.EVENTS
- SYSTEM.BROKER.EDA.COLLECTIONS

These queues are also used by the Resequence node.

However, you can control the queues that are used by different Collector nodes by creating alternative queues that contain a *QueuePrefix* variable, and by using a Collector policy to specify the names of those queues for storing events.

Follow these steps to specify the queues that are used to store event states, and to set the expiry for the collection:

Procedure

1. Create the storage queues to be used by the Collector node.

   The following queues are required:

   - SYSTEM.BROKER.EDA.*QueuePrefix*.EVENTS
   - SYSTEM.BROKER.EDA.*QueuePrefix*.COLLECTIONS

   The *QueuePrefix* variable can contain any characters that are valid in an IBM MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, SET1 and SET.1 are valid queue prefixes, but .SET1 and SET1. are invalid.

   If you do not create the storage queues, IBM App Connect Enterprise creates the queues when the node is deployed; these queues are based on the default queues. If the queues cannot be created, the message flow is not deployed.
2. Create a Collector policy (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).
   a) You can create a policy to be used with either a specific collection or with all collections in an integration server. If you are creating a policy to be used with a specific collection, ensure that the name of the policy is the same as the name that you specify in the `Policy` property on the Collector node.

      To specify a default Collector policy for all message flows that are deployed to an integration server, set the **`Collector`** property in the `server.conf.yaml` file to the name of a Collector policy. For information about setting properties in the `server.conf.yaml` file, see "Configuring an integration server by modifying the server.conf.yaml file" on page 172. If the default policy is in the default policy project, you do not need to specify the name of the policy project. If the default policy is in a non-default policy project, qualify the name of the policy with the name of the policy project in the format *{policyProjectName}:PolicyName*
   b) Set the **`Queue prefix`** property of the Collector policy to the required value.
   c) Optional: Set the **`Collection expiry`** property of the Collector policy to an appropriate value (for example, 60).

   If you delete a Collector policy, the storage queues are not deleted automatically when the policy is deleted, so you must delete them separately.
3. In the Collector node, if the policy is to be used for a specific collection, specify the name of the policy in the `Policy` property on the **Advanced** tab; for example, `myCollectorService`.

   If you do not set the `Policy` property, and if there is a default Collector policy specified in the `server.conf.yaml` file, that policy is used instead.

What to do next

The properties for the policy are not used by the integration server until you restart or redeploy the message flow, or restart the integration server.

Configuring the storage of events for Resequence nodes

You can use a Resequence policy to control the storage of events for Resequence nodes.

About this task

Information about the state of in-flight messages is held on storage queues that are controlled by IBM MQ. The storage queues that hold the state information are owned by the queue manager that is associated with the integration server.

If you are using Resequence nodes on an integration server that is managed by an integration node, you must install IBM MQ on the same computer as your integration node in order to use the capabilities that are provided by the Resequence node. If you are using Resequence nodes on an independent integration server, you can use a remote default queue manager to control the system queues, without the need to install IBM MQ on the same machine as the integration server. Interactions between an independent

integration server and IBM MQ can use a client connection to a remote queue manager, by using a default policy setting. For more information about using a remote default queue manager, see "Using a remote default queue manager" on page 750 and "Configuring an integration server to use a remote default queue manager" on page 751.

If the integration server has the necessary permissions to create the default system queues, they are created automatically when a flow containing Resequence nodes is deployed. If the default queues are not created automatically, you can create them manually by running the **iib_createqueues** command, as described in "Creating the default system queues on an IBM MQ queue manager" on page 99.

By default, the storage queues used by all Resequence nodes are:

- SYSTEM.BROKER.EDA.EVENTS
- SYSTEM.BROKER.EDA.COLLECTIONS

These queues are also used by the Collector node.

However, you can control the queues that are used by different Resequence nodes by creating alternative queues that contain a *QueuePrefix* variable, and by using a Resequence policy to specify the names of those queues for storing events.

Follow these steps to specify the queues that are used to store event states, and to set the timeout and the start and end of the sequence:

Procedure

1. Create the storage queues to be used by the Resequence node.

   The following queues are required:

   - SYSTEM.BROKER.EDA.*QueuePrefix*.EVENTS
   - SYSTEM.BROKER.EDA.*QueuePrefix*.COLLECTIONS

   The *QueuePrefix* variable can contain any characters that are valid in a IBM MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, SET1 and SET`.`1 are valid queue prefixes, but `.`SET1 and SET1`.` are invalid.

   If you do not create the storage queues, IBM App Connect Enterprise creates the set of queues when the node is deployed; these queues are based on the default queues. If the queues cannot be created, the message flow is not deployed.
2. Create a Resequence policy (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).
   a) You can create a policy to be used with either a specific sequence or with all sequences in an integration server. If you are creating a policy to be used with a specific sequence, ensure that the name of the policy is the same as the name that you specify in the `Policy` property on the Resequence node.

      To specify a default Resequence policy for all message flows that are deployed to an integration server, set the **Resequence** property in the `server.conf.yaml` file to the name of a Resequence policy. For information about setting properties in the `server.conf.yaml` file, see "Configuring an integration server by modifying the server.conf.yaml file" on page 172. If the default policy is in the default policy project, you do not need to specify the name of the policy project. If the default policy is in a non-default policy project, qualify the name of the policy with the name of the policy project in the format *{policyProjectName}:PolicyName*
   b) Set the **Queue prefix** property of the Resequence policy to the required value (see Resequence policy).
   c) Optional: Set the **Missing message timeout**, **Start of sequence**, and **End of sequence** properties of the Resequence policy.

   If you delete the Resequence policy, the storage queues are not deleted automatically when the policy is deleted, so you must delete them separately.

3. In the Resequence node, if the policy is to be used for a specific sequence, specify the name of the policy on the **Advanced** tab; for example, `myResequenceService`.

   If you do not set the `Policy` property, and if there is a default Resequence policy specified in the `server.conf.yaml` file, that policy is used instead.

What to do next

The properties for the policy are not used by the integration server until you restart or redeploy the message flow, or restart the integration server.

Configuring the storage of events for timeout nodes

You can use a Timer policy to control the storage of events for TimeoutNotification and TimeoutControl nodes.

About this task

Information about the state of in-flight messages is held on storage queues that are controlled by IBM MQ. The storage queues that hold the state information are owned by the queue manager that is associated with the integration server.

If you are using TimeoutControl and TimeoutNotification nodes on an integration server that is managed by an integration node, you must install IBM MQ on the same computer as your integration node in order to use the capabilities that are provided by these nodes. If you are using TimeoutControl and TimeoutNotification nodes on an independent integration server, you can use a remote default queue manager to control the system queues, without the need to install IBM MQ on the same machine as the integration server. Interactions between an independent integration server and IBM MQ can use a client connection to a remote queue manager, by using a default policy setting. For more information about using a remote default queue manager, see "Using a remote default queue manager" on page 750 and "Configuring an integration server to use a remote default queue manager" on page 751.

If the integration server has the necessary permissions to create the default system queues, they are created automatically when a flow containing TimeoutControl or TimeoutNotification nodes is deployed. If the default queues are not created automatically, you can create them manually by running the **`iib_createqueues`** command, as described in "Creating the default system queues on an IBM MQ queue manager" on page 99.

By default, the storage queue used by all timeout nodes is the SYSTEM.BROKER.TIMEOUT.QUEUE. However, you can control the queues that are used by different timeout nodes by creating alternative queues that contain a *QueuePrefix* variable, and by using a Timer policy to specify the names of those queues for storing events.

Follow these steps to specify the queue that is used to store event states:

Procedure

1. Create the storage queue to be used by the timeout nodes.

   The following queue is required:

   - SYSTEM.BROKER.TIMEOUT.*QueuePrefix*.QUEUE

   The *QueuePrefix* variable can contain any characters that are valid in an IBM MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, SET1 and SET`.`1 are valid queue prefixes, but `.`SET1 and SET1`.` are invalid.

   If you do not create the storage queue, IBM App Connect Enterprise creates the queue when the node is deployed; this queue is based on the default queue. If the queue cannot be created, the message flow is not deployed.

2. Create a Timer policy (see “Creating policies with the IBM App Connect Enterprise Toolkit” on page 327).
   a) You can create a policy to be used with either specific timeout requests or with all timeout requests in an integration server. If the policy is to be used with specific timeout requests, create the policy with the same name as the `Unique identifier` property on the TimeoutNotification and TimeoutControl nodes.

      To specify a default Timer policy for all message flows that are deployed to an integration server, set the **`Timer`** property in the `server.conf.yaml` file to the name of a Timer policy. For information about setting properties in the `server.conf.yaml` file, see “Configuring an integration server by modifying the server.conf.yaml file” on page 172. If the default policy is in the default policy project, you do not need to specify the name of the policy project. If the default policy is in a non-default policy project, qualify the name of the policy with the name of the policy project in the format *{policyProjectName}:PolicyName*.
   b) Set the **`Queue prefix`** property of the Timer policy to the required value (see Timer policy).

   If you delete the Timer policy, the storage queue is not deleted automatically when the policy is deleted, so you must delete it separately.
3. In the TimeoutNotification and TimeoutControl nodes, ensure that the name of the Timer policy is the same as the name specified in the `Unique Identifier` property on the **Basic** tab; for example, `myTimer`. Specify the name of the policy project and the policy on the message flow node in the format *{policyProjectName}:PolicyName*. If there is no Timer policy with the same name as the `Unique Identifier`, and if there is a default Timer policy specified in the `server.conf.yaml` file, that Timer policy is used instead.

What to do next

The properties for the policy are not used by the integration server until you restart or redeploy the message flow, or restart the integration server.

Configuring the XPath cache

The integration server XPath cache size might become a performance bottleneck for customers who use many XPath expressions. Altering the size of the XPath cache might improve message flow performance.

An integration server (or 'execution group' in WebSphere Message Broker Version 8.0 and earlier versions) keeps a cache of compiled XPath expressions to help reduce the processor usage of parsing and re-creating XPath expressions that are used repeatedly during message flow execution. This cache is shared by all message flows within an integration server. The default size of this cache is 10000 elements, and this is expected to be sufficient for most customer configurations.

It might be necessary to alter the size of this cache for optimal message flow performance if hundreds or thousands of XPath expressions are created for each Message Flow invocation. In a highly multi-threaded environment where many XPath expressions are evaluated on each message flow invocation, it might be necessary to disable the cache to remove thread contention on the cache. From IBM Integration Bus Version 10.0 onwards, the XPath cache has its own resource manager **`ComIbmXPathCache`**; run the following command to return the status:

```
mqsireportproperties <INode> -e default -o ComIbmXPathCache -r
```

where *<INode>* is your integration node. The following output is an example of that returned from the command:

```
ComIbmXPathCache
 uuid='ComIbmXPathCache'
 userTraceLevel=''
 traceLevel=''
 userTraceFilter=''
 traceFilter=''
 vrmfIntroducedAt=''
 resourceGroup=''
 mode='enabled'
 maximumSize='10000'
```

```
minimumSize='6000'
currentSize='0'
entryWarningThreshold='1000'
```

The **maximumSize** property controls the maximum number of compiled XPath expressions that can be stored in the XPath cache. When the XPath cache reaches this limit of compiled XPath expressions, entries are evicted from the cache based on the following criteria:

- How often they were used.
- When they were last used.

You can change the value of the **maximumSize** property with the following command:

```
mqsichangeproperties <INode> -e default -o ComIbmXPathCache -n maximumSize -v 20000
```

The **minimumSize** property controls the minimum number of compiled XPath expressions that can be stored in the XPath cache. When the XPath cache reaches this number of compiled XPath expressions, the number of entries does not fall any lower when entries are evicted from the cache. You can change the value of the **minimumSize** property with the following command:

```
mqsichangeproperties <INode> -e default -o ComIbmXPathCache -n minimumSize -v 1000
```

The **currentSize** property reports the number of compiled XPath expressions that are stored in the XPath cache. This property is read-only, and must not be set with the **mqsichangeproperties** command.

The **mode** property controls whether the cache is enabled or disabled. When the cache is disabled, no XPath expressions are cached. This can improve performance in highly multi-threaded environments where each message flow invocation creates unique XPath expressions, which are only used once. To disable the cache, set the mode property to `disabled`. You can change the value of the **mode** property with the following command:

```
mqsichangeproperties <INode> -e default -o ComIbmXPathCache -n mode -v disabled
```

The **entryWarningThreshold** property controls how frequently activity log messages are emitted by the XPath cache as it grows in size. The XPath cache emits an activity log message that gives updates about the size of the cache whenever the size of the cache divided by the value of **entryWarningThreshold** equals 0. The default value of the **entryWarningThreshold** property is 1000 and is ten per cent of the default maximum size of the cache. The cache also emits an activity log message when the cache reaches the maximum size and a cache flush occurs. If the value of the **maximumSize** property is changed, the value of the **entryWarningThreshold** property might also need to be changed. You can change the value of the **entryWarningThreshold** property with the following command:

```
mqsichangeproperties <INode> -e default -o ComIbmXPathCache -n entryWarningThreshold -v 20
```

Configuring monitoring event sources by using a monitoring profile

You can create a monitoring profile to configure your message flows to emit monitoring events.

Before you begin

Read the following topics:

- "Monitoring basics" on page 2772
- "Configuring monitoring for message flows" on page 2788

You must have a message flow that contains a node to which you want to add a monitoring event.

You can use XPath 1.0 expressions to configure a monitoring event.

About this task

To configure monitoring events by using a monitoring profile, complete the following tasks.

1. “Creating a monitoring profile” on page 2793
2. “Applying and activating a monitoring profile” on page 2798

Changing locales

You can change the locale for the system on which a runtime component is installed.

About this task

The way in which you change the locale depends on the operating system:

- “Changing your locale on Linux and UNIX systems” on page 237
- “Changing your locale on Windows” on page 239

IBM App Connect Enterprise uses code page converters to support character sets from different environments. “Code page converters” on page 239 describes what a code page converter is, and how to generate new converters.

Changing your locale on Linux and UNIX systems

You can change your system locale on UNIX and Linux systems.

About this task

You can set environment variables to control the system locale. You can set these variables to be system-wide, or on a per-session basis:

LC_ALL
Overrides all LC_* environment variables with the given value

LC_CTYPE
Character classification and case conversion

LC_COLLATE
Collation (sort) order

LC_TIME
Date and time formats

LC_NUMERIC
Non-monetary numeric formats

LC_MONETARY
Monetary formats

LC_MESSAGES
Formats of informative and diagnostic messages, and of interactive responses

LC_PAPER
Paper size

LC_NAME
Name formats

LC_ADDRESS
Address formats and location information

LC_TELEPHONE
Telephone number formats

LC_MEASUREMENT
Measurement units (Metric or Other)

LC_IDENTIFICATION
Metadata about the locale information

LANG
The default value, which is used when either LC_ALL is not set, or an applicable value for LC_* is not set

NLSPATH
Delimited list of paths to search for message catalogs

TZ
Time zone

LC_MESSAGES and NLSPATH are the most important variables to the integration node. These variables define the language and location of response messages that the integration node uses. The integration node profile file, `mqsiprofile`, sets NLSPATH. Either you, or your system must set LC_MESSAGES. The value set in LC_MESSAGES must be a value that is installed on your machine and that the integration node recognizes. LC_CTYPE is also important to the integration node because it defines the character conversion that the integration node performs when interacting with the local environment.

Before setting these variables, check that the language and code page are installed on your machine, and are supported by IBM App Connect Enterprise.

You can use the command **`locale`** to show your current locale. The command **`locale -a`** displays all the locales that are currently installed on the machine. Make sure that the locale you select for LANG and LC_ALL is in the list that is returned by the command **`locale -a`**. The values that `locale` uses and returns are case sensitive, therefore copy them exactly when assigning them to an environment variable.

For information on languages and code pages supported by IBM App Connect Enterprise, see Supported code pages.

If you use common desktop environment (CDE), use this environment to set the locale instead of setting LANG and LC_ALL directly. The NLSPATH variable respects either method.

For example, to set IBM App Connect Enterprise to run in a UTF-8 environment set the following values in the profile:

```
LANG=en_US.utf-8
LC_ALL=en_US.utf-8
```

where en_US sets the language, and `utf-8` sets the code page.

When you start an integration node component, the locale of that component is inherited from the shell in which it is started. The integration node component uses the LC_MESSAGES environment variable as the search path in the NLSPATH environment variable (LC_MESSAGES is set when variable LC_ALL is exported).

Messages are sent to the syslog in the code page set by this locale. If you have multiple integration node that write to this syslog, their messages are in the code page of the locale in which they were started, for example:

locale	syslog code page	ccsid
pt_BR	iso8859-1	819
pt_BR	ibm-850	850
pt_BR	utf-8	1208

Set the locale of the user ID that runs the syslog daemon to one that is compatible with the locales of all integration node that write to the syslog on that system, for example, `utf-8`. For compatibility, you can set the default locale. On Solaris, set the LANG and LC_ALL variables in `/etc/default/init`. On AIX and Linux, these variables are in `/etc/environment`. This task is not required on HP-UX.

For full-time zone support in the integration node, set the TZ variable using Continent/City notation. For example set TZ to Europe/London to make London, England the time zone, or set it to America/New_York to make New York, America the time zone.

If you want to add a new locale, refer to the operating system documentation for information about how to complete that task. If the code page of the new locale is not supported by IBM App Connect Enterprise you must add it by "Generating a new code page converter" on page 240.

Changing your locale on Windows

Change your system locale on Windows to view objects and information in a different language or code page.

About this task

Integration node are started as services on Windows, and are therefore influenced by the system locale. The command-line functions are influenced by the locale that is set for the current user. IBM App Connect Enterprise on Windows has all locale information installed by default. However, you might have to install additional locale packages, if prompted to do so by the Windows operating system.

To change locale, use one of the following methods:

- Install a locale-specific operating system.
- Alter the system or user locale by selecting *Regional Settings* in the Control Panel.

Messages are sent to the Event Log in the code page set by the current locale.

You can use the **chcp** command to change the active console code page. Enter the command at a command prompt; if you enter **chcp** without a parameter, it displays the current setting. If you enter it with a code page, it changes the locale to that code page.

For example, to check the current code page setting:

```
C:\>chcp
Active code page: 437
```

The current page is displayed (437 represents US-ASCII). If you want to change the value to GB18030, enter:

```
C:\>chcp 54936
Active code page: 54936
```

Before you use a code page, search for `windows-`*`number`* where *`number`* is the active code page you want to use in the list of Supported code pages. If the code page is not in the list, either use a code page that is in the list, or generate a new code page converter.

Code page converters

Integration nodes complete string operations in Universal Character Set coded in 2 octets (UCS-2). If incoming strings are not encoded in UCS-2, they are converted to UCS-2 on arrival.

The integration node uses international components for Unicode (ICU) code page converters to convert data. The Unicode Consortium has further information on Unicode.

A code page converter is a mapping from the byte sequence in one code page to a serialized representation of UCS-2, known as UCS Transformation Format 16-bit form (UTF-16). A code page converter allows the integration node to create a UCS-2 representation of an incoming string.

When you handle UTF-16 data, CCSIDs 1200, 13488 and 17584 are treated differently to others. Traditionally, in ICU usage, the endian encoding of these CSSIDs was platform-specific, and IBM App Connect Enterprise uses an encoding parameter with these CSSIDs. You can specify the encoding parameter as MQENC_INTEGER_REVERSED to use these CCSIDs to explicitly produce little endian data.

Consider this example of the use of a code page converter. A message comes in on a queue from z/OS, with the IBM MQ CCSID field set to 1047 (LATIN-1 Open Systems without euro). The integration node looks up ibm-1047 and uses the resulting converter to create a UCS-2 representation for internal use.

If you try to convert from a Unicode to a Non-Unicode character set, the following errors might occur:

- The target buffer is too small. This error causes a recoverable exception, which you can handle; alternatively, the message is rolled back.
- A code point in the source does not have an equivalent value in the target. At first, fallback mappings are attempted (for example, if you are converting to Japanese, a backslash (\) can be mapped to a yen (¥) if the conversion supplies it as a fallback mapping). If fallback mappings are not present, a recoverable exception is thrown. You can handle the exception, or the message is rolled back.

  The MRM parser substitutes invalid code points with substitution characters.

IBM App Connect Enterprise currently supports the code pages that are listed in Supported code pages. If you need support for an additional code page, or if you require a different variant of a code page, you can extend the integration node to support this code page.

Generating a new code page converter

Generate a code page converter to handle conversions of data that belongs to a code page that is not in the default set of code pages that are provided by IBM App Connect Enterprise.

Before you begin

- Read "Code page converters" on page 239, which provides information about what a code page converter is, and about the code pages that IBM App Connect Enterprise supports.
- If you apply a fix pack to IBM App Connect Enterprise that increases the ICU version, recompile the code page converters that are used by IBM App Connect Enterprise message flows or the DFDL parser. (The ICU version is listed in the fix pack document on the IBM Support site.)

About this task

This information is split into the following sections:

- "Making a new code page converter" on page 240
- "Making the new code page converter available to IBM App Connect Enterprise message flows" on page 241
- "Making the new code page converter available to the DFDL parser" on page 241

Making a new code page converter

Procedure

1. Create or find a mapping data file with the file extension `.ucm` for the converter that you require.

   You can download `.ucm` files from the ICU Character set mapping files archive. These mapping data files are available and can be modified without restriction.

   An example mapping data file is `ibm-1284_P100-1996.ucm`. (ICU is an external open source project, not an IBM tool.)
2. Rename the `.ucm` to a file name with the format `ibm-`*`number`*`.ucm` where *number* is a number that you choose to identify the code page. Make sure that this number is not already used in one of the Supported code pages.
   For example, you could rename `ibm-1284_P100-1996.ucm` to `ibm-1284.ucm`.
3. Go to ICU downloads, download the source code and build binaries for your system. If you have problems building the converter, see the ICU user guide.
4. Extract the files from the binary distribution archive into a temporary directory.

5. Copy the library and binary files to a directory in the environment PATH and LIBPATH. (Alternatively, copy the library and binary files to directory that is not temporary, and modify the environment PATH and LIBPATH to include this directory.)
6. One of the extracted files is `makeconv.exe`; use this **makeconv** tool to convert the mapping data file (`.ucm` files) into a binary converter file (`.cnv` file), by entering the following command:

   ```
   makeconv mapping_file.ucm
   ```

   where *mapping_file.ucm* is the mapping data file that you are using.

   The name of the binary converter file that **makeconv** produces is:

   ```
   mapping_file.cnv
   ```

   where *mapping_file.cnv* is the name of the mapping data file that was converted.

   To make the `.cnv` file for `ibm-1284.ucm`, use the following command:

   ```
   makeconv ibm-1284.ucm
   ```

Making the new code page converter available to IBM App Connect Enterprise message flows

Procedure

1. Copy the file with the file extension `.cnv` for the code page that you need, into a directory that IBM App Connect Enterprise can access.

   The name and location of the file is of the form

   ```
   ibm-1284.cnv
   ```

   and is located in the *$ICU_DATA/icudt##<platform-suffix>* directory, where *icudt##* is the version of ICU, which you can find in the fix pack document on the IBM Support site; for example, *icudt51* for IBM Integration Bus version 10.0.0.11. *<platform-suffix>* is one of the following values:

   - `l` for little-endian ASCII platforms
   - `b` for big-endian ASCII platforms
   - `e` for EBCDIC platforms
2. Optional: If you do not want the new code page converter to be in the same location as other ICU data, you must associate the broker with the new directory where the converter is stored (the directory added must contain the full path, not including the `icudt48x` subdirectory):
   - To create a new broker that is associated with the converter, include the **-c** parameter on the **mqsicreatebroker** command.
   - To affect all the products and the broker command-line tools that are using ICU, add the *directory* to the **ICU_DATA** environment variable. If you have used the **mqsicreatebroker** command to specify the code page converter to be used, the broker ignores the **ICU_DATA** value.

     Note: To ensure consistent behavior in all components, modify the **ICU_DATA** environment variable.

Making the new code page converter available to the DFDL parser

Before you begin

The DFDL component includes its own copy of the ICU libraries. This copy might be a different version level to those libraries used by IBM App Connect Enterprise. In this case, if the new code page is to be used for DFDL parsing, the new code page converter must also be copied into a specific location that can be accessed by DFDL. The DFDL component uses the environment variable **ICU_DATA** as a root location

to search for convert tables. This environment variable should already have been set for you by running **mqsiprofile**.

Procedure

1. Copy the new code page convert `.cnv` file to a subdirectory beneath the location that is specified in the **ICU_DATA** environment variable. This subdirectory might need to be created, and its name must match the version of the ICU libraries that are supplied with the DFDL component.

   For IBM App Connect Enterprise, the new code page converter file is copied into the `$ICU_DATA/icudt48<platform-suffix>` directory, where the number 48 denotes the version of ICU (4.8) that IBM App Connect Enterprise uses.

   To check if the level of ICU that is used by DFDL is different to that used by IBM App Connect Enterprise, complete one of the following tasks for your platform:

   a) Linux UNIX

   On Linux and UNIX system, look under the following path to find a library name that starts with `libicudata*`:

   ```
   <product installation path>/dfdlc/lib
   ```

   The numerical suffix to the file name denotes the ICU version.

   b) Windows

   On Windows systems, look under the following path to find libraries with names that start with `icudt*`:

   ```
   <product installation path>\bin
   ```

   Any libraries that have a numerical suffix that is not 48 are the DFDL ICU libraries, and the suffix denotes the ICU version.

2. If the ICU version that is used by the DFDL component within IBM App Connect Enterprise is not 48, a new subdirectory that is named *icudt<DFDL-icu-version><platform-suffix>* must be created under the $ICU_DATAdirectory.
   For example: If ICU libraries with a suffix of 51 are found, then the new code page converter file for DFDL must be copied to *$ICU_DATA/icudt51<platform-suffix>* directory, where the *<platform-suffix>* is one of the following values:

   - `l` for little-endian ASCII platforms
   - b for big-endian ASCII platforms
   - e for EBCDIC platforms

Chapter 5. Administering IBM App Connect Enterprise

Choose the method you prefer to activate and manage your integration nodes, integration servers, and associated resources.

About this task

Administration of IBM App Connect Enterprise includes some or all of the following tasks, depending on your particular implementation, where you are running App Connect Enterprise (on premises or in the cloud), and the features that you are using:

- “Managing integration nodes” on page 243
- “Managing integration servers” on page 249
- “Managing resources” on page 271
- “Managing deployed resources” on page 316
- “Overriding properties at run time with policies” on page 324
- “Viewing administration activity in the admin log” on page 330
- “Administering Java applications” on page 473
- “Changing the location of the IBM App Connect Enterprise working directory ” on page 474

These methods can be performed by using one or more of the administrative techniques supported by IBM App Connect Enterprise:

- The IBM App Connect Enterprise Toolkit
- The IBM App Connect Enterprise commands
- The IBM Integration API
- The Administration REST API
- The IBM App Connect Enterprise web user interface

For each task, the administrative techniques that you can use are identified.

Managing integration nodes

Work with your existing integration nodes to manage their connections and their active status by using the IBM App Connect Enterprise Toolkit, the IBM Integration API, or the command line.

About this task

- “Connecting to an integration node by using the Toolkit” on page 245

  Connect to a remote integration node from the IBM App Connect Enterprise Toolkit.
- “Connecting to an integration node by creating a .broker file” on page 244

  Export connection details of an integration node to a `.broker` file, so that another user or another integration node can use them.
- “Starting and stopping an integration node” on page 247

  Start and stop an integration node from the IBM App Connect Enterprise Toolkit or by using the command line.
- “Deleting an integration node” on page 165

  Delete an integration node from the IBM App Connect Enterprise Toolkit or by using the command line.

You can also use the IBM Integration API to complete some of these actions. See "Managing resources by using the IBM Integration API" on page 444.

To learn more about creating and configuring integration nodes, see the topics in "Configuring App Connect Enterprise to run on premises (on a physical or virtual machine)" on page 110.

Connecting to an integration node by creating a `.broker` file

View the schema and an example of a `.broker` file, which contains connection settings for a specific integration node.

Use a `.broker` file to define connection details for a specific integration node, including host, port, and optionally password and SSL security credentials. You can then share this stored connection information between different users and commands so that this information does not have to be typed manually each time. For example, you might specify a `.broker` file so that multiple users can connect to a remote integration node that has SSL enabled on its web administration port.

You can create a `.broker` file in a text editor by using the XML schema that is provided in this topic. You can reference the `.broker` file in the IBM App Connect Enterprise Toolkit, by using IBM App Connect Enterprise commands, and in the IBM Integration API.

You can also use a `.broker` file to define connection details for an independent integration server (which is an integration server that is not managed by an integration node).

The following **mqsi*** commands can reference a `.broker` file, by using the **-n** parameter:

- **mqsicacheadmin**
- **mqsichangeflowmonitoring**
- **mqsichangeflowstats**
- **mqsichangeresourcestats**
- **mqsicreateexecutiongroup**
- **mqsicredentials**
- **mqsideleteexecutiongroup**
- **mqsideploy**
- **mqsilist**
- **mqsipushapis**
- **mqsireloadsecurity**
- **mqsireportflowmonitoring**
- **mqsireportflowstats**
- **mqsireportresourcestats**
- **mqsistartmsgflow**
- **mqsistopmsgflow**

A sample `.broker` file is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<IntegrationNodeConnectionParameters Version="11.0.0" host="localhost" listenerPort="4414"
 integrationNodeName="INODE" userName="user"  password="password" useSsl="true"
 sslIncludeProtocols="TLSv1.2  "sslTrustStorePassword="password" sslTrustStorePath="c:\keystore
\my_keystore.jks" xmlns="http://www.ibm.com/xmlns/prod/ace/11" />
```

You can specify either `IntegrationNodeConnectionParameters` or `broker` as the root element in the `.broker` file. In the following example, the root element name is `IntegrationNodeConnectionParameters`.

This example enables an SSL connection to an integration node named INODE that is running on host 'localhost'. INODE uses port 4414 for its HTTPS web administration connections.

The `.broker` file is based on the following XML schema:

```
<?xml version="1.0" encoding="UTF-8"?><xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 targetNamespace="http://www.ibm.com/xmlns/prod/ace/11">
    <xsd:element name="IntegrationNodeConnectionParameters">
     <xsd:complexType>
      <xsd:attribute name="Version" use="required">
       <xsd:simpleType>
        <xsd:restriction base="xsd:string">
         <xsd:pattern value="\d\d[0-9\.]*"></xsd:pattern>
        </xsd:restriction>
       </xsd:simpleType>
      </xsd:attribute>
      <xsd:attribute name="host" type="xsd:string"
       use="optional">
      </xsd:attribute>
      <xsd:attribute name="listenerPort" type="xsd:int"
       use="optional">
      </xsd:attribute>
      <xsd:attribute name="integrationNodeName" type="xsd:string"
       use="optional">
      </xsd:attribute>
      <xsd:attribute name="userName" type="xsd:string"
       use="optional">
      </xsd:attribute>
                  <xsd:attribute name="password" type="xsd:string"
       use="optional">
      </xsd:attribute>
                        <xsd:attribute name="useSsl" type="xsd:boolean"
      use="optional">
      </xsd:attribute>
                 <xsd:attribute name="sslIncludeProtocols" type="xsd:string"
       use="optional">
      </xsd:attribute>
      <xsd:attribute name="sslTrustStorePassword" type="xsd:string"
       use="optional">
      </xsd:attribute>
      <xsd:attribute name="sslTrustStorePath" type="xsd:string"
       use="optional">
      </xsd:attribute>
     </xsd:complexType>
    </xsd:element>
</xsd:schema>
```

Connecting to an integration node by using the Toolkit

Before you can administer an integration node by using the IBM App Connect Enterprise Toolkit, you must connect to the integration node.

Before you begin

- Create an integration node

Before you can connect to an integration node from the Toolkit, the integration node and its web user interface HTTP connection listener must be running. You can check that the listener was started by using the **mqsilist** command or by checking for the BIP3132 message in the integration node system log.

About this task

You can create a connection to an integration node by using the Integration Explorer view in the IBM App Connect Enterprise Toolkit. You can create the connection by using either the connection wizard or settings from a `.broker` file.

By default, when you create a connection to an integration node, the Toolkit connects to it automatically when the Toolkit is started. However, if you want to create the connection details without automatically connecting the Toolkit to the integration node, you can turn off the automatic connection setting by clicking **Window** > **Preferences** > **Integration Development** > **Connection Settings**, and then deselecting **Automatic connection to remote Integration Nodes and Integration Servers**. Then click **Apply and Close**.

Procedure

Create a connection to an integration node by using one of the following methods:

- Create a connection to an integration node by specifying the hostname and port settings in the connection wizard:
  a) Open the Integration Explorer view in the IBM App Connect Enterprise Toolkit.
  b) Right-click the Integration Nodes folder, and click **Connect to an Integration Node**.

     A wizard guides you through the steps involved in connecting to your integration node. As a minimum, you must specify the hostname and port. If administration security has been enabled on the integration node, you must specify authentication details (username and password) or select the **Use HTTPS** option.
  c) In the **Connect to an integration node** wizard, enter the following values:
     - The **Host name** or IP address of the computer on which your integration node is running.
     - The **Port** used by the administration REST API. This property must be a valid positive number.
     - (Optional). The **User name** for a web administration account that you want to use to secure the connection. For more information, see command.
     - (Optional). The **Password** that is associated with the web administration account for the **User name**. For more information, see command and "Managing web user accounts" on page 2510.
     - To save the **Password** value, select the **Save password** checkbox.

       The password is encrypted in Eclipse Secure Storage, which is a local file that is shared by all Eclipse-based products on the computer, including the IBM App Connect Enterprise Toolkit. If you select this option and Eclipse Secure Storage is not already set up, you must complete some additional steps to store the password securely:

       a. Set a master password for Eclipse Secure Storage.

          On Windows, the master password is generated automatically.

          On Linux and UNIX, the **Secure Storage** window opens, and you must set a master password for Eclipse Secure Storage. Enter a value for **Password**, and use the same value for **Confirm password**.

       b. On all distributed systems, you are prompted to set master password recovery.

          If you select **Yes**, the **Password Recovery** pane opens. In the **Password Recovery** pane, enter your questions and answers for password recovery.
     - To connect to the integration node by using HTTP with the Secure Sockets Layer (SSL), select the **Use HTTPS** checkbox.
  d) Click **Finish** to connect to the integration node.
- Create a connection to an integration node by using settings from a `.broker` file:
  a) Open the Integration Explorer view in the IBM App Connect Enterprise Toolkit.
  b) Right-click the Integration Nodes folder, and click **Connect to an Integration Node using an integration connection file**.
  c) Select the `.broker` file and then click **Open** to connect to the integration node.

  The connection to the remote integration node is created in your workspace.

Results

You can now view properties and manage your integration node, and its integration servers and resources, in the IBM App Connect Enterprise Toolkit.

You can export the remote connection details to a `.broker` file by right-clicking the integration node and selecting **Export the Integration Node to an Integration Connection file**.

What to do next

You can use the toolkit to create integration servers for the integration node, as described in Creating an integration server by using the IBM App Connect Enterprise Toolkit.

You can delete or change the value of a saved password for the connection. To change or delete the saved password:

1. Right-click the integration node that has a saved password.
2. Select **Change Saved Connection Password**.
3. Enter a new password, or leave the field empty to delete the saved password.

Starting and stopping an integration node

Run the appropriate command to start or stop an integration node.

Before you begin

- Ensure that your user ID has the correct authorizations to perform the task. Refer to Security requirements for administrative tasks.
- On Linux, UNIX, and Windows systems, you must set up your command line environment before you perform this task, by running the product profile or console; see “Setting up a command environment” on page 64.

About this task

To start and stop an integration node, you can use the commands from the command line.

Follow the links for instructions for the appropriate operating system:

Procedure

- “Starting and stopping an integration node on Windows, Linux, and UNIX systems” on page 247

Starting and stopping an integration node on Windows, Linux, and UNIX systems

Use the **mqsistart** or **mqsistop** commands to start or stop an integration node.

Before you begin

- Ensure that your user ID has the correct authorizations to perform the task. Refer to Security requirements for administrative tasks.
- On Linux, UNIX, and Windows systems, you must set up your command prompt environment before you perform this task, by running the product profile or console; see “Setting up a command environment” on page 64.
- When you start an integration node, all integration servers under that node are started automatically unless one of the following conditions applies:
  1. The integration node was stopped by using the **mqsistop** command, the Enterprise Toolkit, or the web user interface.
  2. You specified that an integration server must not be started. To specify that an integration server must not be started automatically, add an empty file that is named `.stopped` into the server's directory; for example:

     ```
     C:\myACEwork\components\NODEIPL101\servers\ISDEVIPLAA\.stopped
     ```
- If you use the **mqsistop** command or the Enterprise Toolkit or web user interface to stop an integration server, a `.stopped` file is added to the server's directory. When the integration node is next restarted,

the integration server is not started automatically (unless the `.stopped` file is deleted before the integration node is started).

Procedure

- Optional: On Windows, if the integration node is configured to use an IBM App Connect Enterprise vault, copy the `.mqsivaultrc` file into the directory that is referenced by the environment variable *MQSI_WORKPATH*. The default value for *MQSI_WORKPATH* is `C:\ProgramData\IBM\MQSI`.

  For more information about IBM App Connect Enterprise vaults and the `.mqsivaultrc` file, see command - systems and command.
- To start an integration node, enter the following command on the command line:

  ```
  mqsistart INODE
  ```

  Substitute your own integration node name for INODE.

  To start an associated queue manager for the integration node, use the **strmqm** command. For more information, see the topic *Starting and stopping a queue manager* in the IBM MQ documentation.

  The integration node is started. If you are using Windows, the command initiates the Windows service for the integration node.

  You can check that the integration node is running by using the **mqsilist** command; for example:

  ```
  mqsilist
  ...
  BIP1325I: Integration node 'NODEIPL101' with administration URI 'http://<host>:4417' is
   running.
  ```

  You can also check that the integration node initialized successfully by reviewing the following logs:

  – On Windows, check the Application Log in the Event Viewer.

  – On Linux and UNIX, check the system log.

  The log contains messages about verification procedures. If all tests are successful, only an initial start message is recorded. If one or more verification tests are unsuccessful, the log also includes messages that provide details of the tests that failed. If errors are reported, review the messages, and take the suggested actions to resolve these problems.
- To stop an integration node, enter the following command on the command line:

  ```
  mqsistop INODE
  ```

  Substitute your own integration node name for INODE.

  To stop the associated queue manager, run the **endmqm** command. For more information, see the topic *Starting and stopping a queue manager* in the IBM MQ documentation.

  You can check that the integration node is stopped by using the **mqsilist** command; for example:

  ```
  mqsilist
  ...
  BIP1326I: Integration node 'ACE02NODE' is stopped.
  ```

What to do next

For more information about verifying the status of an integration node, see “Verifying an integration node” on page 120.

Viewing integration node properties

You can view integration node properties by looking at the contents of the `node.conf.yaml` configuration file for the integration node.

Procedure

1. Use a YAML editor to open the `node.conf.yaml` configuration file for the integration node, which is created automatically when you create the integration node.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, if you modify the contents of the file, you must ensure that you do not include any tab characters, which are not valid in YAML.

   For more information about working with YAML, see http://www.yaml.org/start.html.
2. Optional: If you want to modify any of the integration node properties, follow the instructions in "Configuring an integration node by modifying the node.conf.yaml file" on page 118.

Managing integration servers

Manage your integration servers by using the IBM App Connect Enterprise Toolkit, the web user interface, or the command line. You can also use the IBM App Connect Enterprise REST API or the IBM Integration API to complete some of these actions.

About this task

The IntegrationServer process is a process that is similar to other operating system processes. You can view how much CPU or memory it is consuming, by using standard operating system tools and commands.

You can see what applications, REST APIs, integration services, and shared libraries are deployed to the integration server, by using the Integration Explorer view in the IBM App Connect Enterprise Toolkit, the IBM App Connect Enterprise web user interface, or the REST API.

For more information about integration servers, see Integration servers and integration nodes.

Complete the steps in the following topics to start and stop an integration server, and connect to an integration server from the IBM App Connect Enterprise Toolkit:

- "Starting an integration server" on page 250
- "Stopping an integration server" on page 254
- "Connecting to an integration server by using the Toolkit" on page 255
- "Connecting to an independent integration server from the Toolkit by specifying a userid and password" on page 256

For more information about creating, configuring, and deleting an integration server, see the following topics:

- "Creating an integration server" on page 168
- "Configuring an integration server by modifying the server.conf.yaml file" on page 172
- "Deleting an integration server" on page 175

Starting an integration server

You can start an integration server and all the resources deployed to it by using the IBM App Connect Enterprise Toolkit, the web user interface, the **IntegrationServer** command, or the administration REST API.

About this task

If resources are deployed to your integration server, the started or stopped state of the resources is retained when you next start the integration server.

To start an integration server, you can use the following methods:

- "Starting an integration server that is managed by an integration node, by using the IBM App Connect Enterprise Toolkit" on page 250
- "Starting an integration server that is managed by an integration node, by using the web user interface" on page 251
- "Starting an independent integration server by using the IntegrationServer command" on page 251
- "Starting a managed integration server by using the mqsistartmsgflow command" on page 253
- "Starting an integration server by using the administration REST API" on page 338

You can also create and start a local, independent integration server by using the IBM App Connect Enterprise Toolkit, as described in "Creating and starting a local, independent integration server by using the Toolkit" on page 170.

Starting an integration server that is managed by an integration node, by using the IBM App Connect Enterprise Toolkit

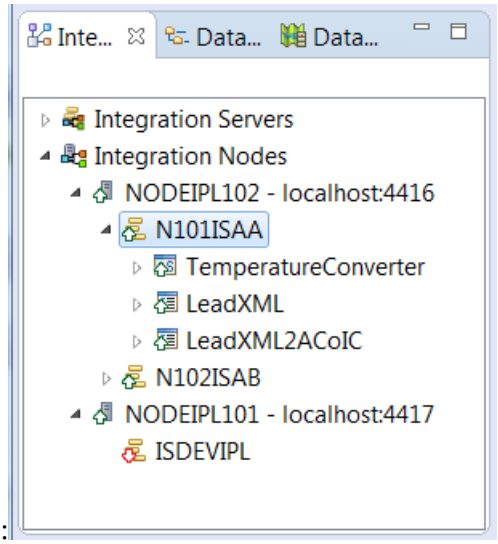
Procedure

To start an integration server under an integration node by using the IBM App Connect Enterprise Toolkit, complete the following steps.

1. Open the IBM App Connect Enterprise Toolkit, and switch to the Integration Development perspective.
2. In the Integration Explorer view, expand the integration node, right-click the integration server, and then click **Start**.

Results

The selected integration server is started. The Integration Explorer view is updated to indicate that the server and resources are running; for example:



Starting an integration server that is managed by an integration node, by using the web user interface

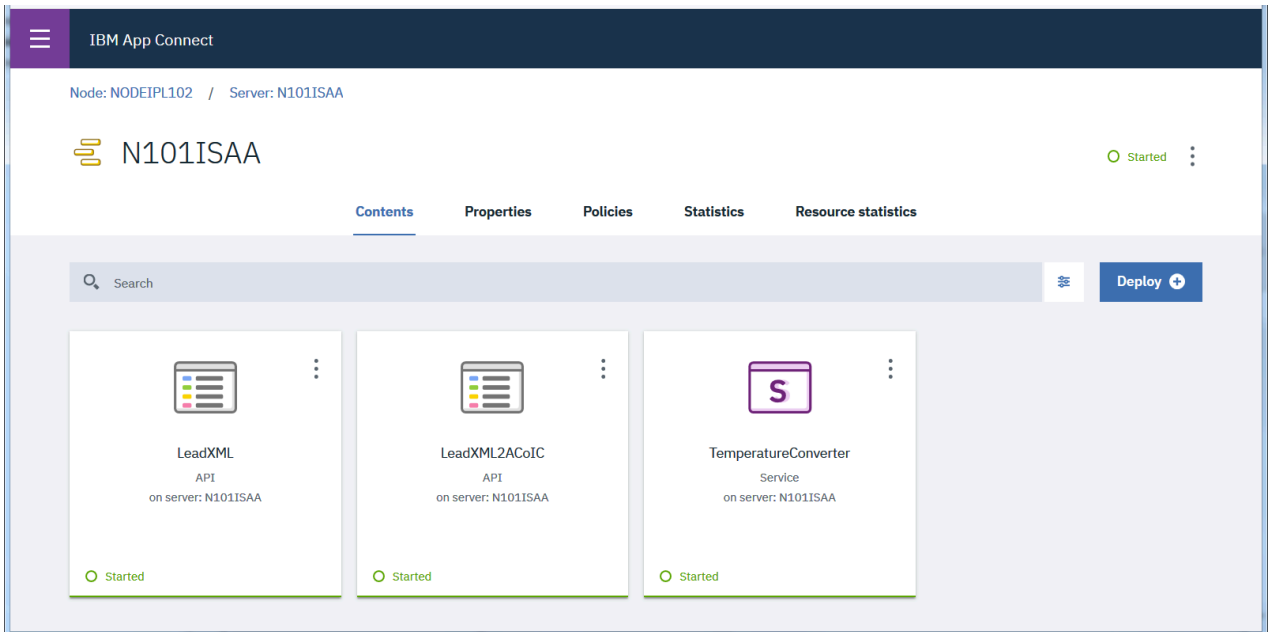
Procedure

To start an integration server under an integration node by using the web user interface, complete the following steps.

1. Start the web user interface for your integration node, as described in “Accessing the web user interface” on page 89.
2. Find the integration server that you want to start, select it, and then click **Start**.

Results

The selected integration server is started, along with the resources deployed to that server. The web user interface is updated to indicate that the server and resources are running; for example:



Starting an independent integration server by using the `IntegrationServer` command

You can use the **`IntegrationServer`** command to start an independent integration server (an integration server that is not managed by an integration node).

Before you begin

- Ensure that you have set up your command environment, as described in “Setting up a command environment” on page 64.
- Create a work directory and configure the integration server, as described in “Configuring an integration server by modifying the server.conf.yaml file” on page 172.

Procedure

To start an independent integration server, complete the following steps:

1. Run the **IntegrationServer** command, specifying the path to the work directory of the integration server.
   For example:

   ```
   IntegrationServer --work-dir c:\mywrk\myaceworkdir
   ```

   where *c:\mywrk\myaceworkdir* is the integration work directory that you created when you configured the integration server.

   For more information about creating the work directory, see "Configuring an integration server by modifying the server.conf.yaml file" on page 172 and command.

   If the integration server contains any independent resources (resources that are not in an application or library), you must specify the **--default-application-name** parameter the first time that you run the **IntegrationServer** command for this integration server. This parameter creates a new default application, and all independent resources that are associated with the integration server are moved into it. For example:

   ```
   IntegrationServer --work-dir c:\mywrk\myaceworkdir --default-application-name myDefaultApp
   ```

   For more information, see command.

   If you have created a vault in your work directory, you must supply the correct vault key when starting the integration server. To supply the vault key, you can specify either the **--vault-key** or **--vaultrc-location** parameters on the **IntegrationServer** command, or you can set the MQSI_VAULT_KEY or MQSI_VAULTRC_LOCATION environment variables. If you specify none of these, the `.mqsivaultrc` file will be looked for in your HOME directory. If you are using the `.mqsivaultrc` file, it must be configured to contain the correct vault key. For more information about using the vault, see "Configuring encrypted security credentials" on page 177.

   If you have created integration tests for flows on the integration server, you can run those tests by using the **--test-project** parameter on the **IntegrationServer** command to specify the name of the integration test project that contains the tests. For example:

   ```
   IntegrationServer –work-dir c:\tmp\work-dir --test-project MyIntegrationTestProject
   ```

   where the **--work-dir** parameter specifies the work directory of the integration server that will run the tests, and the **--test-project** specifies the name of the test project to be run. The tests in the specified test project run automatically when the integration server starts. For more information, see "Running tests by using the command line" on page 1932.

   When you run the **IntegrationServer** command, the integration server starts, using the configuration that is defined in its `server.conf.yaml` file and any overrides that have been set by commands. When you run commands that modify an integration server, an overrides directory is created under the working directory for the integration server, as described in "Configuring an integration server by modifying the server.conf.yaml file" on page 172.
2. You can now interact with the running integration server, by using the IBM App Connect Enterprise Toolkit or the web user interface.

   You can also investigate the administrative REST API provided by IBM App Connect Enterprise. For example, you might want to verify that the integration server is running, by sending a REST GET request to port 7600 and checking to see if there is a response:

   ```
   curl -X GET http://localhost:7600/apiv2
   ```

   If you want to use the curl tool, you might need to download and install it in addition to IBM App Connect Enterprise.

   The REST administration port, which is the primary method of communicating with the integration server, is set by default to 7600 (through the **adminRestApiPort** property in the `server.conf.yaml` configuration file).

3. Optional: Use the IBM App Connect Enterprise Toolkit to connect to the integration server:
   a) In the **Integration Explorer** view, right-click **Integration servers**, and then click **Connect to an integration server**. In the Connection details dialog, enter the host name and port for the integration server. Ensure that the port matches the value of the **admin-rest-api** property specified on the **IntegrationServer** command or the **RestAdminListener / port** property that was specified in the `server.conf.yaml` file (in this example, the port is `7600`, and the host name is `localhost`). If the integration server is secured, you must also specify the user name and password.
   b) Click **Finish**.

      The connection for your integration server is now displayed in the **Integration Explorer** view in the toolkit.
   c) You can now deploy a BAR file (or an application or REST API) by dragging it from the Application Development view and dropping it onto the integration server in the Integration Explorer view. For more information about deployment, see "Deploying integration solutions during development" on page 2464 and "Deploying integration solutions to a production environment" on page 2480.
   d) You can view the properties of the integration server, by selecting it in the Integration Explorer view, and then clicking the **Properties** tab. This shows the properties that were specified for the integration server in the `server.conf.yaml` configuration file, as described in "Configuring an integration server by modifying the server.conf.yaml file" on page 172.

Starting a managed integration server by using the `mqsistartmsgflow` command

Procedure

You can use the **mqsistartmsgflow** command to start an integration server that is managed by an integration node, by completing the following steps:

1. Open a command line for your current installation.
2. Enter the **mqsistartmsgflow** command, specifying the parameters for the integration server that you want to start.
   - If the integration node is local, specify the integration node name. For example:

     ```
     mqsistartmsgflow INODE -e default
     ```
   - If the integration node is remote, you can specify a configuration file. For example:

     ```
     mqsistartmsgflow -n INODE.broker -e default
     ```
   - If the integration node is remote, you can alternatively specify the connection parameters **-i** and **-p**. For example:

     ```
     mqsistartmsgflow -i 9.20.193.11 -p 4414 -e default
     ```
   - If you want to start all the integration servers on an integration node, specify the **--all-integration-servers** flag instead of **-e**.For example:

     ```
     mqsistartmsgflow INODE --all-integration-servers
     ```

   See the **mqsistartmsgflow** command description for more details about these options.

What to do next

Start or stop resources that are deployed on your integration server; see "Starting or stopping deployed resources" on page 317.

Stopping an integration server

You can stop an integration server under an integration node by using the IBM App Connect Enterprise Toolkit, the web user interface, or the administration REST API. You can stop an independent integration server by stopping its IntegrationServer process.

About this task

If resources are deployed to your integration server, the started or stopped state of the applications, integration services, and message flows is remembered when you stop the integration server. You can start or stop deployed resources before the integration server is stopped; see “Starting or stopping deployed resources” on page 317.

For an integration server under an integration node, the integration node processes all inflight messages and associated transactions for each message flow before it stops.

To stop an integration server under an integration node, you can use one of the following methods:

- “Stopping an integration node's server by using the IBM App Connect Enterprise Toolkit” on page 254
- “Stopping an integration server by using the web user interface” on page 254
- “Stopping an integration server by using the administration REST API” on page 338

Tip: If you use the Enterprise Toolkit or web user interface to stop an integration server under an integration node, a `.stopped` file is added to the server's directory. When the integration node is next restarted, the integration server will not be restarted automatically (unless the `.stopped` file is deleted before the integration node is started).

To stop an independent integration server by following these steps:

- **On Windows**, you can stop an integration server either by stopping the IntegrationServer process (for example, in the Windows Task Manager), or by pressing **Ctrl+C** in the App Connect Enterprise command console.
- **On Linux**, you can stop the integration server by sending the SIGINT signal to the IntegrationServer process.

Stopping an integration node's server by using the IBM App Connect Enterprise Toolkit

Procedure

To stop an integration server under an integration node by using the IBM App Connect Enterprise Toolkit, complete the following steps:

1. Open the IBM App Connect Enterprise Toolkit, and switch to the Integration Development perspective.
2. In the Integration Explorer view, expand the integration node, right-click the integration server, and then click **Stop**.

Results

The selected integration server is stopped, and a `.stopped` file is added to the server's directory. The Integration Explorer view is updated to indicate that the server is stopped.

Stopping an integration server by using the web user interface

Procedure

To stop an integration server by using the web user interface:

1. Start the web user interface for your integration node, as described in “Accessing the web user interface” on page 89.

2. Expand the list of folders to find the one that you want to stop, right-click it, and then click **Stop**.

Results

The selected integration server is stopped, and a `.stopped` file is added to the server's directory. The web user interface is updated to indicate that the server is stopped.

Connecting to an integration server by using the Toolkit

Before you can administer an integration server by using the IBM App Connect Enterprise Toolkit, you must connect to the integration server.

Before you begin

- Create an integration server

About this task

You can create a connection to an integration server by using the Integration Explorer view of the IBM App Connect Enterprise Toolkit. You can create the connection by using either the connection wizard or settings from a `.broker` file.

By default, when you create a connection to an integration server, the Toolkit connects to it automatically when the Toolkit is started. However, if you want to create the connection details without automatically connecting the Toolkit to the integration server, you can turn off the automatic connection setting by clicking **Window** > **Preferences** > **Integration Development** > **Connection Settings**, and then deselecting **Automatic connection to remote Integration Nodes and Integration Servers**. Then click **Apply and Close**.

Procedure

Create a connection to an integration server by using one of the following methods:

- Create a connection to an integration server by specifying the hostname and port settings in the connection wizard:
  a) Open the Integration Explorer view in the IBM App Connect Enterprise Toolkit.
  b) Right-click the Integration Servers folder and then click **Connect to an Integration Server**.
  c) In the **Connect to an integration server** wizard, enter the following values:
     – The **Hostname** or IP address of the computer on which your integration server is running.
     – The **Port** used by the administration REST API. This property must be a valid positive number.
     – (Optional). The **User name** for a web administration account that you want to use to secure the connection. For more information, see command.
     – (Optional). The **Password** that is associated with the web administration account for the **User name**. For more information, see command and “Managing web user accounts” on page 2510.
     – To save the **Password** value, select the **Save password** checkbox.

       The password is encrypted in Eclipse Secure Storage, which is a local file that is shared by all Eclipse-based products on the computer, including the IBM App Connect Enterprise Toolkit. If

you select this option and Eclipse Secure Storage is not already set up, you must complete some additional steps to store the password securely:

a. Set a master password for Eclipse Secure Storage.

On Windows, the master password is generated automatically.

On Linux and UNIX, the **Secure Storage** window opens, and you must set a master password for Eclipse Secure Storage. Enter a value for **Password**, and use the same value for **Confirm password**.

b. You are prompted to set master password recovery.

If you select **Yes**, the **Password Recovery** pane opens. In the **Password Recovery** pane, enter your questions and answers for password recovery.

– To connect to the integration server by using HTTP with the Secure Sockets Layer (SSL), select the **Use HTTPS** checkbox.

d) Click **Finish** to connect to the integration server.

- Create a connection to an integration server by using settings from a `.broker` file:
  a) Open the Integration Explorer view in the IBM App Connect Enterprise Toolkit.
  b) Right-click the Integration Servers folder and then click **Connect to an Integration Server using an Integration Connection file**.
  c) Select the `.broker` file and then click **Open** to connect to the integration server.

  The connection to the integration server is created in your workspace.

Results

You can now view properties and manage your integration server and resources, in the IBM App Connect Enterprise Toolkit.

You can export the remote connection details to a `.broker` file by right-clicking the integration server and selecting **Export the Integration Server to an Integration Connection file**.

Connecting to an independent integration server from the Toolkit by specifying a userid and password

Connect to an independent integration server from the IBM App Connect Enterprise Toolkit by specifying a userid and password.

Before you begin

- Create an independent integration server by running the **`IntegrationServer`** command as described in command, or by using a wizard in the IBM App Connect Enterprise Toolkit, as described in “Creating and starting a local, independent integration server by using the Toolkit” on page 170.

About this task

You can configure an independent integration server to require a userid and password to be specified when a user tries to connect to it from the IBM App Connect Enterprise Toolkit.

Procedure

Configure the independent integration server with a userid and password by completing the following steps:

1. Stop the independent integration server by stopping its IntegrationServer process as described in “Stopping an integration server” on page 254.

2. Enable authentication on the independent integration server by running the **mqsichangeauthmode** command.

   For example, if the work directory for your independent integration server is `myWorkDir`, you can run the following command:

   ```
   mqsichangeauthmode -w myWorkDir -b active
   ```

   For more information, see command.
3. Create a web user account and password for an independent integration server by running the **mqsiwebuseradmin** command.

   For example, if the work directory for your independent integration server is `myWorkDir`, you can run the following command to create the web user *Admin* with the password *Passw0rd!*:

   ```
   mqsiwebuseradmin -w myWorkDir -c -u Admin -a Passw0rd!
   ```

   For more information, see mqsiwebuseradmin command.
4. Start the independent integration server by running the **IntegrationServer** command.

   For example, if the work directory for your independent integration server is `myWorkDir`, you can run the following command:

   ```
   IntegrationServer --work-dir myWorkDir
   ```

   For more information, see command.

Connect to the independent integration server from the IBM App Connect Enterprise Toolkit by completing the following steps:

5. In the Integration Explorer view, right-click **Integration servers** and then click **Connect to an integration server**.
6. In the **Connection details** wizard, enter the following information:

   - **Host name**

     Enter the name or the URL of the host where the independent integration server is running. For example, `localhost`.

   - **Port**

     Specify the port number through which the REST API is used for integration server administration. For example, `7600`.

   - **User name**

     Specify user name for the web user account that you created. For example, `Admin`.

   - **Password**

     Specify password for the web user account that you created. For example, `Passw0rd!`.

What to do next

Start or stop resources that are deployed on your integration server. For more information, see “Starting or stopping deployed resources” on page 317.

Viewing integrations by using an IBM App Connect Dashboard

Use an IBM App Connect Dashboard to view local and remote integrations, and integrations that are running on containers.

About this task

You can start an IBM App Connect Dashboard by running the **Dashboard** command, and logging in to it in a web browser. You can then use it to create connections to independent and managed integration servers.

Multiple users can log on to the same IBM App Connect Dashboard. You can view the connections that you create under your account, and you can export them to be viewed by other users in the same dashboard, or in a different dashboard. You can import and view connections that other users create in the same dashboard, or in a different dashboard. When you export connections, you can encrypt credentials by specifying a password, which other users must use when they import your connections.

By selecting the appropriate tab, you can view the state of all integration nodes, or integration servers that have connections in an IBM App Connect Dashboard, and that your account is authorized to view. By traversing the menus, you can view information about any resource that is deployed to any of the integration servers.

Create an IBM App Connect Dashboard, configure integration servers to connect to it, create and share connections, and view information as described in the following topics:

Procedure

- “Starting an IBM App Connect Dashboard by using the Dashboard command” on page 258
- “Logging in and out of an IBM App Connect Dashboard” on page 260
- “Configuring an integration server to connect to an IBM App Connect Dashboard” on page 261
- “Creating connections in an IBM App Connect Dashboard” on page 264

View integrations in an IBM App Connect Dashboard, as described in the following topics:

- “Viewing integration servers that are connected to an IBM App Connect Dashboard ” on page 266
- “Viewing the state of integration servers that are connected to an IBM App Connect Dashboard ” on page 268
- “Viewing information from deployed resources in an IBM App Connect Dashboard ” on page 269

Share connection information with other users in an IBM App Connect Dashboard, as described in the following topic:

- “Sharing connection information with other users in an IBM App Connect Dashboard ” on page 270

Starting an IBM App Connect Dashboard by using the Dashboard command

Start an IBM App Connect Dashboard by using the **Dashboard** command.

Procedure

Start an IBM App Connect Dashboard by using the **Dashboard** command.

You must specify a value for the **--work-dir** parameter. You can create a work directory before you run the command. If the work directory that you specify does not exist, it is created when you run the command.

You can include the **--port-number** parameter in the command. If you do not, the command creates a `dashboard.conf.yaml` file in the work directory with the port number set to the default value of 7700. You can allocate a non-default port by using one of the following methods:

- Before you run the **Dashboard** command, create a work directory and edit the `dashboard.conf.yaml` to reference a non-default port number. Then, run the **Dashboard** command without the **--port-number** parameter.
- Run the **Dashboard** command, and specify a non-default value for the **--port-number** parameter.

If the default port number is in use, or if the port number that you specify is in use, an error message appears in the command output.

If you supply a keystore, you must edit the **sslCertificate** parameter in the **--work-dir**`\dashboard.conf.yaml` file to show the path to the keystore file. You can supply the keystore password by using one of the following methods:

- Before you run the **Dashboard** command, create a work directory and edit the **sslPassword** parameter in **--work-dir**`\dashboard.conf.yaml` to show your password. Then, run the **Dashboard** command without the **--ssl-password** parameter.
- If you prefer not to specify the password in the **--work-dir**`\dashboard.conf.yaml` file, you can run the **Dashboard** command with the **--ssl-password** parameter. For more information, see command.

```
Connections:
  Https:
    # Reject connections to TLS endpoints presenting a certificate not signed by a trusted CA
 (i.e. self-signed certificates)
    rejectUnauthorized: true

RestAdminListener:
  port: 7700               # Set the Admin REST API Port for ACE Web UI and Toolkit. Defaults
 to 7700

  # Note the Admin REST API will be insecure without the following being set
  host: 'localhost'         # Set the hostname otherwise we bind to the unspecified address

  # SSL Server auth
  # sslCertificate: '/path/to/myKeystore.p12'
  # sslPassword: 'passw0rd'

  # SSL Client auth
  # requireClientCert: true                    # Request a certificate from the client
  # caPath: '/path/to/CA/certificates'         # CA certs, all files at this path will be read
```

For example, to start the dashboard, and use a work directory of `C:\myDashboardWorkDir`, and accept the default port, run the following command:

```
Dashboard --work-dir C:\myDashboardWorkDir
```

To start the dashboard, and use a work directory of `C:\myDashboardWorkDir1`, and specify a non-default port, run the following command. In this example, a value of 7701 is used for **--port-number**:

```
Dashboard --work-dir C:\myDashboardWorkDir1 --port-number 7701
```

To start the dashboard, and use a work directory of `C:\myDashboardWorkDir2`, and specify a non-default port, and specify an *ssl* password, run the following command:

```
Dashboard --work-dir C:\myDashboardWorkDir2 --port-number 7702 --ssl-password mySSLPassword
```

In this example, a value of 7702 was used for **--port-number**, and a value of *mySSLPassword* was used for **--ssl-password**.

To use the command with the **--ssl-password** parameter, you must configure the `--work-dir \dashboard.conf.yaml` file with a value for the **sslCertificate** parameter. You can configure the `dashboard.conf.yaml` file after you run the command. Alternatively, before you run the command, you can create the work directory `C:\myDashboardWorkDir2`, and copy the provided sample `dashboard.conf.yaml` file into the directory. Then, configure the `dashboard.conf.yaml` file with values for *sslCertificate*, and *sslPassword* before you run the command.

The sample `dashboard.conf.yaml` file is located in the `samples\configuration` folder of the installation directory. For example, `C:\Program Files\IBM\ACE\11.0.0.11\server\sample\configuration`,

Results
The dashboard process starts.

What to do next
Log in to the IBM App Connect Dashboard, as described "Logging in and out of an IBM App Connect Dashboard" on page 260.

Logging in and out of an IBM App Connect Dashboard
Log in to an IBM App Connect Dashboard by creating a new account, or by logging in with an existing account, and enable multiple users on the same dashboard. Log out of an IBM App Connect Dashboard by selecting **log out** from the **Help menu**.

Before you begin
Start an IBM App Connect Dashboard as described in "Starting an IBM App Connect Dashboard by using the Dashboard command" on page 258.

About this task
You can log in to the IBM App Connect Dashboard by creating a new account, or by logging in with an existing account, and you can enable multiple users to access the same dashboard. You can log out by selecting **Log out** from the **Help menu**.

Procedure
1. Start the IBM App Connect Dashboard in a web browser by using the following method:
   - From a web browser, enter the URL for the web user interface into a web browser, in the following form:

     protocol`://`*hostname*`:`*port*
     - *protocol* is either `http` or `https`.
     - *hostname* is the host that contains the work directory that you created by running the **`Dashboard`** command, as described in "Starting an IBM App Connect Dashboard by using the Dashboard command" on page 258.
     - *port* is the port on which the dashboard listens for requests. The default value is 7700.

     For example, if the dashboard is running on your local workstation on port 7700, you can enter the following URL:

     ```
     https://localhost:7700
     ```

     A web browser window opens, and the logon screen for IBM App Connect Dashboard is displayed.

Log in to the IBM App Connect Dashboard by creating a new account, as described in Step 2, or by logging in with an existing account, as described in Step 3. Multiple users can log in to the same dashboard at the same time by completing either of these steps.

2. Log in to the IBM App Connect Dashboard by creating a new account, by completing the following steps:
   a) Click **Create a new account**. The `Save password` dialog is displayed.
   b) In the `Username` field, type a value for the new username that you want to create.
   c) In the `Password` field, type a value for a password for the new username that you created.
   d) In the `Confirm password` field, type the value of the password that you created.
   e) Click **Create and log in**.

   The IBM App Connect Dashboard is opened, and the Dashboard view is displayed.
3. Log in to the IBM App Connect Dashboard by logging in to an existing account, by completing the following steps:
   a) In the `Username` field, type the username for an existing account.
   b) In the `Password` field, type the password for the username that you entered.
   c) Click **Login**.

   The IBM App Connect Dashboard is opened, and the Dashboard view is displayed.

When you finish working on the IBM App Connect Dashboard, you can log out by completing step 4

4. Optional: Log out of the IBM App Connect Dashboard by clicking **Log out** from the **Help menu**. The dashboard closes, and the logon screen is displayed.

What to do next

Create and configure integration servers to connect to an IBM App Connect Dashboard, as described in "Configuring an integration server to connect to an IBM App Connect Dashboard" on page 261.

Configuring an integration server to connect to an IBM App Connect Dashboard

Configure an integration server to connect to an IBM App Connect Dashboard.

About this task

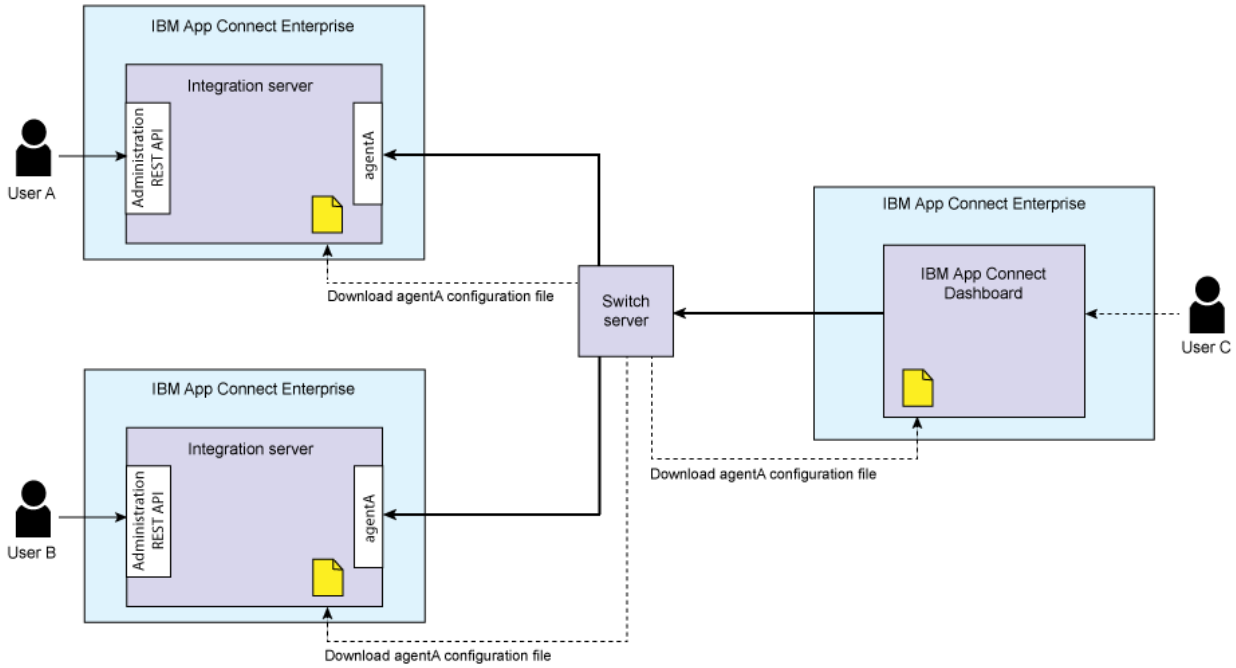
If you start an integration node, you can visualize the managed integration servers in the dashboard by creating a connection to the integration node from the dashboard. The only way that you can visualize a managed integration server in the dashboard is by creating a connection to the integration node in the dashboard.

If you start an independent integration server, you can visualize it in the dashboard by creating a connection to it from the dashboard.

If you configure an independent integration server with an `agentA` configuration file for a switch, it registers with the switch. Then, you can create a connection to the switch in the dashboard to visualize the independent integration server.

If you configure an independent integration server with an `agentA` configuration file, other users who can download the `agentA` file from the switch server can perform remote administration on your integration server from an IBM App Connect Dashboard. Any users and roles that are created for securing the administrative RESTAPI, are not applicable to remote administration with an `agentA` file. For more information, see "Managing resources by using the administration REST API" on page 334.

As shown in the diagram, if multiple integration servers are connected to a single switch server, remote administration can be performed on the connected integration servers from an IBM App Connect Dashboard. In this example, access for users A and B is controlled separately through the administration REST API of the respective Integration Servers. However, user C can perform remote administration on both integration servers by using the switch server and the `agentA` configuration file.



You cannot configure an integration node with an `agentA` configuration file. You can configure only independent servers with an `agentA` configuration file.

Procedure

If an integration server has a publicly accessible end point, you can connect directly to it from the IBM App Connect Dashboard, as described in step 1.

If an integration server is behind a firewall, you must configure the integration server with an `agentA` file, and then connect to it from the IBM App Connect Dashboard by using a switch server. You can obtain an `agentA` file by using a managed service, or by creating a switch operand in IBM Cloud Pak for Integration, as described in step 2.

If you want to connect to an integration server that is running on a container, you must also configure it with an `agentA` file.

1. Connect directly to an integration server that has a publicly accessible end point, as described in “Creating connections in an IBM App Connect Dashboard” on page 264.

If you configure an independent integration server with an `agentA` configuration file for a switch, it registers with the switch. Then, you can create a connection to the switch in the dashboard to visualize the independent integration server.

2. Configure the integration server with an `agentA` file by using a managed service, as described in substep a, or by creating a *SwitchServer* operand in IBM App Connect Operator, as described in substep b.
   a) Configure the integration server with an `agentA` file by using a managed service by completing the following steps:
      i) Download the `agentA` file by completing the following steps:
         a) If you have not created an App Connect Agent, click **New** on the **Private Network Connections** tab in App Connect, and then click **App Connect Agent**.
         b) On the **Actions** menu for the App Connect Agent, select **View setup instructions** to open a window in which the instructions are displayed.
         c) Download the configuration by clicking the button under step 2 of the instructions, which are displayed in the window, which you opened in step 2.
      ii) Copy the downloaded `agenta.json` configuration file to the directory `--work-dir/config/iibswitch/agenta`, where `--work-dir` is the work directory that you specified when you created the integration server. You might need to create the `agenta` directory at the same level as the `agentx` directory that is there by default. You cannot configure `agenta` and `agentx` on the same integration server.
   b) Create an `agentA` file as described in App Connect Switch Server reference. Then, configure the integration server with the `agentA` file by creating a SwitchServer operand in IBM App Connect Operator version 1.0.0 or later (operand 11.0.0.10-r3-eus) by running the following commands. The parameter values that are shown are examples only.
      i) `oc get Configuration my-switch-agenta -o=jsonpath={.spec.secretName} my-switch-agenta`
      ii) `oc get secret my-switch-agenta -o=jsonpath={.data.configuration} eyJuYW1lIjoiYWdlbnRhIiwic3dpdGNoIjp7InVybCI6IndzczovL21hcnRpbi1zcy1zd2l0Y2gtYWNlL0tLVxuIl0sInJlamVjdFVuYXV0aG9yaXplZCI6dHJ1ZX19fQ==`
      iii) `oc get secret my-switch-agenta -o=jsonpath={.data.configuration} | base64 -d | jq`

      The output from running the commands is similar to the following example:

```
{
  "name": "agenta",
  "switch": {
    "url": "wss://example.ibm.com:443",
    "certs": {
      "key": "-----BEGIN PRIVATE KEY-----\nMIIEvwIBADANBgk ... bNo12hvjjI2NJBwVIA==
\n-----END PRIVATE KEY-----\n",
      "cert": "-----BEGIN CERTIFICATE-----\nMIID8jCCAtqgAwIB ... Zu/Ep+k/\n-----END
 CERTIFICATE-----\n",
      "ca": [
        "-----BEGIN CERTIFICATE-----\nMIIEXjCCA0agA ... HpL0V1+U7xrajhpjh+tbTmD6\n-----
END CERTIFICATE-----\n"
      ],
      "rejectUnauthorized": true
    }
  }
```

```
}
```

iv) Save the output to a local file, for example, `/my/work/dir/config/iibswitch/agenta/agenta.json`.

v) Edit `/my/work/dir/config/iibswitch/agenta/agenta.json` by adding an **agentID** field at the same level as the **name** field.

Alternatively, you can set the *MQSI_AGENT_ID* environment variable in the environment for the independent integration server.

The value for **agentID** must be a *uuidv4* string.

The following example shows an `agenta.json` file that was edited to add an **agentID** field that is populated with a *uuidv4* string.

```
{
  "name": "agenta",
  "agentId": "7690095b-3db8-40d2-8584-d09335a0dab9"
  "switch": {
    "url": "wss://example.ibm.com:443",
    "certs": {
      "key": "-----BEGIN PRIVATE KEY-----\nMIIEvwIBADANBgk ... bNo12hvjjI2NJBwVIA==
\n-----END PRIVATE KEY-----\n",
      "cert": "-----BEGIN CERTIFICATE-----\nMIID8jCCAtqgAwIB ... Zu/Ep+k/\n-----END
 CERTIFICATE-----\n",
      "ca": [
        "-----BEGIN CERTIFICATE-----\nMIIEXjCCA0agA ... HpL0V1+U7xrajhpjh+tbTmD6\n-----
END CERTIFICATE-----\n"
      ],
      "rejectUnauthorized": true
    }
  }
}
```

vi) Copy the edited `agenta.json` configuration file to the directory `--work-dir/config/iibswitch/agenta`, where `--work-dir` is the work directory that you specified when you created the integration server. You might need to create the `agenta` directory at the same level as the `agentx` directory that is there by default. You cannot configure `agenta` and `agentx` on the same integration server.

What to do next

Create connections in an IBM App Connect Dashboard, as described "Creating connections in an IBM App Connect Dashboard" on page 264.

Creating connections in an IBM App Connect Dashboard

Create connections in an IBM App Connect Dashboard.

Before you begin

Start an IBM App Connect Dashboard by using the **Dashboard** command, and access it in a web browser, as described in "Starting an IBM App Connect Dashboard by using the Dashboard command" on page 258.

About this task

In the IBM App Connect Dashboard, you can create connections to managed integration servers and independent integration servers that are created with IBM App Connect Enterprise 11.0 Fix Pack 11 or later.

The Switch Server must be IBM App Connect Enterprise 11.0 Fix Pack 11 or later, or be a Switch Server that was created from an App Connect deployment in a containerized environment. For example, IBM App Connect Operator version 1.0.0 or later (operand 11.0.0.10-r3-eus). For more information, see Installing the IBM App Connect Operator.

Alternatively, if you have an instance of the service for App Connect on IBM Cloud, you can use the Switch Server that is created for you. For more information, see App Connect.

Procedure

1. In the IBM App Connect Dashboard, click **Deployment locations** to go the Deployment locations view.
2. Click **Create connection** to open the **Create connection** dialog box.
3. Click in the **Select a connection type** field to open the menu.
4. Select one of the following connection types:
   - Switch
   - Independent server
   - Integration node

   If you want to connect to a local integration node or a remote integration node, select **Integration node**.

   If you want to connect to a local independent integration server, or a remote independent integration server, select **Independent server**.

   If you want to connect to an integration server that runs behind a firewall, or in a container, select **Switch**.
5. Complete the **Name** field. If you want to include a description, you can complete the **Description** field for your connection.
   a) In the **Name** field, type a name for your new connection. If you are connecting to an integration node, or an independent integration server, the connection can have the same name as the integration node or integration server. Alternatively, you can give the connection any name that is not in use for a connection. Valid characters to use for a connection are A-Z, a-z, 0-9, -, and _.
   For example, if you want to create a connection to a local integration node named *myNode*, you can name the connection `myNode`.
   b) Optional: In the **Description** field, type a description.
   For example, `Local integration node`.

If you selected **Integration node** or **Integration server** at Step "4" on page 265, you must complete Step 6. If you selected **Switch** at Step "4" on page 265, you must complete Step 7.

6. Optional: Enter the connection values for an integration node, or an independent integration server.
   a) You must complete the **address** field. In the **address** field, type the URL for the local or remote integration node or the local or remote integration server with the format, *protocol://hostname:port*.
      - *protocol* is either `http` or `https`.
      - *hostname* is for the host of the target integration server you are trying to connect to.
      - *port* is the port (on the *hostname*) of the admin RESTAPI of the target integration node or integration server that you are trying to connect to.

      For example, `http://localhost:4414`
   b) Optional: If you enabled security, you must complete the **Username** field. Type the username that you authorized for access.
   c) Optional: If you enabled security, you must complete the **Password** field. Type the password for the username that you entered in substep b.
   d) If the **address** field URL *protocol* is `https`, you can complete the following fields. These fields are visible only when you input a URL with a *protocol* of `https` into the **address** field.
      - **PEM-formatted CA file**. If the server certificate is from a non-default CA, complete this field. Alternatively, you can update the `--work-dir/dashboard.conf.yaml` file parameter **`rejectUnauthorized`** to *false*.

```
Connections:
```

```
  Https:
    # Reject connections to TLS endpoints presenting a certificate not signed by a
trusted CA (i.e. self-signed certificates)
    rejectUnauthorized: false
```

- **PKCS12 keystore file**. If you need to provide a client certificate for client authentication, complete this field.
- **Keystore passphrase**. If you provide a *PKCS12 Keystore file*, complete this field.

e) In the **Create Connection** dialog box, click **Connect**. The new connection appears in the list of connections in the Deployment locations view.

7. Optional: If you are connecting to a switch server, you must import an `agentA` file. You can obtain an `agentA` file, as described in "Configuring an integration server to connect to an IBM App Connect Dashboard" on page 261.

   a. In the **Create connection** dialog box, click **Click to select an agentA file** in the **AgentA file** field to open a file explorer window.

   b. In the file explorer window, go to the directory where your `agentA` file is located, and select the file.

   c. In the file explorer window, click **Open** to select the file. The field **File imported** appears in the **Create connection** dialog box. The field is populated with the name of the file that you selected.

   d. In the **Create Connection** dialog box, click **Connect**. The new connection appears in the list of connections in the Deployment locations view.

   If you connect to an integration server by using a Switch Server, you must be aware of the properties of the integration server that you connect to.

   If you connect to an independent integration server that is running on a virtual machine, and the integration server is stateful, any changes that you make from the IBM App Connect Dashboard are persistent. If the integration server is stateless, the changes are not persistent, and they are lost if the virtual machine crashes.

   If the integration server is running in a container, then it was created declaratively, and has ephemeral storage. If you change the integration server from the IBM App Connect Dashboard, for example, by deploying a BAR file, that change is performed. However, if multiple replicas of the integration server exist, the change is only performed on one of the replicas. If the container crashes, the changes are lost.

What to do next

View connections in the IBM App Connect Dashboard, as described in "Viewing integration servers that are connected to an IBM App Connect Dashboard " on page 266.

Viewing integration servers that are connected to an IBM App Connect Dashboard

Use an IBM App Connect Dashboard to view managed integration servers, or independent integration servers.

Before you begin

Start an IBM App Connect Dashboard by using the **Dashboard** command, and access it in a web browser, as described in "Starting an IBM App Connect Dashboard by using the Dashboard command" on page 258.

Create connections in an IBM App Connect Dashboard, as described in "Creating connections in an IBM App Connect Dashboard" on page 264.

About this task

In the IBM App Connect Dashboard, you can view only the connections that you create under your account, or connections that other users share with your account. For more information, see “Sharing connection information with other users in an IBM App Connect Dashboard ” on page 270.

Procedure

1. In the IBM App Connect Dashboard, click the **Dashboard** icon to go to the Dashboard view.

You can view any of the following integration servers:

- Local or remote managed integration servers on IBM App Connect Enterprise.
- Local or remote independent integration servers on IBM App Connect Enterprise.
- Integration servers that are connected to the IBM App Connect Dashboard by a switch server.

View a connection in the IBM App Connect Dashboard by completing one of the following steps:

2. Optional: Local or remote managed integration server on IBM App Connect Enterprise. View a local or a remote managed integration server by completing the following steps:
   a) In the Dashboard view, click **Nodes**. Any local or remote integration nodes that are connected to the IBM App Connect Dashboard, and that your account is authorized to view, are displayed.

      The tile for each integration node contains the following information:

      - The name of the integration node.
      - The text "Node" to confirm that the connection is to an integration node.
      - The URL of the connection. For example, *http://localhost:4414*.

      You can search for a specific integration node by typing the name of the integration node into the **Search** field and pressing Enter. If an integration node with the specified name is connected to the IBM App Connect Dashboard, it is highlighted in the Dashboard view.

      For more information about connection names, see “Creating connections in an IBM App Connect Dashboard” on page 264.

   b) View the managed integration server by accessing the menu in the connection tile for the integration node. Click the **Open List of Options** icon in the tile of an integration node. Then, click Open in the menu.

      If the integration node has any managed integration servers, they are displayed in the Dashboard view.

      The tile for each managed integration server contains the following information:

      - The name of the managed integration server.
      - The text "Server" to confirm that the tile is for an integration server.
      - The status of the managed integration server is shown as *Started* or *Stopped*.

      You can search for a specific managed integration server by typing the name or part of the name of the integration server into the **Search** field and pressing Enter. If a managed integration server with the specified name exists on the integration node, it is highlighted in the Dashboard view.

      Alternatively, you can view manged integration servers by accessing the **Servers** tab, as described in step 3.

3. Optional: You can view local or remote independent integration servers, and local or remote managed integration servers by accessing the **Servers** tab. You can also view integration servers that are connected to the IBM App Connect Dashboard by a switch. View integration servers by completing the following steps:
   a) In the Dashboard view, click **Servers**. Integration servers that your account is authorized to view, are displayed. You can view local or remote independent integration servers, and local or

remote managed integration servers. If you have a connection to a switch, the Servers view shows integration servers that are connected at the other side of that switch server.

A tile for an independent integration server differs from a tile for a managed integration server. It includes the URL. The following information is included on the tile of an independent integration server:

- The name of the work directory for the integration server. If you specified a name for the independent integration server when you created it, the name is shown instead of the work directory.
- The text "Server" to confirm that the connection is to an integration server.
- The URL of the connection. For example, *http://localhost:7700*.

The tile for an integration server that is connected to the IBM App Connect Dashboard by a switch also contain the following details:

- If the server is replicated, the number of replications are shown.
- The text "connected via: *<name of switch server>*"

You can search for a specific independent integration server by typing the name of the work directory for the integration server. If you specified a name when you created the independent integration server, you can search by typing the name of the integration server. If an independent integration server with the specified work directory or name is connected to the IBM App Connect Dashboard, it is highlighted in the Dashboard view.

For more information about connection names, see “Creating connections in an IBM App Connect Dashboard” on page 264.

What to do next

View the state of the integration servers, as described in “Viewing the state of integration servers that are connected to an IBM App Connect Dashboard ” on page 268.

Viewing the state of integration servers that are connected to an IBM App Connect Dashboard

View the state of integration servers that are connected to an IBM App Connect Dashboard.

Before you begin

Start an IBM App Connect Dashboard by using the **Dashboard** command, and access it in a web browser, as described in “Starting an IBM App Connect Dashboard by using the Dashboard command” on page 258.

Create connections in an IBM App Connect Dashboard, as described in “Creating connections in an IBM App Connect Dashboard” on page 264.

About this task

You can view the state of local and remote managed integration servers, independent integration servers, or integration servers that are connected to the IBM App Connect Dashboard by a switch server. The integration servers must have a connection in the IBM App Connect Dashboard that your account is authorized to view. You can view the state of the integration servers by inspecting the connection tiles in the Dashboard view.

Procedure

1. Use the IBM App Connect Dashboard to view integration servers, as described in “Viewing integration servers that are connected to an IBM App Connect Dashboard ” on page 266.

2. Inspect the tile for the integration server. The status is shown as *Started* or *Stopped*.

   You cannot change the state of an integration node or an integration server in the IBM App Connect Dashboard. For more information about starting and stopping integration nodes and integration servers, see "Starting and stopping an integration node" on page 247, "Starting an integration server" on page 250, and "Stopping an integration server" on page 254.

What to do next

"Viewing information from deployed resources in an IBM App Connect Dashboard " on page 269.

Viewing information from deployed resources in an IBM App Connect Dashboard

View information from deployed resourced in an IBM App Connect Dashboard.

Before you begin

Start an IBM App Connect Dashboard by using the **Dashboard** command, and access it in a web browser, as described in "Starting an IBM App Connect Dashboard by using the Dashboard command" on page 258.

Create connections in an IBM App Connect Dashboard, as described in "Creating connections in an IBM App Connect Dashboard" on page 264.

About this task

You can view information from integration servers that are connected to the IBM App Connect Dashboard, and that your account is authorized to view. To view information from a specific integration server, complete step "1" on page 269. To view information from all the integration servers, complete step "2" on page 269.

Procedure

1. To view information from a specific integration server, for example, the details of a message flow that is deployed in an application, complete the following steps:
   a) In the Dashboard view of the IBM App Connect Dashboard, click **Servers**. Integration servers that are connected to the IBM App Connect Dashboard, and that your account is authorized to view, are displayed.
   b) Click the **Open List of Options** icon for an integration server. Then, click Open in the menu.

      If any applications are deployed to the integration server, they are displayed in the Dashboard view.
   c) Click the **Open List of Options** icon for an application. Then, click Open in the menu.

      If any message flows are contained in the deployed application, they are displayed in the Dashboard view.
   d) Click the **Open List of Options** icon for a message flow. Then, click Open in the menu.

      You can view information about the message flow by clicking the **Properties** tab or the **Activity log** tab.
2. To view information from all integration servers that are connected to the IBM App Connect Dashboard, and that your account is authorized to view, click **Integrations** in the Dashboard view of the IBM App Connect Dashboard.

   If any resources are deployed to any of the integration servers that your account is authorized to view, they are displayed in the Dashboard view. You can view information by clicking the **Open List of Options** icon on the tile of any resource that is displayed.

What to do next

You can share connection information with other users, as described in “Sharing connection information with other users in an IBM App Connect Dashboard ” on page 270.

Sharing connection information with other users in an IBM App Connect Dashboard

Sharing connection information with other users in an IBM App Connect Dashboard by exporting and importing configuration files.

About this task

You can export connection information from your IBM App Connect Dashboard by downloading it in the form of a `yaml` file. If you want to encrypt any credentials in the exported connections, you must specify a password. If you need to restore this set of connections, you can import the `yaml` file in the same dashboard, or in a different dashboard. Other users can also import the `yaml` file on the same dashboard, or on a different dashboard. If a password was set when the connections were exported, you must use the password to import the connections, unless the exported `yaml` file does not contain any encrypted credentials.

Procedure

1. Export connection information. You can export connection information by completing the following steps:
   a. In the Deployment locations view, click **Export**. The "Export Connections" dialog box opens.
   b. In the "Export Connections" dialog box, type a password in the `Password (optional)` field.

      If you provide a password, it is used to encrypt any credentials in your exported connections. It is possible to view the file, but not the credentials. You need the password to import a connections file that contains encrypted credentials. You do not need a password to import a connections file that does not contain encrypted credentials, even if a password was provided when the file was exported.
   c. If you want to cancel the export action, click **Cancel**.
   d. Click **Export** to export the connections.

      Your connections are downloaded as a YAML file into the `Downloads` folder in your local file system.

   For example, `C:\Users\<your user id>\Downloads`.

   If you need to restore this set of connections, you can import the file. Another user on the same dashboard can also import this file.
2. Import connection information.

   You can import connection information that you or another user export from the same dashboard, or from a different dashboard. If a password was set when the connections were exported, and the `yaml`

file contains encrypted credentials, you must use the password to import the connections. You can import connection information by completing the following steps:

a. In the Deployment locations view, click **Import**. The Import Connections dialog box opens.
b. In the Import Connections dialog box, click **Click to select a yaml file**. A File Explorer window opens.
c. In the **File Explorer** window, go the location where the `yaml` file that you want to import is located.
d. In the **File Explorer** window, select the `yaml` file and click **Open**. The `File imported` field in the Import Connections dialog box is populated with the name of the `yaml` file that you selected.
e. If the `yaml` file that you import contains encrypted credentials, you must enter the password that was used when the `yaml` file was exported in the `Password` field.
f. If you want to cancel the import of the file, click **Cancel**,
g. Click **Import**. The `yaml` file is imported into the `Downloads` folder in your local file system.

For example, `C:\Users\<your user id>\Downloads`.

Managing resources

Manage the resources used by integration servers and integration nodes.

About this task

Read the following topics for information about managing resources that are used by integration servers or integration nodes:

- “Managing data caching” on page 271
- “Listing database connections” on page 314
- “Quiescing a database” on page 314
- “Using a JDBC connection pool to manage database resources used by an integration server” on page 315
- “Configuring properties for TCP/IP” on page 229

For information about managing resources that have been deployed to an integration server, see “Managing deployed resources” on page 316.

Managing data caching

Store data that you want to reuse by using the embedded global cache or an external WebSphere eXtreme Scale grid.

About this task

The topics in this section describe the data caching capability that is provided by WebSphere eXtreme Scale. For information about other caching solutions, see the following topics:

- “Environment tree” on page 508
- “Long-lived variables” on page 1611

WebSphere eXtreme Scale provides IBM App Connect Enterprise with data caching capability.

Find out more about the embedded global cache and external WebSphere eXtreme Scale grids in the following topics:

Data caching overview

WebSphere eXtreme Scale provides IBM App Connect Enterprise with data caching capability.

The topics in this section describe the data caching capability that is provided by WebSphere eXtreme Scale. For information about other caching solutions, see the following topics:

- "Environment tree" on page 508
- "Long-lived variables" on page 1611

Introduction

A global cache is a repository for data that you want to reuse. For example, you can use a global cache in IBM MQ message flows to store correlation information for use beyond a specific message flow node, instance of a message flow, or integration server. The cache facilitates the sharing of data within an integration server and between integration servers, and eliminates the need for an alternative solution, such as a database. You can use one message flow node to store data in the global cache, then a second node (in the same message flow or a separate flow), can retrieve that data from the global cache.

You can use a message flow node to interact with the global cache. Interactions with the cache happen outside the message flow transaction, and are committed immediately. If an exception is thrown downstream of the node that interacts with the cache, the cache interactions are not rolled back.

Scenarios and tutorials

For illustrations of how you can use a global cache, see the following scenarios and tutorials:

- "Global cache scenario: Storing state for integrations" on page 273
- "Global cache scenario: Caching static data" on page 275
- Tutorial: Using a Mapping node to graphically access a Lookup table that is stored in the Global Cache; see the Tutorials Gallery in the IBM App Connect Enterprise Toolkit.

Embedded global cache or external WebSphere eXtreme Scale grid

You can use the global cache that is supplied with IBM App Connect Enterprise, and you can configure IBM App Connect Enterprise to connect to an external WebSphere eXtreme Scale grid. You can work with multiple remote grids, and the embedded grid, at the same time. For more information, see "Differences between the embedded global cache and an external WebSphere eXtreme Scale grid" on page 279.

For a detailed description of the elements involved in a global cache or external grid, see the following information:

- "Embedded global cache" on page 277
- "WebSphere eXtreme Scale grids" on page 278

Interaction with the global cache or external grid

You can interact with the global cache or external grid by using a Mapping node or a JavaCompute node. The node can put data into a map, retrieve data, and create a map if one does not exist. For more information, see Accessing the global cache by using a Mapping node or “Accessing the global cache by using a JavaCompute node” on page 1781.

Monitoring and administration of the global cache or external grid

You can monitor the global cache or external grid by using the following tools:

- The activity log
- Resource statistics

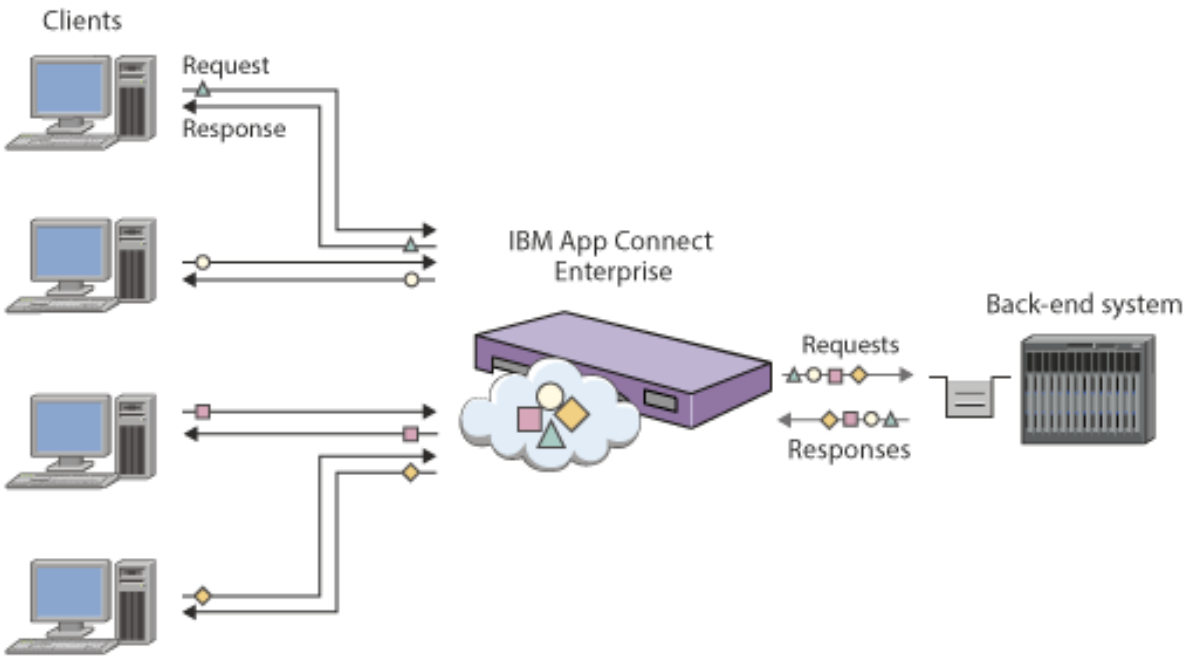
You can administer the embedded cache by using the **mqsicacheadmin** command.

For more information, see “Monitoring the global cache” on page 313.

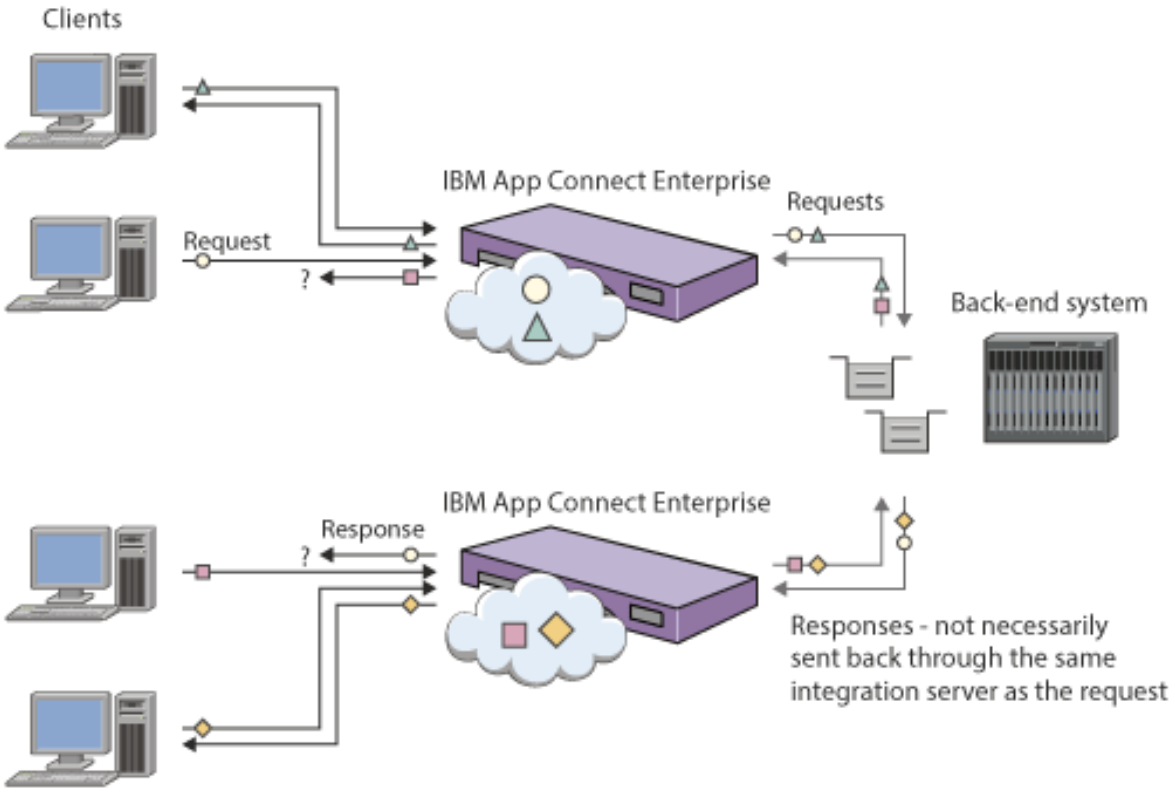
Global cache scenario: Storing state for integrations

You can use a global cache to store state for integrations. With a global cache, each integration server can handle replies, even when the request was processed by another integration server.

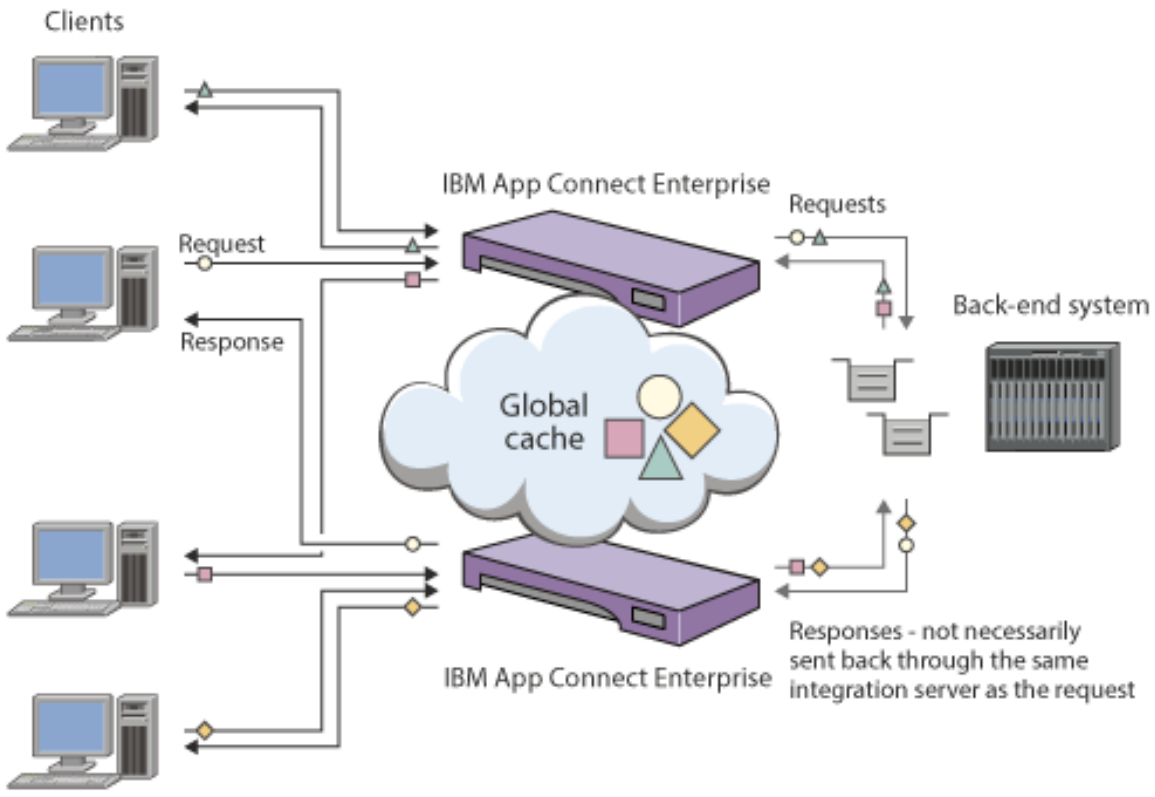
When IBM App Connect Enterprise is used to integrate asynchronous systems, the integration server records information about the requester to correlate the replies correctly, as shown in the following diagram.



When this integration is deployed to multiple integration servers for workload balancing, the reply will not necessarily return through the same integration server as the original request.



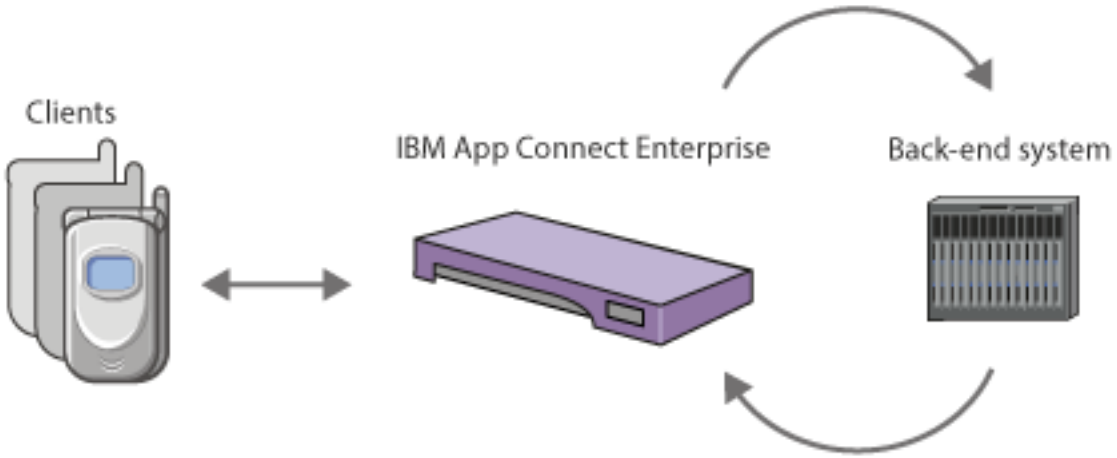
With a global cache, each integration server can handle replies, even when the request was processed by another integration server.



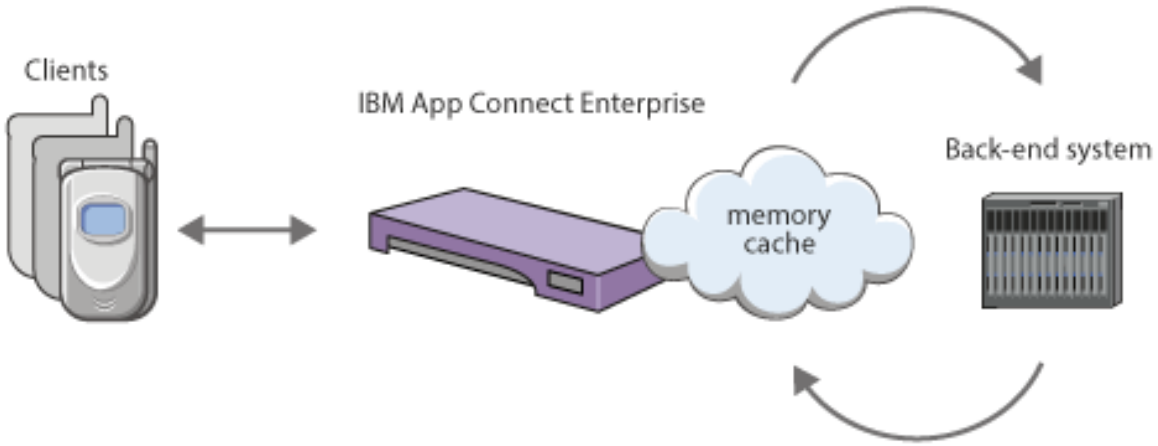
Global cache scenario: Caching static data

You can use a global cache to store static data. The use of a global cache facilitates horizontal scaling in situations where a cache is used to minimize network interactions to a back end system. With a global cache, you can increase the number of clients while maintaining a predictable response time for each client.

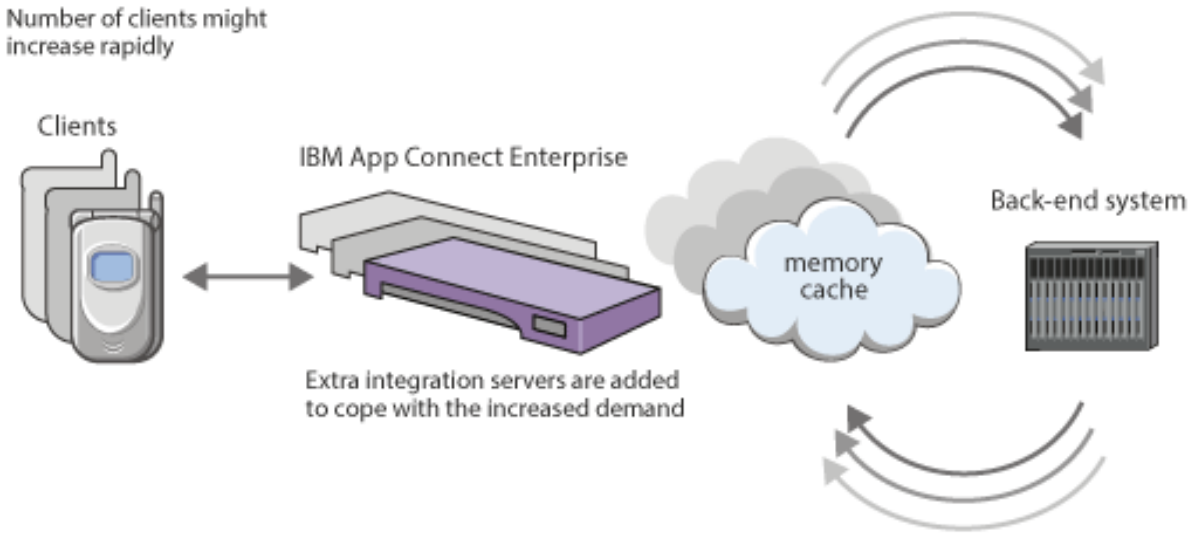
When IBM App Connect Enterprise acts as a façade to a back-end database, it must provide short response times to the client, even though the back-end database has high latency.



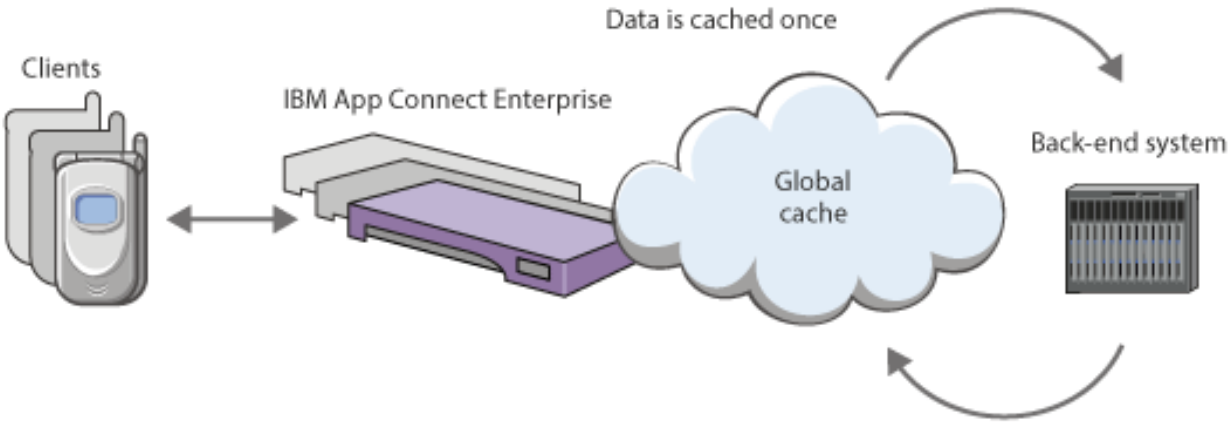
IBM App Connect Enterprise can provide short response times by caching results in memory (for example, ESQL shared variables).



However, this configuration does not scale well horizontally. When the number of clients increases, the number of integration servers can be increased to accommodate the clients, but each integration server has to maintain a separate in-memory cache.



With a global cache, the number of clients can increase while a predictable response time is maintained for each client.



Embedded global cache

Use the global cache that is supplied with IBM App Connect Enterprise to store data that you want to reuse.

The global cache is embedded in IBM App Connect Enterprise, and is disabled by default. To use the cache, you must enable and configure it by setting properties in the `server.conf.yaml` files for the integration servers that will share access to the cache.

The embedded global cache in IBM App Connect Enterprise can use a WebSphere eXtreme Scale enterprise data grid. Enterprise data grids use the eXtreme data format (XDF) instead of Java object serialization. XDF allows for class evolution, which means that you can evolve the class definitions that are used in the data grid without affecting older applications that are using previous versions of the class. For more information, see Enterprise data grid overview in the WebSphere eXtreme Scale product documentation.

Note: The App Connect Enterprise global cache is implemented using WebSphere eXtreme Scale technology. WebSphere eXtreme Scale is designed to offer a resilient cache topology by hosting a known number of catalog and container servers in a fixed topology. This is not compatible with the ephemeral nature of containers running in elastically-scaled cloud environments such as Kubernetes. Therefore, WebSphere eXtreme Scale does not support running the catalog or container server components in containerized environments such as Kubernetes, Docker, or Podman. As a result, App Connect Enterprise does not support the embedded cache when running an integration server in a containerized environment. The embedded cache is supported to make a client connection to an external WebSphere eXtreme Scale grid when running in a container.

To find out more about the differences between the embedded cache and the external grid, see “Differences between the embedded global cache and an external WebSphere eXtreme Scale grid” on page 279.

Customizing the embedded topology

You can set properties explicitly for each integration server, by setting properties in each `server.conf.yaml` configuration file. For example, you might want to specify particular integration servers to host the catalog and container servers so that you can tune performance.

If you stop the integration server that contains the catalog server, the cache becomes unavailable and the data in the cache is lost. Therefore, you must ensure that you define the catalog server appropriately. If you restart the integration server that hosts the catalog server, it can no longer communicate with the container servers in other integration servers. Although these container servers are still running, they are

no longer part of the cache, and your data is lost. Therefore, you must also restart the integration servers that host the container servers.

When you use multiple catalog servers, you can improve performance by taking the following steps:

- Provide other integration servers that host container servers only, rather than having only integration servers that host both catalog and container servers.
- Start and stop integration servers in sequence, rather than using the **mqsistart** or **mqsistop** commands to start or stop all integration servers at once. For example, start the integration servers that host catalog servers before you start the integration servers that host only container servers.

You can configure the global cache by using IBM App Connect Enterprise commands, or the IBM Integration API.

For more information, see "Configuring the embedded global cache" on page 285.

Interaction with the global cache

You can use Mapping nodes or JavaCompute nodes to store and retrieve data in a map in the global cache. When you get a global map from an external grid, the getGlobalMap method makes a connection to the grid if one does not exist. For more information, see Accessing the global cache by using a Mapping node or "Accessing the global cache by using a JavaCompute node" on page 1781.

When you get an MbGlobalMap object, you can also specify how long the data remains in the global cache before it is removed automatically. This time is known as the *time to live* and is counted from when that map entry is last updated. The value applies to all cache entries that are created by using that MbGlobalMap object in that instance of the message flow. Data that is already in the map that you specify, or that is created by another MbGlobalMap object, is not affected by the time to live value. You can create multiple MbGlobalMap objects in different flows or integration servers, all resolving to the same map in the global cache, but with different time to live values.

By default, the time to live is set to zero so that the data is never removed. To set a specific time to live, create a session policy, which you can reference from the MbGlobalMap object. For detailed instructions, see "Specifying how long data remains in the global cache by using the JavaCompute node" on page 1783.

WebSphere eXtreme Scale grids

Use one or more external WebSphere eXtreme Scale grids to store data that you want to reuse.

WebSphere eXtreme Scale provides a scalable, in-memory data grid. The data grid dynamically caches, partitions, replicates, and manages data across multiple servers. The catalog servers and container servers for the IBM App Connect Enterprise global cache collaborate to act as a WebSphere eXtreme Scale grid.

For more information about the grid that is embedded in IBM App Connect Enterprise, see "Embedded global cache" on page 277. To find out more about the differences between the embedded cache and the external grid, see "Differences between the embedded global cache and an external WebSphere eXtreme Scale grid" on page 279.

In addition to the grid that is available in IBM App Connect Enterprise (as the embedded global cache), you can integrate with WebSphere eXtreme Scale grids that are running elsewhere. You can work with multiple external grids, and the embedded grid, at the same time. For a diagram that shows how IBM App Connect Enterprise message flows interact with an external WebSphere eXtreme Scale grid, and for definitions of the terms that are associated with a grid, see "Data caching terminology" on page 281. For more information about grids, see WebSphere Extreme Scale product documentation online.

You might have an existing WebSphere eXtreme Scale environment that uses a topology, such as one of the following examples:

- Embedded WebSphere eXtreme Scale servers in WebSphere Application Server network deployment installations
- A stand-alone WebSphere eXtreme Scale software grid

When you are connecting to an external grid, IBM App Connect Enterprise hosts the WebSphere eXtreme Scale client, but the cache is hosted on an external grid. Therefore, a separate WebSphere eXtreme Scale installation or appliance is required. An installation or appliance can host more than one grid.

To connect to an external grid, you need the following information:

- The name of the grid
- The host name and port of each catalog server for the grid
- Optional: the object grid file that can be used to override WebSphere eXtreme Scale properties

By using a policy to specify the parameters, you can connect to an external WebSphere eXtreme Scale grid. IBM App Connect Enterprise message flows can then access and modify data that is stored in the external grid. If you are connecting to a secure grid, you can create a security identity by using the **mqsisetdbparms** command. To connect to an external grid, follow the instructions in "Connecting to a WebSphere eXtreme Scale grid" on page 309.

You can enable SSL for client connections to external WebSphere eXtreme Scale grids by setting up a public key infrastructure, then enabling SSL for an integration server. For more details, see "Enabling SSL for external WebSphere eXtreme Scale grids" on page 310.

You can use Mapping nodes or JavaCompute nodes to store and retrieve data in a map in the global cache. When you get a global map from an external grid, the getGlobalMap method makes a connection to the grid if one does not exist. For more information, see Accessing the global cache by using a Mapping node or "Accessing the global cache by using a JavaCompute node" on page 1781.

You can monitor the external grid by viewing the activity log and resource statistics. For more information, see "Monitoring the global cache" on page 313.

Differences between the embedded global cache and an external WebSphere eXtreme Scale grid

The embedded cache is optimized for use in IBM App Connect Enterprise. When the default configuration that is provided by the embedded cache does not meet your needs, use an external WebSphere eXtreme Scale grid. With an external grid, you can also make the data in the cache available to both integration flows and other applications outside of IBM App Connect Enterprise.

You can use the embedded global cache or an external WebSphere eXtreme Scale grid (or both) in your IBM App Connect Enterprise solution.

The embedded global cache is a WebSphere eXtreme Scale grid, which consists of WebSphere eXtreme Scale catalog and container servers that are hosted in integration servers. This grid is designed and optimized for use within (and between) integration servers. You can configure the topology of this grid by specifying the number of catalogs and containers, and where they are hosted, but you cannot modify the underlying WebSphere eXtreme Scale configuration of the grid. The embedded cache is supplied as part of IBM App Connect Enterprise and no further installation is needed to use the cache. By contrast, the external grid is not provided with IBM App Connect Enterprise and must be obtained and installed separately. However, with an external grid, you have complete control over the WebSphere eXtreme Scale configuration.

The catalog and container servers for the embedded grid are hosted in integration server processes. Therefore, the catalog and container servers share their Java virtual machines (JVMs) with all other components that are running in the integration server. These components include IBM App Connect Enterprise components, user-defined Java code, and data. As a result, the cache servers do not have control over their containing JVMs, and cannot modify or restart the JVMs. The maximum JVM heap size is determined by the relevant integration server property. Also, the lifecycle of each cache server is tied to the lifecycle of the integration server in which it is hosted.

With an external grid, you must create, administer, and manage the WebSphere eXtreme Scale server components outside of IBM App Connect Enterprise. Therefore, you can separate the availability and management of your cache from IBM App Connect Enterprise.

For more information about connecting to external WebSphere eXtreme Scale grids, see "WebSphere eXtreme Scale grids" on page 278.

Common reasons for choosing an external grid over the embedded cache

Choose an external grid if you have any of the following requirements:

- You need to configure the grid for specific capabilities that are not supported by the embedded global cache.
- You have an architectural preference for the cached data not to be placed in the integration servers themselves.
- You want to separate the availability of the cache from the availability of the integration servers.
- You need an enterprise cache, with multiple applications (other than IBM App Connect Enterprise) that are accessing the data.
- You have (or want) sophisticated, or custom, tools to manage the cache.
- The cache needs to span multiple data centers for disaster recovery.

Comparison of function

The following table shows the requirements that are supported in the embedded global cache or an external grid:

Requirement	Embedded global cache	External WXS grid
A cache is available to IBM App Connect Enterprise with minimal configuration	√	
Cache components are hosted inside integration server processes	√	
Simple MbGlobalMap access exists to the cache	√	√
Access the global cache through the CacheGet, CachePut, and CacheRemove transforms in your maps	√	√
Same cached data can be accessed by multiple integration servers	√	√
Connections are managed by IBM App Connect Enterprise	√	√
Resource statistics and activity log provided for cache interactions	√	√
Manage your cache components outside of IBM App Connect Enterprise processes		√
Configure the number of partitions and the number and type of replicas		√
Configure multiple zones		√
Define your own backing maps, both fixed and templates		√

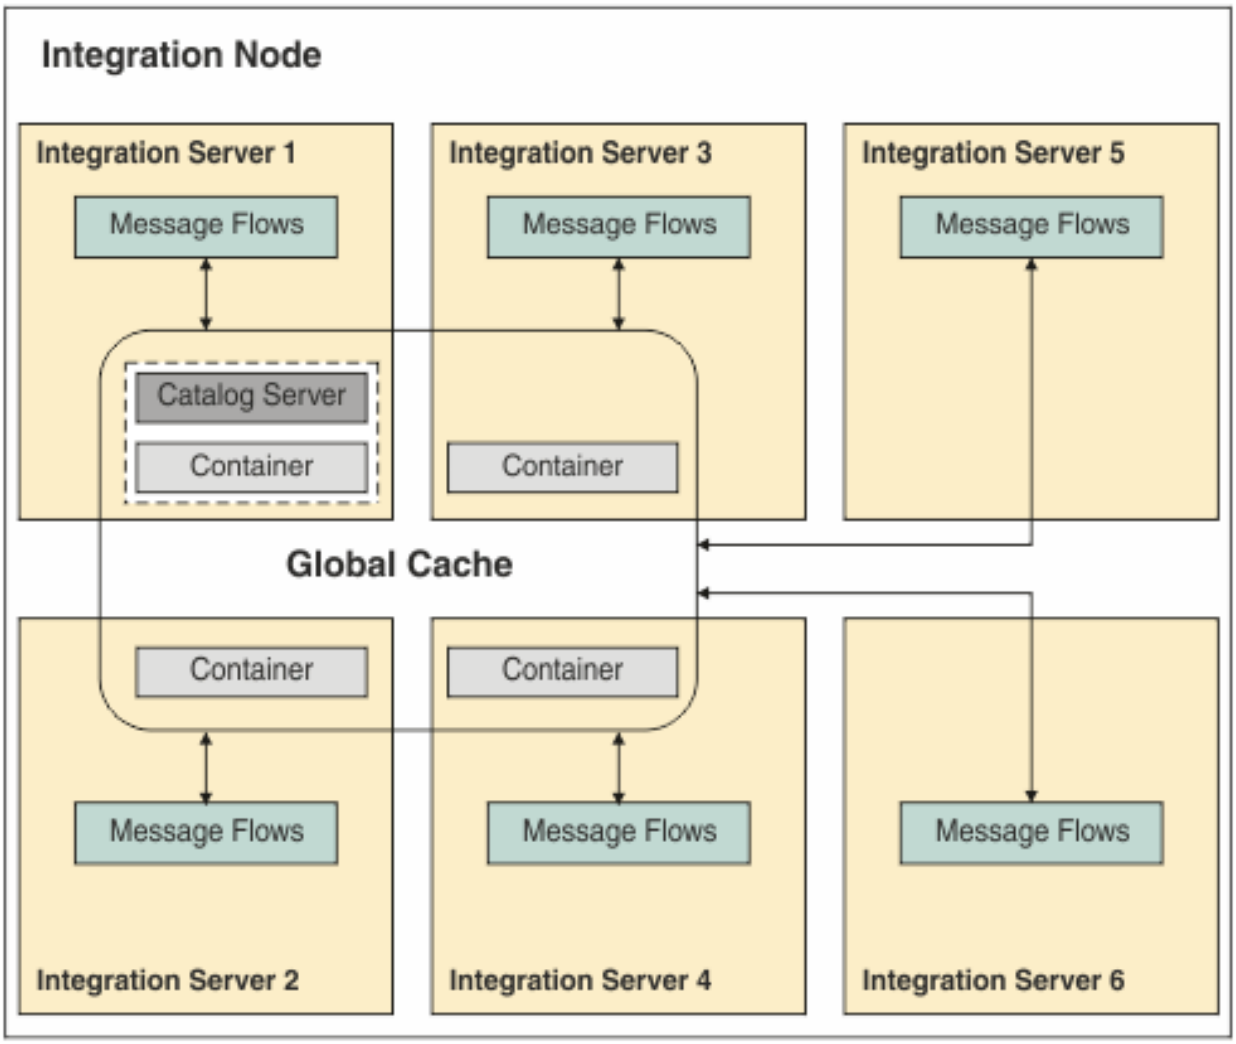
Requirement	Embedded global cache	External WXS grid
Configure your preferred locking strategy, eviction strategy, and copy mode		✓
Use plug-ins (for example, eviction or loading)		✓
Access other configuration options by using WebSphere eXtreme Scale `objectgrid.xml` and `deployment.xml` files		✓
Configure the grid name, zones, quorum, and heartbeat settings on the components		✓
Enterprise grid capability, which can be used by multiple applications		✓
Administer and monitor your grid outside of IBM App Connect Enterprise		✓
Multi-master replication to synchronize grids in different data centers		✓

Data caching terminology

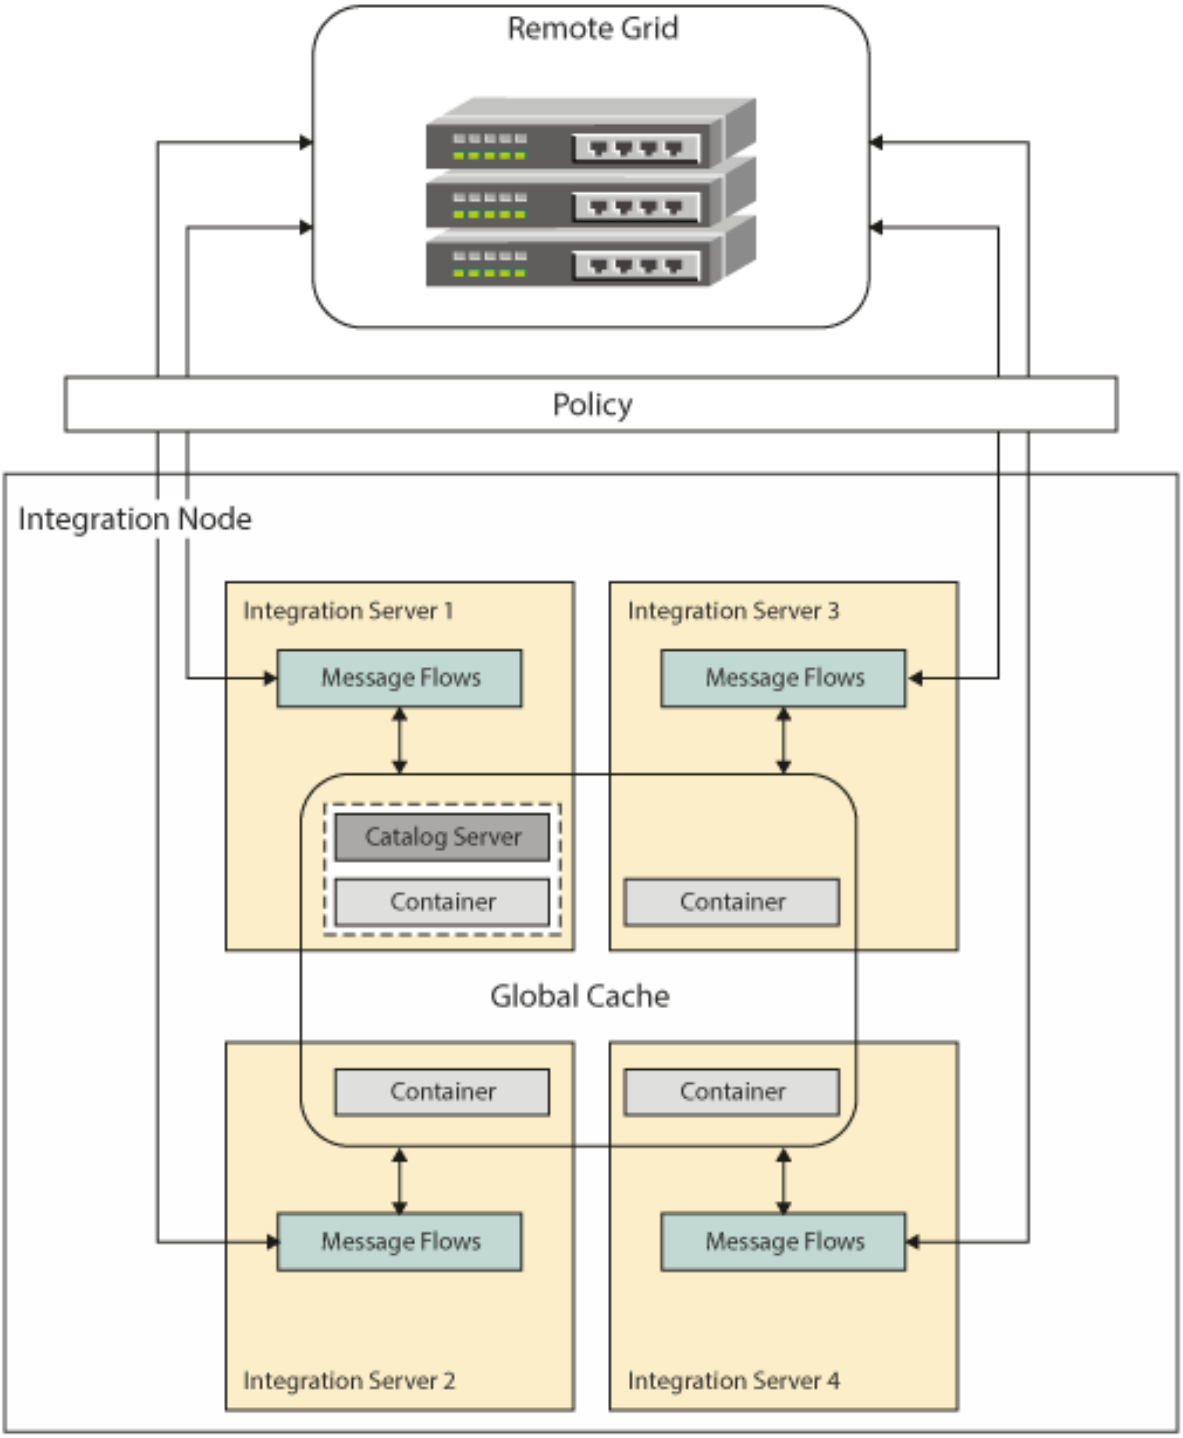
The global cache is embedded in IBM App Connect Enterprise. You can also connect to an external WebSphere eXtreme Scale grid.

The embedded cache can be used by message flows running in any integration server, and you can set properties explicitly for each integration server. The examples in this section show integration servers that are managed by an integration node; however, the global cache can also be used by independent integration servers, which are not managed by an integration node.

The following diagram shows the embedded global cache in an integration node that contains six integration servers. Four integration servers host components for the global cache, but message flows in all six integration servers can use the cache.



The following diagram shows how IBM App Connect Enterprise can connect to both an embedded cache and an external WebSphere eXtreme Scale grid. A policy is used to connect to the external grid.



The following components are involved in the global cache:

Catalog servers

The catalog server is a component that is embedded in an integration server, and it controls the placement of data and monitors the health of containers. You must have at least one catalog server in your global cache.

To avoid losing cache data when a catalog server is lost, you can specify more than one catalog server. If the cache is shared by two integration servers, each of which hosts a catalog server, if one catalog server fails, the remaining catalog server can still be accessed. Having more than one catalog server can affect startup time until the cache is available.

When you are using multiple catalog servers, you can improve performance by taking the following steps:

- Provide other integration servers that host container servers only, rather than having only integration servers that host both catalog and container servers.
- Start and stop integration servers in sequence, rather than using the **mqsistart** or **mqsistop** commands to start or stop all integration servers at once. For example, start the integration servers that host catalog servers before you start the integration servers that host only container servers.

Container servers
A container server is a component that is embedded in the integration server that holds a subset of the cache data. Between them, all container servers in the global cache host all of the cache data at least once. If more than one container exists, the default cache policy ensures that all data is replicated at least once. In this way, the global cache can cope with the loss of container servers without losing data.

You can host more than one container server in a multi-instance integration node. If the active instance of the multi-instance integration node fails, the global cache switches to the container server in the standby instance.

Catalog domain name
When you are using a global cache that spans multiple integration nodes, ensure that all WebSphere eXtreme Scale servers that are clustered in one embedded grid use the same domain name. Only servers with the same domain name can participate in the same grid. WebSphere eXtreme Scale clients use the domain name to identify and distinguish between embedded grids.

Servers in different domains cannot collaborate in the same grid.

Grids
WebSphere eXtreme Scale provides a scalable, in-memory data grid. The data grid dynamically caches, partitions, replicates, and manages data across multiple servers. The catalog servers and container servers for the IBM App Connect Enterprise global cache collaborate to act as a WebSphere eXtreme Scale grid. For more information about grids, see WebSphere Extreme Scale product documentation online.

Maps
Data is stored in maps. A map is a data structure that maps keys to values. One map is the default map, but the global cache can have several maps.

The cache uses WebSphere eXtreme Scale dynamic maps. Any map name is allowed, apart from names that begin with SYSTEM.BROKER, which is reserved for use by the integration node. The default map is named SYSTEM.BROKER.DEFAULTMAP; you can use or clear this map.

ObjectGrid® file
An ObjectGrid XML file is used to configure the WebSphere eXtreme Scale client. You can use this file to override WebSphere eXtreme Scale properties. For more information about configuring clients, see WebSphere Extreme Scale product documentation online.

You can configure WebSphere eXtreme Scale options by using the WXSServer policy. For more information, see “Connecting to a WebSphere eXtreme Scale grid” on page 309.

You can use resource statistics and activity trace to monitor the status of the global cache and external grid, and to diagnose problems. You can also administer the embedded global cache by using the **mqsicacheadmin** command.

Configuring the embedded global cache

Configure the embedded global cache by setting properties in the `server.conf.yaml` configuration files.

Before you begin

- For concept information, see "Data caching overview" on page 272.
- When you are using the global cache, increase the JVM heap size for integration servers that are hosting cache components. For more information, see the *Planning environment capacity* section of the WebSphere Extreme Scale product documentation online.

About this task

To use the global cache, set properties in the `server.conf.yaml` configuration files for the integration servers that will share the global cache. By default, the global cache is turned off.

You can configure the global cache by directly setting the properties in the **GlobalCache** section of the `server.conf.yaml` files for your integration servers. Alternatively, you can copy and paste the content of the global cache section to replace the existing content of the **GlobalCache** section of your `server.conf.yaml` files, and then modify as required. The **GlobalCache** section is a sub-section of the **ResourceManagers** section in the `server.conf.yaml` files. The sample files show how to configure the global cache for different scenarios, from a basic configuration using a single integration server that is hosting both a catalog server and a container server, to more complex configurations involving multiple integration servers.

The following sample configuration files are provided with IBM App Connect Enterprise, in the *install_directory*`\server\samples\globalcache` directory. These files contain examples of various global cache configurations that you might require:

- **basic_1_catalog_1_container**

  This scenario has one integration server, which hosts both a catalog server and a container server. It is recommended for development purposes.

- **basic_1_catalog_4_containers**

  This scenario has four integration servers: one integration server hosts both a catalog server and a container server, and the other three integration servers host a container server each.

- **basic_2_catalogs_4_containers**

  This scenario has four integration servers: two integration servers host both a catalog server and a container server, and the other two integration servers host a container server each.

- **ha_multi_instance**

  This scenario has four integration servers: two integration servers host both a catalog server and a container server, and the other two integration servers host a container server each and must be used as part of a multi-instance integration node. In this scenario, a multi-instance integration node cannot be used to host an integration server with a catalog server.

Each of these sample files contains the global cache section of a `server.conf.yaml` configuration file. You can copy and paste the content of the global cache section to replace the existing content of the **GlobalCache** section of your `server.conf.yaml` files, and then modify as required.

Depending on the type of data you store in your cache, you can configure your embedded global cache to use different locking strategies, and you can configure the use of replica shards for read access. For more information, see "Optimizing the embedded global cache for use with different types of cache data" on page 305.

If you stop the integration server that contains the catalog server, the cache becomes unavailable. If you restart the integration server that hosts the catalog server, it can no longer communicate with the container servers in other integration servers. Although these container servers are still running, they are

no longer part of the cache, and your data is lost. Therefore, you must also restart the integration servers that host the container servers.

Procedure

Configure the global cache by completing the following steps:

1. Open the configuration file for your integration server (`server.conf.yaml`) by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, which are invalid characters in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file. For more information about configuring an integration server, see "Configuring an integration server by modifying the server.conf.yaml file" on page 172.
2. Set the properties in the **`GlobalCache`** section of the `server.conf.yaml` configuration files, either directly or by copying and pasting the content of sample global cache configuration files to replace the existing content of the **`GlobalCache`** section.

   The `server.conf.yaml` and sample configuration files contain information about the valid properties.

   For information about configuring the global cache by using the sample configuration files, see the following topics:

   - "Global cache sample: Configuring one catalog and one container" on page 286
   - "Global cache sample: Configuring one catalog and four containers" on page 288
   - "Global cache sample: Configuring two catalogs and four containers" on page 294
   - "Global cache sample: Configuring for high availability (multi-instance)" on page 300
3. When you have modified and saved a `server.conf.yaml` file, restart the integration server for the changes to take effect.

   For information about how to start an integration server, see "Starting an integration server" on page 250.

Global cache sample: Configuring one catalog and one container

Use this sample to create a basic global cache configuration, in which a single integration server hosts both a catalog server and a container server.

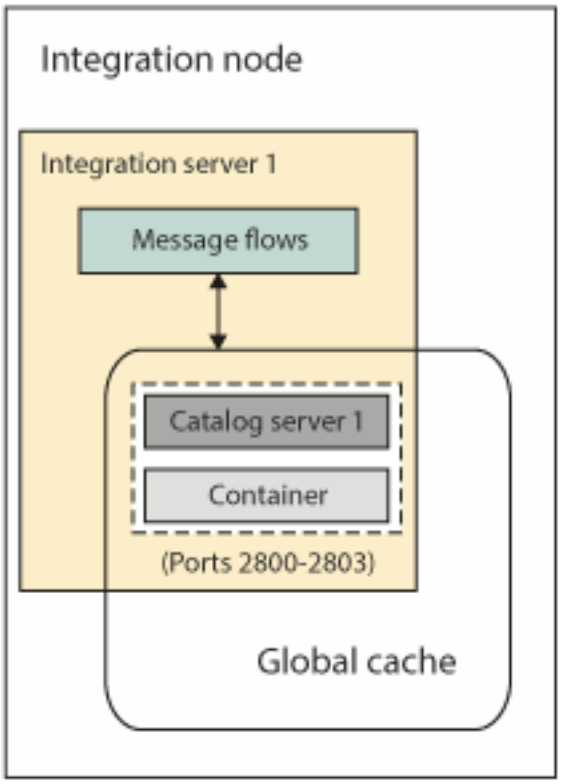
Before you begin

- Read the task topic "Configuring the embedded global cache" on page 285.
- For concept information, see "Data caching overview" on page 272.
- When you are using the global cache, increase the JVM heap size for integration servers that are hosting cache components. For more information, see the *Planning environment capacity* section of the WebSphere Extreme Scale product documentation online.

About this task

You can copy and paste the content of the global cache section of configuration files to replace the existing content of the **`GlobalCache`** section of your `server.conf.yaml` files and then modify them as required. The **`GlobalCache`** section is a sub-section of the **`ResourceManagers`** section in the `server.conf.yaml` files.

This sample shows how to configure the global cache for a basic scenario, using a single integration server that is hosting both a catalog server and a container server, as shown in the following diagram:



For information about other samples, which show how to configure global cache for different scenarios, see the following topics:

- "Global cache sample: Configuring one catalog and four containers" on page 288
- "Global cache sample: Configuring two catalogs and four containers" on page 294
- "Global cache sample: Configuring for high availability (multi-instance)" on page 300

Procedure

Complete the following steps to create a basic global cache configuration, in which a single integration server hosts both a catalog server and a container server:

1. Create an integration server called `integrationServer1`.
2. Open the configuration file for your integration server (`integrationServer1\server.conf.yaml`) by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, which are invalid characters in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
3. Copy and paste the content of the **GlobalCache** section in the supplied `server.conf.yaml` sample file (in the *`install_directory`*`\server\samples\globalcache\basic_1_catalog_1_container` folder) to replace the existing content of the **GlobalCache** section of your `server.conf.yaml` file.

   The **GlobalCache** section is a sub-section of the **ResourceManagers** section in the `server.conf.yaml` file.

```
# Integration server configuration file for use as global cache container
# Provides a "basic" configuration with a single integration server acting as both a catalog
 server and a container server
#
# General notes:
#  - Integration server will load server.conf.yaml from directory set via --work-dir
#  - To ensure valid YAML avoid any use of TAB characters
```

```
#  - File paths may be taken as absolute, or relative to the integration server's work
 directory
#

  GlobalCache:
    cacheOn: true                                    # Set to true to enable Global Cache
 functionality
                                                     # When using Global Cache it is advisable
 to change your jvmMinHeapSize and jvmMaxHeapSize depending on
                                                     # the number of live objects in the heap,
 complexity of live objects in the heap and number of available cores.
                                                     # see https://www.ibm.com/support/
knowledgecenter/SSTVLU_8.6.0/com.ibm.websphere.extremescale.doc/cxsjvmtune.html
    cacheServerName: 'MyCatalogServer1'              # The name of this cache server component
 (a cache server component can be a catalog and/or a container); it must be unique in your
 global cache system
    catalogServiceEndPoints: 'localhost:2800'        # Comma-separated list of hostnames and
 ports for the catalog servers to use, e.g. 'localhost:2800'
    catalogDomainName: 'WMB_MyCacheDomain'           # Name of the shared global cache domain;
 this value should be shared by all catalog servers in the same domain
    catalogClusterEndPoints: 'MyCatalogServer1:localhost:2803:2801'
                                                     # Comma-separated list of catalog server
 connection details in the format 'cacheServerName:catalogCacheServerHost:HAPort:clientPort'
                                                     # If this is a catalog server,
 cacheServerName should match the value above, and if not, it will be the value used on the
 integration server hosting it
                                                     # The list should be in the same order
 for all catalog and container servers which are interacting together in the same domain
    enableCatalogService: true                       # Set to true to launch a catalog service
 cache server component in this integration server
    enableContainerService: true                     # Set to true to launch a container
 service cache server component in this integration server
    enableJMX: true                                  # Allow admin access to this container
 service via JMX
    listenerHost: 'localhost'                        # Comma-separated list of hostnames for
 this cacheServer component, e.g. 'localhost,myserver.mycompany.com'
    listenerPort: 2800                               # Port number this cache server listens
 on; it must be unique on this machine
                                                     # Four consecutive ports are assigned,
 e.g. 2800 for catalogCacheServerListenerPort, 2801 for clientPort, 2802 for JMXServicePort,
 2803 for HAPort

    #deploymentPolicyCustomFile: ''                  # Override the deployment policy  file
 (default is <install directory>/server/cachesupport/config/deployment.xml)
    #objectGridCustomFile: ''                        # Override the ObjectGrid file (default
 is <install directory>/server/cachesupport/config/objectgrid_xio.xml)
    #overrideTraceSpec: ''                           # Set a trace level for the cache server
 components, e.g. ObjectGrid*=event=enabled
    #clientsDefaultToSSL: false                      # Set to true to enable SSL for any
 client connections to the cache servers
    #sslAlias: ''                                    # SSL Alias to use for the cache server
 component
    #sslProtocol: ''                                 # SSL Protocol to use for SSL connections
 eg. default is "TLSv1.2"
```

4. Restart the integration server for the changes to take effect.

   When it is restarted, `integrationServer1` will be both a catalog server and a container server.

What to do next

If you have only one catalog server and you stop it, the cache becomes unavailable and your data is lost. However, if you have multiple catalog servers, one of them can be stopped and restarted without losing data; your data is lost only if all catalog servers are stopped.

Global cache sample: Configuring one catalog and four containers

Use this sample to create a global cache configuration involving four integration servers, one of which hosts both a catalog server and a container server, while the other three integration servers host a container server each.

Before you begin

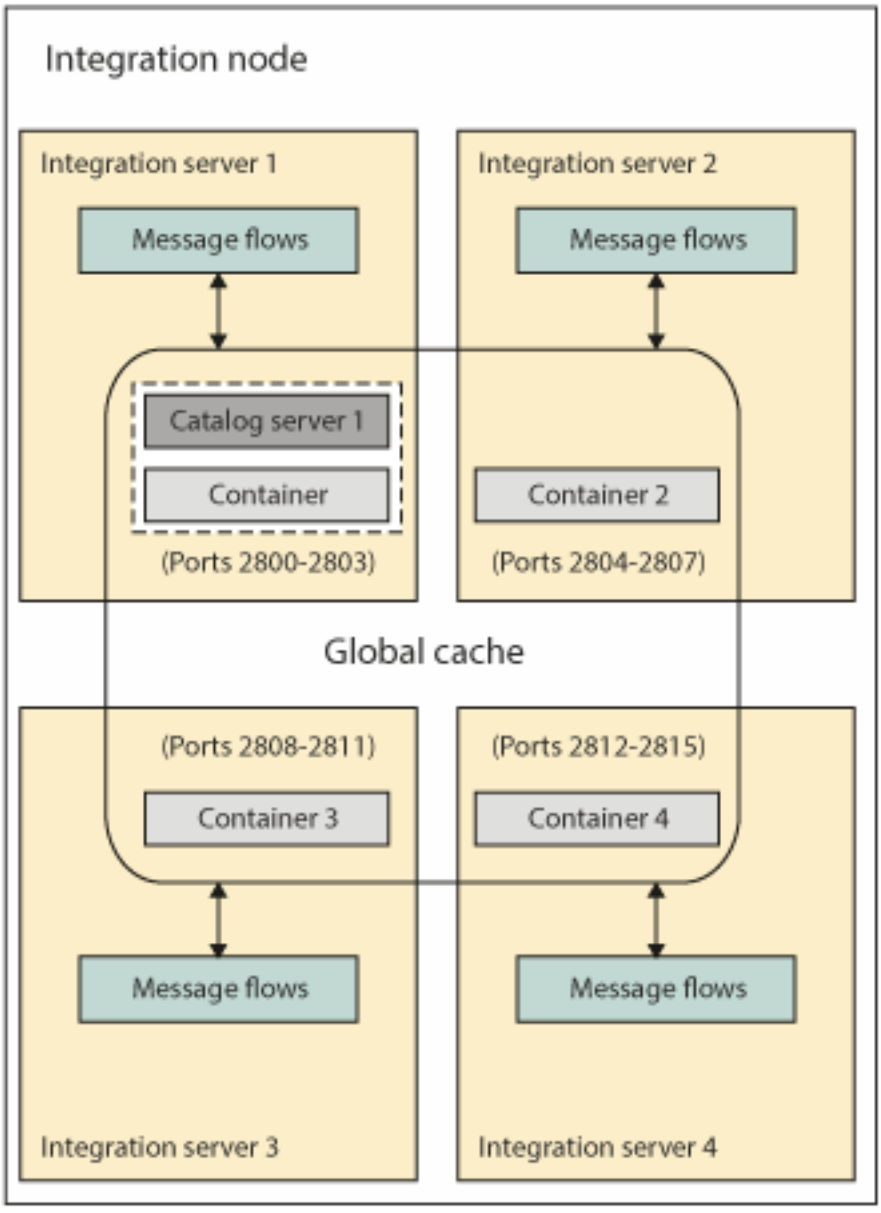
- Read the task topic “Configuring the embedded global cache” on page 285.
- For concept information, see “Data caching overview” on page 272.

- When you are using the global cache, increase the JVM heap size for integration servers that are hosting cache components. For more information, see the *Planning environment capacity* section of the WebSphere Extreme Scale product documentation online.

About this task

You can copy and paste the content of the global cache section of configuration files to replace the existing content of the **GlobalCache** section of your `server.conf.yaml` files and then modify them as required. The **GlobalCache** section is a sub-section of the **ResourceManagers** section in the `server.conf.yaml` files.

This sample shows how to configure a global cache to be used by four integration servers: one integration server hosts both a catalog server and a container server, and the other three integration servers host a container server each, as shown in the following diagram:



This scenario is equivalent to the default cache policy in previous versions of IBM Integration Bus and WebSphere Message Broker. It is also equivalent to the "policy_two_brokers" cache policy XML file, which used one catalog server.

For information about other samples, which show how to configure global cache for different scenarios, see the following topics:

- “Global cache sample: Configuring one catalog and one container” on page 286
- “Global cache sample: Configuring two catalogs and four containers” on page 294
- “Global cache sample: Configuring for high availability (multi-instance)” on page 300

Procedure

Complete the following steps to create a global cache configuration involving four integration servers, one of which hosts both a catalog server and a container server, and the other three host a container server each:

1. Create four integration servers called `integrationServer1`, `integrationServer2`, `integrationServer3`, and `integrationServer4`.
2. Open the configuration files for your integration servers (`integrationServer<n>\server.conf.yaml`) by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, which are invalid characters in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
3. Copy and paste the content of the **GlobalCache** section in the supplied `server.conf.yaml` sample files (in the *`install_directory`*`\server\samples\globalcache\basic_1_catalog_4_containers` folder) to replace the existing content of the **GlobalCache** section of your corresponding `integrationServer<n>\server.conf.yaml` files.

   The **GlobalCache** section is a sub-section of the **ResourceManagers** section in the `server.conf.yaml` files.

   integrationServer1.server.conf.yaml:

```
# Integration server configuration file for use as global cache container
# Provides an equivalent to the "default" configuration in previous versions of IBM
 Integration Bus and Websphere Message Broker
# Uses four integration servers where one is both a catalog server and a container server,
 and the other three are container servers
#
# General notes :
#  - Integration Server will load server.conf.yaml from directory set via --work-dir
#  - To ensure valid YAML avoid any use of TAB characters
#  - File paths may be taken as absolute, or relative to the integration server's work
 directory
#

  GlobalCache:
    cacheOn: true                                    # Set to true to enable Global Cache
 functionality
                                                     # When using Global Cache it is advisable
 to change your jvmMinHeapSize and jvmMaxHeapSize depending on
                                                     # the number of live objects in the heap,
 complexity of live objects in the heap and number of available cores.
                                                     # see https://www.ibm.com/support/
knowledgecenter/SSTVLU_8.6.0/com.ibm.websphere.extremescale.doc/cxsjvmtune.html
    cacheServerName: 'MyCatalogServer1'              # The name of this cache server component
 (a cache server component can be a catalog and/or a container); it must be unique in your
 global cache system
    catalogServiceEndPoints: 'localhost:2800'        # Comma-separated list of hostnames and
 ports for the catalog servers to use, e.g. 'localhost:2800'
    catalogDomainName: 'WMB_MyCacheDomain'           # Name of the shared global cache domain;
 this value should be shared by all catalog servers in the same domain
    catalogClusterEndPoints: 'MyCatalogServer1:localhost:2803:2801'
                                                     # Comma-separated list of catalog server
 connection details in the format 'cacheServerName:catalogCacheServerHost:HAPort:clientPort'
                                                     # If this is a catalog server,
 cacheServerName should match the value above, and if not, it will be the value used on the
 integration server hosting it
                                                     # The list should be in the same order
 for all catalog and container servers which are interacting together in the same domain
    enableCatalogService: true                       # Set to true to launch a catalog service
 cache server component in this integration server
```

```
    enableContainerService: true                    # Set to true to launch a container
 service cache server component in this integration server
    enableJMX: true                                 # Allow admin access to this container
 service via JMX
    listenerHost: 'localhost'                       # Comma-separated list of hostnames for
 this cacheServer component, e.g. 'localhost,myserver.mycompany.com'
    listenerPort: 2800                              # Port number this cache server listens
 on; it must be unique on this machine
                                                    # Four consecutive ports are assigned,
 e.g. 2800 for catalogCacheServerListenerPort, 2801 for clientPort, 2802 for JMXServicePort,
 2803 for HAPort

    #deploymentPolicyCustomFile: ''                 # Override the deployment policy file
 (default is <install directory>/server/cachesupport/config/deployment.xml)
    #objectGridCustomFile: ''                       # Override the ObjectGrid file (default
 is <install directory>/server/cachesupport/config/objectgrid_xio.xml)
    #overrideTraceSpec: ''                          # Set a trace level for the cache server
 components, e.g. ObjectGrid*=event=enabled
    #clientsDefaultToSSL: false                     # Set to true to enable SSL for any
 client connections to the cache servers
    #sslAlias: ''                                   # SSL Alias to use for the cache server
 component
    #sslProtocol: ''                                # SSL Protocol to use for SSL connections
 eg. default is "TLSv1.2"
```

integrationServer2.server.conf.yaml:

```
# Integration server configuration file for use as global cache container
# Provides an equivalent to the "default" configuration in previous versions of IBM
 Integration Bus and Websphere Message Broker
# Uses four integration servers where one is both a catalog server and a container server,
 and the other three are container servers
#
# General notes :
#  - Integration Server will load server.conf.yaml from directory set via --work-dir
#  - To ensure valid YAML avoid any use of TAB characters
#  - File paths may be taken as absolute, or relative to the integration server's work
 directory
#

  GlobalCache:
    cacheOn: true                                   # Set to true to enable Global Cache
 functionality
                                                    # When using Global Cache it is advisable
 to change your jvmMinHeapSize and jvmMaxHeapSize depending on
                                                    # the number of live objects in the heap,
 complexity of live objects in the heap and number of available cores.
                                                    # see https://www.ibm.com/support/
knowledgecenter/SSTVLU_8.6.0/com.ibm.websphere.extremescale.doc/cxsjvmtune.html
    cacheServerName: 'MyContainerServer2'           # The name of this cache server component

 cacheServerName should match the value above, and if not, it will be the value used on the
 integration server hosting it
                                                    # The list should be in the same order
 for all catalog and container servers which are interacting together in the same domain
    enableCatalogService: false                     # Set to true to launch a catalog service
 cache server component in this integration server
    enableContainerService: true                    # Set to true to launch a container
 service cache server component in this integration server
    enableJMX: true                                 # Allow admin access to this container
 service via JMX
    listenerHost: 'localhost'                       # Comma-separated list of hostnames for
 this cacheServer component, e.g. 'localhost,myserver.mycompany.com'
    listenerPort: 2808                              # Port number this cache server listens
 on; it must be unique on this machine
                                                    # Four consecutive ports are assigned,
 e.g. 2808 for catalogCacheServerListenerPort, 2809 for clientPort, 2810 for JMXServicePort,
 2811 for HAPort

    #deploymentPolicyCustomFile: ''                 # Override the deployment policy file
 (default is <install directory>/server/cachesupport/config/deployment.xml)
    #objectGridCustomFile: ''                       # Override the ObjectGrid file (default
 is <install directory>/server/cachesupport/config/objectgrid_xio.xml)
    #overrideTraceSpec: ''                          # Set a trace level for the cache server
 components, e.g. ObjectGrid*=event=enabled
    #clientsDefaultToSSL: false                     # Set to true to enable SSL for any
 client connections to the cache servers
    #sslAlias: ''                                   # SSL Alias to use for the cache server
 component
```

```
    #sslProtocol: ''                                # SSL Protocol to use for SSL connections
 eg. default is "TLSv1.2"
```

integrationServer4.server.conf.yaml:

```
# Integration server configuration file for use as global cache container
# Provides an equivalent to the "default" configuration in previous versions of IBM
 Integration Bus and Websphere Message Broker
# Uses four integration servers where one is both a catalog server and a container server,
 and the other three are container servers
#
# General notes :
#  - Integration Server will load server.conf.yaml from directory set via --work-dir
#  - To ensure valid YAML avoid any use of TAB characters
#  - File paths may be taken as absolute, or relative to the integration server's work
 directory
#

  GlobalCache:
    cacheOn: true                                   # Set to true to enable Global Cache
 functionality
                                                    # When using Global Cache it is advisable
 to change your jvmMinHeapSize and jvmMaxHeapSize depending on
                                                    # the number of live objects in the heap,
 complexity of live objects in the heap and number of available cores.
                                                    # see https://www.ibm.com/support/
knowledgecenter/SSTVLU_8.6.0/com.ibm.websphere.extremescale.doc/cxsjvmtune.html
    cacheServerName: 'MyContainerServer4'           # The name of this cache server component
 (a cache server component can be a catalog and/or a container); it must be unique in your
 global cache system
    catalogServiceEndPoints: 'localhost:2800'       # Comma-separated list of hostnames and
 ports for the catalog servers to use, e.g. 'localhost:2800'
    catalogDomainName: 'WMB_MyCacheDomain'          # Name of the shared global cache domain;
 this value should be shared by all catalog servers in the same domain
    catalogClusterEndPoints: 'MyCatalogServer1:localhost:2803:2801'
                                                    # Comma-separated list of catalog server
 connection details in the format 'cacheServerName:catalogCacheServerHost:HAPort:clientPort'
                                                    # If this is a catalog server,
 cacheServerName should match the value above, and if not, it will be the value used on the
 integration server hosting it
                                                    # The list should be in the same order
 for all catalog and container servers which are interacting together in the same domain
    enableCatalogService: false                     # Set to true to launch a catalog service
 cache server component in this integration server
    enableContainerService: true                    # Set to true to launch a container
 service cache server component in this integration server
    enableJMX: true                                 # Allow admin access to this container
 service via JMX
    listenerHost: 'localhost'                       # Comma-separated list of hostnames for
 this cacheServer component, e.g. 'localhost,myserver.mycompany.com'
    listenerPort: 2812                              # Port number this cache server listens
 on; it must be unique on this machine
                                                    # Four consecutive ports are assigned,
 e.g. 2812 for catalogCacheServerListenerPort, 2813 for clientPort, 2814 for JMXServicePort,
 2815 for HAPort

    #deploymentPolicyCustomFile: ''                 # Override the deployment policy file
 (default is <install directory>/server/cachesupport/config/deployment.xml)
    #objectGridCustomFile: ''                       # Override the ObjectGrid file (default
 is <install directory>/server/cachesupport/config/objectgrid_xio.xml)
    #overrideTraceSpec: ''                          # Set a trace level for the cache server
 components, e.g. ObjectGrid*=event=enabled
    #clientsDefaultToSSL: false                     # Set to true to enable SSL for any
 client connections to the cache servers
    #sslAlias: ''                                   # SSL Alias to use for the cache server
 component
    #sslProtocol: ''                                # SSL Protocol to use for SSL connections
 eg. default is "TLSv1.2"
```

4. Restart the integration servers for the changes to take effect.

   When they are restarted, `integrationServer1` will be both a catalog server and a container server, and `integrationServer2`, `integrationServer3`, and `integrationServer4` will be container servers.

What to do next

If you have only one catalog server and you stop it, the cache becomes unavailable and your data is lost. However, if you have multiple catalog servers, one of them can be stopped and restarted without losing data; your data is lost only if all catalog servers are stopped.

Global cache sample: Configuring two catalogs and four containers

Use this sample to create a global cache configuration involving four integration servers, two of which host both a catalog server and a container server, while the other two integration servers host a container server each.

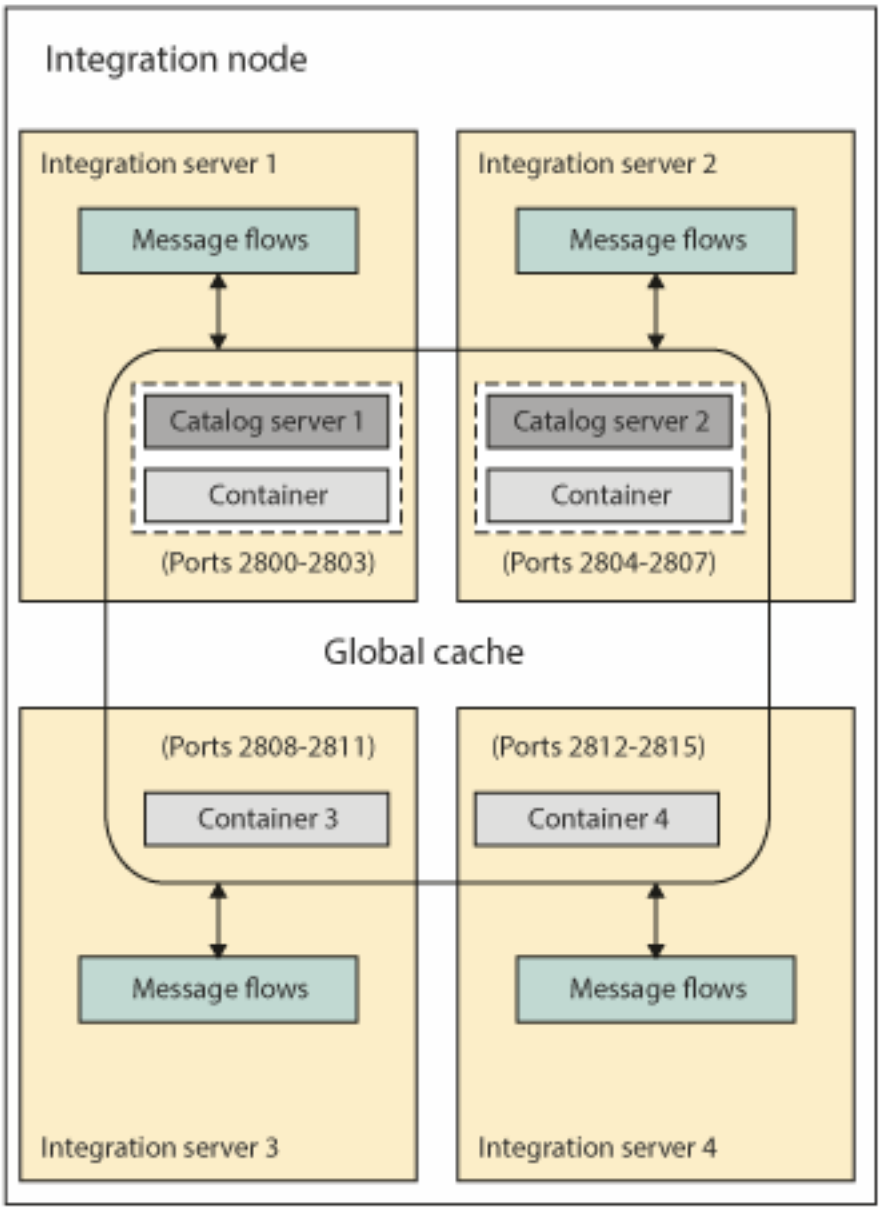
Before you begin

- Read the task topic "Configuring the embedded global cache" on page 285.
- For concept information, see "Data caching overview" on page 272.
- When you are using the global cache, increase the JVM heap size for integration servers that are hosting cache components. For more information, see the *Planning environment capacity* section of the WebSphere Extreme Scale product documentation online.

About this task

You can copy and paste the content of the global cache section of configuration files to replace the existing content of the **`GlobalCache`** section of your `server.conf.yaml` files and then modify them as required. The **`GlobalCache`** section is a sub-section of the **`ResourceManagers`** section in the `server.conf.yaml` files.

This sample shows how to configure a global cache to be used by four integration servers: two integration servers host both a catalog server and a container server, and the other two integration servers host a container server each, as shown in the following diagram:



This scenario is equivalent to the "policy_one_broker_ha" and "policy_two_brokers_ha" cache policy XML files in previous versions of IBM Integration Bus and WebSphere Message Broker. It covers a similar high-availability configuration as the two XML files, by making use of two catalog servers.

For information about other samples, which show how to configure global cache for different scenarios, see the following topics:

- “Global cache sample: Configuring one catalog and one container” on page 286
- “Global cache sample: Configuring one catalog and four containers” on page 288
- “Global cache sample: Configuring for high availability (multi-instance)” on page 300

Procedure

Complete the following steps to create a global cache configuration involving four integration servers, two of which host both a catalog server and a container server, and the other two host a container server each:

1. Create four integration servers called `integrationServer1`, `integrationServer2`, `integrationServer3`, and `integrationServer4`.

2. Open the configuration files for your integration servers (`integrationServer<n>\server.conf.yaml`) by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, which are invalid characters in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

3. Copy and paste the content of the **GlobalCache** section in the supplied `server.conf.yaml` sample files (in the *install_directory*`\server\samples\globalcache\basic_2_catalogs_4_containers` folder) to replace the existing content of the **GlobalCache** section of your corresponding `integrationServer<n>\server.conf.yaml` files.

   The **GlobalCache** section is a sub-section of the **ResourceManagers** section in the `server.conf.yaml` files.

   integrationServer1.server.conf.yaml:

```
# Integration server configuration file for use as global cache container
# Provides an equivalent to the "One Broker HA" and Two Brokers HA" Cache Policy XML
 configurations in previous versions of IBM Integration Bus and Websphere Message Broker
# Uses four integration servers where two are both a catalog server and a container server,
 and the other two are container servers
#
# General notes :
#  - Integration Server will load server.conf.yaml from directory set via --work-dir
#  - To ensure valid YAML avoid any use of TAB characters
#  - File paths may be taken as absolute, or relative to the integration server's work
 directory
#

  GlobalCache:
    cacheOn: true                                                 # Set to true to enable
 Global Cache functionality
                                                                  # When using Global Cache it
 is advisable to change your jvmMinHeapSize and jvmMaxHeapSize depending on
                                                                  # the number of live objects
 in the heap, complexity of live objects in the heap and number of available cores.
                                                                  # see https://www.ibm.com/
support/knowledgecenter/SSTVLU_8.6.0/com.ibm.websphere.extremescale.doc/cxsjvmtune.html
    cacheServerName: 'MyCatalogServer1'                           # The name of this cache
 server component (a cache server component can be a catalog and/or a container); it must be
 unique in your global cache system
    catalogServiceEndPoints: 'localhost:2800,localhost:2804'    # Comma-separated list of
 hostnames and ports for the catalog servers to use, e.g. 'localhost:2800'
    catalogDomainName: 'WMB_MyCacheDomain'                        # Name of the shared global
 cache domain; this value should be shared by all catalog servers in the same domain
    catalogClusterEndPoints:
 'MyCatalogServer1:localhost:2803:2801,MyCatalogServer2:localhost:2807:2805'
                                                                  #
 Comma-separated list of catalog server connection details in the format
 'cacheServerName:catalogCacheServerHost:HAPort:clientPort'
                                                                  # If this is a catalog
 server, cacheServerName should match the value above, and if not, it will be the value used
 on the integration server hosting it
                                                                  # The list should be in the
 same order for all catalog and container servers which are interacting together in the same
 domain
    enableCatalogService: true                                    # Set to true to launch a
 catalog service cache server component in this integration server
    enableContainerService: true                                  # Set to true to launch a
 container service cache server component in this integration server
    enableJMX: true                                               # Allow admin access to this
 container service via JMX
    listenerHost: 'localhost'                                     # Comma-separated list of
 hostnames for this cacheServer component, e.g. 'localhost,myserver.mycompany.com'
    listenerPort: 2800                                            # Port number this cache
 server listens on; it must be unique on this machine
                                                                  # Four consecutive ports
 are assigned, e.g. 2800 for catalogCacheServerListenerPort, 2801 for clientPort, 2802 for
 JMXServicePort, 2803 for HAPort

    #deploymentPolicyCustomFile: ''                               # Override the deployment
 policy file (default is <install directory>/server/cachesupport/config/deployment.xml)

 hostnames for this cacheServer component, e.g. 'localhost,myserver.mycompany.com'
    listenerPort: 2808                                      # Port number this cache
 server listens on; it must be unique on this machine
                                                            # Four consecutive ports
 are assigned, e.g. 2808 for catalogCacheServerListenerPort, 2809 for clientPort, 2810 for
 JMXServicePort, 2811 for HAPort

    #deploymentPolicyCustomFile: ''                         # Override the deployment
 policy file (default is <install directory>/server/cachesupport/config/deployment.xml)
    #objectGridCustomFile: ''                               # Override the ObjectGrid
 file (default is <install directory>/server/cachesupport/config/objectgrid_xio.xml)
    #overrideTraceSpec: ''                                  # Set a trace level for the
 cache server components, e.g. ObjectGrid*=event=enabled
    #clientsDefaultToSSL: false                             # Set to true to enable SSL
 for any client connections to the cache servers
    #sslAlias: ''                                           # SSL Alias to use for the
 cache server component
    #sslProtocol: ''                                        # SSL Protocol to use for SSL
 connections eg. default is "TLSv1.2"
```

integrationServer4.server.conf.yaml:

```
# Integration server configuration file for use as global cache container
# Provides an equivalent to the "One Broker HA" and Two Brokers HA" Cache Policy XML
 configurations in previous versions of IBM Integration Bus and Websphere Message Broker
# Uses four integration servers where two are both a catalog server and a container server,
 and the other two are container servers
#
```

```
# General notes :
#  - Integration Server will load server.conf.yaml from directory set via --work-dir
#  - To ensure valid YAML avoid any use of TAB characters
#  - File paths may be taken as absolute, or relative to the integration server's work
 directory
#

  GlobalCache:
    cacheOn: true                                           # Set to true to enable
 Global Cache functionality
                                                            # When using Global Cache it
 is advisable to change your jvmMinHeapSize and jvmMaxHeapSize depending on
                                                            # the number of live objects
 in the heap, complexity of live objects in the heap and number of available cores.
                                                            # see https://www.ibm.com/
support/knowledgecenter/SSTVLU_8.6.0/com.ibm.websphere.extremescale.doc/cxsjvmtune.html
    cacheServerName: 'MyContainerServer4'                   # The name of this cache
 server component (a cache server component can be a catalog and/or a container); it must be
 unique in your global cache system
    catalogServiceEndPoints: 'localhost:2800,localhost:2804'    # Comma-separated list of
 hostnames and ports for the catalog servers to use, e.g. 'localhost:2800'
    catalogDomainName: 'WMB_MyCacheDomain'                  # Name of the shared global
 cache domain; this value should be shared by all catalog servers in the same domain
    catalogClusterEndPoints:
 'MyCatalogServer1:localhost:2803:2801,MyCatalogServer2:localhost:2807:2805'

 Comma-separated list of catalog server connection details in the format
 'cacheServerName:catalogCacheServerHost:HAPort:clientPort'
                                                            # If this is a catalog
 server, cacheServerName should match the value above, and if not, it will be the value used
 on the integration server hosting it
                                                            # The list should be in the
 same order for all catalog and container servers which are interacting together in the same
 domain
    enableCatalogService: false                             # Set to true to launch a
 catalog service cache server component in this integration server
    enableContainerService: true                            # Set to true to launch a
 container service cache server component in this integration server
    enableJMX: true                                         # Allow admin access to this
 container service via JMX
    listenerHost: 'localhost'                               # Comma-separated list of
 hostnames for this cacheServer component, e.g. 'localhost,myserver.mycompany.com'
    listenerPort: 2812                                      # Port number this cache
 server listens on; it must be unique on this machine
                                                            # Four consecutive ports
 are assigned, e.g. 2812 for catalogCacheServerListenerPort, 2813 for clientPort, 2814 for
 JMXServicePort, 2815 for HAPort

    #deploymentPolicyCustomFile: ''                         # Override the deployment
 policy file (default is <install directory>/server/cachesupport/config/deployment.xml)
    #objectGridCustomFile: ''                               # Override the ObjectGrid
 file (default is <install directory>/server/cachesupport/config/objectgrid_xio.xml)
    #overrideTraceSpec: ''                                  # Set a trace level for the
 cache server components, e.g. ObjectGrid*=event=enabled
    #clientsDefaultToSSL: false                             # Set to true to enable SSL
 for any client connections to the cache servers
    #sslAlias: ''                                           # SSL Alias to use for the
 cache server component
    #sslProtocol: ''                                        # SSL Protocol to use for SSL
 connections eg. default is "TLSv1.2"
```

4. Restart the integration servers for the changes to take effect.

   When they are restarted, `integrationServer1` and `integrationServer2` will be both catalog servers and container servers, while `integrationServer3` and `integrationServer4` will be container servers.

What to do next

If you have only one catalog server and you stop it, the cache becomes unavailable and your data is lost. However, if you have multiple catalog servers, one of them can be stopped and restarted without losing data; your data is lost only if all catalog servers are stopped.

Global cache sample: Configuring for high availability (multi-instance)

Use this sample to create a global cache configuration involving three integration servers, two of which host both a catalog server and a container server. The other integration server hosts only a container server, and must be used as part of a multi-instance integration node.

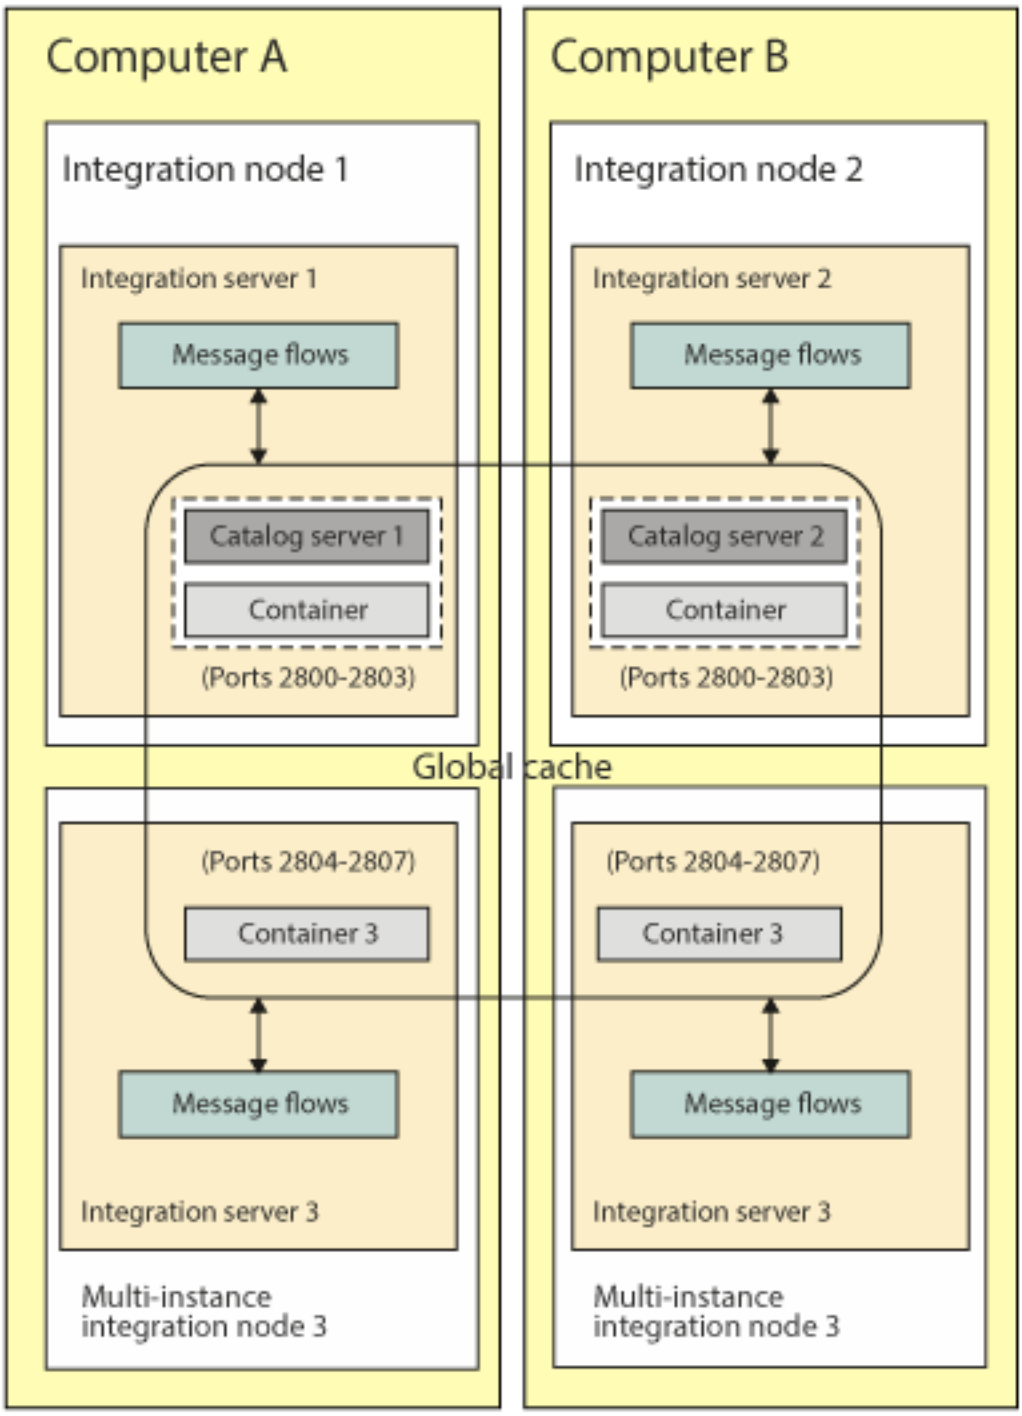
Before you begin

- Read the task topic "Configuring the embedded global cache" on page 285.
- For concept information, see "Data caching overview" on page 272.
- When you are using the global cache, increase the JVM heap size for integration servers that are hosting cache components. For more information, see the *Planning environment capacity* section of the WebSphere Extreme Scale product documentation online.

About this task

You can copy and paste the content of the global cache section of configuration files to replace the existing content of the **`GlobalCache`** section of your `server.conf.yaml` files and then modify them as required. The **`GlobalCache`** section is a sub-section of the **`ResourceManagers`** section in the `server.conf.yaml` files.

This sample shows how to configure a global cache to be used by three integration servers: two integration servers host both a catalog server and a container server, while the other integration server hosts only a container server, and must be used as part of a multi-instance integration node. In this scenario, a multi-instance integration node cannot be used to host an integration server with a catalog server.



This scenario is equivalent to the `policy_multi_instance` cache policy XML file in previous versions of IBM Integration Bus and WebSphere Message Broker. It covers a similar multi-instance integration node configuration as the XML file.

For information about other samples, which show how to configure global cache for different scenarios, see the following topics:

- "Global cache sample: Configuring one catalog and one container" on page 286
- "Global cache sample: Configuring one catalog and four containers" on page 288
- "Global cache sample: Configuring two catalogs and four containers" on page 294

Procedure

Complete the following steps to create a global cache configuration involving three integration servers, two of which host both a catalog server and a container server, while the other integration server hosts only a container server, and must be used as part of a multi-instance integration node:

1. Create two integration servers called `integrationServer1` and `integrationServer2`.
2. Open the configuration files for your integration servers (`integrationServer1\server.conf.yaml` and `integrationServer2\server.conf.yaml`) by using a YAML editor.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, which are invalid characters in YAML and would cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.
3. Copy and paste the content of the **GlobalCache** section from the supplied `integrationServer1.server.conf.yaml` and `integrationServer2.server.conf.yaml` sample files in the *install_directory*`\server\samples\globalcache\ha_multi_instance` folder, to replace the existing content of the **GlobalCache** sections of your corresponding `integrationServer1\server.conf.yaml` and `integrationServer2\server.conf.yaml` files.

   The **GlobalCache** section is a sub-section of the **ResourceManagers** section in the `server.conf.yaml` file.

   integrationServer1.server.conf.yaml:

```
# Integration server configuration file for use as global cache container
# Provides an equivalent to the "Muti-Instance" Cache Policy XML configuration in previous
 versions of IBM Integration Bus and Websphere Message Broker
# Uses two integration servers (1 and 2) that are both a catalog server and a container
 server
# It also uses an integration server (3) which is a container server; this integration server
 must be part of a multi-instance integration node
# A multi-instance integration node cannot be used to host an integration server with a
 catalog server
#
# General notes :
#  - Integration Server will load server.conf.yaml from directory set via --work-dir
#  - To ensure valid YAML avoid any use of TAB characters
#  - File paths may be taken as absolute, or relative to the integration server's work
 directory
#

  GlobalCache:
    cacheOn: true                                                  # Set to true to enable
 Global Cache functionality
                                                                   # When using Global Cache it
 is advisable to change your jvmMinHeapSize and jvmMaxHeapSize depending on
                                                                   # the number of live objects
 in the heap, complexity of live objects in the heap and number of available cores.
                                                                   # see https://www.ibm.com/
support/knowledgecenter/SSTVLU_8.6.0/com.ibm.websphere.extremescale.doc/cxsjvmtune.html
    cacheServerName: 'MyCatalogServer1'                            # The name of this cache
 server component (a cache server component can be a catalog and/or a container); it must be
 unique in your global cache system
    catalogServiceEndPoints: 'server1.mycompany.com:2800,server2.mycompany.com:2800'
                                                                   # Comma-separated list of
 hostnames and ports for the catalog servers to use, e.g. 'localhost:2800'
    catalogDomainName: 'WMB_MyCacheDomain'                         # Name of the shared global
 cache domain; this value will be shared by all catalog servers in the same domain
    catalogClusterEndPoints:
 'MyCatalogServer1:server1.mycompany.com:2803:2801,MyCatalogServer2:server2.mycompany.com:2803:2801'
                                                                   #
 Comma-separated list of catalog server connection details in the format
 'cacheServerName:catalogCacheServerHost:HAPort:clientPort'
                                                                   # If this is a catalog
 server, cacheServerName should match the value above, and if not, it will be the value used
 on the integration server hosting it
                                                                   # The list should be in the
 same order for all catalog and container servers which are interacting together in the same
 domain
```

```
    enableCatalogService: true                                  # Set to true to launch a
 catalog service cache server component in this integration server
    enableContainerService: true                                # Set to true to launch a

 cache server component
   #sslProtocol: ''                                             # SSL Protocol to use for SSL
 connections eg. default is "TLSv1.2"
```

4. Create a multi-instance integration node called `MultiInstanceNode` on two servers, as described in "Creating a multi-instance integration node" on page 122.
5. Create an integration server called `integrationServer3` under the multi-instance integration node.
6. Copy and paste the content of the **GlobalCache** section from the supplied `integrationServer3.server.conf.yaml` sample file in the `samples\globalcache\multi_instance` folder, to replace the existing content of the **GlobalCache** section in the *SharedWorkPath*`\components\INODE\servers\IntegrationServer3\server.conf.yaml` file.

   The **GlobalCache** section is a sub-section of the **ResourceManagers** section in the `server.conf.yaml` file.

   integrationServer3.server.conf.yaml:

```
# Integration server configuration file for use as global cache container
# Provides an equivalent to the "Muti-Instance" Cache Policy XML configuration in previous
 versions of IBM Integration Bus and Websphere Message Broker
# Uses two integration servers (1 and 2) that are both a catalog server and a container
 server
# It also uses an integration server (3) which is a container server; this integration server
 must be part of a multi-instance integration node
# A multi-instance integration node cannot be used to host an integration server with a
 catalog server
#
# General notes :
#  - Integration Server will load server.conf.yaml from directory set via --work-dir
#  - To ensure valid YAML avoid any use of TAB characters
#  - File paths may be taken as absolute, or relative to the integration server's work
 directory
#

  GlobalCache:
    cacheOn: true                                               # Set to true to enable
 Global Cache functionality
                                                                # When using Global Cache it
 is advisable to change your jvmMinHeapSize and jvmMaxHeapSize depending on
                                                                # the number of live objects
 in the heap, complexity of live objects in the heap and number of available cores.
                                                                # see https://www.ibm.com/
support/knowledgecenter/SSTVLU_8.6.0/com.ibm.websphere.extremescale.doc/cxsjvmtune.html
    cacheServerName: 'MyContainerServer3'                       # The name of this cache
 server component (a cache server component can be a catalog and/or a container); it must be
 unique in your global cache system
    catalogServiceEndPoints: 'server1.mycompany.com:2800,server2.mycompany.com:2800'
                                                                # Comma-separated list of
 hostnames and ports for the catalog servers to use, e.g. 'localhost:2800'
    catalogDomainName: 'WMB_MyCacheDomain'                      # Name of the shared global
 cache domain; this value will be shared by all catalog servers in the same domain
    catalogClusterEndPoints:
 'MyCatalogServer1:server1.mycompany.com:2803:2801,MyCatalogServer2:server2.mycompany.com:2803:2801'
                                                                #
 Comma-separated list of catalog server connection details in the format
 'cacheServerName:catalogCacheServerHost:HAPort:clientPort'
                                                                # If this is a catalog
 server, cacheServerName should match the value above, and if not, it will be the value used
 on the integration server hosting it
```

```
                                                        # The list should be in the
same order for all catalog and container servers which are interacting together in the same
domain
   enableCatalogService: false                          # Set to true to launch a
catalog service cache server component in this integration server
   enableContainerService: true                         # Set to true to launch a
container service cache server component in this integration server
   enableJMX: true                                      # Allow admin access to this
container service via JMX
   listenerHost: 'server1.mycompany.com,server2.mycompany.com' # Comma-separated list of
hostnames for this cacheServer component, e.g. 'localhost,myserver.mycompany.com'
   listenerPort: 2804                                   # Port number this cache
server listens on; it must be unique on this machine
                                                        # Four consecutive ports
are assigned, e.g. 2804 for catalogCacheServerListenerPort, 2805 for clientPort, 2806 for
JMXServicePort, 2807 for HAPort

   #deploymentPolicyCustomFile: ''                      # Override the deployment
policy file (default is <install directory>/server/cachesupport/config/deployment.xml)
   #objectGridCustomFile: ''                            # Override the ObjectGrid
file (default is <install directory>/server/cachesupport/config/objectgrid_xio.xml)
   #overrideTraceSpec: ''                               # Set a trace level for the
cache server components, e.g. ObjectGrid*=event=enabled
   #clientsDefaultToSSL: false                          # Set to true to enable SSL
for any client connections to the cache servers
   #sslAlias: ''                                        # SSL Alias to use for the
cache server component
   #sslProtocol: ''                                     # SSL Protocol to use for SSL
connections eg. default is "TLSv1.2"
```

7. Change `server1.mycompany.com` and `server2.mycompany.com` in the files to match the host names of the servers hosting the integration nodes.
8. Restart the integration servers for the changes to take effect.

   When they are restarted, `IntegrationServer1` and `IntegrationServer2` will be both catalog servers and container servers. `IntegrationServer3` will be a container server.

What to do next

If you have only one catalog server and you stop it, the cache becomes unavailable and your data is lost. However, if you have multiple catalog servers, one of them can be stopped and restarted without losing data; your data is lost only if all catalog servers are stopped.

Optimizing the embedded global cache for use with different types of cache data

You can configure your embedded global cache to use different locking strategies for different cache maps, and you can configure the use of replica shards of a cache map for read access.

Before you begin

For more information about the default global cache topology, see "Data caching overview" on page 272.

About this task

The embedded global cache in IBM App Connect Enterprise supports the configuration of the following properties:

- Locking strategies: Using the appropriate locking strategy can reduce the associated computational work and help improve achievable throughput. The following table details the strategies that are supported and the situations in which the strategies might be used:

Locking strategy	Use case
Pessimistic (default)	Cache data is updated frequently from multiple sources.

Locking strategy	Use case
Optimistic	Cache data is updated from multiple sources but the same cache record is unlikely to be updated by two sources simultaneously.
None	Cache data is static or updated infrequently from a single source.

For more information about the locking strategies, see the WebSphere eXtreme Scale documentation, http://www.ibm.com/support/knowledgecenter/SSTVLU_8.6.1/com.ibm.websphere.extremescale.doc/cxslockstrategy.html.

Note: The optimistic locking strategy that is used in IBM App Connect Enterprise uses the "Optimistic no versioning locking" configuration that is described in the WebSphere eXtreme Scale documentation.

- Read access to replica shards of a cache map. Reading from replica shards of a cache map can help to distribute workload amongst container servers. By default, data is read from only the primary shard of a cache map but you can configure the embedded global cache to support read access to replica shards. You might configure this property if your applications can tolerate the use of cache data that might be out-of-date. For more information about read access to replica shards of a cache map, see the WebSphere eXtreme Scale documentation, http://www.ibm.com/support/knowledgecenter/SSTVLU_8.6.1/com.ibm.websphere.extremescale.doc/cxsreadreplx.html.

Procedure

If you want to configure locking strategies or read access to replica shards of a cache map, you must complete the following steps:

1. Create a copy of the following files from the *InstallDir*`\server\sample\globalcache` directory where *InstallDir* is the IBM App Connect Enterprise installation directory:
   - `objectgrid.xml`
   - `deployment.xml`
2. Open the `objectgrid.xml` file and add or edit the `backingMap name` entries in the `<objectGrid name="WMB">` section with patterns that match the names of your cache maps.
3. Open the `deployment.xml` file and add or edit the `map ref` entries in the `<objectgridDeployment objectgridName="WMB">` section with patterns that match the names of your cache maps.

   Note:

   - You must not remove the entry that matches the default cache map for the IBM App Connect Enterprise embedded global cache (`SYSTEM.BROKER.*`).
   - The `backingMap name` entries in the `objectgrid.xml` file must be the same as the `map ref` entries in the `deployment.xml` file.
4. Optional: If you want to configure locking strategies for cache maps in the embedded global cache, see “Configuring locking strategies for the embedded global cache” on page 306.
5. Optional: If you want to configure the embedded global cache to read data from a replica shard of a cache map, see “Configuring the embedded global cache to read data from replica shards of a cache map” on page 308.

Configuring locking strategies for the embedded global cache
You can configure your embedded global cache to use locking strategies to suit the types of data that you store in your cache.

Before you begin

Complete the following steps:

- Create the `objectgrid.xml` and `deployment.xml` files and configure the cache map names; for more information, see "Optimizing the embedded global cache for use with different types of cache data" on page 305.

About this task

You define the locking strategy for each cache map in your embedded global cache by configuring the `objectgrid.xml` file. You then configure the embedded global cache by updating the `server.conf.yaml` configuration file for the integration server to point to the `objectgrid.xml` file. The embedded global cache can use only one `objectgrid.xml` file.

Procedure

1. Open the `objectgrid.xml` file, and configure the locking strategy for each `backingMap` entry by completing one of the following steps:

   - To configure the pessimistic locking strategy for a cache map, set the **`lockStrategy`** parameter to `PESSIMISTIC`.

     For example:

     ```
     <backingMap name="USER.PESSIMISTIC.*" template="true" timeToLive="0"
      ttlEvictorType="LAST_UPDATE_TIME" lockStrategy="PESSIMISTIC" copyMode="COPY_TO_BYTES"/>
     ```

   - To configure the optimistic locking strategy for a cache map, set the **`lockStrategy`** parameter to `OPTIMISTIC_NO_VERSIONING`. You can also set the **`nearCacheInvalidationEnabled`** parameter to `true`.

     For example:

     ```
     <backingMap name="USER.OPTIMISTIC.*" template="true" timeToLive="0"
      ttlEvictorType="LAST_UPDATE_TIME" lockStrategy="OPTIMISTIC_NO_VERSIONING"
      nearCacheInvalidationEnabled="true" copyMode="COPY_TO_BYTES"/>
     ```

   - To configure no locking for a cache map, set the **`lockStrategy`** parameter to `NONE`. You can also set the **`nearCacheInvalidationEnabled`** parameter to `true`.

     For example:

     ```
     <backingMap name="USER.NONE.*" template="true" timeToLive="0"
      ttlEvictorType="LAST_UPDATE_TIME" lockStrategy="NONE" nearCacheInvalidationEnabled="true"
      copyMode="COPY_TO_BYTES"/>
     ```

   Note: Enabling near-cache invalidation removes stale data from the cache as quickly as possible. For more information, see the WebSphere eXtreme Scale documentation, https://www.ibm.com/support/knowledgecenter/SSTVLU_8.6.1/com.ibm.websphere.extremescale.doc/txsnearcacheinv.html.

   The following example file shows three entries, and includes an entry (`SYSTEM.BROKER.*`) that matches the default cache map for the IBM App Connect Enterprise embedded global cache.

   Note: You can modify the locking strategy for the `SYSTEM.BROKER.*` entry but you must not remove the entry.

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <objectGridConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
     xsi:schemaLocation="http://ibm.com/ws/objectgrid/config ../objectGrid.xsd"
     xmlns="http://ibm.com/ws/objectgrid/config">
    <objectGrids>
     <objectGrid name="WMB">
      <backingMap name="USER.OPTIMISTIC.*" template="true" timeToLive="0"
    ttlEvictorType="LAST_UPDATE_TIME" lockStrategy="OPTIMISTIC_NO_VERSIONING"
    nearCacheInvalidationEnabled="true" copyMode="COPY_TO_BYTES"/>
      <backingMap name="USER.PESSIMISTIC.*" template="true" timeToLive="0"
    ttlEvictorType="LAST_UPDATE_TIME" lockStrategy="PESSIMISTIC" copyMode="COPY_TO_BYTES"/>
      <backingMap name="USER.NONE.*" template="true" timeToLive="0"
    ttlEvictorType="LAST_UPDATE_TIME" lockStrategy="NONE" nearCacheInvalidationEnabled="true"
    copyMode="COPY_TO_BYTES"/>
   ```

```
   <backingMap name="SYSTEM.BROKER.*" template="true" timeToLive="0"
 ttlEvictorType="LAST_UPDATE_TIME" lockStrategy="PESSIMISTIC" copyMode="COPY_TO_BYTES"/>
  </objectGrid>
 </objectGrids>
</objectGridConfig>
```

Note: If you add any additional `backingMap` entries, you must add the equivalent entries in the `deployment.xml`; see "Optimizing the embedded global cache for use with different types of cache data" on page 305. You cannot configure any other options in this file.

2. Save the `objectgrid.xml` file.
3. Configure the location of the `objectgrid.xml` file, by modifying the **objectGridCustomFile** property in the `server.conf.yaml` configuration file for the integration server.

   If you made changes to the `deployment.xml` file to keep the file consistent with the `objectgrid.xml`, you must also complete this step for your copy of the `deployment.xml` file. For information about the equivalent commands, see "Configuring the embedded global cache to read data from replica shards of a cache map" on page 308.
4. Restart the integration server for the changes to take effect.

Results

You have configured the IBM App Connect Enterprise embedded global cache to use one or more locking strategies.

Configuring the embedded global cache to read data from replica shards of a cache map

You can configure your embedded global cache to read data from replica shards of a cache map instead of the primary cache map.

Before you begin

Complete the following steps:

- Read the information about reading data from replica shards and the applications for which it is appropriate, in "Optimizing the embedded global cache for use with different types of cache data" on page 305.
- Create the `objectgrid.xml` and `deployment.xml` files and configure the cache map names, as described in "Optimizing the embedded global cache for use with different types of cache data" on page 305.

About this task

If more than one container server exists, the default cache policy ensures that all data is replicated at least once, so that each container server can host primary and replica shards of the cache data. By default, data is read only from the primary shard but you can configure the embedded global cache to support read access to replica shards.

You define that your embedded global cache can read data from replica shards of a cache map by configuring the `deployment.xml` file. You then configure the embedded global cache by updating the `server.conf.yaml` configuration file for the integration server to point to the `deployment.xml` file. The embedded global cache can use only one `deployment.xml` file.

Procedure

1. Open the `deployment.xml` file, and set the **replicaReadEnabled** parameter to `true` on the mapSet element.
   For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<deploymentPolicy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://ibm.com/ws/objectgrid/deploymentPolicy ../
deploymentPolicy.xsd"
   xmlns="http://ibm.com/ws/objectgrid/deploymentPolicy">
```

```
   <objectgridDeployment objectgridName="WMB">
      <mapSet name="mapSet" numberOfPartitions="13" minSyncReplicas="0" maxSyncReplicas="1"
 replicaReadEnabled="true">
         <map ref="USER.OPTIMISTIC.*"/>
         <map ref="USER.PESSIMISTIC.*"/>
         <map ref="USER.NONE.*"/>
         <map ref="SYSTEM.BROKER.*"/>
         <zoneMetadata>
            <shardMapping shard="P" zoneRuleRef="wmbRule"/>
            <shardMapping shard="S" zoneRuleRef="wmbRule"/>
            <zoneRule name="wmbRule" exclusivePlacement="false">
               <zone name="WMBZone"/>
            </zoneRule>
         </zoneMetadata>
      </mapSet>
   </objectgridDeployment>
</deploymentPolicy>
```

Note: If you add any additional `map` entries, you must add the equivalent entries in the `objectgrid.xml`; see "Optimizing the embedded global cache for use with different types of cache data" on page 305. You cannot configure any other options in this file.

2. Save the `deployment.xml` file.
3. Configure the location of the `deployment.xml` file in the integration server by modifying the **deploymentPolicyCustomFile** property in the `server.conf.yaml` configuration file.

   If you made changes to the `objectgrid.xml` file to keep the file consistent with the `deployment.xml`, you must also complete this step for your copy of the `objectgrid.xml` file. For information about the equivalent commands, see "Configuring locking strategies for the embedded global cache" on page 306.
4. Restart the integration server for the changes to take effect.

Results

You have configured read access to replica shards of one or more cache maps in the IBM App Connect Enterprise embedded global cache.

Connecting to external WebSphere eXtreme Scale grids

About this task

For information about WebSphere eXtreme Scale grids, see the concept topic "WebSphere eXtreme Scale grids" on page 278.

IBM App Connect Enterprise supports the IBM eXtremeIO (XIO) transport mechanism for communicating with WebSphere eXtreme Scale external grids. You do not need to specify this transport mechanism as part of the integration server configuration.

For detailed information about how to connect to an external WebSphere eXtreme Scale grid, and how to enable SSL on those connections, see the following topics:

- "Connecting to a WebSphere eXtreme Scale grid" on page 309
- "Enabling SSL for external WebSphere eXtreme Scale grids" on page 310

Connecting to a WebSphere eXtreme Scale grid

You can store data in a WebSphere eXtreme Scale grid for use by other message flows.

Before you begin

- Read the concept information about external grids in "WebSphere eXtreme Scale grids" on page 278.

- Ask your WebSphere eXtreme Scale administrator for the following information about the external grid to which you are connecting:
  - The name of the grid
  - The host name and port of each catalog server for the grid
  - Optional: The object grid file that can be used to override WebSphere eXtreme Scale properties
- To enable SSL for connections to external WebSphere eXtreme Scale grids, follow the instructions in "Enabling SSL for external WebSphere eXtreme Scale grids" on page 310.

Procedure

To connect to a WebSphere eXtreme Scale grid by using a policy, complete the following steps.

1. Optional: If you are connecting to a secure grid, use the **mqsisetdbparms** command to create a security identity, as shown in the following example.

   ```
   mqsisetdbparms INODE -n wxs::id1 -u userId -p password
   ```

2. Create a WXS Server policy by using the Policy editor in the IBM App Connect Enterprise Toolkit (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).
3. Use the values that are provided by your WebSphere eXtreme Scale administrator to configure the connection to the external grid.

   When you specify the security identity, omit the prefix (wxs::) that you used when creating the security identity with the **mqsisetdbparms** command.

   If the object grid file is on a shared drive on Windows, you must use the `\\hostname\directory` path syntax to the shared drive, instead of a mapped drive letter. The IBM App Connect Enterprise user ID that is used to access the `\\hostname\directory` path must have read access to the file system and must use the same password that is required to access the shared drive.

What to do next

After you create the WXS Server policy, you can interact with the external grid by using a Mapping node or a JavaCompute node (see Accessing the global cache by using a Mapping node or "Accessing the global cache by using a JavaCompute node" on page 1781).

When you get a global map from an external grid, the getGlobalMap method makes a connection to the grid if one does not exist. To modify a flow that previously used the embedded cache to connect to an external grid instead, you must update your Mapping node or JavaCompute node by specifying the name of the map on the external grid and the name of the policy that is used to connect to the grid. You can work with multiple external grids, and the embedded grid, at the same time.

Statistics are recorded for the interactions between message flows and the external grid. The global cache activity log also provides a high-level overview of how IBM App Connect Enterprise interacts with the external grid. For more information, see "Monitoring the global cache" on page 313.

Enabling SSL for external WebSphere eXtreme Scale grids

Enable SSL for an external WebSphere eXtreme Scale grid by setting up a public key infrastructure, then enabling SSL on the integration server.

Before you begin

Read the concept information in "WebSphere eXtreme Scale grids" on page 278 and "Public key cryptography" on page 2492.

About this task

You can enable SSL for client connections to external WebSphere eXtreme Scale grids. You cannot enable SSL for servers in the embedded global cache.

To enable SSL communication, configure the keystore, truststore, passwords, and certificates. To enable server authentication, import the public certificate from the WebSphere eXtreme Scale server into the integration server truststore. If the server requires client authentication, you must also create a private key in the integration server keystore that the WebSphere eXtreme Scale server trusts.

You then modify the `server.conf.yaml` configuration file for the integration server and set properties to enable SSL and specify the required protocol. You can also nominate a particular key to use if you have more than one. SSL connections can be made only from integration servers that are not hosting catalog or container servers.

The following steps describe how to enable SSL for an external WebSphere eXtreme Scale grid.

Procedure

1. Set up a public key infrastructure by following the instructions in "Setting up a public key infrastructure" on page 2635.

   You can set up the public key infrastructure at integration node or integration server level.

   Connections to external WebSphere eXtreme Scale grids cannot implicitly use public certificates that are located in the JVM cacerts file.

Modify the properties in the `server.conf.yaml` configuration file for the integration server:

2. Use a YAML editor to open the `server.conf.yaml` file.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor. However, you must ensure that you do not include any tab characters, which are not accepted in YAML and would cause your integration server configuration to fail. If you choose to use a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

   For more information about working with YAML, see http://www.yaml.org/start.html.
3. Ensure that you are enabling SSL on an integration server that does not host a catalog or container server, by setting the **`enableCatalogService`** and **`enableContainerService`** properties in the `server.conf.yaml` configuration file to `false`.
4. To enable SSL, set the following properties in the `server.conf.yaml` file:
   - To enable SSL, set the **`clientsDefaultToSSL`** property `true`.
   - To specify an SSL protocol, set **`sslProtocol`** to a value that is recognized by the IBM JSSE2 security provider.
   - If the external grid requires client authentication and you have more than one trusted private key in the integration node keystore, set **`sslAlias`** to the appropriate key.
5. Restart the integration server for the changes to take effect.
6. Connect to the WebSphere eXtreme Scale grid by following the instructions in "Connecting to a WebSphere eXtreme Scale grid" on page 309.

Results

Keystore, truststore, and protocol settings are verified the first time that a connection is made from the integration server (either to the embedded grid, or for the first remote connection). Errors in the configuration are reported as a warning, and SSL connections are then prohibited. For example, a warning is issued if a keystore file is not found, the file is corrupted, or the keystore password is incorrect.

If you enable SSL and try to connect from an integration server that hosts WebSphere eXtreme Scale server components, the connection fails with a detailed exception message, BIP7144, which explains why the connection failed. If an SSL handshake exception occurs, the message flow fails and the exception message BIP7147 is issued.

Migrating global cache configuration settings

You can migrate your global cache settings by completing some additional configuration as part of your migration from IBM Integration Bus V10 to IBM App Connect Enterprise V11.

When you migrate from IBM Integration Bus V10 to IBM App Connect Enterprise V11, you can migrate your global cache configuration settings by completing the following steps, in addition to those described in the Chapter 2, “Migrating,” on page 19 section:

- “Migrating settings from your IBM Integration Bus cache policy XML files” on page 312
- “Migrating settings from your IBM Integration Bus objectgrid.xml and deployment.xml files” on page 313

Migrating settings from your IBM Integration Bus cache policy XML files

In IBM Integration Bus V10, cache policy XML files were used to configure the global cache. In IBM App Connect Enterprise, the properties that were set in those files are now set in the `server.conf.yaml` configuration files instead.

The following example shows a policy XML file that is similar to the sample `policy_two_brokers_ha.xml` file that was provided with IBM Integration Bus Version 10:

```
<cachePolicy xmlns="http://www.ibm.com/xmlns/prod/websphere/messagebroker/globalcache/
policy-1.0">
    <broker name="integrationNode1" listenerHost="localhost">
        <catalogs>1</catalogs>
        <portRange>
            <startPort>2800</startPort>
            <endPort>2803</endPort>
        </portRange>
    </broker>

    <broker name="integrationNode2" listenerHost="localhost">
        <catalogs>1</catalogs>
        <portRange>
            <startPort>2804</startPort>
            <endPort>2815</endPort>
        </portRange>
    </broker>
</cachePolicy>
```

In IBM Integration Bus Version 10, if you applied the example cache policy XML file to two integration nodes called `integrationNode1` and `integrationNode2`, which were running on the same host (in this example, `localhost`) with several integration servers, your integration nodes would have the following configuration as a result:

- Integration Node 1:
  - Integration Server 1: one catalog server and one container server (taking ports 2800-2803)
  - Further integration servers would have no catalog servers or container servers
- Integration Node 2:
  - Integration Server 2: one catalog server and one container server (taking ports 2804 - 2807)
  - Integration Server 3: container server (taking ports 2808 - 2811)
  - Integration Server 4: container server (taking ports 2812 - 2815)
  - Further integration servers would have no catalog or container servers

In IBM App Connect Enterprise, equivalent sample `server.conf.yaml` configuration files are provided under the sample directory `basic_2_catalogs_4_containers`, in which `IntegrationServer1` would be under `IntegrationNode1`, and `IntegrationServer2`, `IntegrationServer3`, and `IntegrationServer4` would be under `IntegrationNode2`.

This configuration is static and persists across integration server restarts, which means that an integration server that is configured as a catalog server will always be a catalog server, and you can tune your integration servers accordingly. For example, this might include giving container servers a larger JVM heap size, because this is where your cache is stored.

Migrating settings from your IBM Integration Bus objectgrid.xml and deployment.xml files

In IBM Integration Bus V10, the `objectgrid.xml` and `deployment.xml` files had to be copied into set locations beneath your integration node and integration server workpaths, before they would take effect. In IBM App Connect Enterprise, you set the **objectGridCustomFile** and **deploymentPolicyCustomFile** properties in the `server.conf.yaml` configuration file to point to these files. You can choose to put the files in the same workpath locations as in IBM Integration Bus V10, but, if you do so, you must specify the custom file properties in the `server.conf.yaml` file to point to this location.

Monitoring the global cache

You can use the **mqsicacheadmin** command, resource statistics, and the activity log to monitor the global cache. You can use resource statistics and the activity log to monitor external grids.

About this task

The following tools provide information about the global cache and how it is performing.

mqsicacheadmin command
The **mqsicacheadmin** command provides information about the global cache that is embedded in an integration server. For example, you can find out the size of a map and list the hosts that are participating in the cache. You can also use this command to clear data from a map. See "Running the mqsicacheadmin command" on page 313.

Activity log
Activity logs provide a high-level overview of how IBM App Connect Enterprise interacts with external resources, therefore helping you to understand what your message flows are doing. See "Viewing Activity Logs for message flows in the web user interface" on page 2856.

Resource statistics
Resource statistics are collected by an integration server to record performance and operating details of the resources that it uses. See "Managing resource statistics collection" on page 2741.

Running the `mqsicacheadmin` command

Procedure

To use the command to find information about the global cache that is embedded in an integration server, complete the following steps.

1. Before you run the **mqsicacheadmin** command, ensure that the integration server is running and that the global cache is available.

   The cache is disabled by default. To use the cache, set the properties in the Global Cache section of the `server.conf.yaml` configuration file for the integration server. For more information, see "Configuring the embedded global cache" on page 285.

2. Run the **mqsicacheadmin** command, specifying the appropriate parameters, as described in command. Use the **-c** parameter to run a WebSphere eXtreme Scale command.

   For example, to list all container servers and their shards in the embedded cache, run the WebSphere eXtreme Scale command, **showPlacement**:

   ```
   mqsicacheadmin myIntegrationNode -c showPlacement
   ```

   To clear all data from the map called *myMap* in the integration node *myIntegrationNode*, run the following command:

   ```
   mqsicacheadmin myIntegrationNode -c clearGrid -m myMap
   ```

   The data is cleared immediately; you do not need to restart the integration node for this action to take effect.

   You do not have to specify an integration node name with this command. For example, use the **-cep** parameter to connect to a catalog server and show the routing table for each WebSphere eXtreme Scale shard:

   ```
   mqsicacheadmin -cep server.company.com:2800 -c routetable
   ```

   The **-cep** parameter specifies the catalog service endpoints, and you can use this parameter to specify a comma-separated list of catalog servers; the first valid server to be contacted will be used.
3. Examine the output and usage information that is returned by the command.

Listing database connections

IBM App Connect Enterprise does not provide an interface that you can use to list the connections that it has to a database. You must use the facilities of the database suppliers to list connections.

For further information about how to list database connections, refer to the documentation that is provided by your database vendor.

Quiescing a database

The integration node and database exhibit specific behaviors when you quiesce the database.

If you access databases from one or more message flows, your database administrator might occasionally want to issue the quiesce instruction on a database. This action is a function of the database, not of the integration node.

The following three assumptions are made for the database that you are quiescing:

- The database can be quiesced (not all databases support this function).
- New connections to the database are blocked by the database when it is quiescing.
- Message flows that access the database eventually become idle.

The following list shows the behavior that is expected while a database is quiescing:

- Run the command that quiesces the database. When this command starts, the connections that are in use remain in use, but no new connections to the database are allowed.
- Messages that are being processed by message flows, which use existing connections to the database, continue to use their connections until the connections become idle. Therefore if messages continue to be received by the message flow, it might be a long time before the quiesce occurs. To ensure that messages are no longer processed, stop the message flow. Stopping the message flow stops messages being processed, and releases the database connections that the flow was using. This action ensures that the database connections that the flow holds become idle.
- Database connections for the message flow become idle. This situation causes the integration node to release the connections to the databases that the message flow is using. When all connections to the

database from the integration node, and from any other applications that are using the database, are released, the database can complete its quiesce function.

For more information, see "Database connections" on page 1131.

Using a JDBC connection pool to manage database resources used by an integration server

Use integration node JDBC provider resources to configure the use of thread pools independently of message flow and input node thread pools.

About this task

IBM App Connect Enterprise manages JDBC connections in the following ways:

- Non-pooled connections:
  - IBM App Connect Enterprise creates a JDBC connection on demand for each message flow instance that requires one.
  - Each JDBC connection is associated with the message flow instance for which it was created. This association is maintained until the connection is closed.
  - Each JDBC connection that is idle for 60 seconds is closed, and is no longer associated with a message flow instance.
  - After a JDBC connection that was associated with a message flow instance is closed, if the same message flow instance requires a JDBC connection, IBM App Connect Enterprise creates a new JDBC connection on demand.
- Pooled connections:
  - When a message flow instance requires a JDBC connection, IBM App Connect Enterprise assigns an unused connection from the pool.
  - If all pooled JDBC connections are being used, and the maximum pool size has not been reached, IBM App Connect Enterprise creates a new pooled JDBC connection. The maximum pool size is specified in the `Maximum size of connection pool` property of the JDBC Providers policy (JDBCProviders).
  - Each pooled JDBC connection remains associated with a message flow instance only for the processing of one input message.
  - When a message flow instance completes the processing of an input message, the association with a JDBC connection is removed, and the JDBC connection is returned to the pool.
  - Each pooled JDBC connection that is idle for 15 minutes is closed, and is removed from the pool.
  - Pooled JDBC connections are not applicable to the DatabaseRetrieve and DatabaseRoute nodes.

Using a JDBC connection pool enables you to scale database access independently of the number of message flow threads.

The purpose of the JDBC connection pooling function in IBM App Connect Enterprise is to:

- Minimize the time and resource needed to create new connections, by making pooled connections available for reuse by other message flow threads when transactions complete.
- Enable greater control over the number of concurrent database connections that can be in use at any time for a specific JDBC data source.

Although these aims overlap with those of J2EE Java connection pooling, the priority is not to maximize the performance of individual JDBC calls to the database. In this respect, non-pooled JDBC connections might be more efficient in some scenarios.

You can create a JDBC connection pool by setting the `Maximum size of connection pool` property of the JDBC Providers policy to a non-zero integer value. This property acts at the integration server level to specify the maximum number of JDBC connection threads that can be used. A value of zero defaults to

the standard WebSphere Message Broker Version 8.0 behavior, where one JDBC connection is created for each message flow thread.

All message flows within an integration server that use the same JDBC Providers policy also share a connection pool. You can monitor the behavior of a JDBC connection pool by using integration node resource statistics

The `Maximum size of connection pool` property is applicable to JDBC connections obtained using the `getJDBCType4Connection()` API of the JavaCompute node, and to database operations in graphical data maps that are called by the Mapping node.

Note: The `Maximum size of connection pool` property does not apply to the JDBC connections used by the DatabaseRetrieve or DatabaseRoute nodes.

Managing deployed resources

You can manage the resources that you have deployed to integration servers by using commands, the IBM App Connect Enterprise Toolkit, or the web user interface. You can also use the IBM Integration API or commands to complete some of these actions.

About this task

- “Setting the start mode of message flows and applications at run time” on page 316
- “Starting or stopping deployed resources” on page 317
- “Viewing version information and custom keyword values in your deployed solutions” on page 319
- “Deleting deployed resources” on page 319
- “Managing a deployed REST API” on page 323

Setting the start mode of message flows and applications at run time

You can configure the run state of applications, integration services, and message flows when you deploy or when you restart an integration server.

Before you begin

This topic assumes that a BAR file has been created and contains an application, integration service or message flow. For more information, see the following topics:

- “Creating a BAR file” on page 2469
- “Adding resources to a BAR file” on page 2470

About this task

You can set the default behavior of message flows and applications when you deploy or restart an integration server. For example, you might have a message flow that creates resources that are required by other message flows. Therefore, you might want to start one message flow before all others when the flows are deployed, or when the integration server or containing application is started. You can set one message flow to start automatically, then set other message flows to require a manual restart.

You can configure the run state by using the `startMode` property on the **`mqsiapplybaroverride`** command. Use the **`mqsireadbar`** command to view the current values of properties in the BAR file. You can set the `startMode` property to one of the following values:

Maintained
: This value is the default, and indicates that the flow or application is started when deployment is complete, and remains running until a stop command is issued. After a stop command has been issued, the flow or application remains stopped until a start command is issued. The state of the flow or application remains unchanged after redeployment, or after the integration server or containing

application has been restarted. When an application holds one or more flows, the state of the flows within the application is preserved if the application is stopped and then started again.

Manual
This value indicates that the flow or application must always be started manually after deployment. or after the integration server or containing application has been restarted. The flow or application is in stopped state after deployment or redeployment, and after the integration server or containing application is restarted, even if the flow or application was running before the deployment or restart.

Automatic
This value indicates that the flow or application is always started automatically after deployment, redeployment, or after the integration server or containing application is restarted.

You can set this property for message flows and applications. The state of an application overrides the state of any message flows that it contains. For example, if an application is stopped, no flows in that application can run, even if they have been set to start automatically.

To find out how to use the **mqsiapplybaroverride** command to set the `startMode` property, see command.

What to do next

Deploy the BAR file by following the instructions in "Deploying integration solutions to a production environment" on page 2480.

Starting or stopping deployed resources

Use the IBM App Connect Enterprise Toolkit or the web user interface to start or stop applications, integration services, and message flows. Use the **mqsistart** or **mqsistop** commands to start or stop applications, libraries or message flows.

About this task

You cannot start or stop libraries or subflows. If a message flow includes a subflow that is defined in a `.subflow` file, you can start your message flow only if the subflow is deployed to the same integration server.

If you stop the integration server in which an application, integration service, or message flow is running then, by default, the mode of the resource (started or stopped) is retained. However, you can configure the resources so that, when you deploy or restart an integration server, the resources start in a specific mode; see "Setting the start mode of message flows and applications at run time" on page 316.

You can use the following methods to stop and start applications, libraries, integration services, and message flows:

- "Starting and stopping an application, integration service, or message flow by using the IBM App Connect Enterprise Toolkit" on page 317
- "Starting and stopping an application, integration service, or message flow by using the web user interface" on page 318
- "Starting and stopping an application or a message flow by using the mqsistart or mqsistop commands" on page 318
- "Starting and stopping an application or a message flow by using the mqsistartmsgflow or mqsistopmsgflow commands" on page 318

Starting and stopping an application, integration service, or message flow by using the IBM App Connect Enterprise Toolkit

Procedure

1. In the Integration Explorer view, expand the integration server.

2. Right-click the application, integration service, or message flow:
   - To start the resource, click **Start**.
   - To stop the resource, click **Stop**.

Results

A message is sent to the integration server to start or stop the resource.

Starting and stopping an application, integration service, or message flow by using the web user interface

Procedure

1. Start the IBM App Connect Enterprise web user interface, as described in "Accessing the web user interface" on page 89.

   Your integration servers, message flows, and other resources are displayed.
2. Navigate to the resource that you want to work with, select it, and then click **Start** or **Stop**.

Results

A message is sent to start or stop the applications, integration services, and message flows that you specified.

Starting and stopping an application or a message flow by using the `mqsistart` or `mqsistop` commands

Procedure

In the Command Console, run the **`mqsistart`** or **`mqsistop`** commands with the appropriate parameters for the deployed resource you want to start or stop. For more information, see command and command.

Results

A message is sent to the integration server to start or stop the resource.

Starting and stopping an application or a message flow by using the `mqsistartmsgflow` or `mqsistopmsgflow` commands

Procedure

In the Command Console, run the **`mqsistartmsgflow`** or **`mqsistopmsgflow`** commands with the appropriate parameters for the deployed resource you want to start or stop. For more information, see command and command.

Results

A message is sent to the integration server to start or stop the resource.

Viewing version information and custom keyword values in your deployed solutions

You can view version and custom keyword information in your deployed resources.

About this task

If version or custom keyword information was added to your resources during development, you can view the values in resources that are deployed to an integration server by using the following methods:

- "Viewing version and custom keyword information by using the IBM App Connect Enterprise Toolkit" on page 319

Viewing version and custom keyword information by using the IBM App Connect Enterprise Toolkit

Procedure

To view the version and custom keyword information that is associated with the resources that are deployed to an integration server by using the IBM App Connect Enterprise Toolkit, complete the following steps:

1. In the **Integration servers** pane of the IBM App Connect Enterprise Toolkit, locate the integration server where your resources are deployed.
2. Click a deployed resource to see the properties that are associated with the resource.

Results

If the resource has a version or custom keyword value, the values are displayed in the **Keywords** section of the **Properties** tab.

What to do next

For information about adding version or custom keyword information to your development resources, or viewing version or custom keyword information in your packaged resources, see the following topics:

- "Adding version information and custom keyword values to your development resources" on page 2466
- "Viewing version information and custom keyword values in your packaged solutions" on page 2468

Deleting deployed resources

Use the IBM App Connect Enterprise Toolkit or the web user interface to remove deployed integration solution resources such as applications and libraries from an integration server.

About this task

You can delete applications, libraries, integration services, and message flows from an integration server by using any of the following methods:

- "Deleting a deployed resource by using the web user interface" on page 320
- "Removing a deployed object by using the IBM App Connect Enterprise Toolkit" on page 320
- "Removing a deployed object by using the mqsideploy command" on page 320
- "Removing a deployed object by using the IBM Integration API" on page 321

Note: You cannot delete message flows or other resources that are contained in an integration service, application, or library.

You cannot delete shared libraries if they are being referenced by any of the other resources that are deployed on the integration server.

You cannot delete policy projects that contain non-dynamic policies. The changing or deletion of policies within a policy project is only supported for certain types of policy. To delete a policy project, which contains non-dynamic policies, it is necessary to delete all deployed resources from the integration server and then redeploy all resources.

For more information about policy properties, see Policy properties.

Deleting a deployed resource by using the web user interface

Procedure

1. Start the IBM App Connect Enterprise web user interface, as described in "Accessing the web user interface" on page 89.

   Your servers (integration servers), message flows, and other resources are displayed.
2. Select the resource that you want to delete and click **Delete**.

Results

A message is sent to the integration server to delete the selected resource.

Removing a deployed object by using the IBM App Connect Enterprise Toolkit

About this task

To remove an object from an integration server by using the IBM App Connect Enterprise Toolkit, complete the following steps.

Procedure

1. In the Integration Explorer view, right-click the object that you want to remove.
2. Click **Delete**, then **OK** to confirm.

Results

The request is sent to the integration server, and a synchronous response is sent back.

Removing a deployed object by using the `mqsideploy` command

About this task

To remove an object from an integration server by using the **mqsideploy** command, complete the following steps.

Procedure

1. Open a command window that is configured for your environment.
2. Enter the appropriate command for your operating system and configuration, by using the following examples as a guide.

```
mqsideploy -i ipAddress -p port -e integrationServerName
-d file1.cmf:file2.bar:file3.dictionary:file4.xml
```

```
mqsideploy --admin-host ipAddress --admin-port port -e integrationServerName
-d file1.cmf:file2.bar:file3.dictionary:file4.xml
```

   The **-i** (IP address) and **-p** (port) parameters represent the connection details for an independent integration server or an integration node. If you want to run this command against an integration

node on the same computer, you can specify the integration node name instead, as in the following example:

```
mqsideploy integrationNodeName -e integrationServerName
-d file1.cmf:file2.bar:file3.dictionary:file4.xml
```

If you have a `.broker` file that contains the connection details for an independent integration server or integration node, you can specify this file by using the **-n** parameter, as in the following example:

```
mqsideploy -n integrationNodeFileName -e integrationServerName
-d file1.cmf:file2.bar:file3.dictionary:file4.xml
```

where *integrationNodeFileName* is the path and file name of the `.broker` file.

The **-d** parameter is a colon-separated list of files that you want to remove from the named integration server. When you run the command, the deployed objects (`file1.cmf, file2.bar, file3.dictionary, file4.xml`) are removed from the specified integration server.

Optionally, specify the **-m** parameter to remove all currently deployed message flows and message sets from the integration server as part of the deployment. If you do not set **-m**, the contents of the BAR file are deployed in addition to what is already deployed to the integration server. Any deployed objects with the same name as an item inside the BAR file are replaced by the version inside the BAR file. When you remove a message flow or message set, the **-m** parameter is ignored.

For more information about alternative long names for parameters, and for more information about the command, see command.

Results

The command reports when responses are received from the integration node. If the command completes successfully, a zero return code (0) is displayed.

Removing a deployed object by using the IBM Integration API

About this task

To remove deployed objects from an integration server, get a handle to the relevant `ExecutionGroupProxy` object, then run the `deleteDeployedObjectsByName` method. Use the following code as an example.

```
import com.ibm.broker.config.proxy.*;

public class DeleteDeployedObjects {
  public static void main(String[] args) {
    BrokerConnectionParameters bcp =
            new IntegrationNodeConnectionParameters
                      ("localhost", 4414);
    try {
      BrokerProxy b =
            BrokerProxy.getInstance(bcp);
      ExecutionGroupProxy e =
            b.getExecutionGroupByName("default");
      e.deleteDeployedObjectsByName(
            new String[] { "file1.msgflow",
                           "file2.msgflow",
                           "file3.xsd",
                           "file4.msgflow" }, 0);
    }
    catch (ConfigManagerProxyException e) {
      e.printStackTrace();
    }
  }
}
```

What to do next

If you remove one or more message flows, you can now remove the resource files that are associated with those message flows; for example, JAR files.

Deleting deployed policies

You can delete only policy projects that contain dynamic policies. To delete a policy project that contains non-dynamic policies, you must delete all deployed resources from the integration server.

You can delete the following types of policy after they are deployed. When you redeploy the policy project, all message flows that are using the policy are stopped and restarted:

- ActivityLog
- Aggregation
- CDServer
- CICSConnection
- Collector
- CORBA
- EmailServer
- FtpServer
- IMSConnect
- JDEdwardsConnection
- Kafka
- MQEndpoint
- MQTTPublish
- MQTTSubscribe
- ODMServer
- PeopleSoftConnection
- Resequence
- SAPConnection
- SecurityProfiles
- SiebelConnection
- SMTP
- TCPIP Client policy (TCPIPClient)
- TCPIP Server policy (TCPIPServer)
- Timer
- UserDefined
- WorkloadManagement

To delete the following policies after they are deployed, you must delete all deployed resources from the integration server:

- DotNet Application Domain policy (DotNetAppDomain)
- Java Class Loader policy (JavaClassLoader)
- JDBC Providers policy (JDBCProviders)
- JMS Providers policy (JMSProviders)
- Monitoring profiles
- WXSServer policy

For more information about policy properties, see Policy properties.

Managing a deployed REST API

After you deploy a REST API, you can manage it from the command line or the web user interface.

Before you begin

You must create a REST API in the IBM App Connect Enterprise Toolkit, see "Creating a REST API" on page 2019 and "Packaging and deploying a REST API" on page 2045.

You can view the REST API after it is deployed by using the web user interface, see web user interface.

About this task

After you deploy the REST API, you can manage it from the command line or the web user interface. When you are using the command line to manage a deployed REST API and the command you are using requires the name of an application, you must specify the name of the REST API. For example:

```
mqsilist integrationNodeName -e integrationServerName -k restApiName -d2
```

You can view the REST API after it is deployed by using the web user interface, see web user interface.

Procedure

To view information about the deployed REST API in the web user interface, complete the following steps:

1. Open the web user interface in a web browser. Locate the deployed REST API in the navigator.

   The REST API is listed under the integration server, in the REST APIs category.
2. Expand the navigation of the deployed REST API.

   The currently deployed message flow, subflows, and any other deployed resources are displayed.
3. Click the drop-down arrow for the deployed REST API.

   A list of actions that you can perform on a deployed REST API displayed. Depending on your access rights, you can start, stop, or delete the REST API, or start or stop statistics for the REST API.
4. Click the deployed REST API.

   The **Overview** tab for the deployed REST API is displayed.

   In the **Quick View** section of the **Overview** tab, the base URL for REST API invocations is displayed. The REST API base URL value contains the scheme (`http://` or `https://`), hostname, port number, and base path of the REST API that is running. By using an HTTP client, you can use this URL, along with other details of the operation that is being called, to call an operation in the deployed REST API.

   In the **Quick View** section of the **Overview** tab, the URL for the REST API definitions is displayed. You can use the REST API definitions URL to access the Swagger document or the OpenAPI 3.0 document for the deployed REST API. You can use this URL with Swagger tools, such as Swagger UI or Swagger Codegen or OpenAPI 3.0 tools. The Swagger document or OpenAPI 3.0 document available at this URL is automatically updated to contain the correct scheme (`http://` or `https://`), hostname , port number, and base path of the REST API that is running. Therefore, you can use the Swagger document or OpenAPI 3.0 document without modification.
5. Click the **API** tab.

   The details of resources and operations within the deployed REST API are displayed. Operations are displayed with their HTTP method, name, description, and information about whether that operation is implemented as a subflow.
6. Click an operation.

   The parameters for that operation are displayed, along with their name, type, description, and whether a parameter is required.

Results

The information about a deployed REST API is displayed.

Overriding properties at run time with policies

Use policies to control the behavior of message flows, and the nodes in message flows, at run time.

Before you begin

For more information about policies, read "Policies overview" on page 324.

About this task

By taking advantage of policies, you can define a common approach to controlling particular node properties, such as connection credentials, and certain aspects of message flow behavior, including flow rate. You can create and update policies at any time in the solution lifecycle.

Procedure

1. Create a policy by using the Policy editor and, if appropriate, attach it to a message flow node (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).

   Policies are XML files; therefore, you can create a policy by using an XML editor if you do not want to use the Toolkit. Policy documents are defined by an XML Schema Definition (`Policy.xsd`), which is found in the default installation directory. For example, on Windows, you can find the policy definition file at `C:\Program Files\IBM\ACE\version\common\schemas\Policy`.
2. Deploy the policy in a policy project.

   You can either deploy the policy project in an independent BAR file or in the same BAR file as the associated message flow (see "Adding resources to a BAR file" on page 2470).

   Deployed policies are shown in the `run` sub-directory of the integration server work directory, within a sub-directory with the name of the policy project. You can see the properties of deployed policies in the Integration Explorer of the IBM App Connect Enterprise Toolkit or on the Policies tab of the web user interface (see "Accessing the web user interface" on page 89). You can also see which properties are being used by the deployed flow at run time by using the REST API or web user interface.
3. Optional: You can override a deployed policy by putting an updated policy project in the `overrides` sub-directory of the integration server work directory (see "Overriding deployed policies at run time with the overrides directory" on page 328).

Policies overview

Policies can control particular node properties, such as connection credentials, and certain aspects of message flow behavior, including flow rate. Policies provide a shared and managed definition that you can reuse.

Policies contain defined operational properties, and enable the following user capabilities:

- Developers can use policies to control runtime behavior and reuse configuration information in multiple places, therefore eliminating duplication of effort. Where policies are used to override message flow properties at run time, information like connection details can be updated without having to update message flows.
- Administrators can use policies to define key configuration data for each environment and to override properties that were specified by message flow developers. This ability is useful if connection details are different for different environments (such as development, test, and production systems.) Administrators can also update policies with sensitive data that might not be available to developers.
- Operators can use policies to monitor and modify configuration data dynamically.

You can attach a policy to one or more entities that you want to control, such as message flows, message flow nodes, or integration servers. For example, if you add an AggregateControl node to your flow, the

`Aggregate name` property on the message flow node can be used to associate fan-in and fan-out flows. Alternatively, it can specify the name of an Aggregation policy. If you specify just the name of the policy in the `Aggregate name` property, the policy is retrieved from the default policy project. Alternatively, you can specify a policy in a different policy project by using the following format in the message flow node property:

```
{PolicyProjectName}:PolicyName
```

If the named policy cannot be found, the message flow cannot be started.

You can also reference a policy from a JavaCompute node by using the name of the policy in the Java code; for example,

```
MbPolicy myUserPolicy = getPolicy("UserDefined", "{MyPolicyProject}:MyUserPolicy");
```

Policies are XML documents, which are defined by an XML Schema Definition (`Policy.xsd`) that is found in the default installation directory. For example, on Windows, you can find the policy definition file at `C:\Program Files\IBM\ACE\`*`version`*`\common\schemas\Policy`.

Configurable services

Policies replace configurable services in App Connect Enterprise. You can migrate your existing configurable services to policies by using the **mqsiextractcomponents** command (see command).

The **mqsicreateconfigurableservice** command is deprecated in App Connect Enterprise, and no longer creates configurable services. However, if you use the **mqsicreateconfigurableservice** command in your IBM Integration Bus scripts, this command creates equivalent policies (where supported) in App Connect Enterprise (see command (deprecated)).

Policies that are created by the **mqsicreateconfigurableservice** command are created in the default policy project (`DefaultPolicies`) and are associated with an integration node. These policies are inherited by all integration servers on that integration node. You can override a policy that is inherited by an integration server from the integration node by deploying an updated version of the policy to that integration server. Alternatively, you can put an updated policy in the `overrides` subdirectory of the integration server work directory (see “Order of precedence for overrides” on page 326).

Policy projects

When you run the **mqsicreateworkdir** command, a configuration file called `server.conf.yaml` is created, which contains default settings for your integration server. This configuration file defines a default policy project, which is used to store unqualified policies. When you create a policy in the IBM App Connect Enterprise Toolkit, you must create it in a policy project. When you reference a policy from a message flow or message flow node, use the policy name if the policy is in the default policy project. If the policy is in a different policy project, prefix the name of the policy with the name of the policy project, with the format *{policyProject}:PolicyName*. You can use policy projects to organize your resources, and you can add as many policies to a policy project as you want. For example, your policy project might organize policies in the following ways:

- Your policy project might contain all policies for a particular integration server.
- The project might contain all policies of a particular type (for example, all JDBC Providers policies) for an integration server.
- It might contain all policies for a specific application.

For more information about creating policies, see “Creating policies with the IBM App Connect Enterprise Toolkit” on page 327.

Default policy project and policies

A default policy project called `DefaultPolicies` is defined in the `server.conf.yaml` file for the integration server. Policies that are created by the **mqsicreateconfigurableservice** command are

created in this default policy project. You can also specify certain default policies to control resources on an integration server by setting them in the `server.conf.yaml` file for that integration server (see “Configuring an integration server by modifying the server.conf.yaml file” on page 172). For example, the following excerpt from the `server.conf.yaml` file shows that you can specify a default Monitoring Profile policy to configure monitoring for message flows. For more information, see “Monitoring profiles” on page 2775.

```
Defaults:
  #defaultApplication: ''            # Name a default application under which independent
 resources will be placed
  #policyProject: 'DefaultPolicies'  # Name of the Policy project that will be used for
 unqualified Policy references. Default is 'DefaultPolicies'
  Policies:
    # Set default policy names, optionally qualified with a policy project as {policy
 project}:name
    #monitoringProfile: ''           # Default Monitoring profile
```

After you create the policy, set the name of the policy in the `server.conf.yaml` file. If the default policy is in the default policy project, you do not need to specify the name of the policy project. If the default policy is in a non-default policy project, qualify the name of the policy with the name of the policy project (*{policyProject}:PolicyName*).

Policy deployment

You deploy policies in policy projects in an independent BAR file, or in a BAR file with the associated message flow. As an administrator, you can also override deployed policies by using the `overrides` subdirectory of the integration server. For more information, see “Overriding deployed policies at run time with the overrides directory” on page 328. If a policy name is set specifically on a message flow or message flow node, you must deploy the policy before the message flow can be started. If a policy is not specified explicitly on a message flow or message flow node, you must deploy the policy before or with the message flow.

You can change and redeploy policies after they are deployed, by redeploying the policy project. When you redeploy a dynamic policy, all message flows that are using it are stopped and restarted. For non-dynamic policies, which cannot be deployed while applications and message flows are using them, you must restart all applications as part of the deploy operation by specifying the **--restart-all-applications** parameter on the **mqsideploy** or **ibmint deploy** command. For more information about the types of policy that can be redeployed, see Policy properties.

Deployed policies are shown in the `run` subdirectory of the integration server work directory, within a subdirectory that has the name of the policy project. You can see the properties of deployed policies in the Integration Explorer of the IBM App Connect Enterprise Toolkit or on the **Policies** tab of the web user interface (see “Accessing the web user interface” on page 89). You can also see which properties are being used by the deployed flow at run time by using the REST API or web user interface.

For more information about policy deployment, see "What to do next" in “Creating policies with the IBM App Connect Enterprise Toolkit” on page 327.

Order of precedence for overrides

You can override a deployed policy by putting an updated policy project in the `overrides` subdirectory of the integration server work directory and restarting the integration server (see “Overriding deployed policies at run time with the overrides directory” on page 328).

The following precedence rules apply to operational property values:

- The properties in HTTP or HTTPS Connector policies completely override those properties that were set by the HTTP or HTTPS Connector in the ResourceManagers section of the `server.conf.yaml` file.
- A value in a policy in the overrides subdirectory of the work directory overrides a value in a deployed policy.

- A value in a deployed policy overrides a value in an integration node-level policy that is created by the **mqsicreateconfigurableservice** command .
- A value in an integration node-level policy takes precedence over a value that is overridden in a BAR file or set on the node.
- When no policy exists for an operational property value, the value that is overridden in a BAR file takes precedence over the value that is set on the node.
- When no policy or BAR file override exists for an operational property value, the value that is set on the node takes precedence.

Tip: If you designed your message flow to include a local environment override, any property value that is set by the local environment override overrides a value that is set by a policy, a BAR file override, or on the node.

Policies replace configurable services in IBM App Connect Enterprise 11.0. In previous versions, if you used a configurable service to override node properties at run time, a blank property in a configurable service overrode a node property with an empty value. However, when you use a policy, an empty property in a policy does not override the node property with an empty value. In this case, the value that is set by the node property is used.

Policy types

In addition to the policy types that are listed in Policy properties, monitoring profiles and policy sets and bindings are forms of policy that can be used to override properties at run time. For more information about these types of policy, see “Monitoring profiles” on page 2775 and “Policy sets” on page 2662.

Creating policies with the IBM App Connect Enterprise Toolkit

To control message flow behavior at run time, create one or more policies in one or more policy projects and deploy the policy projects.

Before you begin

For more information about policies, read “Policies overview” on page 324.

About this task

Policies are used to override property values so that you can control the behavior of message flows and message flow nodes at run time. You create one or more policies in a policy project, then you deploy one or more policy projects. Policies are XML files; therefore you can create a policy by using an XML editor. Policies are defined by an XML Schema Definition (`Policy.xsd`), which is found in the default installation directory. (For example, on Windows, you can find the policy definition file at `C:\Program Files\IBM\ACE\version\common\schemas\Policy`.) However, the following steps describe how to create a policy and a policy project in the IBM App Connect Enterprise Toolkit.

Procedure

1. In the Application Development view of the IBM App Connect Enterprise Toolkit, click **New**, then select **Policy**.
2. Select an existing policy project or click **New** to create a policy project.
3. Enter a name for your policy.

   The policy name can include alphanumeric characters and the underscore character. The name cannot include spaces and must start with a letter.
4. Click **Finish**.

   A `.policyxml` file is created and is opened in the Policy editor.
5. In the Policy editor, select the policy type from the list.
6. If your chosen policy type has more than one template, select the appropriate template from the list.

   The template provides default values for some fields.

7. Edit or set appropriate values for your policy.

   Mandatory properties are marked with an asterisk. For more information about property values for specific policies, see Policy properties.

8. Save your policy.

   Any errors are reported on the **Problems** tab.

Results

A policy that contains the overriding property values is generated. You can see your policy and policy project in the Application Development view.

The values in the policy override the equivalent properties that were configured in the **Properties** view for the node when the message flow was developed.

What to do next

1. Attach the policy to a message flow node by setting the policy name in the appropriate property of the message flow node.

   If you want to override a message flow node property with a policy at run time, you need to set the policy name on the message flow node. For example, to configure storage of events for aggregation nodes at run time, first create an Aggregation policy. Next, set the **Aggregate name** property on the AggregateControl or AggregateReply node to the name of the policy. If you do not use an Aggregation policy, the **Aggregate name** property on the Aggregation nodes is used to associated fan-in and fan-out flows.

   If the policy is deployed in the default policy project for the integration server, specify just the policy name in the message flow property.If the policy is deployed in a non-default policy project, prefix the name of the policy with the policy project name:

   ```
   {PolicyProjectName}:PolicyName
   ```

   You can also reference a policy from a JavaCompute node by using the name of the policy in the Java code; for example:

   ```
   Connection conn = getJDBCType4Connection("MyJDBCPolicy", JDBC_TransactionType.MB_TRANSACTION_AUTO);
   ```

2. Deploy the policy.

   You can deploy one or more policy projects, either in an independent BAR file, or in the same BAR file as the associated message flow.

   If a policy name is set specifically on a message flow or message flow node, you must deploy the policy before the message flow can be started. If a policy is not specified explicitly on a message flow or message flow node, you must deploy the policy before or with the message flow (see “Adding resources to a BAR file” on page 2470).

Deployed policies are shown in the `run` sub-directory of the integration server work directory, within a sub-directory with the name of the policy project. You can see the properties of deployed policies in the Integration Explorer of the IBM App Connect Enterprise Toolkit or on the Policies tab of the web user interface (see “Accessing the web user interface” on page 89). You can also see which properties are being used by the deployed flow at run time by using the REST API or web user interface.

Overriding deployed policies at run time with the overrides directory

You can override a deployed policy by putting an updated policy in the `overrides` subdirectory of the integration server work directory.

About this task

Policies that are deployed to an integration server are stored in the `run` directory for that integration server. Each integration server also has an `overrides` directory, which can contain policies that are

read by the integration server when it is starting up. If a policy in the overrides subdirectory has the same name as a policy that is deployed in a BAR file, the policy in the overrides subdirectory takes precedence.

Procedure

To override a deployed policy at run time, complete the following steps.

1. In the `overrides` subdirectory of the integration server, create a subdirectory with the name of the policy project that contains the policy that you want to override. For example, *myPolicyProject*.
2. Export the policy project that contains the policy that you want to update from the IBM App Connect Enterprise Toolkit to your file system. You need to include the file `policy.descriptor`.
3. Edit the appropriate property values in the `.monprofile.xml` file.
4. Save the updated `.policyxml` file and the `policy.descriptor` file to the subdirectory that you created in Step 1.
5. Restart the integration server.

Configuring a default policy project

You can configure a default policy project for an integration server by setting the policy project name in the integration server's `server.conf.yaml` configuration file.

Before you begin

- Read "Overriding properties at run time with policies" on page 324 for background information.
- Create a policy project for the required message flow nodes.
- Deploy your message flows to the integration server.

About this task

You can configure a default policy project to be used by an integration server, by setting the **`policyProjects`** property in the `Defaults` section of the integration server's `server.conf.yaml` configuration file, as shown in the following example. The policy project that you specify is then used when a policy is required but no policy name has been specified. The default value for the **`policyProject`** property is `DefaultPolicies`.

```
Defaults:
  #defaultApplication: ''            # Name a default application under which independent
 resources will be placed
  #policyProject: 'DefaultPolicies'  # Name of the Policy project that will be used for
 unqualified Policy references, default is 'DefaultPolicies'
  Policies:
    # Set default policy names, optionally qualified with a policy project as {policy
 project}:name
    #monitoringProfile: ''       # Default Monitoring profile
  Credentials:
    # Names a default credential name to be used when a more specific credential is not
 available for the credential type.
    #httpproxy: ''
    #jdbc: ''
    #kafka: ''
    #kerberos: ''
    #ldap: ''
    #odbc: ''
    #mq: ''
    #wsrr: ''
```

Procedure

To configure a default policy project for an integration server, complete the following steps:

1. Use a YAML editor to open the `server.conf.yaml` file.

   If you do not have access to a YAML editor, you can edit the file by using a plain text editor. However, you must ensure that you do not include any tab characters, which are not accepted in YAML and would cause your integration server configuration to fail. If you choose to use a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

   For more information about working with YAML, see http://www.yaml.org/start.html.
2. Set the **`policyProject`** property in the `Defaults` section of the `server.conf.yaml` file, by removing the comment (`#`) from the start of the `policyProject` line and either specifying the name of an existing policy project or keeping the default value of `'DefaultPolicies'`, as shown in the following example:

   ```
   policyProject: 'DefaultPolicies'   # Name of the Policy project that will be used for
    unqualified Policy references
   ```
3. Restart the integration server. The properties that you set in the `server.conf.yaml` file take effect when the integration server is started. If you modify these properties again, you must also start the integration server again for the subsequent changes to take effect. For more information, see “Starting an integration server” on page 250.

Viewing administration activity in the admin log

App Connect Enterprise stores a log of administration activity for each integration node and integration server.

About this task

Admin logs are generated for administration activities that occur at the level of integration nodes, managed integration servers, and independent integration servers. At the integration node level, the admin log contains information about events such as starting and stopping integration servers. At the integration server level, the admin log contains information about the admin events that occur on that server. The logs contain information such as the date and time of an action, the description and result of the action (success or failure), and the username and authorized role of the user who initiated the action.

The admin log is enabled by default, and you can view the data either by selecting the **Admin Log** tab in the App Connect Enterprise web user interface, or by using the administration REST API. The web user interface shows the most recent data for the integration node or server since it started, including the BIP message number, message text, timestamp, username, and authorized role. It also shows a set of tags for each entry, which can be used to identify such things as the message flow, the application, and the action that was performed. Admin events that are held in the integration node or server in-memory buffer are loaded and displayed when the tab is first selected. To display events that have occurred since the tab was opened, click **Refresh**. The timestamp shows when the tab was last refreshed.

You can filter the entries that are displayed in the web user interface, as described in “Filtering admin log entries in the web user interface” on page 331.

In addition to displaying admin log entries in the web user interface, you can write admin log entries for an integration node or server to a file, as described in “Writing admin log entries to a file” on page 332. For independent integration servers, you can configure administration logging to write to the console. For information about configuring administration logging, see “Configuring administration logging” on page 333.

Admin log entries are created for administration actions that are made through all MQSI commands, regardless of whether the integration node or server is running. When a command is run against a running integration node or server, the admin log entries are made by the integration node or server. These admin log events are held in an in-memory list, which can be accessed through the administration REST API and viewed through the **Admin Log** tab of the web user interface. If the admin logging **`fileLog`** option has been enabled for the integration node or server, the entries are also written to the `AdminLog` file. When a command is run against an integration node or server that is not running, the command writes the

event to the AdminLog file, but it is not accessible to the administration REST API and cannot be viewed through the web user interface.

The username and role that are logged in an admin log entry depend on whether the request is made against a local or remote integration node or integration server (independent or managed), and on whether REST administration basic authentication or authorization is enabled:

- For command, toolkit, web user interface, and REST API requests issued to a *local* integration node or integration server (where *local* means on the same machine):
  - The username is always the logged-in user on the machine.
  - If authorization is enabled, the authorized role is also set to the username.
- For command, toolkit, web user interface, and REST API requests issued to a *remote* integration node or integration server (where *remote* means on a separate machine or using a connection that is specified using a hostname and port):
  - If basic authentication is enabled, the username is set to the authenticated user as verified through a locally-created user using the **mqsiwebuseradmin** command or LDAP.
  - If basic authentication is not enabled, the username is `no-auth-user`.
  - If authorization is enabled, the authorized role is the role that the user is assigned through the **mqsiwebuseradmin** command or LDAP groups. If the user has multiple roles, the authorized role is the one that granted them access for the request URL and method.
  - If authorization is not enabled, the authorized role is always `no-auth-role`.

You can disable the admin log by setting the **enabled** property in the **AdminLog** section of the `node.conf.yaml` or `server.conf.yaml` file for the integration node or server to **false**. The changes take effect when the integration node or server is restarted. For more information about how to configure administration logging for an integration node or server, see “Configuring administration logging” on page 333.

Filtering admin log entries in the web user interface

You can filter the admin log entries that are displayed in the App Connect Enterprise web user interface.

Before you begin

Read the following topics:

- “Viewing administration activity in the admin log” on page 330
- “Configuring administration logging” on page 333

About this task

You can apply filters to control the set of events that are displayed in the web user interface, by entering a search string. You can include one or more tags in the search string, and use exact matching, wildcards, and full regular expressions.

For example, if you want to find all entries that relate to a message flow called `myAsyncRequestResponseFlow`, you can enter the `MSGFLOW:` tag followed by the name of the message flow in the search field:

```
MSGFLOW:myAsyncRequestResponseFlow
```

As a result of this search, the entries are filtered to display only the activities that were carried out against the `myAsyncRequestResponseFlow` message flow.

You can use the `*` wildcard character to represent a tag with any value (a tag must be present but it can have any value). For example, to find out details of the BAR file in which the message flow was deployed,

you can filter the entries to show all events that relate to the specified message flow and that also contain a BAR_FILE: tag:

```
MSGFLOW:myAsyncRequestResponseFlow BAR_FILE:*
```

The resulting filtered list displays only events relating to the myAsyncRequestResponseFlow message flow, including details of the BAR file in which it was deployed.

You can also use regular expression syntax in the search string to set patterns for matching the entries required. For example, to display all the deploy events that have occurred as a result of the **mqsideploy** command being run, you can search for matches to the REQUEST_ID: tags that include mqsideploy, preceded by a regular expression .* to match the timestamp prefix, and followed by .* to match the process ID suffix. By also including the HTTP_METHOD tag that matches POST, only the event that occurs when the command is run is displayed, and not all the events relating to the deployment resource changes that result from the deploy:

```
REQUEST_ID:.*mqsideploy.* HTTP_METHOD:POST
```

Writing admin log entries to a file

Configure an integration node or server to write admin log entries to a file, by setting properties in the node.conf.yaml or server.conf.yaml configuration file.

Before you begin

Read the following topics:

- "Viewing administration activity in the admin log" on page 330
- "Configuring administration logging" on page 333

About this task

In addition to displaying admin log entries in the web user interface, you can configure the integration node or integration server to write the contents of the admin log to a file.

For independent integration servers, the admin log files are created in the adminLog subdirectory of the integration server's working directory:

```
workDir/adminLog
```

For integration nodes and their managed integration servers, the admin log files are created in the common/adminLog directory (*workDir*/common/adminLog), with a subdirectory for each integration node and integration server:

```
workDir/common/adminLog/integrationNodeName/integrationServerName
```

For integration nodes that were created with a shared work path, the admin logs are created in the shared work path to ensure that they are accessible to both nodes in a multi-instance configuration.

Procedure

Configure an integration node or server to write a log of admin events to a file, by modifying the node.conf.yaml or server.conf.yaml configuration file for the integration node or server:

1. Open the appropriate node.conf.yaml or server.conf.yaml configuration file by using a YAML editor.

   If you are not able to access a YAML editor, you can edit the file by using a plain text editor. However, you must ensure that you do not include any tab characters. Tab characters are not valid in YAML files and they will cause your configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

2. Set the following properties in the **AdminLog** section of the appropriate `node.conf.yaml` or `server.conf.yaml` file:
   a) Enable the contents of the admin log to be written to a file, by setting the **fileLog** property to `true`. By default, this property is set to `false`.
   b) Specify the number of days for which the log files are to be stored in the file system before being deleted, by setting the **fileLogRetentionPeriod** property.
   c) Specify the number of files that are to be stored each day, by setting the **fileLogCountDaily** property.
   d) Specify the maximum file log size to be stored each day, by setting the **fileLogSize** property. By default, if file logging is enabled, each daily log file is stored for 30 days before it is deleted, and for each of those 30 days, up to 10 files are stored, up to a maximum of 100MB each per day.
   For example:

```
AdminLog:
  enabled: true               # Control logging admin log messages. Set to true or false,
 default is true.
  # When enabled the maximum amount of disk space required for admin log files is
  # fileLogRetentionPeriod * fileLogCountDaily * fileLogSize
  fileLog: false              # Control writing admin log messages to file. Set to true or
 false, default is false.
  fileLogRetentionPeriod: 30  # Sets the number of days to record admin log.
                              # After this, old files are deleted as new ones are created.
 Default is 30 days.
  fileLogCountDaily: 10       # Maximum number of admin log files to write per day,
 default is 10 per day.
  fileLogSize: 100            # Maximum size in MB for each admin log file. Maximum size
 is 2000MB, default size is 100MB.
  consoleLog: false           # Control writing admin log messages to standard out. Set to
 true or false, default is false.
  consoleLogFormat: 'idText'    # Control the format of admin log messages written to
 standard out. Set to idText, text, or ibmjson. Default is idText.
```

   At the end of the specified retention period, the next log file to be created causes any log files older than the retention period to be deleted. When the maximum number of daily files is exceeded, the oldest file on that day is deleted, and the remaining files are renamed.
3. Restart the integration node or integration server for the changes to take effect. Changes to the `server.conf.yaml` and `node.conf.yaml` files take effect only when the modified integration node or server is restarted.

Configuring administration logging

Configure the logging of administration activity for an integration node or server by setting properties in the `node.conf.yaml` or `server.conf.yaml` configuration file.

Before you begin

Read the topic "Viewing administration activity in the admin log" on page 330.

About this task

The admin log is enabled by default. You can view the events that are held in memory by integration nodes or servers, either in the App Connect Enterprise web user interface or by using the administration REST API.

You can also configure an integration node or server to write the admin log data to a file, as described in "Writing admin log entries to a file" on page 332.

For independent integration servers, you can enable the admin log to write to the App Connect Enterprise console, by setting the **consoleLog** property in the **AdminLog** section of the `server.conf.yaml` file to `true`. By default, this value is set to `false`. You can specify the format of the admin log messages that

are written to standard out by setting the **consoleLogFormat** property to `ibmjson`, `text`, or `idText`. If no value is set, the default format is `idText`. For example:

```
AdminLog:
  enabled: true               # Control logging admin log messages. Set to true or false,
 default is true.
  # When enabled the maximum amount of disk space required for admin log files is
  # fileLogRetentionPeriod * fileLogCountDaily * fileLogSize
  fileLog: false              # Control writing admin log messages to file. Set to true or
 false, default is false.
  fileLogRetentionPeriod: 30  # Sets the number of days to record admin log.
                              # After this, old files are deleted as new ones are created.
 Default is 30 days.
  fileLogCountDaily: 10       # Maximum number of admin log files to write per day, default is
 10 per day.
  fileLogSize: 100            # Maximum size in MB for each admin log file. Maximum size is
 2000MB, default size is 100MB.
  consoleLog: true            # Control writing admin log messages to standard out. Set to true
 or false, default is false.
  consoleLogFormat: 'ibmjson' # Control the format of admin log messages written to standard
 out. Set to idText, text, or ibmjson. Default is idText if unset.
```

You can disable the admin log by setting the *enabled* property to **false**.

The changes to the `server.conf.yaml` or `node.conf.yaml` file take effect only when the integration node or server is restarted.

Managing resources by using the administration REST API

IBM App Connect Enterprise supports the Representational State Transfer Application Programming Interface (REST API), which you can use to administer integration nodes, integration servers, and other resources.

About this task

IBM App Connect Enterprise provides support for the REST API on Linux, AIX, and Windows platforms.

The REST API classes and methods are described in the App Connect Enterprise REST API V2 specification, which you can view in a browser by specifying the address of your integration node or integration server, and the administration REST API port, followed by `/apidocs`. For example, to display the REST API specification for an integration node, enter a URL as shown in the following example (specifying either `http` or `https`):

```
https://localhost:4414/apidocs
```

where `localhost` is the address of the integration node, and 4414 is the admin REST API port specified in the `node.conf.yaml` file.

To display the REST API specification for an integration server, enter a URL as shown in the following example (specifying either `http` or `https`):

```
https://green.company.com:7600/apidocs
```

where `green.company.com` is the address of the integration server, and 7600 is the admin REST API port specified in the `server.conf.yaml` file.

You can also see details of the REST API here: REST API for administering integration nodes and integration servers where:

- `openapi-appconnectenterprise.yaml` details the REST API for administering integration nodes.
- `openapi-appconnectenterpriseserver.yaml` details the REST API for administering integration servers.

The REST API documentation is also provided with your installation of App Connect Enterprise, in the following directories:

- *install_dir*\server\nodejs\node_modules\@ibm-app-connect\ace-admin-api\docs\server
- *install_dir*\server\nodejs\node_modules\@ibm-app-connect\ace-admin-api\docs\node

where *install_dir* is the directory in which App Connect Enterprise is installed.

For more information about how to use the administration REST API, see the following topics:

- "Administering integration servers by using the administration REST API" on page 335
- "Using trace through the administration REST API" on page 345
- "Monitoring by using the administration REST API" on page 364
- "Administering applications, REST APIs, and integration services by using the administration REST API" on page 388
- "Using resources statistics through the administration REST API" on page 432
- "Setting message flow user-defined properties at run time by using the administration REST API" on page 436
- "Updating the HTTPS Connector resource manager by using the administration REST API" on page 440

Administering integration servers by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to administer integration servers.

About this task

You can use the administration REST API to perform the following functions:

- Create, display, start, stop, restart, and delete integration servers that are managed by an integration node.
- Deploy resources to, and delete resources from independent integrations servers and managed integration servers.
- Shut down independent integration servers.

The REST API classes and methods are described in the App Connect Enterprise REST API V2 specification, which you can view in a browser, on GitHub, or in the documentation that is provided as part of your App Connect Enterprise installation. For more information on how to access this information, see "Managing resources by using the administration REST API" on page 334.

Displaying integration servers by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to display the properties of managed integration servers.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Administering integration servers by using the administration REST API" on page 335

Procedure

- Display the properties of an integration server:

```
GET http://hostname:port/apiv2/servers/integrationServerName
```

For example, to display the properties of integration server ACESERV1, run the following curl command:

```
curl -X GET http://hostname:port/apiv2/servers/ACESERV1
```

If the command is successful, an HTTP status code 200 and a response similar to the following are returned:

```
{
    "hasChildren": true,
    "name": "ACESERV1",
    "type": "integrationServer",
    "uri": "/apiv2/servers/ACESERV1",
    "properties": {
        "brokerDefaultCCSID": "5348",
        "dataSourceName": "",
        "dataSourcePassword": "********",
        "dataSourceUserId": "LocalSystem",
        "defaultConfigurationTimeout": 300,
        "defaultQueueManager": "",
        "forceServerHTTPS": false,
        "jvmDebugPort": 0,
        "jvmMaxHeapSize": 268435456,
        "jvmMinHeapSize": 33554432,
        "lilPath": "",
        "mqTrustedQueueManager": "no",
        "name": "ACESERV1",
        "stopIfDefaultQMUnavailable": false,
        "trace": "none",
        "traceNodeLevel": true,
        "traceSize": "1G",
        "type": "IntegrationServer"
    },
    "descriptiveProperties": {
        "buildLevel": "ib000-L200318.17215 (S000-L200318.16524)",
        "platformArchitecture": "AMD64",
        "platformName": "Windows 10 Enterprise",
        "platformVersion": "6.3 build 19041 ",
        "productName": "IBM App Connect Enterprise",
        "version": "11.0.0.8"
    },
    "active": {
        "defaultApplicationName": "ACESERV1_DefaultApplication",
        "exceptionLoggingOn": false,
        "isRunning": true,
        "lastMessageEpoch": 0,
        "lastMessageTime": "1970-01-01T00:00:00Z",
        "monitoring": "inactive",
        "monitoringProfile": "",
        "processId": 24096,
        "serviceTraceOn": false,
        "startupEpoch": 1604864621,
        "startupTime": "2020-11-08T19:43:41Z",
        "state": "started",
        "userTraceOn": false
    },

    "links": []
}
```

Additionally, you can use the depth query parameter in the API call to obtain information about more properties of the integration server. For example, use the following curl command:

```
curl -X GET http://hostname:port/apiv2/servers/ACESERV1?depth=2
```

- Display the properties of all managed integration servers:

```
GET http://hostname:port/apiv2/servers
```

For example, run the following curl command:

```
curl -X GET http://hostname:port/apiv2/servers
```

If the command is successful, an HTTP status code 200 and a response similar to the following are returned:

```
{
    "type": "integrationServers",
    "children": [
        {
            "name": "ACESERV1",
            "hasChildren": true,
            "uri": "/apiv2/servers/ACESERV1",
            "type": "integrationServer",
            "active": {
                "processId": 22920,
                "isRunning": true,
                "state": "started"
            }
        },
        {
            "name": "ACESERV2",
            "hasChildren": true,
            "uri": "/apiv2/servers/ACESERV2",
            "type": "integrationServer",
            "active": {
                "processId": 24536,
                "isRunning": true,
                "state": "started"
            }
        }
    ]
}
```

Additionally, you can use the depth query parameter in the API call to obtain information about more properties of the integration server. For example, use the following curl command:

```
curl -X GET http://hostname:port/apiv2/servers?depth=2
```

Creating an integration server by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to create an integration server that is managed by the integration node.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Administering integration servers by using the administration REST API” on page 335

Procedure

- Create a managed integration server:

```
POST http://hostname:port/apiv2/servers
```

For example, to create an integration server called ACESERV1, run the following curl command:

```
curl -X POST http://hostname:port/apiv2/servers --header 'content-type:application/json' --
data '{"name":"ACESERV1","type":"integrationServer"}'
```

If the command is successful, an HTTP status code 202 is returned.

Starting an integration server by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to start a managed integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Administering integration servers by using the administration REST API" on page 335

Procedure

- Start an integration server:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/start
  ```

  For example, to start the integration server called ACESERV1, run the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/start
  ```

  If the command is successful, an HTTP status code 202 is returned.

Stopping an integration server by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to stop a managed integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Administering integration servers by using the administration REST API" on page 335

Procedure

- Stop an integration server:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/stop
  ```

  For example, to stop the integration server called ACESERV1, run the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/stop
  ```

  If the command is successful, an HTTP status code 204 is returned.

Restarting integration servers by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to restart a specific managed integration server or all integration servers that are managed by the integration node.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Administering integration servers by using the administration REST API" on page 335

Procedure

- Restart an integration server:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/restart
  ```

  For example, to restart the integration server called ACESERV1, run the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/restart
  ```

  If the command is successful, an HTTP status code 200 is returned.
- Restart all integration servers:

  ```
  POST http://hostname:port/apiv2/restart-all-servers
  ```

  For example, run the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/restart-all-servers
  ```

  If the command is successful, an HTTP status code 200 is returned.

Deleting an integration server by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to delete a managed integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Administering integration servers by using the administration REST API” on page 335

Procedure

- Delete an integration server:

  ```
  DELETE http://hostname:port/apiv2/servers/integrationServerName
  ```

  For example, to delete the integration server called ACESERV1, run the following curl command:

  ```
  curl -X DELETE http://hostname:port/apiv2/servers/ACESERV1
  ```

  If the command is successful, an HTTP status code 200 is returned.

Deploying resources to an integration server by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to deploy resources such as BAR files to an integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Administering integration servers by using the administration REST API” on page 335

About this task

This topic describes how to deploy resources to an integration server by using the administration REST API. You can use one of two operations in your administration REST API command to deploy resources:

- `delete-all` with one of the following values:
  - `true` to ensure deletion of all resources already deployed to the integration server before deploying your resource.
  - `false` to perform deployment of the resource without deleting any resources that are already deployed to the integration server.
- `deploy-action` with a value of `ImpactAnalysis` to perform an impact analysis of the deployment without actually deploying the resource.

You can specify `delete-all` or `deploy-action`. You cannot specify both in the same administration REST API command.

Procedure

Deploy a resource.

- For an independent integration server:

```
POST http://hostname:port/apiv2/deploy
```

  For example, to deploy a BAR file called `httpreqreply.bar` and delete all resources already deployed to the integration server, use the following curl command:

```
curl -X POST "http://hostname:port/apiv2/deploy?delete-all=true" -H 'accept:application/json'
 -H 'content-type:application/octet-stream' --data-binary @/tmp/httpreqreply.bar
```

  If the command is successful, an HTTP status code 200 and a response similar to the following are returned:

```
{
  "type": "responseLog",
  "count": 3,
  "uri": "",
  "LogEntry": [
    {
      "type": "logEntry",
      "message": {
        "number": 9521,
        "severity": 0,
        "severityCode": "I",
        "source": "BIPmsgs",
        "inserts": 2,
        "timestamp": 1592141204,
        "threadId": 20730,
        "threadSequenceNumber": 1
      },
      "text": "BIP9521I: Application 'HttpReqReply' has been deleted. ",
      "detailedText": "The resource 'HttpReqReply' of type 'Application' has been deleted. "
    },
    {
      "type": "logEntry",
      "message": {
        "number": 9332,
        "severity": 0,
        "severityCode": "I",
        "source": "BIPmsgs",
        "inserts": 3,
        "timestamp": 1592141204,
        "threadId": 20730,
        "threadSequenceNumber": 2
      },
      "text": "BIP9332I: Application 'HttpReqReply' has been created successfully. ",
      "detailedText": "The resource 'HttpReqReply' of type 'Application' has been
 successfully created. "
    },
    {
```

```
      "type": "logEntry",
      "message": {
        "number": 9326,
        "severity": 0,
        "severityCode": "I",
        "source": "BIPmsgs",
        "inserts": 1,
        "timestamp": 1592141204,
        "threadId": 20730,
        "threadSequenceNumber": 3
      },
      "text": "BIP9326I: The source 'rest-deploy.bar' has been successfully deployed. ",
      "detailedText": ""
    }
  ]
}
```

To employ the query parameter `ImpactAnalysis` before deploying a BAR file called `httpreqreply.bar`, use the following curl command:

```
curl -X POST   "http://hostname:port/apiv2/deploy?deploy-action=ImpactAnalysis" -H
 'accept:application/json' -H 'content-type:application/octet-stream' --data-binary @/tmp/
httpreqreply.bar
```

If the command is successful, an HTTP status code 200 and a response similar to the following are returned:

```
{
  "type": "responseLog",
  "count": 2,
  "uri": "",
  "LogEntry": [
    {
      "type": "logEntry",
      "message": {
        "number": 2795,
        "severity": 0,
        "severityCode": "I",
        "source": "BIPmsgs",
        "inserts": 2,
        "timestamp": 1592148512,
        "threadId": 31842,
        "threadSequenceNumber": 1
      },
      "text": "BIP2795I: Modified Application 'HttpReqReply' has passed validation. ",
      "detailedText": ""
    },
    {
      "type": "logEntry",
      "message": {
        "number": 2781,
        "severity": 0,
        "severityCode": "I",
        "source": "BIPmsgs",
        "inserts": 1,
        "timestamp": 1592148512,
        "threadId": 31842,
        "threadSequenceNumber": 2
      },
      "text": "BIP2781I: BAR file 'rest-deploy.bar' has successfully completed analysis. ",
      "detailedText": ""
    }
  ]
}
```

- For a managed integration server:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/deploy
  ```

  For example, to deploy a BAR file called `httpreqreply.bar` to integration server ACESERV1 without deleting any resources that are deployed to the integration server, use the following curl command:

  ```
  curl --request POST --url "http://hostname:port/apiv2/servers/ACESERV1/deploy?delete-
  all=false" --header 'accept:application/json' --header 'content-type:application/octet-
  stream' --data-binary @C:\Toolkit_workspace\ACET11\workspace\BARfiles\httpreqreply.bar
  ```

  If the command is successful, an HTTP status code 200 is returned.

Deleting resources deployed to an integration server by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to delete resources that are deployed to an integration server. The resources to be deleted must already be deployed on the integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Administering integration servers by using the administration REST API” on page 335

About this task

The following sections contain instructions for deleting deployed resources on an integration server:

- “Deleting a specific deployed resource on an integration server” on page 342
- “Deleting all deployed resources on an integration server” on page 343

Deleting a specific deployed resource on an integration server

Procedure

Delete a resource

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/delete
  ```

  For example, to delete the deployed application called `HTTPTestApplication`, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/delete?names=HTTPTestApplication
  ```

  If the command is successful, an HTTP status code 200 and a response similar to the following are returned:

  ```
  {
      "type": "responseLog",
      "count": 2,
      "uri": "/apiv2/delete",
      "LogEntry": [
          {
              "type": "logEntry",
              "message": {
                  "number": 1062,
                  "severity": 0,
                  "severityCode": "I",
                  "source": "BIPmsgs",
                  "inserts": 2,
  ```

```
                "timestamp": 1604862778,
                "threadId": 21116,
                "threadSequenceNumber": 1
            },
            "text": "BIP1062I: Removing the following objects from integration server
 'KCTEST':  HTTPTestApplication ",
            "detailedText": ""
        },
        {
            "type": "logEntry",
            "message": {
                "number": 9521,
                "severity": 0,
                "severityCode": "I",
                "source": "BIPmsgs",
                "inserts": 2,
                "timestamp": 1604862783,
                "threadId": 21116,
                "threadSequenceNumber": 2
            },
            "text": "BIP9521I: Application 'HTTPTestApplication' has been deleted. ",
            "detailedText": "The resource 'HTTPTestApplication' of type 'Application' has
 been deleted. "
        }
    ]
}
```

To delete more than one resource, specify a colon-delimited set of deployed resource names. For example, to delete the deployed applications called `HTTPTestApplication` and `MonitoringApp`, use following curl command.

```
curl -X POST http://hostname:port/apiv2/delete?names=HTTPTestApplication:MonitoringApp
```

- For a managed integration server:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/delete
  ```

  For example, to delete the application called `HTTPTestApplication`, which is deployed on integration server ACESERV1, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/delete?names=HTTPTestApplication
  ```

  To delete more than one resource, specify a colon-delimited set of deployed resource names. For example, to delete the applications called `HTTPTestApplication` and `MonitoringApp`, which are deployed on integration server ACESERV1, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/delete?
  names=HTTPTestApplication:MonitoringApp
  ```

  To delete a policy project that contains non-dynamic policies, the **"restart-all-applications=true"** query parameter is required. When you specify this parameter, all applications are stopped prior to the resources being deleted, and the applications are then restarted according to the value specified in the **startMode** parameter. Errors are reported for any remaining resources that cannot be started due to missing dependencies.

  For example, to delete the policy project called `theJDBCPolicies`, which is deployed on integration server ACESERV1, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/delete?
  names=theJDBCPolicies&restart-all-applications=true
  ```

Deleting all deployed resources on an integration server

Procedure

Delete all deployed resources.

- For an independent integration server:

```
POST http://hostname:port/apiv2/delete-all
```

For example, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/delete-all
```

If the command is successful, an HTTP status code 200 and a response similar to the following are returned:

```
{
    "type": "responseLog",
    "count": 3,
    "uri": "/apiv2/delete-all",
    "LogEntry": [
        {
            "type": "logEntry",
            "message": {
                "number": 9521,
                "severity": 0,
                "severityCode": "I",
                "source": "BIPmsgs",
                "inserts": 2,
                "timestamp": 1604862622,
                "threadId": 19616,
                "threadSequenceNumber": 1
            },
            "text": "BIP9521I: Application 'MonitoringPayloadApp' has been deleted. ",
            "detailedText": "The resource 'MonitoringPayloadApp' of type 'Application' has
 been deleted. "
        },
        {
            "type": "logEntry",
            "message": {
                "number": 9521,
                "severity": 0,
                "severityCode": "I",
                "source": "BIPmsgs",
                "inserts": 2,
                "timestamp": 1604862622,
                "threadId": 19616,
                "threadSequenceNumber": 2
            },
            "text": "BIP9521I: Application 'MyHttpTestApp' has been deleted. ",
            "detailedText": "The resource 'MyHttpTestApp' of type 'Application' has been
 deleted. "
        },
        {
            "type": "logEntry",
            "message": {
                "number": 9521,
                "severity": 0,
                "severityCode": "I",
                "source": "BIPmsgs",
                "inserts": 2,
                "timestamp": 1604862622,
                "threadId": 19616,
                "threadSequenceNumber": 3
            },
            "text": "BIP9521I: PolicyProject 'MonitoringPolicyProject' has been deleted. ",
            "detailedText": "The resource 'MonitoringPolicyProject' of type 'PolicyProject'
 has been deleted. "
        }
    ]
}
```

- For a managed integration server:

```
POST http://hostname:port/apiv2/servers/integrationServerName/delete-all
```

For example, to delete all resources deployed on integration server ACESERV1, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/servers/ACESERV1/delete-all
```

Shutting down an integration server by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to shut down an independent integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Administering integration servers by using the administration REST API" on page 335

Procedure

- Shut down an integration server:

  ```
  POST http://hostname:port/apiv2/shutdown
  ```

  For example, run the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/shutdown
  ```

  If the command is successful, an HTTP status code 204 is returned.

Using trace through the administration REST API

You can use the IBM App Connect Enterprise administration REST API to administer integration nodes, integration servers, and other resources.

About this task

You can set, update, and display trace properties on integration nodes, integration servers, and Trace nodes in integration flows.

The REST API classes and methods are described in the App Connect Enterprise REST API V2 specification, which you can view in a browser, on GitHub, or in the documentation that is provided as part of your App Connect Enterprise installation. For more information on how to access this information, see "Managing resources by using the administration REST API" on page 334.

Using trace on an integration node by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to set, update, and display the trace properties of an integration node.

Before you begin

Read "Managing resources by using the administration REST API" on page 334.

Procedure

Use the information in the following topics to help you set, update, and display trace properties for an integration node.

- "Displaying trace properties on an integration node by using the administration REST API" on page 347
- "Setting trace on an integration node by using the administration REST API" on page 346
- "Updating trace properties on an integration node by using the administration REST API" on page 346

Setting trace on an integration node by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to enable trace for an integration node dynamically, without having to restart the integration node.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Using trace on an integration node by using the administration REST API" on page 345

About this task

You can use the following REST API method to enable trace on an integration node:

```
POST http://hostname:port/apiv2/trace/agent/service-trace
```

The changes take effect without restarting the integration node.

For example, use the following curl command to enable trace at debug level with trace size of 2048576KB (200MB):

```
curl -X POST -H 'accept:application/json' -H 'content-type:application/json' http://
hostname:port/apiv2/trace/agent/service-trace
-d '{"properties":{"traceLevel":"debug", "traceMode":"safe", "traceSizeKb":2048576}}'
```

The POST operation updates the **Active** section of the trace object. If the command is successful, an HTTP status code `200` is returned.

Updating trace properties on an integration node by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to update the trace properties of an integration node dynamically, without having to restart the integration node.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Using trace on an integration node by using the administration REST API" on page 345

About this task

You can use the following REST API method to update and persist the trace properties of an integration node:

```
POST http://hostname:port/apiv2/trace/agent/service-trace
```

For example, use the following curl command to enable trace at debug level with trace size of 2048576KB (200MB). These options are persisted in the `node.conf.yaml` configuration file in the `overrides` directory of the integration node.

```
curl -X PATCH -H 'accept:application/json' -H 'content-type:application/json' http://
hostname:port/apiv2/trace/agent/service-trace
-d '{"properties":{"traceLevel":"debug", "traceMode":"safe", "traceSizeKb":2048576}}'
```

The PATCH operation updates the **properties** section of the trace object.

If the command is successful, an HTTP status code `204` is returned. You can see the updated values in the `overrides` directory of the integration node.

Displaying trace properties on an integration node by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to display the trace properties of an integration node.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Using trace on an integration node by using the administration REST API" on page 345

About this task

You can use the following REST API method to query the trace properties of an integration node:

```
GET http://hostname:port/apiv2/trace/agent
GET http://hostname:port/apiv2/trace/agent/service-trace
```

For example, use the following curl command:

```
CURL -X GET http://hostname:port/apiv2/trace/agent
```

A response similar to the following is returned:

```
{
    "name": "agentTrace",
    "type": "trace",
    "children": {
        "serviceTrace": {
            "name": "serviceTrace",
            "type": "serviceTrace",
            "properties": {
                "traceLevel": "none",
                "traceMode": "safe",
                "traceSizeKb": 1048576
            },
            "active": {
                "traceLevel": "none",
                "traceMode": "safe",
                "traceSizeKb": 1048576
            }
        }
    }
}
```

The **properties** section displays the values that are persisted and the **active** section displays the values that are currently in effect.

Using trace on an integration server by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to set, update, and display the trace properties of an integration server.

Before you begin

Read "Managing resources by using the administration REST API" on page 334.

About this task

You can dynamically update the trace properties of an integration server by using the PATCH verb in the administration REST API. Updates that are made by using the PATCH verb are persisted in the `overrides` subdirectory of the integration server's working directory, which means that the updates are not lost if the integration server is restarted.

The following topics contain information about how to use service trace, user trace, and Trace nodes on an integration server, by using the administration REST API:

Procedure

- “Using service trace on an integration server by using the administration REST API” on page 348
- “Using user trace on an integration server by using the administration REST API” on page 354
- “Using Trace nodes on an integration server by using the administration REST API” on page 360
- “Displaying trace properties on an integration server by using the administration REST API” on page 362

Using service trace on an integration server by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to start, stop, and reset service trace on an integration server, and to set, update, and display service trace properties.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Using trace on an integration server by using the administration REST API” on page 347

Procedure

The following topics contain information about how to use service trace by using the administration REST API.

- “Setting service trace on an integration server by using the administration REST API” on page 348
- “Updating service trace properties on an integration server by using the administration REST API” on page 349
- “Starting service trace on an integration server by using the administration REST API” on page 350
- “Stopping service trace on an integration server by using the administration REST API” on page 352
- “Resetting service trace on an integration server by using the administration REST API” on page 352
- “Displaying service trace properties for an integration server by using the administration REST API” on page 353

Setting service trace on an integration server by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to set service trace on an integration server dynamically, without having to restart the integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Using trace on an integration server by using the administration REST API” on page 347

Procedure

You can use the following REST API methods to set service trace on an integration server.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/trace/service-trace
  ```

  For example, use the following curl command:

  ```
  curl -X POST -H 'accept:application/json' -H 'content-type:application/json' http://
  hostname:port/apiv2/trace/service-trace
  ```

```
-d '{"properties": { "stopOn": "2060", "traceLevel": "debug", "traceMode":
 "temp","traceSizeKb": 1048576 }}'
```

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/trace/service-trace
  ```

  For example, to enable debug-level service trace for integration server ACESERV1, with a trace size of `100MB`, a trace mode of `temp`, and automatic termination of the trace on occurrence of a BIP 2060 message, run the following command:

  ```
  curl -X POST -H 'accept:application/json' -H 'content-type:application/json' http://
  hostname:port/apiv2/servers/ACESERV1/trace/service-trace
  -d '{"properties": { "stopOn": "2060", "traceLevel": "debug", "traceMode":
   "temp","traceSizeKb": 1048576 }}'
  ```

  In both cases, the POST operation updates the **Active** section of the trace object. If the command is successful, an HTTP status code 200 is returned.

  You can control the granularity of the information captured in the service trace, by setting the **`traceLevel`** property to one of the following values:

  – normal
  – debug
  – debugTree
  – diagnostic
  – diagnosticTree

Updating service trace properties on an integration server by using the administration REST API
You can use the IBM App Connect Enterprise administration REST API to update and persist the service trace properties for an integration server dynamically, without having to restart the integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Using trace on an integration server by using the administration REST API” on page 347

About this task

You can dynamically update service trace properties by using the PATCH verb in the administration REST API. Updates that are made by using the PATCH verb are persisted in the `overrides` subdirectory of the integration server's working directory, which means that the updates are not lost if the integration server is stopped.

You can use the following REST API method to update and persist the service trace properties of an integration server:

Procedure

- For an independent integration server:

  ```
  PATCH http://hostname:port/apiv2/trace/service-trace
  ```

  For example, to enable and persist a debug-level service trace with a trace size of `100MB`, a trace mode of `safe`, and automatic termination of the trace on occurrence of a BIP 2060 message, run the following command:

  ```
  curl -X PATCH -H 'accept:application/json' -H 'content-type:application/json' http://
  hostname:port/apiv2/trace/service-trace
  ```

```
-d '{"properties": { "stopOn": "2060", "traceLevel": "debug", "traceMode":
 "safe","traceSizeKb": 1048576 }}'
```

- For an integration server that is managed by an integration node:

  ```
  PATCH http://hostname:port/apiv2/servers/integrationServerName/trace/service-trace
  ```

  For example, to enable and persist a debug-level service trace for integration server ACESERV1, with a trace size of `100MB`, a trace mode of `temp`, and automatic termination of the trace on occurrence of a BIP 2060 message, run the following command:

  ```
  curl -X PATCH -H 'accept:application/json' -H 'content-type:application/json' http://
  hostname:port/apiv2/servers/ACESERV1/trace/service-trace
  -d '{"properties": { "stopOn": "2060", "traceLevel": "debug", "traceMode":
   "temp","traceSizeKb": 1048576 }}'
  ```

  The PATCH operation updates the **`properties`** section of the trace object. If the command is successful, an HTTP status code 204 is returned. You can see the updated values in the `overrides` subdirectory of the integration server's working directory.

Starting service trace on an integration server by using the administration REST API
You can use the IBM App Connect Enterprise administration REST API to start service trace at the required level.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Using trace on an integration server by using the administration REST API” on page 347

About this task

You can control the granularity of the information captured in the service trace, by setting the **`traceLevel`** property to one of the following values:

- normal
- debug
- debugTree
- diagnostic
- diagnosticTree

Use the following REST API methods to start service trace on an integration server at the specified debug level:

Procedure

- For an independent integration server:
  - To enable service trace at **debug** level:

    ```
    POST http://hostname:port/apiv2/start-service-trace
    ```

    For example:

    ```
    curl -X POST http://hostname:port/apiv2/start-service-trace
    ```

  - To enable service trace at **debugTree** level:

    ```
    POST http://hostname:port/apiv2/start-service-debugtree-trace
    ```

    For example:

    ```
    curl -X POST http://hostname:port/apiv2/start-service-debugtree-trace
    ```

  - To enable service trace at **diagnostic** level:

    ```
    POST http://hostname:port/apiv2/start-service-diagnostic-trace
    ```

    For example:

    ```
    curl -X POST http://hostname:port/apiv2/start-service-diagnostic-trace
    ```

  - To enable service trace at **diagnosticTree** level:

    ```
    POST http://hostname:port/apiv2/start-service-diagnostictree-trace
    ```

    For example:

    ```
    curl -X POST http://hostname:port/apiv2/start-service-diagnostictree-trace
    ```

  - To enable service trace at **normal** level:

    ```
    POST http://hostname:port/apiv2/start-service-normal-trace
    ```

    For example:

    ```
    curl -X POST http://hostname:port/apiv2/start-service-normal-trace
    ```

- For an integration server that is managed by an integration node:

  To enable service trace at **debug** level:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/start-service-trace
  ```

  For example, use the following curl command to enable debug-level service trace for integration server ACESERV1:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/start-service-trace
  ```

  You can also start the service trace at different trace levels, as shown in the following examples:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/start-service-debugtree-trace
  ```

  ```
  POST http://hostname:port /apiv2/servers/integrationServerName/start-service-diagnostic-trace
  ```

  ```
  POST http://hostname:port /apiv2/servers/integrationServerName/start-service-diagnostictree-
  trace
  ```

  ```
  POST http://hostname:port /apiv2/servers/integrationServerName/start-service-normal-trace
  ```

Stopping service trace on an integration server by using the administration REST API
You can use the IBM App Connect Enterprise administration REST API to stop service trace on an integration server dynamically, without having to restart the integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Using trace on an integration server by using the administration REST API” on page 347

Procedure

You can use the following REST API method to stop service trace (for any trace level) on an integration server.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/stop-service-trace
  ```

  For example, run the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/stop-service-trace
  ```

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/stop-service-trace
  ```

  For example, run the following curl command to stop service trace for integration server ACESERV1:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/stop-service-trace
  ```

Resetting service trace on an integration server by using the administration REST API
You can use the IBM App Connect Enterprise administration REST API to reset server trace properties for an integration server dynamically, without having to restart the integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Using trace on an integration server by using the administration REST API” on page 347

Procedure

You can use the following REST API method to reset the service trace on an integration server and remove any previously-captured trace logs.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/reset-service-trace
  ```

  For example, run the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/reset-service-trace
  ```

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/reset-service-trace
  ```

  For example, use the following curl command to reset service trace for integration server ACESERV1:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/reset-service-trace
  ```

Displaying service trace properties for an integration server by using the administration REST API
You can use the IBM App Connect Enterprise administration REST API to display service trace properties for an integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Using trace on an integration server by using the administration REST API” on page 347

Procedure

You can use one of the following REST API methods to query the service trace properties of an integration server.

- For an independent integration server:

  ```
  GET http://hostname:port/apiv2/trace/service-trace
  ```

  For example, use the following curl command:

  ```
  curl -X GET http://hostname:port/apiv2/trace/service-trace
  ```

  A response similar to the following is returned:

  ```
  {
      "hasChildren": false,
      "name": "service-trace",
      "type": "serviceTrace",
      "uri": "/apiv2/trace/service-trace",
      "properties": {
          "identifier": "service-trace",
          "name": "service-trace",
          "stopOn": "",
          "traceLevel": "debug",
          "traceMode": "safe",
          "traceSizeKb": 2048576,
          "type": "serviceTrace"
      },
      "descriptiveProperties": {},
      "active": {
          "stopOn": "",
  ```

```
        "traceLevel": "debug",
        "traceMode": "safe",
        "traceSizeKb": 2048576
    },
    "actions": {},
    "children": {},
    "links": []
}
```

- For an integration server that is managed by an integration node:

  ```
  GET http://hostname:port/apiv2/servers/integrationServerName/trace/service-trace
  ```

  For example, use the following curl command to get information on the current service trace settings for integration server ACESERV1:

  ```
  curl -X GET http://hostname:port/apiv2/servers/ACESERV1/trace/service-trace
  ```

Using user trace on an integration server by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to start, stop, and reset user trace on an integration server, and to set, update, and display user trace properties.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Using trace on an integration server by using the administration REST API” on page 347

Procedure

To configure user trace with the administration REST API, complete the following steps.

- “Setting user trace on an integration server by using the administration REST API” on page 354
- “Updating user trace properties on an integration server by using the administration REST API” on page 355
- “Starting user trace on an integration server by using the administration REST API” on page 356
- “Stopping user trace on an integration server by using the administration REST API” on page 357
- “Resetting user trace on an integration server by using the administration REST API” on page 358
- “Displaying user trace properties for an integration server by using the administration REST API” on page 358

Setting user trace on an integration server by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to set user trace on an integration server dynamically, without having to restart the integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Using trace on an integration server by using the administration REST API” on page 347

Procedure

You can use the following REST API methods to set user trace on an integration server.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/trace/user-trace
  ```

  For example, use the following curl command to enable the user trace at debug level with a trace size of 1GB:

  ```
  curl -X POST http://hostname:port/apiv2/trace/user-trace -H 'accept:application/json' -H
   'content-type:application/json'
  -d "{"properties":{"traceLevel":"debug","traceMode":"safe","traceSizeKb":1048576}}"
  ```

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/trace/user-trace
  ```

  For example, use the following curl command to enable debug-level user trace for integration server ACESERV1, with a trace size of 1GB:

  ```
  curl -X POST -H 'accept:application/json' -H 'content-type:application/json' http://
  hostname:port/apiv2/servers/ACESERV1/trace/user-trace
  -d '{"properties": {"traceLevel": "debug", "traceMode": "safe","traceSizeKb": 1048576 }}'
  ```

  You can control the granularity of the information captured in the user trace, by setting the **`traceLevel`** property to one of the following values:

  – debug
  – debugTree
  – normal
  – none

Updating user trace properties on an integration server by using the administration REST API
You can use the IBM App Connect Enterprise administration REST API to update and persist the user trace properties for an integration server dynamically, without having to restart the integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Using trace on an integration server by using the administration REST API” on page 347

About this task

You can dynamically update user trace properties by using the PATCH verb in the administration REST API. Updates that are made by using the PATCH verb are persisted in the `overrides` subdirectory of the integration server's working directory, which means that the updates are not lost if the integration server is stopped.

You can use the following REST API method to update and persist the user trace properties of an integration server:

Procedure

- For an independent integration server:

  ```
  PATCH http://hostname:port/apiv2/trace/user-trace
  ```

  For example, use the following curl command to enable a debug-level user trace with a trace size of 1GB:

  ```
  curl -X PATCH -H 'accept:application/json' -H 'content-type:application/json' http://
  hostname:port/apiv2/trace/user-trace
  ```

```
-d '{"properties": {"traceLevel": "debug", "traceMode": "safe","traceSizeKb": 1048576 }}'
```

- For an integration server that is managed by an integration node:

  ```
  PATCH http://hostname:port/apiv2/servers/integrationServerName/trace/user-trace
  ```

  For example, use the following curl command to enable a debug-level user trace for integration server ACESERV1, with a trace size of 1GB:

  ```
  curl -X PATCH -H 'accept:application/json' -H 'content-type:application/json' http://
  hostname:port/apiv2/servers/ACESERV1/trace/user-trace
  -d '{"properties": {"traceLevel": "debug", "traceMode": "safe","traceSizeKb": 1048576 }}'
  ```

  The PATCH operation updates the **properties** section of the trace object. If the command is successful, an HTTP status code 204 is returned. You can see the updated values in the `overrides` subdirectory of the integration server's working directory.

Starting user trace on an integration server by using the administration REST API
You can use the IBM App Connect Enterprise administration REST API to start user trace at the required level.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Using trace on an integration server by using the administration REST API” on page 347

About this task

You can control the granularity of the information captured in the user trace, by setting the **traceLevel** property to one of the following values:

- debug
- debugTree
- normal
- none

You can use the following REST API methods to start user trace on an integration server at the specified debug level, without having to pass the body to the REST API:

Procedure

- For an independent integration server:
  - To enable user trace at **debug** level:

    ```
    POST http://hostname:port/apiv2/start-user-trace
    ```

    For example:

    ```
    curl -X POST http://hostname:port/apiv2/start-user-trace
    ```

  - To enable user trace at **debugTree** level:

    ```
    POST http://hostname:port/apiv2/start-user-debugtree-trace
    ```

    For example:

    ```
    curl -X POST http://hostname:port/apiv2/start-user-debugtree-trace
    ```

  - To enable user trace at **normal** level:

    ```
    POST http://hostname:port/apiv2/start-user-normal-trace
    ```

    For example:

    ```
    curl -X POST http://hostname:port/apiv2/start-user-normal-trace
    ```

- For an integration server that is managed by an integration node:

  To enable user trace at **debug** level:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/start-user-trace
  ```

  For example, use the following curl command to enable debug-level user trace for integration server ACESERV1:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/start-user-trace
  ```

  You can also start the user trace at different trace levels, as shown in the following examples:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/start-user-debugtree-trace
  ```

  ```
  POST http://hostname:port /apiv2/servers/integrationServerName/start-user-normal-trace
  ```

Stopping user trace on an integration server by using the administration REST API
You can use the IBM App Connect Enterprise administration REST API to stop user trace on an integration server dynamically, without having to restart the integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Using trace on an integration server by using the administration REST API" on page 347

Procedure

You can use the following REST API method to stop user trace (for any trace level) on an integration server.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/stop-user-trace
  ```

  For example, run the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/stop-user-trace
  ```

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/stop-user-trace
  ```

  For example, run the following curl command to stop user trace for integration server ACESERV1:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/stop-user-trace
  ```

Resetting user trace on an integration server by using the administration REST API
You can use the IBM App Connect Enterprise administration REST API to reset user trace properties for an integration server dynamically, without having to restart the integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Using trace on an integration server by using the administration REST API" on page 347

Procedure

You can use the following REST API method to reset the user trace on an integration server and remove any previously captured trace logs.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/reset-user-trace
  ```

  For example, run the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/reset-user-trace
  ```

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/reset-user-trace
  ```

  For example, use the following curl command to reset user trace for integration server ACESERV1:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/reset-user-trace
  ```

Displaying user trace properties for an integration server by using the administration REST API
You can use the IBM App Connect Enterprise administration REST API to display user trace properties for an integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Using trace on an integration server by using the administration REST API" on page 347

Procedure

You can use one of the following REST API methods to query the user trace properties of an integration server.

- For an independent integration server:

  ```
  GET http://hostname:port/apiv2/trace/user-trace
  ```

  For example, use the following curl command:

  ```
  curl -X GET http://hostname:port/apiv2/trace/user-trace
  ```

  A response similar to the following is returned:

  ```
  {
      "hasChildren": false,
      "name": "user-trace",
      "type": "userTrace",
      "uri": "/apiv2/trace/user-trace",
      "properties": {
          "name": "",
          "traceLevel": "none",
          "traceMode": "safe",
          "traceSizeKb": 1048576,
          "type": ""
      },
      "descriptiveProperties": {},
      "active": {
          "traceLevel": "none",
          "traceMode": "safe",
          "traceSizeKb": 1048576
      },
      "actions": {},
      "children": {},
      "links": []
  }
  ```

- For an integration server that is managed by an integration node:

  ```
  GET http://hostname:port/apiv2/servers/integrationServerName/trace/user-trace
  ```

  For example, use the following curl command to get user trace details for integration server ACESERV1:

  ```
  curl -X GET http://hostname:port/apiv2/servers/ACESERV1/trace/user-trace
  ```

  A response similar to the following is returned:

  ```
  {
      "hasChildren": false,
      "name": "user-trace",
      "type": "userTrace",
      "uri": "/apiv2/servers/ACESERV1/trace/user-trace",
      "properties": {
          "name": "",
          "traceLevel": "none",
          "traceMode": "safe",

Using Trace nodes on an integration server by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to enable and disable Trace nodes and to display the Trace node properties of an integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Using trace on an integration server by using the administration REST API" on page 347

Procedure

The following topics contain information about enabling, disabling, and displaying properties for Trace nodes.

- "Enabling and disabling Trace nodes on an integration server by using the administration REST API" on page 360
- "Displaying Trace node properties on an integration server by using the administration REST API" on page 361

Enabling and disabling Trace nodes on an integration server by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to enable or disable Trace nodes on an integration server, without having to restart the integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Using trace on an integration server by using the administration REST API" on page 347

Procedure

You can use the following REST API methods to set service trace on an integration server.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/trace/trace-nodes
  ```

  For example, use the following curl command to disable Trace nodes on the integration server:

  ```
  curl -X POST  -H 'accept:application/json' -H 'content-type:application/json' http://
  hostname:port/apiv2/trace/trace-nodes
  -d '{ "properties": {"enabled": false  } }'
  ```

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/trace/trace-nodes
  ```

  For example, use the following curl command to disable Trace nodes in integration server ACESERV1:

  ```
  curl -X POST  -H 'accept:application/json' -H 'content-type:application/json'  http://
  hostname:port/apiv2/servers/ACESERV1/trace/trace-nodes
  -d '{ "properties": {"enabled": false  } }'
  ```

  The POST operation updates the **Active** section of the traceNode object. If the command is successful, an HTTP status code 200 is returned.

You can persist the Trace node options by using the PATCH API:

- For an independent integration server:

```
PATCH http://hostname:port /apiv2/trace/trace-nodes
```

  For example, use the following curl command to disable Trace nodes and persist the setting in the integration server's `server.conf.yaml` configuration file:

```
curl -X PATCH -H 'accept:application/json' -H 'content-type:application/json' http://
hostname:port/apiv2/trace/trace-nodes
-d '{ "properties": {"enabled": false  } }'
```

- For an integration server that is managed by an integration node:

```
PATCH http://hostname:port /apiv2/servers/integrationServerName/trace/trace-nodes
```

  For example, use the following curl command to disable Trace nodes in integration server ACESERV1 and persist the setting in the `server.conf.yaml` file:

```
curl -X PATCH -H 'accept:application/json' -H 'content-type:application/json' http://
hostname:port/apiv2/servers/ACESERV1/trace/trace-nodes
-d '{ "properties": {"enabled": false  } }'
```

  The PATCH operation updates the **`properties`** section of the traceNode object. If the command is successful, an HTTP status code 204 is returned. You can see the updated values in the `overrides` subdirectory of the integration server's working directory.

Displaying Trace node properties on an integration server by using the administration REST API
You can use the IBM App Connect Enterprise administration REST API to display the Trace node properties of an integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Using trace on an integration server by using the administration REST API” on page 347

Procedure

You can use the following REST API method to view the Trace node properties of an integration server.

- For an independent integration server:

```
GET http://hostname:port/apiv2/trace/trace-nodes
```

  For example, use the following curl command:

```
curl -X GET http://hostname:port/apiv2/trace/trace-nodes
```

  A response similar to the following is returned:

```
{
    "hasChildren": false,
    "name": "trace-nodes",
    "type": "traceNodes",
    "uri": "/apiv2/trace/trace-nodes",
    "properties": {
        "enabled": true,
        "identifier": "user-trace",
        "name": "user-trace",
        "type": "userTrace"
    },
    "descriptiveProperties": {},
    "active": {
        "enabled": true
    },
    "actions": {},
    "children": {},
```

```
    "links": []
}
```

- For an integration server that is managed by an integration node:

  ```
  GET http://hostname:port/apiv2/servers/integrationServerName/trace/trace-nodes
  ```

  For example, use the following curl command to get user trace details of integration server ACESERV1:

  ```
  curl -X GET http://hostname:port/apiv2/servers/ACESERV1/trace/trace-nodes
  ```

  A response similar to the following is returned:

  ```
  {
      "hasChildren": false,
      "name": "trace-nodes",
      "type": "traceNodes",
      "uri": "/apiv2/servers/ACESERV1/trace/trace-nodes",
      "properties": {
          "enabled": false,
          "identifier": "user-trace",
          "name": "user-trace",
          "type": "userTrace"
      },
      "descriptiveProperties": {},
      "active": {
          "enabled": true
      },
      "actions": {},
      "children": {},
      "links": []
  }
  ```

Displaying trace properties on an integration server by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to display trace properties for an integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Using trace on an integration server by using the administration REST API” on page 347

Procedure

Use one of the following REST API methods to query the trace properties of an integration server.

- For an independent integration server:

  ```
  GET http://hostname:port/apiv2/trace
  ```

  For example, use the following curl command:

  ```
  curl -X GET http://hostname:port/apiv2/trace
  ```

  A response similar to the following is returned:

  ```
  {
      "hasChildren": true,
      "name": "trace",
      "type": "trace",
      "uri": "/apiv2/trace",
      "properties": {
          "name": "",
          "type": ""
      },
      "descriptiveProperties": {},
  ```

```
    "active": {},
    "actions": {},
    "children": {
        "userTrace": {
            "hasChildren": false,
            "name": "user-trace",
            "type": "userTrace",
            "uri": "/apiv2/trace/user-trace"
        },
        "serviceTrace": {
            "hasChildren": false,
            "name": "service-trace",
            "type": "serviceTrace",
            "uri": "/apiv2/trace/service-trace"
        },
        "traceNodes": {
            "hasChildren": false,
            "name": "trace-nodes",
            "type": "traceNodes",
            "uri": "/apiv2/trace/trace-nodes"
        }
    },
    "links": []
}
```

- For an integration server that is managed by an integration node:

```
GET http://hostname:port/apiv2/servers/integrationServerName/trace
```

For example, use the following curl command to query the trace properties of integration server ACESERV1:

```
curl -X GET http://hostname:port/apiv2/servers/ACESERV1/trace
```

A response similar to the following is returned:

```
{
    "hasChildren": true,
    "name": "trace",
    "type": "trace",
    "uri": "/apiv2/servers/ACESERV1/trace",
    "properties": {
        "name": "",
        "type": ""
    },
    "descriptiveProperties": {},
    "active": {},
    "actions": {},
    "children": {
        "userTrace": {
            "hasChildren": false,
            "name": "user-trace",
            "type": "userTrace",
            "uri": "/apiv2/servers/ACESERV1/trace/user-trace"
        },
        "serviceTrace": {
            "hasChildren": false,
            "name": "service-trace",
            "type": "serviceTrace",
            "uri": "/apiv2/servers/ACESERV1/trace/service-trace"
        },
        "traceNodes": {
            "hasChildren": false,
            "name": "trace-nodes",
            "type": "traceNodes",
            "uri": "/apiv2/servers/ACESERV1/trace/trace-nodes"
        }
    },
    "links": []
}
```

Monitoring by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to administer the monitoring of applications, message flows, and integration solutions that have been developed by using the REST API or integration services.

About this task

You can use the administration REST API to start and stop monitoring, and to extract, attach, and detach monitoring profiles.

The REST API classes and methods are described in the App Connect Enterprise REST API V2 specification, which you can view in a browser, on GitHub, or in the documentation that is provided as part of your App Connect Enterprise installation. For more information on how to access this information, see “Managing resources by using the administration REST API” on page 334.

Activating monitoring by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to activate the monitoring of applications, message flows, and integration solutions that have been developed by using the REST API or integration services.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Monitoring by using the administration REST API” on page 364

About this task

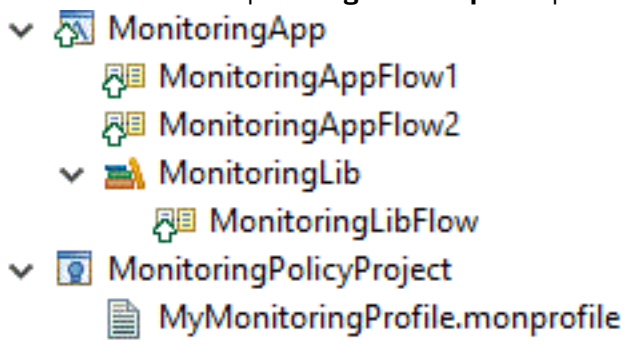
This topic describes:

- “Activating monitoring on an application” on page 365
- “Activating monitoring on a REST API integration solution” on page 366
- “Activating monitoring on an integration services integration solution ” on page 367
- “Activating monitoring on all integration solutions” on page 368

The examples in this topic are based on the following resources:

- An application: `MonitoringApp`
- Message flows packaged with the application: `MonitoringAppFlow1` and `MonitoringAppFlow2`
- A library associated with the application: `Monitoring Lib`
- A message flow in the library: `MonitoringLibFlow`

as shown in this example **Integration Explorer** pane excerpt:



Activating monitoring on an application

About this task

You can activate monitoring on an application and the message flows that are packaged in it, or you can activate monitoring on a single message flow:

Procedure

- Activate monitoring on an application and its message flows:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/applications/applicationName/start-monitoring
```

  For example, to activate monitoring on the application `MonitoringApp`, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/applications/MonitoringApp/start-monitoring
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
applications/applicationName/start-monitoring
```

  For example, to activate monitoring on the application `MonitoringApp` on integration server ACESERV1, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/MonitoringApp/start-
monitoring
```

  If the command is successful, an HTTP status code 200 is returned.

- Activate monitoring on a single message flow:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/applications/applicationName/messageflows/messageflowName/
start-monitoring
```

  For example, to activate monitoring on the message flow `MonitoringAppFlow1`, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/applications/MonitoringApp/messageflows/
MonitoringAppFlow1/start-monitoring
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/applications/applicationName/libraries/libraryName/
messageflows/messageflowName/start-monitoring
```

  For example, to activate monitoring on the message flow `MonitoringLibFlow`, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/applications/MonitoringApp/libraries/
MonitoringLib/messageflows/MonitoringLibFlow/start-monitoring
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
applications/applicationName/messageflows/messageflowName/start-monitoring
```

  For example, to activate monitoring on the message flow `MonitoringAppFlow1` that is deployed on integration server ACESERV1, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/MonitoringApp/
messageflows/MonitoringAppFlow1/start-monitoring
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
applications/applicationName/libraries/libraryName/messageflows/messageflowName/start-
monitoring
```

  For example, to activate monitoring on the message flow `MonitoringLibFlow` that is deployed on integration server ACESERV1, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/MonitoringApp/
libraries/MonitoringLib/messageflows/MonitoringLibFlow/start-monitoring
```

  If the command is successful, an HTTP status code 200 is returned.

What to do next

You can use the **mqsireportflowmonitoring** command to verify the monitoring status of the application and message flows.

Activating monitoring on a REST API integration solution

About this task

You can activate monitoring on an integration solution, including the message that are packaged in it, that has been developed by using a REST API or you can activate monitoring on a single message flow in such an integration solution:

Procedure

- Activate monitoring on a REST API integration solution and its message flows:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/start-monitoring
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
start-monitoring
```

  If the command is successful, an HTTP status code 200 is returned.
- Activate monitoring on a single message flow:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/messageflows/messageflowName/start-
monitoring
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/libraries/libraryName/
messageflows/messageflowName/start-monitoring
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
messageflows/messageflowName/start-monitoring
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
libraries/libraryName/messageflows/messageflowName/start-monitoring
```

  If the command is successful, an HTTP status code 200 is returned.

What to do next

You can use the **mqsireportflowmonitoring** command to verify the monitoring status of the application and message flows.

Activating monitoring on an integration services integration solution

About this task

You can activate monitoring on an integration solution, including the message that are packaged in it, that has been developed by using integration services or you can activate monitoring on a single message flow in such an integration solution:

Procedure

- Activate monitoring on an integration services integration solution and its message flows:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/services/integrationServiceName/start-monitoring
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/integrationServiceName/start-monitoring
```

  If the command is successful, an HTTP status code 200 is returned.

- Activate monitoring on a single message flow:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/services/intergrationServiceName/
messageflows/messageflowName/start-monitoring
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/services/intergrationServiceName/libraries/libraryName/
messageflows/messageflowName/start-monitoring
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/intergationServiceName/messageflows/messageflowName/start-monitoring
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/intergationServiceName/libraries/libraryName/messageflows/messageflowName/start-
monitoring
```

  If the command is successful, an HTTP status code 200 is returned.

What to do next

You can use the **mqsireportflowmonitoring** command to verify the monitoring status of the integration solution and message flows.

Activating monitoring on all integration solutions

About this task

You can use a single command in the administration REST API to activate monitoring on all integration solutions and message flows that have been developed in applications, including those that have been developed by using a REST API or integrations services, and all those in libraries.

Procedure

- Activate monitoring on all integration solutions and their message flows:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/monitoring/flow-monitoring/start-monitoring
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2 servers/integrationServerName/monitoring/flow-monitoring/
start-monitoring
```

  If the command is successful, an HTTP status code 200 is returned.

What to do next

You can use the **mqsireportflowmonitoring** command to verify the monitoring status of the integration solutions and message flows.

Deactivating monitoring by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to deactivate the monitoring of applications, message flows, and integration solutions that have been developed by using the REST API or integration services.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Monitoring by using the administration REST API” on page 364

About this task

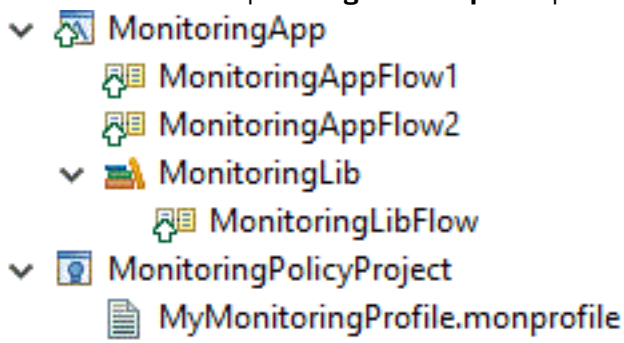
This topic describes:

- “Deactivating monitoring on an application” on page 369
- “Deactivating monitoring on a REST API integration solution” on page 371
- “Deactivating monitoring on an integration services integration solution ” on page 372
- “Deactivating monitoring on all integration solutions” on page 373

The examples in this topic are based on the following resources:

- An application: `MonitoringApp`
- Message flows packaged with the application: `MonitoringAppFlow1` and `MonitoringAppFlow2`
- A library associated with the application: `Monitoring Lib`
- A message flow in the library: `MonitoringLibFlow`

as shown in this example **Integration Explorer** pane excerpt:



Deactivating monitoring on an application

About this task

You can deactivate monitoring on an application and the message flows that are packaged in it, or you can deactivate monitoring on a single message flow:

Procedure

- Deactivate monitoring on an application and its message flows:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/applications/applicationName/stop-monitoring
```

  For example, to deactivate monitoring on the application MonitoringApp, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/applications/MonitoringApp/stop-monitoring
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
applications/applicationName/stop-monitoring
```

  For example, to deactivate monitoring on the application MonitoringApp on integration server ACESERV1 , use the following curl command:

```
curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/MonitoringApp/stop-
monitoring
```

  If the command is successful, an HTTP status code 200 is returned.

- Deactivate monitoring on a single message flow:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/applications/applicationName/messageflows/messageflowName/
stop-monitoring
```

  For example, to deactivate monitoring on the message flow `MonitoringAppFlow1`, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/applications/MonitoringApp/messageflows/
MonitoringAppFlow1/stop-monitoring
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/applications/applicationName/libraries/libraryName/
messageflows/messageflowName/stop-monitoring
```

  For example, to deactivate monitoring on the message flow `MonitoringLibFlow`, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/applications/MonitoringApp/libraries/
MonitoringLib/messageflows/MonitoringLibFlow/stop-monitoring
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
applications/applicationName/messageflows/messageflowName/stop-monitoring
```

  For example, to deactivate monitoring on the message flow `MonitoringAppFlow1` that is deployed on integration server ACESERV1, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/MonitoringApp/
messageflows/MonitoringAppFlow1/stop-monitoring
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
applications/applicationName/libraries/libraryName/messageflows/messageflowName/stop-
monitoring
```

  For example, to deactivate monitoring on a message flow called `MonitoringLibFlow` on integration server ACESERV1, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/MonitoringApp/
libraries/MonitoringLib/messageflows/MonitoringLibFlow/stop-monitoring
```

  If the command is successful, an HTTP status code 200 is returned.

What to do next

You can use the **mqsireportflowmonitoring** command to verify the monitoring status of the application and message flows.

Deactivating monitoring on a REST API integration solution

About this task

You can deactivate monitoring on an integration solution, including the message that are packaged in it, that has been developed by using a REST API or you can deactivate monitoring on a single message flow in such an integration solution:

Procedure

- Deactivate monitoring on a REST API integration solution and its message flows:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/stop-monitoring
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/stop-
monitoring
```

  If the command is successful, an HTTP status code 200 is returned.
- Deactivate monitoring on a single message flow:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/messageflows/messageflowName/stop-
monitoring
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/libraries/libraryName/
messageflows/messageflowName/stop-monitoring
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
messageflows/messageflowName/stop-monitoring
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
libraries/libraryName/messageflows/messageflowName/stop-monitoring
```

  If the command is successful, an HTTP status code 200 is returned.

What to do next

You can use the **mqsireportflowmonitoring** command to verify the monitoring status of the application and message flows.

Deactivating monitoring on an integration services integration solution

About this task

You can use deactivate monitoring on an integration solution, including the message that are packaged in it, that has been developed by using integration services or you can deactivate monitoring on a single message flow in such an integration solution:

Procedure

- Deactivate monitoring on an integration services integration solution and its message flows:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/services/integrationServiceName/stop-monitoring
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/integrationServiceName/stop-monitoring
```

  If the command is successful, an HTTP status code 200 is returned.

- Deactivate monitoring on a single message flow:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/services/intergrationServiceName/
messageflows/messageflowName/stop-monitoring
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/services/intergrationServiceName/libraries/libraryName/
messageflows/messageflowName/stop-monitoring
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/intergationServiceName/messageflows/messageflowName/stop-monitoring
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/intergationServiceName/libraries/libraryName/messageflows/messageflowName/stop-
monitoring
```

  If the command is successful, an HTTP status code 200 is returned.

What to do next

You can use the **mqsireportflowmonitoring** command to verify the monitoring status of the integration solution and message flows.

Deactivating monitoring on all integration solutions

About this task

You can use a single command in the administration REST API to deactivate monitoring on all integration solutions and message flows that have been developed in applications, including those that have been developed by using a REST API or integrations services, and all those in libraries.

Procedure

- Deactivate monitoring on all integration solutions and their message flows:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/monitoring/flow-monitoring/stop-monitoring
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2 servers/integrationServerName/monitoring/flow-monitoring/
stop-monitoring
```

  If the command is successful, an HTTP status code 200 is returned.

What to do next

You can use the **mqsireportflowmonitoring** command to verify the monitoring status of the integration solutions and message flows.

Extracting a monitoring profile by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to extract monitoring profiles of message flows that are running in applications and in integration solutions that have been developed by using the REST API or integration services.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Monitoring by using the administration REST API” on page 364

About this task

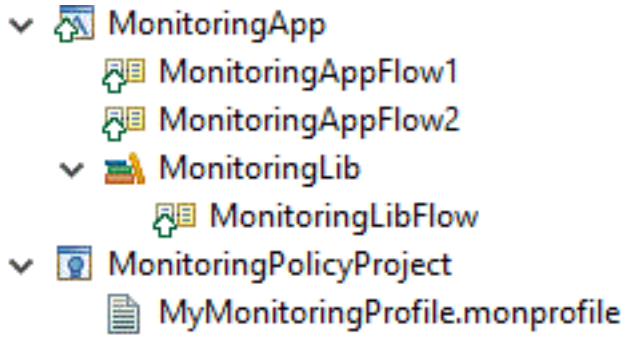
This topic describes the following scenarios.

- “Extracting the monitoring profile of a message flow in an application ” on page 374
- “Extracting the monitoring profile of a message flow in a REST API integration solution” on page 377
- “Extracting the monitoring profile of a message flow in an integration services integration solution” on page 377

The examples in this topic are based on the following resources:

- An application: `MonitoringApp`
- Message flows packaged with the application: `MonitoringAppFlow1` and `MonitoringAppFlow2`
- A library associated with the application: `Monitoring Lib`
- A message flow in the library: `MonitoringLibFlow`

as shown in this example **Integration Explorer** pane excerpt:



Extracting the monitoring profile of a message flow in an application

Procedure

You can extract the monitoring profile of a message flow in an application.

- For an independent integration server:

```
POST http://hostname:port/apiv2/applications/applicationName/messageflows/messageflowName/
extract-monitoring-profile
```

For example, to extract the monitoring profile of the message flow `MonitoringAppFlow1`, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/applications/MonitoringApp/messageflows/
MonitoringAppFlow1/extract-monitoring-profile
```

A response similar to the following is returned:

```
{
    "MonitoringProfile": {
        "HTTP Input.transaction.Start": {
            "bitstreamData": [
                {
                    "Content": "none",
                    "Encoding": "none"
                }
            ],
            "eventFilter": [
                {
                    "Text": "true()",
                    "isXPath": true
                }
            ],
            "eventName": [
                {
                    "Text": "HTTP Input.TransactionStart",
                    "isXPath": false
                }
            ],
            "eventType": "Transaction start"
        }
    }
}
```

If the message flow is in a library:

```
POST http://hostname:port/apiv2/applications/applicationName/libraries/libraryName/
messageflows/messageflowName/extract-monitoring-profile
```

For example, to extract the monitoring profile of the message flow `MonitoringLibFlow`, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/applications/MonitoringApp/libraries/MonitoringLib/
messageflows/MonitoringLibFlow/extract-monitoring-profile
```

A response similar to the following is returned:

```
{
    "MonitoringProfile": {
        "HTTP Input.transaction.Start": {
            "bitstreamData": [
                {
                    "Content": "none",
                    "Encoding": "none"
                }
            ],
            "eventFilter": [
                {
                    "Text": "true()",
                    "isXPath": true
                }
            ],
            "eventName": [
                {
                    "Text": "HTTP Input.TransactionStart",
                    "isXPath": false
                }
            ],
            "eventType": "Transaction start"
```

```
        },
        "HTTP Input.transaction.End": {
            "bitstreamData": [
                {
                    "Content": "none",
                    "Encoding": "none"
                }
            ],
            "eventFilter": [
                {
                    "Text": "true()",
                    "isXPath": true
                }
            ],
            "eventName": [
                {
                    "Text": "HTTP Input.TransactionEnd",
                    "isXPath": false
                }
            ],
            "eventType": "Transaction end"
        },
        "HTTP Reply.terminal.in": {
            "bitstreamData": [
                {
                    "Content": "none",
                    "Encoding": "none"
                }
            ],
            "eventFilter": [
                {
                    "Text": "true()",
                    "isXPath": true
                }
            ],
            "eventName": [
                {
                    "Text": "HTTP Reply.InTerminal",
                    "isXPath": false
                }
            ],
            "eventType": "In terminal"
        }
    }
}
```

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
  messageflows/messageflowName/extract-monitoring-profile
  ```

  For example, to extract the monitoring profile of the message flow `MonitoringAppFlow1` that is deployed on integration server ACESERV1, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/MonitoringApp/
  messageflows/MonitoringAppFlow1/extract-monitoring-profile
  ```

  If the message flow is in a library:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
  libraries/libraryName/messageflows/messageflowName/extract-monitoring-profile
  ```

  For example, to extract the monitoring profile of the message flow `MonitoringLibFlow` that is deployed on integration server ACESERV1, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/MonitoringApp/
  libraries/MonitoringLib/messageflows/MonitoringLibFlow/extract-monitoring-profile
  ```

  If the command is successful, an HTTP status code 200 is returned.

Extracting the monitoring profile of a message flow in a REST API integration solution

Procedure

You can extract the monitoring profile of a message flow in a REST API integration solution.

- For an independent integration server:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/messageflows/messageflowName/extract-
monitoring-profile
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/libraries/libraryName/
messageflows/messageflowName/extract-monitoring-profile
```

- For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
messageflows/messageflowName/extract-monitoring-profile
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
libraries/libraryName/messageflows/messageflowName/extract-monitoring-profile
```

  If the command is successful, an HTTP status code 200 is returned.

Extracting the monitoring profile of a message flow in an integration services integration solution

Procedure

You can extract the monitoring profile of a message flow in an integration services integration solution.

- For an independent integration server:

```
POST http://hostname:port/apiv2/services/integrationServiceName/messageflows/messageflowName/
extract-monitoring-profile
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/services/integrationServiceName/libraries/libraryName/
messageflows/messageflowName/extract-monitoring-profile
```

- For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/integrationServiceName/messageflows/messageflowName/extract-monitoring-profile
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/integrationServiceName/libraries/libraryName/messageflows/messageflowName/extract-
monitoring-profile
```

  If the command is successful, an HTTP status code 200 is returned.

Attaching a monitoring profile by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to attach a monitoring profile to an application and the message flows that are packaged with it. You can also attach a monitoring profile to an individual message flow that is deployed in an application or static library.

Before you begin

Read the following topics:

- "Monitoring basics" on page 2772
- "Managing resources by using the administration REST API" on page 334
- "Monitoring by using the administration REST API" on page 364

Follow the instructions in "Creating a monitoring profile" on page 2793 to learn how to create a monitoring profile.

After you have created the monitoring profile, save it in a policy project and deploy the policy project in either an independent BAR file or in the same BAR file as an associated application or message flow. Attach the monitoring profile to an application or message flow. You can then activate monitoring by using the administration REST API as described in "Activating monitoring by using the administration REST API" on page 364.

About this task

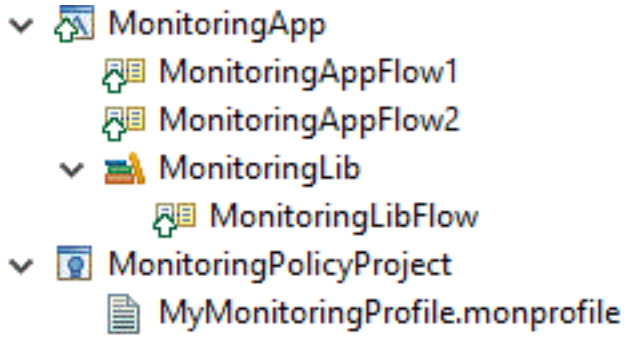
This topic describes:

- "Attaching a monitoring profile to an application" on page 378
- "Attaching a monitoring profile to a REST API integration solution" on page 381
- "Attaching a monitoring profile to an integration services integration solution " on page 381

The examples in this topic are based on the following resources:

- An application: `MonitoringApp`
- Message flows packaged with the application: `MonitoringAppFlow1` and `MonitoringAppFlow2`
- A library associated with the application: `Monitoring Lib`
- A message flow in the library: `MonitoringLibFlow`
- A policy project: `MonitoringPolicyProject`
- A monitoring profile in the policy project: `MyMonitoringProfile`

as shown in this example **Integration Explorer** pane excerpt:



Attaching a monitoring profile to an application

About this task

You can attach a monitoring profile to an application and it message flows, or you can attach a monitoring profile to a single message flow:

Procedure

- Attach a monitoring profile to an application and its message flows:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/applications/applicationName/attach-monitoring-profile
```

  For example, to attach the monitoring profile `MyMonitoringProfile` to the application `MonitoringApp`, use the following curl command:

```
curl -X POST "http://hostname:port/apiv2/applications/MonitoringApp/attach-monitoring-
profile?profile=MyMonitoringProfile&project=MonitoringPolicyProject"
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
applications/applicationName/attach-monitoring-profile
```

  For example, to attach the monitoring profile `MyMonitoringProfile` to the application `MonitoringApp` on integration server ACESERV1, use the following curl command:

```
curl -X POST "http://hostname:port/apiv2/servers/ACESERV1/applications/MonitoringApp/
attach-monitoring-profile?profile=MyMonitoringProfile&project=MonitoringPolicyProject"
```

  If the command is successful, an HTTP status code 200 is returned.

- Attach a monitoring profile to a single message flow:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/applications/applicationName/messageflows/messageflowName/
attach-monitoring-profile
```

  For example, to attach the monitoring profile `MyMonitoringProfile` to the message flow `MonitoringAppFlow1`, use the following curl command:

```
curl -X POST "http://hostname:port/apiv2/applications/MonitoringApp/
messageflows/MonitoringAppFlow1/attach-monitoring-profile?
profile=MyMonitoringProfile&project=MonitoringPolicyProject"
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/applications/applicationName/libraries/libraryName/
messageflows/messageflowName/attach-monitoring-profile
```

  For example, to attach the monitoring profile `MyMonitoringProfile` to the message flow `MonitoringLibFlow`, use the following curl command:

```
curl -X POST "http://hostname:port/apiv2/applications/MonitoringApp/libraries/
MonitoringLib/messageflows/MonitoringLibFlow/attach-monitoring-profile?
profile=MyMonitoringProfile&project=MonitoringPolicyProject"
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
applications/applicationName/messageflows/messageflowName/attach-monitoring-profile
```

  For example, to attach the monitoring profile `MyMonitoringProfile` to the message flow `MonitoringAppFlow1` on integration server ACESERV1, use the following curl command:

```
curl -X POST "http://hostname:port/apiv2/servers/ACESERV1/applications/
MonitoringApp/messageflows/MonitoringAppFlow1/attach-monitoring-profile?
profile=MyMonitoringProfile&project=MonitoringPolicyProject"
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
applications/applicationName/libraries/libraryName/messageflows/messageflowName/attach-
monitoring-profile
```

  For example, to attach the monitoring profile `MyMonitoringProfile` to the message flow `MonitoringLibFlow` on integration server ACESERV1, use the following curl command:

```
curl -X POST "http://hostname:port/apiv2/servers/ACESERV1/applications/
MonitoringApp/messageflows/MonitoringLibFlow/attach-monitoring-profile?
profile=MyMonitoringProfile&project=MonitoringPolicyProject"
```

  If the command is successful, an HTTP status code 200 is returned.

What to do next

You can use the **mqsireportflowmonitoring** command to verify that the monitoring profile has been attached to the application or message flow.

Attaching a monitoring profile to a REST API integration solution

Procedure

- Attach a monitoring profile to a REST API integration solution and its message flows:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/attach-monitoring-profile
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
attach-monitoring-profile
```

  If the command is successful, an HTTP status code 200 is returned.
- Attach a monitoring profile to a single message flow:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/messageflows/messageflowName/
attach-monitoring-profile
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/libraries/libraryName/
messageflows/messageflowName/attach-monitoring-profile
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
messageflows/messageflowName/attach-monitoring-profile
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
libraries/libraryName/messageflows/messageflowName/attach-monitoring-profile
```

  If the command is successful, an HTTP status code 200 is returned.

What to do next

You can use the **mqsireportflowmonitoring** command to verify that the monitoring profile has been attached to the application or message flow.

Attaching a monitoring profile to an integration services integration solution

Procedure

- Attach a monitoring profile to an integration service integration solution and its message flows:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/services/integrationServiceName/attach-monitoring-profile
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/integrationServiceName/attach-monitoring-profile
```

  If the command is successful, an HTTP status code 200 is returned.

- Attach a monitoring profile to a single message flow:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/services/intergrationServiceName/
messageflows/messageflowName/attach-monitoring-profile
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/services/integrationServiceName/libraries/libraryName/
messageflows/messageflowName/attach-monitoring-profile
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/intergationServiceName/messageflows/messageflowName/attach-monitoring-profile
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/integrationServiceName/libraries/libraryName/messageflows/messageflowName/attach-
monitoring-profile
```

  If the command is successful, an HTTP status code 200 is returned.

What to do next

You can use the **mqsireportflowmonitoring** command to verify that the monitoring profile has been attached to the application or message flow.

Detaching a monitoring profile by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to detach a monitoring profile from an application and the message flows that are packaged with it. You can also detach a monitoring profile from an individual message flow that is deployed in an application or static library.

Before you begin

Read the following topics:

- “Monitoring basics” on page 2772
- “Managing resources by using the administration REST API” on page 334
- “Monitoring by using the administration REST API” on page 364

About this task

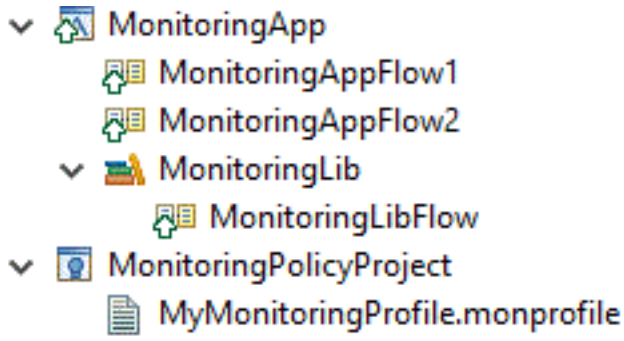
This topic describes:

- “Detaching a monitoring profile from an application” on page 383
- “Detaching a monitoring profile from a REST API integration solution” on page 385
- “Detaching a monitoring profile from an integration services integration solution ” on page 385

The examples in this topic are based on the following resources:

- An application: `MonitoringApp`
- Message flows packaged with the application: `MonitoringAppFlow1` and `MonitoringAppFlow2`
- A library associated with the application: `Monitoring Lib`
- A message flow in the library: `MonitoringLibFlow`

as shown in this example **Integration Explorer** pane excerpt:



Detaching a monitoring profile from an application

About this task

You can detach a monitoring profile from an application or from a single message flow:

Procedure

- Detach a monitoring profile from an application and its message flows:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/applications/applicationName/detach-monitoring-profile
```

  For example, to detach the monitoring profile from the application `MonitoringApp`, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/applications/MonitoringApp/detach-monitoring-
profile
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/servers/integrationServerName/apiv2/
applications/applicationName/detach-monitoring-profile
```

  For example, to detach the monitoring profile from the application `MonitoringApp` on integration server ACESERV1, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/MonitoringApp/
detach-monitoring-profile
```

  If the command is successful, an HTTP status code 200 is returned.

- Detach a monitoring profile from a single message flow:
  a) For an independent integration server:

```
 POST http://hostname:port/apiv2/applications/applicationName/
messageflows/messageflowName/detach-monitoring-profile
```

  For example, to detach the monitoring profile from the message flow `MonitoringAppFlow1`, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/applications/MonitoringApp/messageflows/
MonitoringAppFlow1/detach-monitoring-profile
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/applications/applicationName/libraries/libraryName/
messageflows/messageflowName/detach-monitoring-profile
```

  For example, to detach the monitoring profile from the message flow `MonitoringLibFlow`, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/applications/MonitoringApp/libraries/
MonitoringLib/messageflows/MonitoringLibFlow/detach-monitoring-profile
```

  b) For an integration server that is managed by an integration node:

```
http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
messageflows/messageflowName/detach-monitoring-profile
```

  For example, to detach the monitoring profile from the message flow `MonitoringAppFlow1` on integration server ACESERV1, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/MonitoringApp/
messageflows/MonitoringAppFlow1/detach-monitoring-profile
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
applications/applicationName/libraries/libraryName/messageflows/messageflowName/detach-
monitoring-profile
```

  For example, to detach the monitoring profile from the message flow `MonitoringLibFlow` on integration server ACESERV1, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/MonitoringApp/
libraries/MonitoringLib/messageflows/MonitoringLibFlow/detach-monitoring-profile
```

  If the command is successful, an HTTP status code 200 is returned.

What to do next

You can use the **mqsireportflowmonitoring** command to verify that the monitoring profile has been detached from the application or message flow.

Detaching a monitoring profile from a REST API integration solution

Procedure

- Detach a monitoring profile to a REST API integration solution and its message flows:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/detach-monitoring-profile
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
detach-monitoring-profile
```

  If the command is successful, an HTTP status code 200 is returned.
- Detach a monitoring profile from a single message flow:
  a) For an independent integration server:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/messageflows/messageflowName/
detach-monitoring-profile
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/libraries/libraryName/
messageflows/messageflowName/detach-monitoring-profile
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
messageflows/messageflowName/detach-monitoring-profile
```

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
libraries/libraryName/messageflows/messageflowName/detach-monitoring-profile
```

  If the command is successful, an HTTP status code 200 is returned.

What to do next

You can use the **mqsireportflowmonitoring** command to verify that the monitoring profile has been detached from the application or message flow.

Detaching a monitoring profile from an integration services integration solution

Procedure

- Detach a monitoring profile from an integration service integration solution and its message flows:
  a) For an independent integration server:

```
POST http://hostname:port /apiv2/services/integrationServiceName/detach-monitoring-profile
```

  b) For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/integrationServiceName/detach-monitoring-profile
```

  If the command is successful, an HTTP status code 200 is returned.

- Detach a monitoring profile from a single message flow:

  a) For an independent integration server:

  ```
  POST http://hostname:port/apiv2/services/intergrationServiceName/
  messageflows/messageflowName/detach-monitoring-profile
  ```

  If the message flow is in a library:

  ```
  POST http://hostname:port/apiv2/services/intergrationServiceName/libraries/libraryName/
  messageflows/messageflowName/detach-monitoring-profile
  ```

  b) For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/
  services/intergationServiceName/messageflows/messageflowName/detach-monitoring-profile
  ```

  If the message flow is in a library:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/
  services/intergrationServiceName/libraries/libraryName/messageflows/messageflowName/
  detach-monitoring-profile
  ```

  If the command is successful, an HTTP status code 200 is returned.

What to do next

You can use the **mqsireportflowmonitoring** command to verify that the monitoring profile has been detached from the application or message flow.

Displaying monitoring status by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to display the monitoring status for an integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Monitoring by using the administration REST API" on page 364

Procedure

- For an independent integration server:

  ```
  GET http://hostname:port/apiv2/monitoring/flow-monitoring
  ```

  For example, run the following curl command:

  ```
  curl -X GET http://localhost:port/apiv2/monitoring/flow-monitoring
  ```

  If the command is successful, an HTTP status code 200 and a response similar to the following are returned:

  ```
  {
      "hasChildren": false,
      "name": "flow-monitoring",
      "type": "flowMonitoring",
      "uri": "/apiv2/monitoring/flow-monitoring",
      "properties": {
          "eventFormat": "MonitoringEventV2",
          "name": "MessageFlow",
          "publicationOn": "active",
          "type": "MessageFlow",
          "useParserNameInPayload": false
      },
  ```

```
    "descriptiveProperties": {},
    "active": {
        "publicationOn": "active"
    },
    "actions": {
        "unavailable": {
            "start-monitoring": "/apiv2/monitoring/flow-monitoring/start-monitoring"
        },
        "available": {
            "stop-monitoring": "/apiv2/monitoring/flow-monitoring/stop-monitoring"
        }
    },
    "children": {},
    "links": []
}
```

- For an integration server that is managed by an integration node:

  ```
  GET http://hostname:port/apiv2/servers/integrationServerName/monitoring/flow-monitoring
  ```

  For example, to display the monitoring status for integration server ACESERV1, run the following command:

  ```
  curl -X GET http://hostname:port/apiv2/servers/ACESERV1/monitoring/flow-monitoring
  ```

  If the command is successful, an HTTP status code 200 and a response similar to the following are returned:

  ```
  {
      "hasChildren": false,
      "name": "flow-monitoring",
      "type": "flowMonitoring",
      "uri": "/apiv2/servers/ACESERV1/monitoring/flow-monitoring",
      "properties": {
          "eventFormat": "MonitoringEventV2",
          "name": "MessageFlow",
          "publicationOn": "active",
          "type": "MessageFlow",
          "useParserNameInPayload": false
      },
      "descriptiveProperties": {},
      "active": {
          "publicationOn": "active"
      },
      "actions": {
          "unavailable": {
              "start-monitoring": "/apiv2/servers/ACESERV1/monitoring/flow-monitoring/start-
  monitoring"
          },
          "available": {
              "stop-monitoring": "/apiv2/servers/ACESERV1/monitoring/flow-monitoring/stop-
  monitoring"
          }
      },
      "children": {},
      "links": []
  }
  ```

Updating monitoring status by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to update and persist the monitoring status for an integration server dynamically, without having to restart the integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Monitoring by using the administration REST API” on page 364

About this task

You can dynamically update monitoring status by using the PATCH verb in the administration REST API. Updates that are made by using the PATCH verb are persisted in the `overrides` subdirectory of the integration server's working directory, which means that the updates are not lost if the integration server is stopped.

You can use the following REST API method to update and persist the monitoring status of an integration server:

Procedure

- For an independent integration server:

  ```
  PATCH http://hostname:port/apiv2/monitoring/flow-monitoring
  ```

  For example, to set monitoring status to `inactive` and persist this status, run the curl following command:

  ```
  curl -X PATCH http://hostname:port/apiv2/monitoring/flow-monitoring -d {"properties":
   { "publicationOn": "active" }}
  ```

- For an integration server that is managed by an integration node:

  ```
  PATCH http://hostname:port/apiv2/servers/integrationServerName/monitoring/flow-monitoring
  ```

  For example, to set monitoring status to `inactive` and persist this status on integration server ACESERV1, run the following curl command:

  ```
  curl -X PATCH http://hostname:port/apiv2/servers/ACESERV1/monitoring/flow-monitoring -d
   {"properties": { "publicationOn": "active" }}
  ```

  The PATCH operation updates the **publicationOn** setting in the Monitoring object. If the command is successful, an HTTP status code 204 is returned. You can see the updated values in the `overrides` subdirectory of the integration server's working directory.

Administering applications, REST APIs, and integration services by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to administer applications, REST APIS, and integration services that have been deployed to an integration server.

About this task

Use the administration REST API to perform the following tasks:

- Display the applications, REST APIs, and integration services that are deployed in an integration server.
- Start applications, REST APIs, and integration services.
- Stop applications, REST APIs, and integration services.
- Tear down applications, REST APIs, and integration services.
- Delete applications, REST APIs, and integration services.

The REST API classes and methods are described in the App Connect Enterprise REST API V2 specification, which you can view in a browser, on GitHub, or in the documentation that is provided as part of your App Connect Enterprise installation. For more information on how to access this information, see “Managing resources by using the administration REST API” on page 334.

Displaying applications, REST APIs, and integration services by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to display the applications, REST APIs, and integration services that are deployed in an integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Administering applications, REST APIs, and integration services by using the administration REST API" on page 388

About this task

This topic describes:

- "Displaying applications in an integration server" on page 389
- "Displaying REST APIs in an integration server" on page 391
- "Displaying integration services in an integration server " on page 391

Displaying applications in an integration server

Procedure

Display the applications.

- For an independent integration server:

  ```
  GET http://hostname:port/apiv2/applications
  ```

  For example, use the following curl command:

  ```
  curl -X GET http://hostname:port/apiv2/applications
  ```

  If the command is successful and there are applications deployed in the integration server, an HTTP status code 200 and a response similar to the following are returned. In this example, there are 2 applications deployed in the integration server: `HTTPInputApplication` and `Transformation_Map`:

  ```
  {
    "hasChildren": true,
    "name": "applications",
    "type": "applications",
    "uri": "/apiv2/ applications",
    "properties": {},
    "descriptiveProperties": {},
    "active": {},
    "actions": {},
    "children": [
      {
        "hasChildren": true,
        "name": "HTTPInputApplication",
        "type": "application",
        "uri": "/apiv2/applications/HTTPInputApplication"
      },
      {
        "hasChildren": true,
        "name": "Transformation_Map",
        "type": "application",
        "uri": "/apiv2/ applications/Transformation_Map"
      }
    ],
    "links": []
  ```

```
}
```

If the command is successful but there are no applications deployed in the integration server, an HTTP status code 200 and a response similar to the following are returned:

```
{
  "hasChildren": false,
  "name": "applications",
  "type": "applications",
  "uri": "/apiv2/applications",
  "properties": {},
  "descriptiveProperties": {},
  "active": {},
  "actions": {},
  "children": [],
  "links": []
}
```

Additionally, you can use the depth query parameter in the API call to obtain more information about the applications. For example, use the following curl command:

```
curl -X GET http://hostname:port/apiv2/applications?depth=2
```

For an example of the response that is returned for such an API call, see “Display applications on an independent integration server” on page 402.

- For an integration server that is managed by an integration node:

```
GET http://hostname:port/apiv2/servers/integrationServerName/applications
```

For example, to display the applications that are deployed on integration server ACESERV1, which is managed by an integration node, use the following curl command:

```
curl -X GET http://hostname:port/apiv2/servers/ACESERV1/applications
```

If the command is successful and there are applications deployed in the integration server, an HTTP status code 200 and a response similar to the following are returned. In this example, there are 2 applications deployed in the integration server: `HTTPInputApplication` and `Transformation_Map`:

```
{
  "hasChildren": true,
  "name": "applications",
  "type": "applications",
  "uri": "/apiv2/servers/ACESERV1/applications",
  "properties": {},
  "descriptiveProperties": {},
  "active": {},
  "actions": {},
  "children": [
    {
      "hasChildren": true,
      "name": "HTTPInputApplication",
      "type": "application",
      "uri": "/apiv2/servers/ACESERV1/applications/HTTPInputApplication"
    },
    {
      "hasChildren": true,
      "name": "Transformation_Map",
      "type": "application",
      "uri": "/apiv2/servers/ACESERV1/applications/Transformation_Map"
    }
  ],
  "links": []
}
```

If the command is successful but there are no applications deployed in the integration server, an HTTP status code 200 and a response similar to the following are returned:

```
{
  "hasChildren": false,
  "name": "applications",
```

```
  "type": "applications",
  "uri": "/apiv2/servers/ACESERV1/applications",
  "properties": {},
  "descriptiveProperties": {},
  "active": {},
  "actions": {},
  "children": [],
  "links": []
}
```

Additionally, you can use the depth query parameter in the API call to obtain more information about the applications. For example, use the following curl command:

```
curl -X GET http://hostname:port/apiv2/servers/integrationServerName/applications?depth=2
```

For an example of the response that is returned for such an API call, see "Display applications on an integration server that is managed by an integration node" on page 404.

Displaying REST APIs in an integration server

Procedure

Display the REST APIs.

- For an independent integration server:

  ```
  GET http://hostname:port/apiv2/rest-apis
  ```

  If the command is successful, an HTTP status code 200 and information about the REST APIS that are deployed, if any, in the integration server are returned.

- For an integration server that is managed by an integration node:

  ```
  GET http://hostname:port/apiv2/servers/integrationServerName/rest-apis
  ```

  If the command is successful, an HTTP status code 200 and information about the REST APIS that are deployed, if any, in the integration server are returned.

Displaying integration services in an integration server

Procedure

Display the integration services.

- For an independent integration server:

  ```
  GET http://hostname:port/apiv2/services
  ```

  If the command is successful, an HTTP status code 200 and information about the integration services that are deployed, if any, in the integration server are returned.

- For an integration server that is managed by an integration node:

  ```
  GET http://hostname:port/apiv2/servers/integrationServerName/services
  ```

  If the command is successful, an HTTP status code 200 and information about the integration services that are deployed, if any, in the integration server are returned.

Starting applications, REST APIs, and integration services by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to start named applications, REST APIs, and integration services that are deployed on an integration server. The application, REST API, or integration service to be started must already be deployed in the integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Administering applications, REST APIs, and integration services by using the administration REST API" on page 388

About this task

This topic describes:

- "Starting an application on an integration server" on page 392
- "Starting a REST API on an integration server" on page 393
- "Starting an integration service on an integration server " on page 393

Starting an application on an integration server

Procedure

Start an application.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/applications/applicationName/start
  ```

  For example, to start the application that is called `HTTPInputApplication`, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/applications/HTTPInputApplication/start
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the application has started, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the detailed information that shows whether the application has started. For example, use the following curl command:

  ```
  curl -X GET http://hostname:port/apiv2/applications?depth=2
  ```

  For an example of the response that is returned for such an API call, see "Check that an application has started on an independent integration server" on page 407.

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
  start
  ```

  For example, to start the application that is called HTTPInputApplication and deployed on integration server ACESERV1, which is managed by an integration node, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/HTTPInputApplication/
  start
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the application has started, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the detailed information that shows whether the application has started. For example, to display detailed information about applications on integration server ACESERV1, use the following curl command:

  ```
  curl -X GET http://hostname:port/apiv2/servers/ACESERV1/applications?depth=2
  ```

  For an example of the response that is returned for such an API call, see "Check that an application has started on an integration server that is managed by an integration node" on page 409.

Starting a REST API on an integration server

Procedure

Start a REST API.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/rest-apis/rest-apiName/start
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the REST API has started, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the detailed information that shows whether the REST API has started.

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/start
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the REST API has started, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the detailed information that shows whether the REST API has started.

Starting an integration service on an integration server

Procedure

Start an integration service.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/services/integrationServiceName/start
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the integration service has started, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the detailed information that shows whether the integration service has started.
- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/
  services/integrationServiceName/start
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the integration service has started, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the detailed information that shows whether the integration service has started.

Stopping applications, REST APIs, and integration services by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to stop named applications, REST APIs, and integration services that are deployed on an integration server. The application, REST API, or integration service to be stopped must already be deployed on the integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Administering applications, REST APIs, and integration services by using the administration REST API" on page 388

About this task

This topic describes:

- "Stopping an application on an integration server" on page 394
- "Stopping a REST API on an integration server" on page 395
- "Stopping an integration service on an integration server " on page 396

Stopping an application on an integration server

Procedure

Stop an application.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/applications/applicationName/stop
  ```

  For example, to stop the application that is called `HTTPInputApplication`, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/applications/HTTPInputApplication/stop
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the application has stopped, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the detailed information that shows whether the application has stopped. For example, use the following curl command:

  ```
  curl -X GET http://hostname:port/apiv2/applications?depth=2
  ```

  For an example of the response that is returned for such an API call, see "Check that an application has stopped on an independent integration server" on page 410.
- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
  stop
  ```

  For example, to stop the application that is called `HTTPInputApplication` deployed on integration server ACESERV1, which is managed by an integration node, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/HTTPInputApplication/
  stop
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the application has stopped, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the detailed information that shows whether the application has stopped. For example, to display the information about applications on integration server ACESERV1, use the following curl command:

  ```
  curl -X GET http://hostname:port/apiv2/servers/ACESERV1/applications?depth=2
  ```

  For an example of the response that is returned for such an API call, see "Check that an application has stopped on an integration server that is managed by an integration node" on page 412.

Stopping a REST API on an integration server

Procedure

Stop a REST API.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/rest-apis/rest-apiName/stop
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the REST API has stopped, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the detailed information that shows whether the REST API has stopped.

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/stop
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the REST API has stopped, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the detailed information that shows whether the REST API has stopped.

Stopping an integration service on an integration server

Procedure

Stop an integration service.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/services/integrationServiceName/stop
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the integration service has stopped, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the detailed information that shows whether the integration service has stopped.

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/
  services/integrationServiceName/stop
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the integration service has stopped, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the detailed information that shows whether the integration service has stopped.

Tearing down applications, REST APIs, and integration services by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to tear down named applications, REST APIs, and integration services that are deployed on an integration server. The application, REST API, or integration service to be torn down must already be deployed on the integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Administering applications, REST APIs, and integration services by using the administration REST API" on page 388

About this task

The action of tearing down terminates all connections and threads that are associated with the application, REST API, or integration service. The application, REST API, or integration service remains in the runtime image of the integration server and can be restarted by using a start action without the need to redeploy. There is no need to stop and restart the integration server to restart the application, REST API, or integration service.

This topic describes:

Tearing down an application on an integration server

Procedure

Tear down an application.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/applications/applicationName/teardown
  ```

  For example, to tear down the application that is called `HTTPInputApplication`, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/applications/HTTPInputApplication/teardown
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the tear down request has been successful, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the information that shows whether the request was successful. For example, use the following curl command:

  ```
  curl -X GET http://hostname:port/apiv2/applications?depth=2
  ```

  For an example of the response that is returned for such an API call, see "Check that a teardown action has completed on an independent integration server" on page 414.

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
  teardown
  ```

  For example, to tear down the application that is called `HTTPInputApplication` deployed on integration server ACESERV1, which is managed by an integration node, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/HTTPInputApplication/
  teardown
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the tear down request has been successful, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the information that shows whether the request was successful. For example, use the following curl command:

  ```
  curl -X GET http://hostname:port/apiv2servers/ACESERV1/applications?depth=2
  ```

  For an example of the response that is returned for such an API call, see "Check that a teardown action has completed on an integration server that is managed by an integration node" on page 415.

Tearing down a REST API on an integration server

Procedure

Tear down a REST API.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/rest-apis/rest-apiName/teardown
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the tear down request has been successful, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the information that shows whether the request was successful.

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/teardown
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the tear down request has been successful, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the information that shows whether the request was successful.

Tearing down an integration service on an integration server

Procedure

Tear down an integration service.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/services/integrationServiceName/teardown
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the tear down request has been successful, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the information that shows whether the request was successful.

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/
  services/integrationServiceName/teardown
  ```

  If the command is successful, an HTTP status code 200 is returned. No response message is returned.

  To verify that the tear down request has been successful, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the information that shows whether the request was successful.

  ```
  curl -X GET http://hostname:port/apiv2/servers/integrationServerName/services?depth=2
  ```

Deleting applications, REST APIs, and integration services by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to delete named applications, REST APIs, and integration services that are deployed on an integration server. The application, REST API, or integration service to be deleted must already be deployed on the integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Administering applications, REST APIs, and integration services by using the administration REST API" on page 388

About this task

The action of deleting an application, REST API, or integration service includes issuing a tear down request followed by the deletion. The teardown operation is part of the deletion operation: you do not have to issue a teardown request. The application, REST API, or integration service is deleted from the integration server and from the configuration on disk; the application, REST API, or integration service is undeployed.

This topic describes:

- "Deleting an application on an integration server" on page 399
- "Deleting a REST API on an integration server" on page 401
- "Deleting an integration service on an integration server " on page 401

Deleting an application on an integration server

Procedure

Delete an application.

- For an independent integration server:

  ```
  DELETE http://hostname:port/apiv2/applications/applicationName
  ```

  For example, to delete the application that is called `HTTPInputApplication`, use the following curl command:

  ```
  curl -X DELETE http://hostname:port/apiv2/applications/HTTPInputApplication
  ```

  If the command is successful, an HTTP status code 200 and a response similar to the following are returned:

  ```
  {
    "type": "responseLog",
    "count": 1,
    "uri": "",
    "LogEntry": [
      {
        "type": "logEntry",
        "message": {
          "number": 9521,
          "severity": 0,
          "severityCode": "I",
          "source": "BIPmsgs",
          "inserts": 2,
          "timestamp": 1592387071,
          "threadId": 4460,
          "threadSequenceNumber": 1
        },
        "text": "BIP9521I: Application 'HTTPInputApplication' has been deleted. ",
  ```

```
      "detailedText": "The resource 'HTTPInputApplication' of type 'Application' has been
 deleted. "
    }
  ]
}
```

Additionally, to verify that the application has been deleted, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the information that shows whether the application has been deleted. For example, use the following curl command:

```
curl -X GET http://hostname:port/apiv2/applications?depth=2
```

For an example of the response that is returned for such an API call, see "Check that an application has been deleted from an independent integration server" on page 416.

- For an integration server that is managed by an integration node:

```
DELETE http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName
```

For example, to delete the application that is called `HTTPInputApplication` deployed on integration server ACESERV1, which is managed by an integration node, use the following curl command:

```
curl -X DELETE http://hostname:port/apiv2/servers/ACESERV1/applications/HTTPInputApplication
```

If the command is successful, an HTTP status code 200 and a response similar to the following are returned:

```
{
  "type": "responseLog",
  "count": 1,
  "uri": "",
  "LogEntry": [
    {
      "type": "logEntry",
      "message": {
        "number": 9521,
        "severity": 0,
        "severityCode": "I",
        "source": "BIPmsgs",
        "inserts": 2,
        "timestamp": 1591203977,
        "threadId": 4460,
        "threadSequenceNumber": 1
      },
      "text": "BIP9521I: Application 'HTTPInputApplication' has been deleted. ",
      "detailedText": "The resource 'HTTPInputApplication' of type 'Application' has been
 deleted. "
    }
  ]
}
```

Additionally, to verify that the application has been deleted, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the information that shows whether the application has been deleted. For example, to display the information about applications on integration server ACESERV1, use the following curl command:

```
curl -X GET http://hostname:port/apiv2/servers/ACESERV1/applications?depth=2
```

For an example of the response that is returned for such an API call, see "Check that an application has been deleted from an integration server that is managed by an integration node" on page 417.

Deleting a REST API on an integration server

Procedure

Delete a REST API.

- For an independent integration server:

  ```
  DELETE http://hostname:port/apiv2/rest-apis/rest-apiName
  ```

  If the command is successful, an HTTP status code 200 is returned.

  To verify that the REST API has been deleted, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the information that shows whether the REST API has been deleted.

- For an integration server that is managed by an integration node:

  ```
  DELETE http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName
  ```

  If the command is successful, an HTTP status code 200 is returned.

  To verify that the REST API has been deleted, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the information that shows whether the REST API has been deleted.

Deleting an integration service on an integration server

Procedure

Delete an integration service.

- For an independent integration server:

  ```
  DELETE http://hostname:port/apiv2/services/integrationServiceName
  ```

  If the command is successful, an HTTP status code 200 is returned.

  To verify that the integration service has been deleted, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the information that shows whether the integration service has been deleted.

- For an integration server that is managed by an integration node:

  ```
  DELETE http://hostname:port/apiv2/servers/integrationServerName/
  services/integrationServiceName
  ```

  If the command is successful, an HTTP status code 200 is returned.

  To verify that the integration service has been deleted, use the GET API call as described in "Displaying applications, REST APIs, and integration services by using the administration REST API" on page 389. Specify a value of 2 on the depth query parameter in the API call to obtain the information that shows whether the integration service has been deleted.

Example responses to the GET API administration REST API call with a value of 2 on the depth query parameter

Using a GET API administration REST API call with a value of 2 on the depth query parameter, you can display useful information about the status of your applications.

This topic provides example responses to a GET API administration REST API call with a value of 2 on the depth query parameter.

For example, use the following curl command to display information about applications on an independent integration server:

```
curl -X GET http://hostname:port/apiv2/applications?depth=2
```

To display the information about applications on integration server ACESERV1, which is managed by an integration node, use the following curl command:

```
curl -X GET  http://hostname:port/apiv2/servers/ACESERV1/applications?depth=2
```

The following sections show example responses.

- "Display applications" on page 402
- "Check that an application has started" on page 407
- "Check that an application has stopped" on page 410
- "Check that a teardown action has completed" on page 414
- "Check that an application has been deleted" on page 416

Display applications

Display applications on an independent integration server

In this case, two applications named HTTPInputApplication and Transformation_Map are deployed.

Check that a teardown action has completed on an integration server that is managed by an integration node

A teardown request was issued for the application named HTTPInputApplication on integration server ACESERV1, which is managed by an integration node. Note the "stopped" value in "state" and the "stateInitialized" value in "resourceState" that are indicated in the "active" section in the JSON response.

```

Check that an application has been deleted

Check that an application has been deleted from an independent integration server

If the application that was deleted was the only application to be deployed in the integration server, the response from running the command is similar to the following example. If other applications had also been deployed at the time of the command, they are listed in the response.

```
{
  "hasChildren": false,
  "name": "applications",
  "type": "applications",
  "uri": "/apiv2/applications",
  "properties": {},
  "descriptiveProperties": {},
  "active": {},
  "actions": {},
  "children": [],
```

```

}
```

Check that an application has been deleted from an integration server that is managed by an integration node

If the application that was deleted was the only application to be deployed in the integration server, ACESERV1, which is managed by an integration node, the response from running the command is similar to the following example. If other applications had also been deployed at the time of the command, they are listed in the response.

```
{
  "hasChildren": false,
  "name": "applications",
  "type": "applications",
  "uri": "/apiv2/servers/ACESERV1/applications",
  "properties": {},
  "descriptiveProperties": {},
  "active": {},
  "actions": {},
  "children": [],
  "links": []
}
```

Administering message flows by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to administer message flows that are deployed to an integration server in applications, REST API projects, and integration service projects.

About this task

Use the administration REST API to perform the following tasks:

- Display message flows that are deployed to an integration server.
- Start message flows.
- Stop message flows.
- Tear down message flows.

The REST API classes and methods are described in the App Connect Enterprise REST API V2 specification, which you can view in a browser, on GitHub, or in the documentation that is provided as part of your App Connect Enterprise installation. For more information on how to access this information, see “Managing resources by using the administration REST API” on page 334.

Displaying message flows by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to display the message flows that are deployed to an integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Administering message flows by using the administration REST API” on page 417

About this task

This topic describes:

- “Displaying message flows in an application” on page 418
- “Displaying message flows in a REST API project” on page 419
- “Displaying message flows in an integration service project ” on page 420

Displaying message flows in an application

About this task

You can display the message flows that are deployed to an integration server in an application.

Procedure

Display the message flows.

- For an independent integration server:

```
GET http://hostname:port/apiv2/applications/applicationName/messageflows
```

For example, to display the message flows in application HTTPInputApplication, use the following curl command:

```
curl -X GET http://hostname:port/apiv2/applications/HTTPInputApplication/messageflows
```

If the command is successful and there are message flows deployed to the integration server in application HTTPInputApplication, an HTTP status code 200 and a response similar to the following are returned:

```
{
    "hasChildren": true,
    "name": "messageflows",
    "type": "messageFlows",
    "uri": "/apiv2/applications/HTTPInputApplication/messageflows",
    "properties": {},
    "descriptiveProperties": {},
    "active": {},
    "actions": {
        "available": {
            "start": "/apiv2/applications/HTTPInputApplication/messageflows/start",
            "stop": "/apiv2/applications/HTTPInputApplication/messageflows/stop"
        }
    },
    "children": [
        {
            "hasChildren": true,
            "name": "RequestService",
            "type": "messageFlow",
            "uri": "/apiv2/applications/HTTPInputApplication/messageflows/RequestService"
        },
        {
            "hasChildren": true,
            "name": "ResponseService",
            "type": "messageFlow",
            "uri": "/apiv2/applications/HTTPInputApplication/messageflows/ResponseService"
        }
    ],
    "links": []
}
```

Additionally, you can use the depth query parameter in the API call to obtain more information about the message flows. For example, use the following curl command:

```
curl -X GET http://hostname:port/apiv2/applications/applicationName/messageflows?depth=2
```

- For an integration server that is managed by an integration node:

```
GET http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
messageflows
```

  For example, to display the message flows that are deployed in application HTTPInputApplication to integration server ACESERV1, which is managed by an integration node, use the following curl command:

```
curl -X GET http://hostname:port/apiv2/servers/ACESERV1/applications/HTTPInputApplication/
messageflows
```

  If the command is successful and there are message flows deployed to the integration server, an HTTP status code 200 and a response similar to the following are returned:

```
{
    "hasChildren": true,
    "name": "messageflows",
    "type": "messageFlows",
    "uri": "/apiv2/servers/ACESERV1/applications/HTTPInputApplication/messageflows",
    "properties": {},
    "descriptiveProperties": {},
    "active": {},
    "actions": {
        "available": {
            "start": "/apiv2/servers/ACESERV1/applications/HTTPInputApplication/messageflows/
start",
            "stop": "/apiv2/servers/ACESERV1/applications/HTTPInputApplication/messageflows/
stop"
        }
    },
    "children": [
        {
            "hasChildren": true,
            "name": "RequestService",
            "type": "messageFlow",
            "uri": "/apiv2/servers/ACESERV1/applications/HTTPInputApplication/messageflows/
RequestService"
        },
        {
            "hasChildren": true,
            "name": "ResponseService",
            "type": "messageFlow",
            "uri": "/apiv2/servers/ACESERV1/applications/HTTPInputApplication/messageflows/
ResponseService"
        }
    ],
    "links": []
}
```

  Additionally, you can use the depth query parameter in the API call to obtain more information about the message flows. For example, use the following curl command:

```
curl -X GET http://hostname:port/apiv2/servers/integrationServerName/
applications/applicationName/messageflows?depth=2
```

Displaying message flows in a REST API project

About this task

You can display the message flows that are deployed to an integration server in a REST API project.

Procedure

Display the message flows.

- For an independent integration server:

  ```
  GET http://hostname:port/apiv2/rest-apis/rest-apiName/messageflows
  ```

  If the command is successful, an HTTP status code 200 and information about the message flows that are deployed in the REST API project, if any, are returned.
- For an integration server that is managed by an integration node:

  ```
  GET http://hostname:port/apiv2/server/integrationServerName/rest-apis/rest-apiName/
  messageflows
  ```

  If the command is successful, an HTTP status code 200 and information about the message flows that are deployed in the REST API project, if any, are returned.

Displaying message flows in an integration service project

About this task

You can display the message flows that are deployed to an integration server in an integration service project.

Procedure

Display the message flows.

- For an independent integration server:

  ```
  GET http://hostname:port/apiv2/services/integrationServiceName/messageflows
  ```

  If the command is successful, an HTTP status code 200 and information about the message flows that are deployed in the integration service project, if any, are returned.
- For an integration server that is managed by an integration node:

  ```
  GET http://hostname:port/apiv2/servers/integrationServerName/services/integrationServiceName/
  messageflows
  ```

  If the command is successful, an HTTP status code 200 and information about the message flows that are deployed in the integration service project, if any, are returned.

Starting message flows by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to start message flows that are deployed to an integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Administering message flows by using the administration REST API” on page 417

About this task

This topic describes:

- “Starting all message flows in an application” on page 421
- “Starting a specific message flow in an application” on page 422
- “Starting all message flows in a REST API project” on page 423
- “Starting a specific message flow in a REST API project” on page 423
- “Starting all message flows in an integration service project” on page 424

- "Starting a specific message flow in an integration service project" on page 424

Starting all message flows in an application

About this task

You can start all the message flows that are deployed to an integration server in an application.

Procedure

Start the message flows.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/applications/applicationName/messageflows/start
  ```

  For example, to start the message flows in application HTTPInputApplication, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/applications/HTTPInputApplication/messageflows/start
  ```

  If the command is successful, an HTTP status code 204 is returned. No response message is returned.

  If the message flows are in a library:

  ```
  POST http://hostname:port/apiv2/applications/applicationName/libraries/libraryName/
  messageflows/start
  ```

  For example, to start the message flows that are in the library called HTTPStaticLib that is associated with an application called HTTPInputApplication, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/applications/HTTPInputApplication/libraries/
  HTTPStaticLib/messageflows/start
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
  messageflows/start
  ```

  For example, to start the message flows in application HTTPInputApplication that is deployed on integration server ACESERV1, which is managed by an integration node, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/HTTPInputApplication/
  messageflows/start
  ```

  If the command is successful, an HTTP status code 204 is returned. No response message is returned.

  If the message flows are in a library:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
  libraries/libraryName/messageflows/start
  ```

  For example, to start the message flows that are in the library called HTTPStaticLib associated with an application called HTTPInputApplication that is deployed on integration server ACESERV1, which is managed by an integration node, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/HTTPInputApplication/
  libraries/HTTPStaticLib/messageflows/start
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

Starting a specific message flow in an application

About this task

You can start a specific message flow that is deployed to an integration server in an application.

Procedure

Start a message flow.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/applications/applicationName/messageflows/messageFlowName/
  start
  ```

  For example, to start a message flow called `RequestServiceFlow` in an application called `HTTPInputApplication`, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/applications/HTTPInputApplication/messageflows/
  RequestServiceFlow/start
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

  If the message flow is in a library:

  ```
  POST http://hostname:port/apiv2/applications/applicationName/libraries/libraryName/
  messageflows/messageFlowName/start
  ```

  For example, to start a message flow called `RequestServiceFlow` that is in a library called `HTTPStaticLib` that is associated with an application called `HTTPInputApplication`, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/applications/HTTPInputApplication/libraries/
  HTTPStaticLib/messageflows/RequestServiceFlow/start
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
  messageflows/messageFlowName/start
  ```

  For example, to start a message flow called `RequestServiceFlow` in application `HTTPInputApplication` that is deployed on integration server ACESERV1, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/HTTPInputApplication/
  messageflows/RequestServiceFlow/start
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

  If the message flow is in a library:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
  libraries/libraryName/messageflows/messageFlowName/start
  ```

  For example, to start a message flow called `RequestServiceFlow` that is in a library called `HTTPStaticLib` associated with an application called `HTTPInputApplication` that is deployed on integration server ACESERV1, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/HTTPInputApplication/
  libraries/HTTPStaticLib/messageflows/RequestServiceFlow/start
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

Starting all message flows in a REST API project

About this task

You can start all the message flows that are deployed to an integration server in a REST API project.

Procedure

Start the message flows.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/rest-apis/rest-apiName/messageflows/start
  ```

  If the command is successful, an HTTP status code 204 is returned. No response message is returned.

  If the message flows are in a library:

  ```
  POST http://hostname:port/apiv2//rest-apis/rest-apiName/libraries/libraryName/messageflows/
  start
  ```

  If the command is successful, an HTTP status code 200 and response message OK are returned.

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
  messageflows/start
  ```

  If the command is successful, an HTTP status code 204 is returned. No response message is returned.

  If the message flows are in a library:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
  libraries/libraryName/messageflows/start
  ```

  If the command is successful, an HTTP status code 200 and response message OK are returned.

Starting a specific message flow in a REST API project

About this task

You can start a specific message flow that is deployed to an integration server in a REST API project.

Procedure

Start a message flow.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/rest-apis/rest-apiName/messageflows/messageFlowName/start
  ```

  If the command is successful, an HTTP status code 200 and response message OK are returned.

  If the message flow is in a library:

  ```
  POST http://hostname:port/apiv2/rest-apis/rest-apiName/libraries/libraryName/
  messageflows/messageFlowName/start
  ```

  If the command is successful, an HTTP status code 200 and response message OK are returned.

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
  messageflows/messageFlowName/start
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

  If the message flow is in a library:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
  libraries/libraryName/messageflows/messageFlowName/start
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

Starting all message flows in an integration service project

About this task

You can start all the message flows that are deployed to an integration server in an integration service project.

Procedure

Start the message flows.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/services/integrationServiceName/messageflows/start
  ```

  If the command is successful, an HTTP status code 204 is returned. No response message is returned.

  If the message flows are in a library:

  ```
  POST http://hostname:port/apiv2/services/integrationServiceName/libraries/libraryName/
  messageflows/start
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/
  services/integrationServiceName/messageflows/start
  ```

  If the command is successful, an HTTP status code 204 is returned. No response message is returned.

  If the message flows are in a library:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/
  services/integrationServiceName/libraries/libraryName/messageflows/start
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

Starting a specific message flow in an integration service project

About this task

You can start a specific message flow that is deployed to an integration server in an integration service project.

Procedure

Start the message flow.

- For an independent integration server:

```
POST http://hostname:port/apiv2/services/integrationServiceName/messageflows/messageFlowName/
start
```

  If the command is successful, an HTTP status code 204 is returned. No response message is returned.

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/services/integrationServiceName/libraries/libraryName/
messageflows/messageFlowName/start
```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.
- For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/integrationServiceName/messageflows/messageFlowName/start
```

  If the command is successful, an HTTP status code 204 is returned. No response message is returned.

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/integrationServiceName/libraries/libraryName/messageflows/messageFlowName/start
```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

Stopping message flows by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to stop message flows that are deployed to an integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Administering message flows by using the administration REST API” on page 417

About this task

This topic describes:

- “Stopping all message flows in an application” on page 425
- “Stopping a specific message flow in an application” on page 426
- “Stopping all message flows in a REST API project” on page 427
- “Stopping a specific message flow in a REST API project” on page 428
- “Stopping all message flows in an integration service project” on page 429
- “Stopping a specific message flow in an integration service project” on page 429

Stopping all message flows in an application

About this task

You can stop all the message flows that are deployed to an integration server in an application.

Procedure

Stop the message flows.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/applications/applicationName/messageflows/stop
  ```

  For example, to stop the message flows in application HTTPInputApplication, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/applications/HTTPInputApplication/messageflows/stop
  ```

  If the command is successful, an HTTP status code 204 is returned. No response message is returned.

  If the message flows are in a library:

  ```
  POST http://hostname:port/apiv2/applications/applicationName/libraries/libraryName/
  messageflows/stop
  ```

  For example, to stop the message flows that are in the library called HTTPStaticLib that is associated with an application called HTTPInputApplication, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/applications/HTTPInputApplication/libraries/
  HTTPStaticLib/messageflows/stop
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.
- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
  messageflows/stop
  ```

  For example, to stop the message flows in application HTTPInputApplication that is deployed on integration server ACESERV1, which is managed by an integration node, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/HTTPInputApplication/
  messageflows/stop
  ```

  If the command is successful, an HTTP status code 204 is returned. No response message is returned.

  If the message flows are in a library:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
  libraries/libraryName/messageflows/stop
  ```

  For example, to stop the message flows that are in the library called HTTPStaticLib associated with an application called HTTPInputApplication that is deployed on integration server ACESERV1, which is managed by an integration node, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/HTTPInputApplication/
  libraries/HTTPStaticLib/messageflows/stop
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

Stopping a specific message flow in an application

About this task

You can stop a specific message flow that is deployed to an integration server in an application.

Procedure

Stop a message flow.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/applications/applicationName/messageflows/messageFlowName/
  stop
  ```

  For example, to stop a message flow called RequestServiceFlow in an application called HTTPInputApplication, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/applications/HTTPInputApplication/messageflows/
  RequestServiceFlow/stop
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

  If the message flow is in a library:

  ```
  POST http://hostname:port/apiv2/applications/applicationName/libraries/libraryName/
  messageflows/messageFlowName/stop
  ```

  For example, to stop a message flow called RequestServiceFlow that is in a library called HTTPStaticLib that is associated with an application called HTTPInputApplication, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/applications/HTTPInputApplication/libraries/
  HTTPStaticLib/messageflows/RequestServiceFlow/stop
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.
- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
  messageflows/messageFlowName/stop
  ```

  For example, to stop a message flow called RequestServiceFlow in application HTTPInputApplication that is deployed on integration server ACESERV1, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/HTTPInputApplication/
  messageflows/RequestServiceFlow/stop
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

  If the message flow is in a library:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
  libraries/libraryName/messageflows/messageFlowName/stop
  ```

  For example, to stop a message flow called RequestServiceFlow that is in a library called HTTPStaticLib associated with an application called HTTPInputApplication that is deployed on integration server ACESERV1, use the following curl command:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/HTTPInputApplication/
  libraries/HTTPStaticLib/messageflows/RequestServiceFlow/stop
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

Stopping all message flows in a REST API project

About this task

You can stop all the message flows that are deployed to an integration server in a REST API project.

Procedure

Stop the message flows.

- For an independent integration server:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/messageflows/stop
```

If the command is successful, an HTTP status code 204 is returned. No response message is returned.

If the message flows are in a library:

```
POST http://hostname:port/apiv2//rest-apis/rest-apiName/libraries/libraryName/messageflows/
stop
```

If the command is successful, an HTTP status code 200 and response message 0K are returned.

- For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
messageflows/stop
```

If the command is successful, an HTTP status code 204 is returned. No response message is returned.

If the message flows are in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
libraries/libraryName/messageflows/stop
```

If the command is successful, an HTTP status code 200 and response message 0K are returned.

Stopping a specific message flow in a REST API project

About this task

You can stop a specific message flow that is deployed to an integration server in a REST API project.

Procedure

Stop a message flow.

- For an independent integration server:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/messageflows/messageFlowName/stop
```

If the command is successful, an HTTP status code 204 is returned. No response message is returned.

If the message flow is in a library:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/libraries/libraryName/
messageflows/messageFlowName/stop
```

If the command is successful, an HTTP status code 200 and response message 0K are returned.

- For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
messageflows/messageFlowName/stop
```

If the command is successful, an HTTP status code 204 is returned. No response message is returned.

If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
libraries/libraryName/messageflows/messageFlowName/stop
```

If the command is successful, an HTTP status code 200 and response message 0K are returned.

Stopping all message flows in an integration service project

About this task

You can stop all the message flows that are deployed to an integration server in an integration service project.

Procedure

Stop the message flows.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/services/integrationServiceName/messageflows/stop
  ```

  If the command is successful, an HTTP status code 204 is returned. No response message is returned.

  If the message flows are in a library:

  ```
  POST http://hostname:port/apiv2/services/integrationServiceName/libraries/libraryName/
  messageflows/stop
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/
  services/integrationServiceName/messageflows/stop
  ```

  If the command is successful, an HTTP status code 204 is returned. No response message is returned.

  If the message flows are in a library:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/
  services/integrationServiceName/libraries/libraryName/messageflows/stop
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

Stopping a specific message flow in an integration service project

About this task

You can stop a specific message flow that is deployed to an integration server in an integration service project.

Procedure

Stop the message flow.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/services/integrationServiceName/messageflows/messageFlowName/
  stop
  ```

  If the command is successful, an HTTP status code 204 is returned. No response message is returned.

  If the message flow is in a library:

  ```
  POST http://hostname:port/apiv2/services/integrationServiceName/libraries/libraryName/
  messageflows/messageFlowName/stop
  ```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

- For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/integrationServiceName/messageflows/messageFlowName/stop
```

  If the command is successful, an HTTP status code 204 is returned. No response message is returned.

  If the message flow is in a library:

```
POST http://hostname:port/apiv2/servers/integrationServerName/
services/integrationServiceName/libraries/libraryName/messageflows/messageFlowName/stop
```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

Tearing down a message flow by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to tear down named message flows that are deployed to an integration server. The message flow to tear down must already be deployed on the integration server.

Before you begin

- "Managing resources by using the administration REST API" on page 334
- "Administering message flows by using the administration REST API" on page 417

About this task

The action of tearing down terminates all connections and threads that are associated with the message flow. The message flow remains in the runtime image of the integration server and can be restarted by using a start action without the need to redeploy. There is no need to stop and restart the integration server to restart the message flow.

This topic describes:

- "Tearing down a message flow in an application" on page 430
- "Tearing down a message flow in a REST API project" on page 431
- "Tearing down a message flow in an integration service project " on page 431

Tearing down a message flow in an application

About this task

You can tear down a message flow that is deployed to an integration server in an application.

Procedure

Tear down a message flow.

- For an independent integration server:

```
POST http://hostname:port/apiv2/applications/applicationName/messageflows/messageFlowName/
teardown
```

  For example, to tear down the message flow called `RequestServiceFlow` in application `HTTPInputApplication`, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/applications/HTTPInputApplication/messageflows/
RequestServiceFlow/teardown
```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

- For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/applications/applicationName/
messageflows/messageFlowName/teardown
```

  For example, to tear down the message flow called `RequestServiceFlow` in application `HTTPInputApplication` deployed to integration server ACESERV1, which is managed by an integration node, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/servers/ACESERV1/applications/HTTPInputApplication/
messageflows/RequestServiceFlow/teardown
```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

Tearing down a message flow in a REST API project

About this task

You can tear down a message flow that is deployed to an integration server in a REST API project.

Procedure

Tear down a message flow.

- For an independent integration server:

```
POST http://hostname:port/apiv2/rest-apis/rest-apiName/messageflows/messageFlowName/teardown
```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.
- For an integration server that is managed by an integration node:

```
POST http://hostname:port/apiv2/servers/integrationServerName/rest-apis/rest-apiName/
messageflows/messageFlowName/teardown
```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

Tearing down a message flow in an integration service project

About this task

You can tear down a message flow that is deployed to an integration server in an integration service project.

Procedure

Tear down a message flow.

- For an independent integration server:

```
POST http://hostname:port/apiv2/services/integrationServiceName/messageflows/messageFlowName/
teardown
```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.
- For an integration server that is managed by an integration node:

```
POST /apiv2/servers/integrationServerName/services/integrationServiceName/
messageflows/messageFlowName/teardown
```

  If the command is successful, an HTTP status code 200 and response message 0K are returned.

Using resources statistics through the administration REST API

You can use the IBM App Connect Enterprise administration REST API to administer the collection of resource statistics on an integration server.

About this task

Use the administration REST API to perform the following tasks:

- Display the properties that relate to the collection of resource statistics.
- Update the properties that relate to the collection of resource statistics.
- Start collecting resource statistics.
- Stop collecting resource statistics.

The REST API classes and methods are described in the App Connect Enterprise REST API V2 specification, which you can view in a browser, on GitHub, or in the documentation that is provided as part of your App Connect Enterprise installation. For more information on how to access this information, see "Managing resources by using the administration REST API" on page 334.

Displaying the properties that relate to resource statistics collection by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to display the properties that relate to resource statistics collection on an integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Using resources statistics through the administration REST API" on page 432

Procedure

Use one of the following REST API methods to query the resource statistics properties of an integration server.

- For an independent integration server:

  ```
  GET http://hostname:port/apiv2/statistics/resource-stats
  ```

  For example, use the following curl command:

  ```
  curl -X GET http://hostname:port/apiv2/statistics/resource-stats
  ```

  If the command is successful, an HTTP status code 200 and a response similar to the following are returned:

  ```
  {
    "hasChildren": false,
    "name": "resource-stats",
    "type": "resourceStats",
    "uri": "/apiv2/statistics/resource-stats",
    "properties": {
      "name": "Resource",
      "outputFormat": "inherit",
      "reportingOn": true,
      "type": "Resource"
    },
    "descriptiveProperties": {},
    "active": {
      "reportingOn": true
    },
    "actions": {
      "unavailable": {
  ```

```
      "start-collection": "/apiv2/statistics/resource-stats/start-collection"
    },
    "available": {
      "stop-collection": "/apiv2/statistics/resource-stats/stop-collection"
    }
  },
  "children": {},
  "links": []
}
```

- For an integration server that is managed by an integration node:

```
GET http://hostname:port/apiv2/servers/integrationServerName/statistics/resource-stats
```

For example, to display the resource statistics properties on integration server ACESERV1, which is managed by an integration node, use the following curl command:

```
curl -X GET http://hostname:port/apiv2/servers/ACESERV1/statistics/resource-stats
```

If the command is successful, an HTTP status code 200 and a response similar to the following are returned.:

```
{
  "hasChildren": false,
  "name": "resource-stats",
  "type": "resourceStats",
  "uri": "/apiv2/servers/ACESERV1/statistics/resource-stats",
  "properties": {
    "name": "Resource",
    "outputFormat": "inherit",
    "reportingOn": true,
    "type": "Resource"
  },
  "descriptiveProperties": {},
  "active": {
    "reportingOn": true
  },
  "actions": {
    "unavailable": {
      "start-collection": "/apiv2/servers/ACESERV1/statistics/resource-stats/start-
collection"
    },
    "available": {
      "stop-collection": "/apiv2/servers/ACESERV1/statistics/resource-stats/stop-collection"
    }
  },
  "children": {},
  "links": []
}
```

Updating properties that relate to resource statistics collection by using the administation REST API

You can use the IBM App Connect Enterprise administration REST API to update and persist the resource statistics properties for an integration server dynamically, without having to restart the integration server.

Before you begin

Read the following topics:

- “Managing resources by using the administration REST API” on page 334
- “Using resources statistics through the administration REST API” on page 432

About this task

You can dynamically update the properties that relate to resource statistics collection by using the PATCH verb in the administration REST API. Updates that are made by using the PATCH verb are persisted in the `overrides` subdirectory of the integration server's working directory, which means that the updates are not lost if the integration server is stopped.

Procedure

Use one of the following REST API methods to update the resource statistics properties of an integration server.

- For an independent integration server:

  ```
  PATCH http://hostname:port/apiv2/statistics/resource-stats
  ```

  For example, use the following curl command:

  ```
  curl -X PATCH http://hostname:port/apiv2/statistics/resource-stats
  ```

  The following example shows how to enable and persist a value of `false` on the **`reportingOn`** property. Setting **`reportingOn`** to `false` turns resource statistics off.

  ```
  curl -X PATCH -H 'accept:application/json' -H 'content-type:application/json' http://
  localhost:port/apiv2/statistics/resource-stats -d '{  "properties": { "reportingOn": "false"
    }}'
  ```

  If the command is successful, an HTTP status code 204 is returned.

  You can verify the successful setting of the property by issuing a GET API call as described in "Displaying the properties that relate to resource statistics collection by using the administration REST API" on page 432, or by looking in the `server.conf.yaml` file in the `overrides` subdirectory of the integration server's working directory to see that the modified value is persisted.

- For an integration server that is managed by an integration node:

  ```
  PATCH http://hostname:port/apiv2/servers/integrationServerName/statistics/resource-stats
  ```

  For example, to enable and persist a value of `false` on the **`reportingOn`** property on integration server ACESERV1, which is managed by an integration node:

  ```
  curl -X PATCH -H 'accept:application/json' -H 'content-type:application/json' http://
  hostname:port/apiv2/servers/ACESERV1/statistics/resource-stats -d '{  "properties":
   { "reportingOn": "false"  }}'
  ```

  If the command is successful, an HTTP status code 204 is returned.

  You can verify the successful setting of the property by issuing a GET API call as described in "Displaying the properties that relate to resource statistics collection by using the administration REST API" on page 432 , or by looking in the `server.conf.yaml` file in the `overrides` subdirectory to see that the modified value is persisted.

Starting resource statistics collection by using the administation REST API

You can use the IBM App Connect Enterprise administration REST API to start the collection of resource statistics for an integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Using resources statistics through the administration REST API" on page 432

Procedure

Use one of the following REST API methods to start resource statistics collection on an integration server.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/statistics/resource-stats/start-collection
  ```

  For example, use the following curl command:

  ```
  curl -X POST  http://hostname:port/apiv2/statistics/resource-stats/start-collection
  ```

  If the command is successful, an HTTP status code 200 is returned.

  You can verify that resource statistics collection has started by issuing a GET API call as described in "Displaying the properties that relate to resource statistics collection by using the administration REST API" on page 432; the value of the **reportingOn** property is `true` when resource statistics collection is started.
- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/statistics/resource-stats/
  start-collection
  ```

  For example, to start resource statistics collection on integration server ACESERV1, which is managed by an integration node:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/statistics/resource-stats/start-
  collection
  ```

  If the command is successful, an HTTP status code 200 is returned.

  You can verify that resource statistics collection has started by issuing a GET API call as described in "Displaying the properties that relate to resource statistics collection by using the administration REST API" on page 432; the value of the **reportingOn** property is `true` when resource statistics collection is started.

Stopping resource statistics collection by using the administation REST API

You can use the IBM App Connect Enterprise administration REST API to stop the collection of resource statistics for an integration server.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "Using resources statistics through the administration REST API" on page 432

Procedure

Use one of the following REST API methods to stop resource statistics collection on an integration server.

- For an independent integration server:

  ```
  POST http://hostname:port/apiv2/statistics/resource-stats/stop-collection
  ```

  For example, use the following curl command:

  ```
  curl -X POST  http://hostname:port/apiv2/statistics/resource-stats/stop-collection
  ```

  If the command is successful, an HTTP status code 200 is returned.

  You can verify that resource statistics collection has stopped by issuing a GET API call as described in "Displaying the properties that relate to resource statistics collection by using the administration REST API" on page 432; the value of the **reportingOn** property is `false` when resource statistics collection is stopped.

- For an integration server that is managed by an integration node:

  ```
  POST http://hostname:port/apiv2/servers/integrationServerName/statistics/resource-stats/stop-collection
  ```

  For example, to stop resource statistics collection on integration server ACESERV1, which is managed by an integration node:

  ```
  curl -X POST http://hostname:port/apiv2/servers/ACESERV1/statistics/resource-stats/stop-collection
  ```

  If the command is successful, an HTTP status code 200 is returned.

  You can verify that resource statistics collection has stopped by issuing a GET API call as described in "Displaying the properties that relate to resource statistics collection by using the administration REST API" on page 432; the value of the **reportingOn** property is `false` when resource statistics collection is stopped.

Setting message flow user-defined properties at run time by using the administration REST API

You can change the behavior of a message flow at run time by using the IBM App Connect Enterprise administration REST API to modify the values of user-defined properties on the message flow.

Before you begin

Read the following topics:

- "Managing resources by using the administration REST API" on page 334
- "User-defined properties" on page 569

About this task

When a message flow node references a user-defined property, it searches these levels of the message flow:

- If the message flow has the user-defined property named as a dynamic UDP override, this takes precedence over any other definitions.
- If the message flow node is in a subflow, and the subflow has the named user-defined property, this is used.
- If the message flow has the named user-defined property, this is used.
- If the integration server has the named user-defined property, this is used.

You can use the administration REST API to apply and remove user-defined property overrides. These overrides are not persistent, which means that they must be reapplied after the integration server is restarted.

The following REST API methods are provided for applying and removing user-defined property overrides:

- `HTTP POST to /apiv2/servers/{server}/applications/{application}/messageflows/{messageflow}/apply-global-udp-override?name=NAME&value=VALUE&type=TYPE`
- `HTTP POST to /apiv2/servers/{server}/applications/{application}/messageflows/{messageflow}/remove-global-udp-override?name=NAME`

The REST API classes and methods are described in the App Connect Enterprise REST API V2 specification, which you can view in a browser by specifying the address of your integration node or server, followed by the administration REST API port, and then `/apidocs`. For example, to display the REST API specification for an integration server, enter a URL as shown in the following example (specifying either `http` or `https`):

```
https://green.company.com:7600/apidocs
```

where `green.company.com` is the address of the integration server, and `7600` is the admin REST API port specified in the `server.conf.yaml` file.

The REST API specification is also provided with your installation of App Connect Enterprise, in the following directories:

- *install_dir*`\server\nodejs\node_modules\@ibm-app-connect\ace-admin-server\node_modules\@ibm-app-connect\ace-admin-api\docs\server`
- *install_dir*`\server\nodejs\node_modules\@ibm-app-connect\ace-admin-server\node_modules\@ibm-app-connect\ace-admin-api\docs\node`

where *install_dir* is the directory in which App Connect Enterprise is installed.

See the following topics for more information about setting user-defined property overrides:

- "Applying a user-defined property override" on page 437
- "Removing a user-defined property override" on page 438
- "Example: setting user-defined property overrides" on page 439

Applying a user-defined property override

You can apply a user-defined property override by using the IBM App Connect Enterprise administration REST API.

Before you begin

Read the following topics:

- "User-defined properties" on page 569
- "Setting message flow user-defined properties at run time by using the administration REST API" on page 436

About this task

You can use the `apply-global-udp-override` method to create an override value for a named user-defined property. When an override value is created, the value is seen anywhere that the user-defined property is referenced in the message flow, both in the main flow and in subflows, including:

- ESQL: DECLARE myVar EXTERNAL datatype defaultValue
- Java: MbNode.getUserDefinedAttribute()
- .NET: NBNode::GetUserDefinedProperty
- Mapping node access to user defined properties

User-defined property overrides are not persistent, which means that they must be reapplied after the integration node or server is restarted.

The `apply-global-udp-override` action takes the following query parameters:

Parameter	Description
name*	The name of the user-defined property for which an override is to be applied. This parameter is required.

Parameter	Description
value	The value of the user-defined property override. If the value includes characters that are not supported in REST URIs, these characters must be URI encoded. For example, a space in a value must be encoded as `%20`. This parameter is optional; if it is not supplied, the default for the datatype is used.
type	The datatype of the user-defined property override (matching ESQL datatypes). This parameter is optional; if it is omitted, the datatype of the existing override is used. If this parameter is omitted and there is no existing override, `CHARACTER` is used by default.

The following examples show how to use the `apply-global-udp-override` method:

```
apiv2/applications/UDPAPP/messageflows/FLOWWITHUDP/apply-global-udp-override?
name=myCharUDP&value=NewValue&type=CHARACTER
```

```
apiv2/applications/UDPAPP/messageflows/FLOWWITHUDP/apply-global-udp-override?
name=myBoolUDP&value=TRUE&type=BOOLEAN
```

```
apiv2/applications/UDPAPP/messageflows/FLOWWITHUDP/apply-global-udp-override?
name=myIntUDP&value=350&type=INTEGER
```

```
apiv2/applications/UDPAPP/messageflows/FLOWWITHUDP/apply-global-udp-override?
name=myCharUDP&value=NewValue
```

```
apiv2/applications/UDPAPP/messageflows/FLOWWITHUDP/apply-global-udp-override?
name=myCharUDP&value=New%20Value%20with%20spaces
```

For more information about how to set user-defined property overrides, see “Example: setting user-defined property overrides” on page 439.

You can also remove a user-defined property override by using the IBM App Connect Enterprise administration REST API, as described in “Removing a user-defined property override” on page 438.

Removing a user-defined property override

You can remove a user-defined property override by using the IBM App Connect Enterprise administration REST API.

Before you begin

Read the following topics:

- “User-defined properties” on page 569
- “Setting message flow user-defined properties at run time by using the administration REST API” on page 436

About this task

You can use the `remove-global-udp-override` method to remove an override value for a named user-defined property.

The `remove-global-udp-override` action takes the following query parameters:

Parameter	Description
name*	The name of the user-defined property for which an override is to be removed. This parameter is required. This parameter must match the name of the override that was used on the `apply-global-udp-override` method when the override was created. When an override has been removed, the message flow reverts to the value that was defined in the deployed message flow definitions, before any override was applied.

You can also use the administration REST API to apply a user-defined property override, as described in "Applying a user-defined property override" on page 437.

For more information about how to set user-defined property overrides, see "Example: setting user-defined property overrides" on page 439.

Example: setting user-defined property overrides

You can change the behavior of a message flow at run time by using the IBM App Connect Enterprise administration REST API to modify the values of user-defined properties on the message flow.

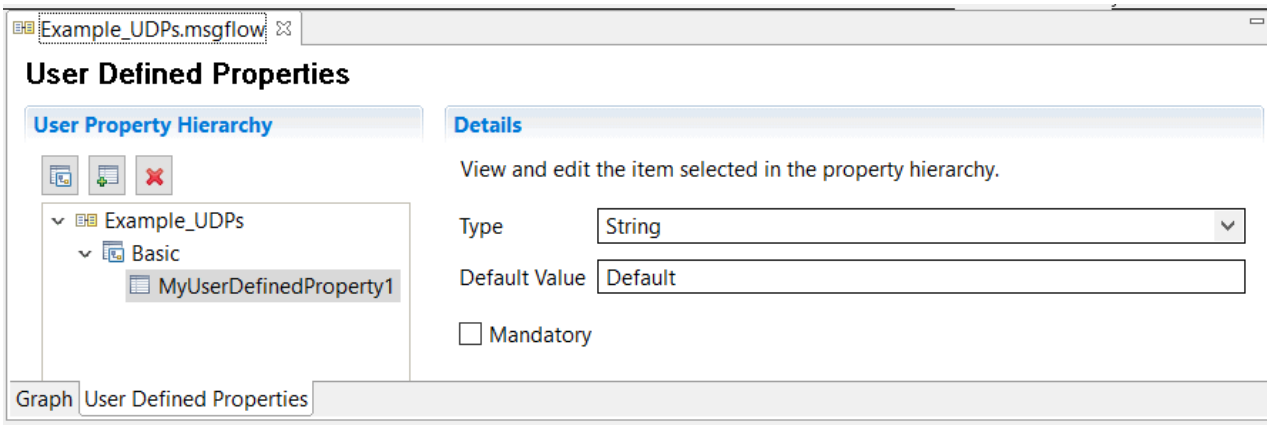
Before you begin

Read the following topics:

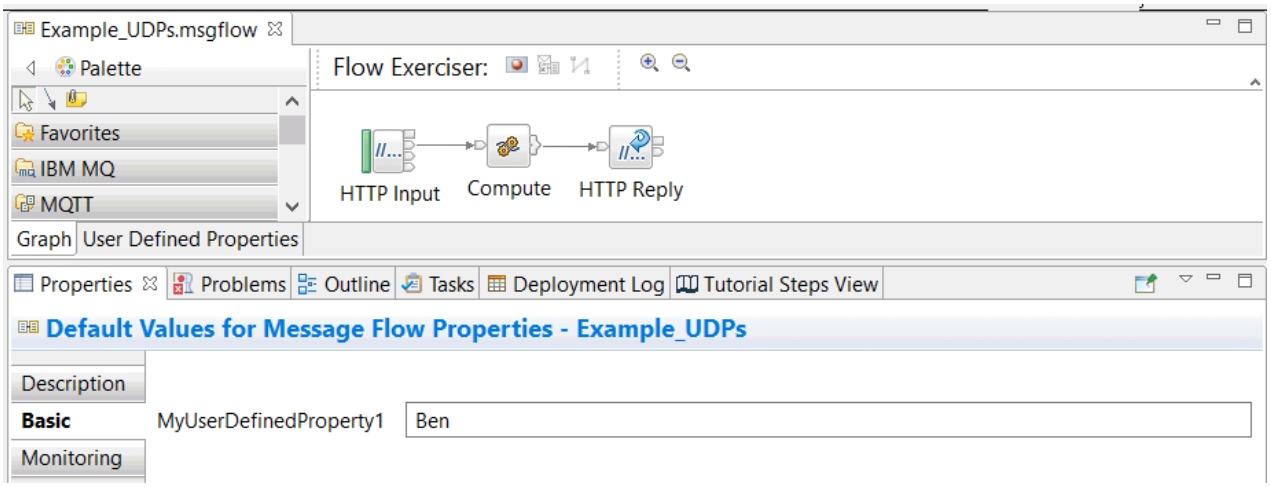
- "Setting message flow user-defined properties at run time by using the administration REST API" on page 436
- "User-defined properties" on page 569

About this task

In this example, the User Defined Properties tab in the IBM App Connect Enterprise Toolkit shows the default value of a user-defined property called `MyUserDefinedProperty1`, which is `Default`:



The value assigned to the property before deploying the message flow is then set to Ben:

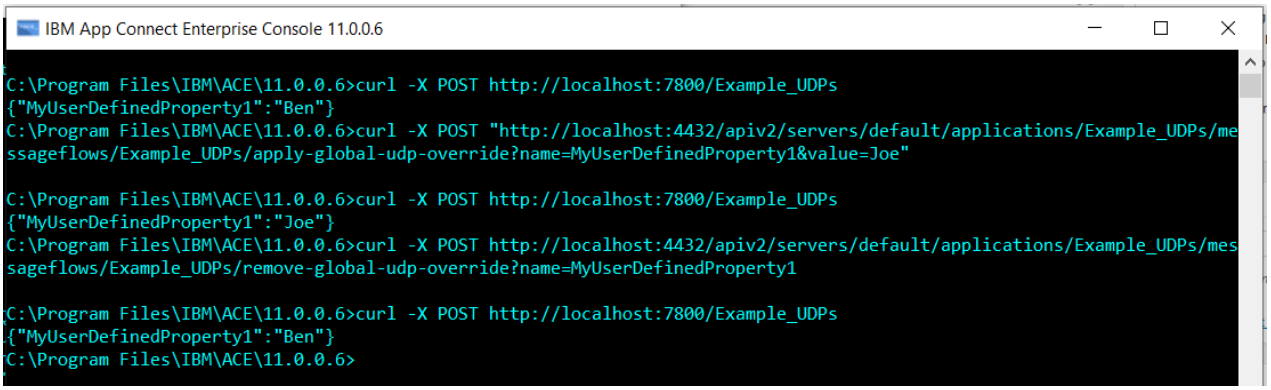


This message flow uses a simple ESQL instruction to assign the current value of the user-defined property to an output JSON message, which is sent as an HTTP reply from the message flow:

```
DECLARE MyUserDefinedProperty1 EXTERNAL CHARACTER 'Default';

CREATE COMPUTE MODULE Example_UDPs_Compute
    CREATE FUNCTION Main() RETURNS BOOLEAN
    BEGIN
        CALL CopyMessageHeaders();
        CREATE LASTCHILD OF OutputRoot DOMAIN('JSON');
        SET OutputRoot.JSON.Data.MyUserDefinedProperty1 = MyUserDefinedProperty1;
        RETURN TRUE;
    END;
```

When this message has been deployed, you can query the current value of the user-defined property and apply a new value to it, by using a simple HTTP client program such as Curl:



For information about applying and removing user-defined property overrides, see “Applying a user-defined property override” on page 437 and “Removing a user-defined property override” on page 438.

For more information about using the administration REST API, see “Managing resources by using the administration REST API” on page 334.

Updating the HTTPS Connector resource manager by using the administration REST API

You can use the IBM App Connect Enterprise administration REST API to query and update resource managers that are available to the integration server. This topic describes how to use the administration

REST API to update the HTTPS Connector integration server resource manager with particular focus on reloading the inbound security certificate.

Before you begin

Read the following topic:

- "Managing resources by using the administration REST API" on page 334

About this task

When receiving secured inbound connections over HTTPS, integration servers use the HTTPS Connector resource manager. You can query and update the HTTPS Connector resource manager by using the App Connect Enterprise administration REST API. You do not have to restart the integration server for such updates to take effect.

There are a number of situations that might require updates to the properties of the HTTPS Connector resource manager in an integration server. You can dynamically update the properties in question by using the PATCH verb in the administration REST API. Updates that are made by using the PATCH verb are persisted in the `overrides` sub-directory of the integration server working directory meaning that, if the integration server is restarted, the updates are not lost.

This topic describes:

- "Querying the available resource managers of an integration server " on page 441
- "Querying the properties of the HTTPS Connector resource manager " on page 441
- "Dynamically updating the properties of the HTTPS Connector resource manager " on page 442
- "Dynamically loading a new server certificate by reusing the same keystore file " on page 443

Querying the available resource managers of an integration server

Procedure

Use one of the following REST API methods to query the available resource managers of an integration server.

- For an independent integration server:

```
GET http://hostname:port/apiv2/resource-managers
```

- For a managed integration server:

```
GET http://hostname:port/apiv2/servers/{server}/resource-managers
```

Querying the properties of the HTTPS Connector resource manager

Procedure

Use one of the following REST API methods to query the properties of the HTTPS Connector resource manager.

- For an independent integration server:

```
GET http://hostname:port/apiv2/resource-managers/https-connector
```

  For example, use the curl command:

```
curl -X GET http://hostname:port/apiv2/resource-managers/https-connector
```

  A response similar to the following is returned:

```
{"hasChildren":false,"name":"https-connector","type":"resourceManager","uri":"/apiv2/
resource-managers/https-connector",
"properties":
{"AutoRespondToHTTPHEADRequests":false,"CORSAllowCredentials":false,"CORSAllowHeaders":"Accept,Accept-
Language,
Content-Language,Content-
Type","CORSAllowMethods":"GET,HEAD,POST,PUT,PATCH,DELETE,OPTIONS","CORSAllowOrigins":"*",
"CORSEnabled":false,"CORSExposeHeaders":"Content-Type","CORSMaxAge":-1,"CipherSpec":"!
RC4+RSA:HIGH:+MEDIUM:+LOW",
"ConnBacklog":100,"EnableLookups":true,"EnableTLSTrace":false,"IWATimeout":300,"IntegratedWindowsAuthentic
"KeyAlias":"","KeyPassword":"********","KeystoreFile":"","KeystorePassword":"********","KeystoreType":"JKS
"ListenerAddress":"0.0.0.0","ListenerPort":7843,"ListenerThreads":-1,"MaxConnections":-1,"MaxKeepAliveRequ
"MaxPostSize":-1,"QueueCapacity":1000,"ReqClientAuth":false,"ServerName":"","TLSCertVerifyDepth":100,"TLSC
"TLSProtocols":"","TimeoutSweepInterval":20,"TruststoreFile":"","TruststorePassword":"********","Truststor
"name":"HTTPSConnector","type":"Policy"},"descriptiveProperties":
{"className":"HTTPSConnector","isDynamic":"true",
"policyType":"HTTPSConnector"},"active":
{"ListenerPort":-1,"serverRestartRequired":false},"actions":{"available":{"refresh-tls-
config":
"/apiv2/resource-managers/https-connector/refresh-tls-config"}},"children":{},"links":[]}
```

- For a managed integration server:

```
GET http://hostname:port/apiv2/servers/{server}/resource-managers/https-connector
```

  For example, use the curl command:

```
curl -X GET http://hostname:port/apiv2/servers/{server}/resource-managers/https-connector
```

Dynamically updating the properties of the HTTPS Connector resource manager

Procedure

Use one of the following REST API methods to dynamically update the properties of the HTTPS Connector resource manager.

Being able to dynamically update these properties, in particular **KeystoreFile** is useful in the situation where you are using certificate authorities that refresh their certificates on a frequent basis but you do not want to restart the integration server whenever the refresh occurs.

Updates take effect on the first inbound connection following the update; preexisting connections retain the original configuration. You do not have to restart the integration server for the changes to take effect.

You can update the following HTTPS Connector resource manager properties:

- **KeyAlias**
- **KeystoreFile** - you can specify the path to an updated inbound server certificate without the need to restart the integration server for the certificate to be applied on subsequent inbound connections.
- **KeystorePassword**
- **KeystoreType**
- **TruststoreFile**
- **TruststorePassword**
- **TruststoreType**

For more information about these parameters, see Integration server HTTP listener parameters (SOAP and HTTP nodes).

- For example, to update the **KeyAlias**, **KeystoreFile**, **KeystorePassword**, and **KeystoreType** properties for the HTTPS Connector resource manager for an independent integration server, use the following curl command with the PATCH verb:

```
curl -X PATCH -H "Content-Type: application/json" http://hostname:port/apiv2/resource-
managers/https-connector
-d "{\"properties\": {\"KeyAlias\":\"server1cert\",\"KeystoreFile\": \"C:\\temp\
\myserver_keystore.p12\",\
"KeystorePassword\": \"server::keystorePass\",\"KeystoreType\": \"p12\"}}"
```

- For a managed integration server, to update the same properties for the HTTPS Connector resource manager for a managed integration server, use the following curl command with the PATCH verb:

```
curl -X PATCH -H "Content-Type: application/json" http://hostname:port/apiv2/servers/
{server}/resource-managers/https-connector
-d "{\"properties\": {\"KeyAlias\":\"server1cert\",\"KeystoreFile\": \"C:\\temp\
\myserver_keystore.p12\",\"KeystorePassword\": \
"server::keystorePass\",\"KeystoreType\": \"p12\"}}"
```

If the command is successful, an HTTP status code 204 is returned. You can see the updated values in the`overrides` sub-directory of the integration server working directory.

Dynamically loading a new server certificate by reusing the same keystore file

About this task

You can reuse the same keystore file but with a different value for the server security certificate to refresh the server certificate to be used by the integration server without having to restart the integration server. Instead of updating the server certificate by using the PATCH verb in the REST API, as described in “Dynamically updating the properties of the HTTPS Connector resource manager ” on page 442, you must use the POST method to load a new server certificate that you have defined in a certificate file with the same name as one that you have previously used.

Procedure

Use the following commands to refresh the integration server TLS configuration, including the updated server certificate value in the reused certificate file.

Updates take effect on the first inbound connection following the update. You do not have to restart the integration server for the changes to take effect.

- For example, to ensure the use of an updated server certificate specified in a reused certificate file for an independent integration server, use the following curl command:

```
curl -X POST http://hostname:port/apiv2/resource-managers/https-connector/refresh-tls-config
```

- For a managed integration server:

```
curl -X POST http://hostname:port/apiv2/servers/{server}/resource-managers/https-connector/
refresh-tls-config
```

If the command is successful, an HTTP status code 200 is returned.

Managing resources by using the IBM Integration API

Develop Java applications that use the IBM Integration API to manage integration nodes, integration servers, and their associated resources.

Before you begin

Understand how you can use the IBM Integration API to manage the resources associated with your integration nodes and servers. For more information, see #unique_95.

Samples are provided to demonstrate typical IBM Integration API scenarios. Run and explore the samples to learn about what you can do with the IBM Integration API; for more information, see "The IBM Integration API samples" on page 467.

About this task

You can use the IBM Integration API to develop administrative applications or to develop message flows.

To develop administrative applications that run tasks in your integration nodes and servers, see the following information:

- Configuring the environment
- "Connecting to an integration node from a custom integration application" on page 447
- Navigating integration node and integration node resources
- Deploying resources
- "Managing integration nodes by using JavaCompute nodes" on page 454

Results

When you have created your applications, test their operation in your test environment. Check the results of the operations that the programs have performed by using the Deployment Log view.

What to do next

When you have written and tested your applications, distribute them to the computers from which you want your administrators to perform the tasks that you have developed.

Configuring an environment for developing and running custom integration applications

Prepare the environment in which you want to run your custom integration applications.

Before you begin

To develop and run Java applications that use the IBM Integration API, you must install the following prerequisite software in your local computer environment:

- An IBM Java Development Kit (JDK) at a supported Java level. Java support is defined in the IBM App Connect Enterprise system requirements; see IBM App Connect Enterprise system requirements.

  IBM App Connect Enterprise does not supply a JDK; you must acquire and install a suitable product yourself.

  You must use an IBM JDK to develop custom integration applications and an IBM Java Runtime Environment (JRE) to run these applications.

About this task

Follow the instructions for the appropriate environment:

- "Configuring the command-line environment to run custom integration applications" on page 445

- "Configuring the Eclipse environment to run custom integration applications" on page 446

You can also run custom integration applications, and therefore control one or more integration node components, from computers on which you have not installed IBM App Connect Enterprise. For more information, see "Configuring environments without IBM App Connect Enterprise installed" on page 446.

Configuring the command-line environment to run custom integration applications

Use the command line on your computers to configure the environment to run your custom integration applications.

About this task

To run your custom integration applications with your chosen operating system, you must update the CLASSPATH environment variable:

Procedure

1. Add the IBM Integration API JAR files to your CLASSPATH.
   To add the JAR files to your CLASSPATH:
   - Linux UNIX On Linux and UNIX:

```
export CLASSPATH = $CLASSPATH%;$install_dir/server/classes/IntegrationAPI.jar:
$install_dir/common/jackson/lib/jackson-annotations-2.9.8.jar:
$install_dir/common/jackson/lib/jackson-core-2.9.8.jar:
$install_dir/common/jackson/lib/jackson-databind-2.9.8.jar:
$install_dir/common/jackson/lib/jackson-dataformat-yaml-2.9.8.jar:
$install_dir/common/jackson/lib/snakeyaml-1.23.jar:
$install_dir/common/jetty/lib/jetty-io.jar:
$install_dir/common/jetty/lib/jetty-util.jar:
$install_dir/common/jetty/lib/websocket-api.jar:
$install_dir/common/jetty/lib/websocket-client.jar:
$install_dir/common/jetty/lib/websocket-common.jar:
$install_dir/common/jetty/lib/jetty-client.jar:
$install_dir/common/jetty/lib/jetty-http.jar:
```

     - For local connections on Linux and UNIX, also add:

```
$install_dir/common/jnr/lib/jnr-a64asm-1.0.0.jar:
$install_dir/common/jnr/lib/jnr-constants-0.9.12.jar:
$install_dir/common/jnr/lib/jnr-enxio-0.21.jar:
$install_dir/common/jnr/lib/jnr-ffi-2.19.jar:
$install_dir/common/jnr/lib/jnr-posix-3.0.50.jar:
$install_dir/common/jnr/lib/jnr-unixsocket-0.23.jar:
$install_dir/common/jnr/lib/jnr-x86asm-1.0.2.jar:
$install_dir/common/jnr/lib/asm-7.0.jar:
```

   - Windows On Windows:

```
set CLASSPATH = %CLASSPATH%;%install_dir%\server\classes\IntegrationAPI.jar
%install_dir\common\jackson\lib\jackson-annotations-2.9.8.jar;
%install_dir\common\jackson\lib\jackson-core-2.9.8.jar;
%install_dir\common\jackson\lib\jackson-databind-2.9.8.jar;
%install_dir\common\jackson\lib\jackson-dataformat-yaml-2.9.8.jar;
%install_dir\common\jackson\lib\snakeyaml-1.23.jar;
%install_dir\common\jetty\lib\jetty-io.jar;
%install_dir\common\jetty\lib\jetty-util.jar;
%install_dir\common\jetty\lib\websocket-api.jar;
%install_dir\common\jetty\lib\websocket-client.jar;
%install_dir\common\jetty\lib\websocket-common.jar;
%install_dir\common\jetty\lib\jetty-client.jar;
%install_dir\common\jetty\lib\jetty-http.jar;
```

2. Add your Java development directory to the CLASSPATH in the same way.

What to do next

Use the tools that are provided by your JDK to build and run your custom integration applications.

Configuring the Eclipse environment to run custom integration applications

Use Eclipse facilities to configure the environment to run your custom integration applications.

About this task

To run your custom integration applications by using Eclipse, you must update the CLASSPATH environment variable:

Procedure

1. In your Eclipse environment, select **File** > **New** > **Project**.

   The **New Project** wizard opens.
2. Select **Java Project** from the options displayed.

   Click **Next**. The **New Java Project** window opens.
3. Enter a name for your new project.

   Click **Next**.
4. Select the **Libraries** tab, and click **Add External Jars**.
5. To set up the build environment, navigate to the *install_dir*/common/classes subdirectory. For example, for Version 12.0 on Windows operating systems, navigate to the directory `C:\Program Files\IBM\ACE\12.0.n.0\common\classes`.

   Select the file `IntegrationAPI.jar`, and click **Open**. The file is added to the list in the window for the **Libraries** tab.
6. When you have added the file `IntegrationAPI.jar` to the build path, set up the runtime environment.

   Click **Add External Jars** again, and navigate to the *install_dir*/common/jackson/lib subdirectory.

   Select each of the JAR files in that directory, and click **Open**. These files are also added to the list.
7. For local connections, also add *install_dir*/common/jnr/lib.
8. Click **Finish**.

What to do next

Use the Eclipse development tools to build and run your custom integration applications.

Configuring environments without IBM App Connect Enterprise installed

Install and run custom integration applications and other utilities on computers, when you are using a local ID only, on which you have not installed IBM App Connect Enterprise.

About this task

You can run Java applications that use the IBM Integration API even where you have not installed IBM App Connect Enterprise. These applications include your own custom integration applications, and some of the command utilities.

To install Java applications that use the IBM Integration API in an environment that does not have IBM App Connect Enterprise installed, complete the following steps:

Procedure

1. Ensure that the target computer has a compatible Java Runtime Environment (JRE).

   Because you are not installing IBM App Connect Enterprise, which includes a JRE, you must use an alternative option.

   Note, that you must also set MQSI_JREPATH to the installation path of your JRE.

   Java support is defined in the IBM App Connect Enterprise system requirements; see IBM App Connect Enterprise system requirements.
2. Copy the following set of files from a computer that has IBM App Connect Enterprise installed to the target computer:
   a. The `IntegrationAPI.jar` file from the `install_dir/common/classes` directory.
   b. All the `.jar` files from the `install_dir/common/jackson/lib` directory.
   c. All the `.jar` files from the `install_dir/common/jnr/lib` directory.
   d. Your custom integration applications and all configuration files, for example `.broker` files.
3. On the target computer, use system facilities to update the CLASSPATH environment variable to include the following files:
   - The JAR file that contains the definitions of the IBM Integration API classes: `IntegrationAPI.jar`.
   - The JAR files that you copied from the `install_dir/common/jackson/lib` directory and the `install_dir/common/jnr/lib` directory.
   - Your applications that import the IBM Integration API classes.
   - The JAR files that contain the definitions of the `IntegrationNodeConnectionParameters` classes.
   - Any other required JAR files and directories. For example, if you require any of the available command utilities on the target computer, include `brokerutil.jar`; if you require the integration node (BIP) messages to be displayed in locales other than US English, include a directory that contains BIPmsgs*.properties.
4. Ensure that the user ID that the target computer uses has the following authorities:
   - Authority to manipulate integration node objects.

What to do next

You can run your custom integration applications, and the supported command utilities, on the target computer.

Connecting to an integration node from a custom integration application

Connect an application that uses the IBM Integration API to an integration node, to send requests about its status and its resources.

Before you begin

You must complete the steps in “Configuring an environment for developing and running custom integration applications” on page 444.

About this task

Review the following example application, `IntegrationNodeStateChecker.java`, which demonstrates how to use the IBM Integration API classes:

```
import com.ibm.integration.admin.proxy.*;

public class IntegrationNodeStateChecker {
```

```
 public static void main(String[] args) {
  // The IP address of where the integration node is running
  // and the web administration port number of the integration node.
  displayNodeRunState("localhost", 4414);
 }

 public static void displayNodeRunState(String hostname, int port) {

  IntegrationNodeProxy node = new IntegrationNodeProxy(hostname,port,"","",false);

  try {
   String nodeName = node.getName();

   System.out.println("Integration node '"+nodeName+
     "' is available!");
  } catch (IntegrationAdminException ex) {
   System.out.println("Integration node is NOT available"+
     " because "+ex);
  }
 }
}
```

This example application connects to a remote integration node.

Review each part of the application that uses the IBM Integration API to understand what is required to connect to an integration node. Use the following steps to assist you in creating your own custom integration applications.

Procedure

1. Import the `com.ibm.integration.admin.proxy` package, which contains the IBM Integration API Java classes.

   This action is in the first line of the application:

   ```
   import com.ibm.integration.admin.proxy.*;
   ```

The first line of code inside the `try` block of the `displayNodeRunState()` method instantiates an `IntegrationNodeProxy` object. `IntegrationNodeProxy` is an interface that states that implementing classes are able to provide the parameters to connect to an integration node.

The `IntegrationNodeConnectionParameters` class implements this interface by defining a set of HTTP connection parameters. The constructor that is used in the program has two required parameters:

a. The host name of the computer that the integration node is running on.

b. The web administration port (the default is 4414). For more information about port numbers for an integration node, see “Configuring the IBM App Connect Enterprise web user interface” on page 87.

If you have administration security enabled, use constructors for the user name and password. For example:

```
IntegrationNodeConnectionParameters node =
 new IntegrationNodeConnectionParameters(hostname,port,"userid","password",false);
```

2. The `getName()` method, and other methods that request information from the integration node, cause a block until the information is supplied, or a timeout occurs. Therefore, if the integration node is not running, the application hangs for a period. You can control the timeout period by using the `BrokerProxy.setRetryCharacteristics()` method. Typically, blocking occurs only when a resource is accessed for the first time within an application.

Results

You can create a custom integration application that can connect to an integration node.

Navigating integration node and integration node resources in a custom integration application

Explore the status and attributes of the integration node that your custom integration application is connected to, and discover information about its resources.

Before you begin

You must have completed "Connecting to an integration node from a custom integration application" on page 447.

About this task

Each resource that the integration node can control is represented as a single object in the IBM Integration API. A custom integration application can request status and other information about the following objects:

- Integration nodes
- Integration servers
- Deployed message flows

The IBM Integration API also handles deployed message sets; these resources are handled as attributes of deployed integration servers.

Collectively known as *administered objects*, these objects provide most of the interface to the integration node, and are therefore fundamental to an understanding of the IBM Integration API.

Each administered object is an instance of a Java class that describes the underlying type of object in the integration node. The main Java classes are shown in the following table.

Java class	Class function
ApplicationProxy	Describes applications that have been deployed to integration servers.
IntegrationNodeProxy	Describes integration nodes.
IntegrationServerProxy	Describes integration servers.
MessageFlowProxy	Describes message flows that have already been deployed to integration servers through an application, REST API, or integration service; it does not describe message flows in the Integration Development perspective of the IBM App Connect Enterprise Toolkit.
RestApiProxy	Describes the REST API application details that have been deployed to an integration server.
ServiceProxy	Describes the integration service details that have been deployed to an integration server.
SharedLibraryProxy	Describes the shared library details that have been deployed to an integration server.
StaticLibraryProxy	Describes the static library details that have been deployed to an integration server through an application, REST API, or integration service.
SubFlowProxy	Describes subflows that have already been deployed to integration servers through an application, REST API, or integration service.

Each administered object describes a single object that can be controlled by the integration node. For example, every integration server within an integration node has one `IntegrationServerProxy` instance that represents it within the application.

A set of public methods is available for each administered object, which applications can use to inquire and manipulate properties of the underlying integration node to which the instance refers. To access an administered object through its API, your application must first request a handle to that object from the object that logically owns it.

For example, because integration nodes logically own integration servers, to gain a handle to integration server EG1 running on integration node B1, the application must ask the `IntegrationNodeProxy` object represented by B1 for a handle to the `IntegrationServerProxy` object represented by EG1.

On a `IntegrationNodeProxy` object that refers to integration node B1, the application can call methods that cause the integration node to reveal its run-state, or cause it to start all its message flows. You can write applications to track the changes that are made to the integration node objects by reading the messages maintained as `LogEntry` objects.

In the following example, a handle is requested to the `IntegrationNodeProxy` object. The `IntegrationNodeProxy` is logically the root of the administered object tree, therefore your application can access all other objects in the integration node directly, or indirectly.

The integration node directly owns the integration servers, therefore applications can call a method on the `IntegrationNodeProxy` object to gain a handle to the `IntegrationServerProxy` objects. Similarly, the integration server logically contains the set of all message flows, therefore the application can call methods on the `IntegrationServerProxy` object to access the `MessageFlowProxy` objects.

Each object with an asterisk after its name inherits from the DeployedObjectGroupProxy class, and therefore has further child objects.

The following application traverses the administered object hierarchy to discover the run-state of a deployed message flow. The application assumes that message flow MF1 is deployed to EG1 on integration node B1; you can substitute these values in the code for other values that are valid in the integration node.

```
import com.ibm.integration.admin.proxy.*;

public class GetMessageFlowRunState {

  public static void main(String[] args) {

    IntegrationNodeProxy node = new IntegrationNodeProxy("localhost",4414,"","",false);

    System.out.println("Getting message flow status of MF1 in the default application");
      displayMessageFlowRunState(node, "Server1", "MF1");
    }

    private static void displayMessageFlowRunState(
                                IntegrationNodeProxy node,
                                String serverName,
                                String flowName) {
    try {
      IntegrationServerProxy server =
        node.getIntegrationServerByName(serverName);

      if (server != null) {
        MessageFlowProxy mf =
          server.getDefaultApplication(true).getMessageFlowByName(flowName,"",false);
          /* locate the message flow from the default application. boolean flag indicates */
          /* if we need to fresh the model or use the cache one from proxy. */

        if (mf != null) {
          boolean isRunning = mf.getMessageFlowModel(false).getActive().isRunning();
          System.out.print("Flow "+flowName+" on " +
            serverName+" on "+server.getName()+" is ");

          if (isRunning) {
            System.out.println("running");
          } else {
            System.out.println("stopped");
          }
        } else {
          System.err.println("No such flow "+flowName);
        }
      } else {
        System.err.println("No such integration server "+serverName+"!");
      }
```

```
    } catch(IntegrationAdminException ex) {
      System.err.println("Comms problem! "+ex);
    }
  }
}
```

The method `displayMessageFlowRunState()` does most of the work. This method takes the valid `IntegrationNodeProxy` handle gained previously, and discovers the run-state of the message flow in the following way:

1. The `IntegrationNodeProxy` instance is used to gain a handle to the `IntegrationServerProxy` object with the name described by the string `serverName`
2. If a valid integration server is returned, the `IntegrationServerProxy` instance is used to gain a handle to the `MessageFlowProxy` object with the name described by the string `flowName`.
3. If a valid message flow is returned, the run-state of the `MessageFlowProxy` object is queried, and the result is displayed.

The application does not have to know the names of objects that it can manipulate. Each administered object contains methods to return sets of objects that it logically owns. The following example demonstrates this technique by looking up the names of all integration servers within the integration node.

```
import java.util.List;

import com.ibm.integration.admin.proxy.IntegrationAdminException;
import com.ibm.integration.admin.proxy.IntegrationNodeProxy;
import com.ibm.integration.admin.proxy.IntegrationServerProxy;

public class DisplayIntegrationServerNames {

  public static void main(String[] args) {

    IntegrationNodeProxy node = new IntegrationNodeProxy("localhost",4414,"","",false);

    System.out.println("Get the Integration Server Names");
    displayIntegrationServerNames(node);
   }
private static void displayIntegrationServerNames(IntegrationNodeProxy node)
  {
    try {
      List<IntegrationServerProxy> serverNames = node.getAllIntegrationServers();
      if (serverNames != null)
      {
        for(IntegrationServerProxy name: serverNames)
          {
          System.out.println("Found : "+name.getName());
          }
        }
      else
      { // no servers found or a Rest call returned a bad response
        // check the status of the last http response
        int status = node.getLastHttpResponse().getStatusCode();
      if (node.getLastHttpResponse().getStatusCode() == 200)
        {
          System.out.println("No servers Found");
        }
      else
        {
          System.out.println("Http response from Integration Node is "+status);
          System.out.println("Http response reason: "+node.getLastHttpResponse().getReason());
        }
      }

      } catch(IntegrationAdminException ex) {
      System.err.println("Comms problem! "+ex);
    }
  }
}
```

The properties of any proxy are obtained by calling a `getxxxxModel` method call, where `xxx` is the current proxy object being used. The model class is a representation of the JSON response message

returned from the REST calls. The following example shows how to obtain the process identifier of an integration node and an integration server:

```
import com.ibm.integration.admin.model.IntegrationNodeModel;
import com.ibm.integration.admin.model.IntegrationServerModel;
import com.ibm.integration.admin.proxy.*;

public class GetProperties {

  public static void main(String[] args) {

    IntegrationNodeProxy node = new IntegrationNodeProxy("localhost",4414,"","",false);
    try {
      IntegrationNodeModel nodeModel = node.getIntegrationNodeModel(true);
      System.out.println("Node Process ID: "+nodeModel.getActive().getProcessId());

      IntegrationServerProxy server = node.getIntegrationServerByName("Server1");
      IntegrationServerModel serverModel = server.getIntegrationServerModel(true);
      System.out.println("Server Process ID: "+serverModel.getActive().getProcessId());
    } catch (IntegrationAdminException e) {
      System.out.println("Error connecting: "+e);
    }
  }
}
```

Each proxy class caches the last model that was obtained from the REST call. Subsequent calls return the cached value from the proxy. If you want the model to be updated, set the refresh flag on the call to `true`, which causes the proxy to discard the cached version and obtain the latest properties.

Deploying resources to an integration node by using a custom integration application

Deploy BAR files to the integration nodes in your integration node network by using a custom integration application.

About this task

You can also check the result of a deployment by using the IBM Integration API.

To use the IBM Integration API to deploy files and check the results:

Procedure

1. Connect to the integration node by clicking **File** > **Connect to Local Integration node** or **File** > **Connect to Remote Integration node**.

   This action opens the Connect to Integration node dialog.
2. Enter the relevant connection parameters in the dialog.

   A hierarchical representation of the integration node and its resources is displayed.
3. Complete one or more of the following operations:
   - Click an object in the tree to display the attributes of that object.
   - Right-click an object in the tree to call IBM Integration API methods that manipulate that object. For example, right-clicking an integration node opens a menu that includes the items **Start user trace**.
   - Use the log pane to view useful information that relates to the operation in progress.

Example

The following example custom integration application connects to an integration node that is running on the local computer. The integration node is listening for RestAdminListener requests on the web administration port (the default is 4414). The code deploys a BAR file that is called `MyBAR.bar` to an integration server called `default` that is running on the integration node, and displays the result.

```
import com.ibm.integration.admin.model.common.LogEntry;
```

```
import com.ibm.integration.admin.model.server.DeployResult;
import com.ibm.integration.admin.proxy.IntegrationAdminException;
import com.ibm.integration.admin.proxy.IntegrationNodeProxy;
import com.ibm.integration.admin.proxy.IntegrationServerProxy;

public class DeployExample {

 public static void main(String[] args) {
  IntegrationNodeProxy node = new IntegrationNodeProxy("localhost",4414,"","",false);
  try {
   IntegrationServerProxy server = node.getIntegrationServerByName("server1");
   DeployResult result  = server.deploy("C:\\temp\\mybarfile.bar");
   int deployStatus = server.getLastHttpResponse().getStatusCode();
   if (deployStatus >= 400)
   {
    System.out.println("Http response error: " + deployStatus );
   }
   else
   { // deploy worked, check for any Log entries
    LogEntry[] logEntries  = result.getLogEntry();
    if (logEntries != null)
    {
     for (LogEntry logEntry: logEntries)
     {
      System.out.println("Deploy log entry: "+logEntry.getDetailedText());
     }
    }
   }
  } catch (IntegrationAdminException e) {
   System.out.println("Error connecting: "+e);
  }
 }
}
```

Checking the results of deployment in a custom integration application

When you deploy from a custom integration application, you can check the results of that action.

About this task

Code your application to test the results of the deployment actions that it takes. For example:

```
import com.ibm.integration.admin.model.common.LogEntry;
import com.ibm.integration.admin.model.server.DeployResult;
import com.ibm.integration.admin.proxy.IntegrationAdminException;
import com.ibm.integration.admin.proxy.IntegrationNodeProxy;
import com.ibm.integration.admin.proxy.IntegrationServerProxy;

public class DeployExample {

  public static void main(String[] args) {
    IntegrationNodeProxy node = new IntegrationNodeProxy("localhost",4414,"","",false);
    try {
      IntegrationServerProxy server = node.getIntegrationServerByName("server1");
      DeployResult result  = server.deploy("C:\\temp\\mybarfile.bar");
      int deployStatus = server.getLastHttpResponse().getStatusCode();
      if (deployStatus >= 400)
      {
        System.out.println("Http response error: " + deployStatus );
      }
      else
      { // deploy worked, check for any Log entries
        LogEntry[] logEntries  = result.getLogEntry();
        if (logEntries != null)
        {
          for (LogEntry logEntry: logEntries)
          {
            System.out.println("Deploy log entry: "+logEntry.getDetailedText());
          }
        }
      }
    } catch (IntegrationAdminException e) {
      System.out.println("Error deploying: "+e);
    }
  }
}
```

If the deployment message could not be sent to the integration node, an `IntegrationAdminException` exception is thrown at the time of the deployment. If the integration node receives the deployment message, log messages for the overall deployment are displayed, followed by completion codes specific to each integration node that is affected by the deployment.

Managing integration nodes by using JavaCompute nodes

You can use the IBM Integration API to manage integration nodes and their associated resources from JavaCompute nodes in deployed message flows.

Before you begin

You must create a node in a message flow.

About this task

Use IBM Integration API methods and classes in your JavaCompute node to explore and manage integration nodes and other resources.

Procedure

1. Create the Java class for the node in which you want to include IBM Integration API methods.
2. Add the IBM Integration API JAR file (`IntegrationAPI.jar`), which is in the *`install_dir`*`/common/classes/` directory, to the Java build path for the associated Java project.
3. To work with the integration node, add the following constructor to your code:

   ```
   IntegrationNodeProxy node = new IntegrationNodeProxy();
   ```

   This method returns an instance of the IntegrationNodeProxy object for the integration node to which the message flow (that contains this node) is deployed.
4. To work with an integration server on this integration node, or an independent integration server, add the following constructor to your code:

   ```
   IntegrationServerProxy server = new IntegrationServerProxy();
   ```

   This method returns an instance of the IntegrationServerProxy object for the integration server to which the message flow is deployed.
5. If you want to connect to a different integration node on the computer to which your node and message flow are deployed, you can use a variant of this class:

   ```
   IntegrationNodeProxy node = new IntegrationNodeProxy(string);
   ```

   Specify the name of the alternative local integration node as the value of the variable *string*.
   Your code can manage this second integration node, and its associated resources, by using the IntegrationNodeProxy object that is returned by this call.
6. Include additional IBM Integration API methods in your Java code to run the operations that you want against the integration node or integration server by using the objects that are obtained by following the previous steps.

   You can follow the guidance that is provided in other topics in this section for further information and examples that show how to use IBM Integration API methods in custom integration applications.

   If you include methods that affect the message flow in which your custom integration application is running, it might not be able to receive all notifications that these operations are successfully complete. Stopping, deleting, and redeploying the message flow are examples in this category; consider carefully the consequences of using these methods.
7. Deploy the JAR file, and all associated message flows, in a BAR file.

   You do not have to deploy the `IntegrationAPI.jar` file to the target integration server, because the integration node can access these classes independently.

Creating objects by using a custom integration application

Create new objects associated with an integration node.

About this task

The following example adds an integration server called EG2 to the connected integration node.

```
import com.ibm.integration.admin.proxy.*;

public class AddIntegrationServer {

  public static void main(String[] args) {

    IntegrationNodeProxy node = new IntegrationNodeProxy("localhost",4414,"","",false);
    try {
      IntegrationServerProxy server = node.createIntegrationServer("EG2");
    } catch (IntegrationAdminException e) {
      System.out.println("Error connecting: "+e);
    }
  }
}
```

If the request to create the object described by the skeleton fails, all requests that use the skeleton also fail. Therefore, if integration server EG2 cannot be created, all subsequent requests that concern the skeleton object fail. However, unless the application explicitly checks for errors, it works in the same way as it does in the successful case, because no exception is thrown unless, because of a communication problem, a message cannot be sent to the integration node.

Developing applications using the IBM Integration API: Example code

Examples of IBM Integration API code for common tasks, to help you write your own Java code to develop message flow applications or modify user-defined patterns.

About this task

The IBM Integration API uses the `com.ibm.broker.appdev.*` classes in the `IntegrationAPI.jar` file.

The following topics show examples of Java code that you can use to complete common tasks:

Procedure

- “Running PHP code” on page 466
- “Saving a message flow file from memory” on page 466

Loading an existing message flow into memory

Use the IBM Integration API when developing message flow applications to load a message flow into memory. You can then access the message flow in your Java code.

You must load a message flow into memory to use it with the IBM Integration API methods within your Java code. To load a message flow into memory, create a `File` object and use the `read()` method of the `FlowRendererMSGFLOW`, which makes the message flow available for your Java code. The `read()` method takes the message flow project that contains the required message flow file and the relative path to the message flow file from this project.

The following example shows how to load a message flow that is in the `mqsi` directory:

```
import java.io.File;
import java.io.IOException;
import com.ibm.broker.MessageBrokerAPIException;
import com.ibm.broker.config.appdev.MessageFlow;
import com.ibm.broker.config.appdev.FlowRendererMSGFLOW;

public class LoadMessageFlow {
    public static void main(String[] args) {
        File msgFlow = new File("../mqsi/main.msgflow");
        try {
            MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
        } catch (IOException e) {
            // Add your own code here
            e.printStackTrace();
        } catch (MessageBrokerAPIException e) {
            // Add your own code here
            e.printStackTrace();
        }
    }
}
```

Pattern authoring

When you create patterns with the pattern authoring tool, use the `getMessageFlow()` method of the `PatternInstanceManager` object, which is automatically passed to your Java code. Modify a pattern instance to load a message flow into memory and make it available to other IBM Integration API methods.

The following example shows how to load a message flow that is in the default schema:

```
public class MyJava implements GeneratePatternInstanceTransform {
    public void onGeneratePatternInstance(PatternInstanceManager patternInstanceManager) {
        MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject",
 "main.msgflow");
        if (mf1 != null) {
           // Message flow was found
        }
        else {
           // Message flow was not found
        }
    }
}
```

The following example shows how to load a message flow that is in the `mqsi` schema:

```
public class MyJava implements GeneratePatternInstanceTransform {
    public void onGeneratePatternInstance(PatternInstanceManager patternInstanceManager) {
        MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "mqsi/
main.msgflow");
        if (mf1 != null) {
           // Message flow was found
        }
        else {
           // Message flow was not found
        }
    }
```

```
}
```

Renaming a node

Use the IBM Integration API when developing message flow applications to rename a node.

To rename a node, you must first access the required node. You can access the node by using the existing name of the node and the `getNodeByName()` method. You can then rename the node by using the `setNodeName()` method, which takes the new node name as a parameter.

The following example shows how to rename a node that is named `My Input Node`:

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
Node mqinNode = mf1.getNodeByName("My Input Node");
mqinNode.setNodeName("New Input Node");
```

Pattern authoring

The following example shows how to rename the previous example node for a pattern:

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
Node mqinNode = mf1.getNodeByName("My Input Node");
mqinNode.setNodeName("New Input Node");
```

Adding a node and a subflow node

Use the IBM Integration API when developing message flow applications to add a new node or subflow node to a message flow.

You can add a new built-in node, or a new subflow node to a message flow.

- When you add a subflow node by using the IBM Integration API, you must link the subflow node with the subflow message flow by using the `setSubFlow()` method of the subflow node object. For example, if you have assigned your subflow message flow to message flow instance *sub1* and you have assigned your subflow node to subflow node instance *sfNode*, you must use the following statement to link the subflow node with the subflow message flow:

  ```
  sfNode.setSubFlow(sub1);
  ```

- If you want to set a node property on a subflow node, use the `addNodeProperty()` method to set the property before you link the node to the subflow by using the `setSubFlow()` method. If you use `addNodeProperty()` after `setSubFlow()`, the node property might not be stored.

The following example shows you how to add a new built-in node:

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
MQInputNode mqinNode = new MQInputNode();
mqinNode.setNodeName("My Input Node");
mqinNode.setQueueName("INPUTQ");
mf1.addNode(mqinNode);
```

The following example shows you how to add a new subflow node to a message flow:

1. The new subflow node is added to the message flow held in object `mf1`.
2. The subflow node is linked to the subflow message flow by using the setSubFlow() method.
3. The subflow node name is set to `My Sub Flow Node`.
4. A new subflow node is created and assigned to object `sfNode`.

The subflow can be stored in a `.msgflow` format:

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
File subFlow = new File("subflow.msgflow");
```

```
MessageFlow sub1 = FlowRendererMSGFLOW.read(subFlow);
SubFlowNode sfNode = new SubFlowNode();
sfNode.setNodeName("My Sub Flow Node");
sfNode.setSubFlow(sub1);
mf1.addNode(sfNode);
```

The subflow can be stored in a `.subflow` format:

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
sFile subFlow = new File("subflow.subflow");
MessageFlow sub1 = FlowRendererMSGFLOW.read(subFlow);
SubFlowNode sfNode = new SubFlowNode();
sfNode.setNodeName("My Sub Flow Node");
sfNode.setSubFlow(sub1);
mf1.addNode(sfNode);
```

Pattern authoring

The following example shows you how to add a new built-in node to a pattern instance:

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
MQInputNode mqinNode = new MQInputNode();
mqinNode.setNodeName("My Input Node");
mqinNode.setQueueName("INPUTQ");
mf1.addNode(mqinNode);
```

The following example shows you how to add a new subflow node to a message flow:

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
MessageFlow sub1 = patternInstanceManager.getMessageFlow("MyFlowProject", "subflow.msgflow");
SubFlowNode sfNode = new SubFlowNode();
sfNode.setNodeName("My Sub Flow Node");
sfNode.setSubFlow(sub1);
mf1.addNode(sfNode);
```

Setting the position of a node

Use the IBM Integration API to set the position of a node on the canvas in the Application Development view.

Set the position of a node on the canvas by using the `setLocation()` method of the node object. The following example sets the position of a new MQOutput node to coordinates x=300 pixels, y=100 pixels:

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
MQOutputNode mqoutNode = new MQOutputNode();
mqoutNode.setLocation(300, 100);
```

Pattern authoring

The following example is the same as the previous, but for pattern authoring:

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
MQOutputNode mqoutNode = new MQOutputNode();
mqoutNode.setLocation(300, 100);
```

Copying a node

Use the IBM Integration API to copy a node or subflow node to a message flow.

You can copy a built-in or subflow node by using the `clone()` method. In the following example, a new MQInput node *mqinNode* is created and properties on the node are set. A new MQInput node *mqinNode1* is then created by copying *mqinNode* by using the `clone()` method. When the node is copied, the node properties are also copied.

Example:

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
MQInputNode mqinNode = new MQInputNode();
mqinNode.setNodeName("My Input Node");
mqinNode.setQueueName("INPUTQ");
MQInputNode mqinNode1 = (MQInputNode) mqinNode.clone();
mqinNode1.setNodeName("Copy of My Input Node");
mf1.addNode(mqinNode1);
```

Pattern authoring

The following example is the same as the previous, but for pattern authoring:

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
MQInputNode mqinNode = new MQInputNode();
mqinNode.setNodeName("My Input Node");
mqinNode.setQueueName("INPUTQ");
MQInputNode mqinNode1 = (MQInputNode) mqinNode.clone();
mqinNode1.setNodeName("Copy of My Input Node");
mf1.addNode(mqinNode1);
```

Removing a node

Use the IBM Integration API when developing message flow applications to remove a node from a message flow.

To remove a node, you must first get the required node from the message flow object. In the following example, the `getNodeByName()` method is used to get the required node from message flow object *mf1*. The node is then removed by using the `removeNode()` method. When a node is removed, any connections to or from the node are also removed.

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
Node mqinNode = mf1.getNodeByName("My Input Node");
mf1.removeNode(mqinNode);
```

Pattern authoring

The following example is the same as the previous, but for pattern authoring:

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
Node mqinNode = mf1.getNodeByName("My Input Node");
mf1.removeNode(mqinNode);
```

Adding connections between nodes

Use the IBM Integration API when developing message flow applications to add connections between nodes.

Pattern authoring

You can connect both subflow and built-in nodes. The first example shows you how to connect two built-in nodes. The second example shows you how to connect a built-in node to a subflow node.

To use the terminals of a subflow node, you must link the subflow node with the subflow message flow by using the `setSubFlow()` method of the subflow node object. For example, if you have assigned your subflow message flow to message flow instance *sub1* and you have assigned your subflow node to subflow node instance *sfNode*, you must use the following statement to link the subflow node with the subflow message flow:

```
sfNode.setSubFlow(sub1);
```

The following example shows you how to connect two built-in nodes:

1. A MQInput node and a Collector node are created.
2. The `getInputTerminal()` method is used to create a dynamic Input terminal called *NEWIN* on the Collector node.
3. The Input terminal is connected to the Output terminal of the MQInput node by using the `connect()` method of the message flow object *mf1*.

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
MQInputNode mqinNode = new MQInputNode();
mqinNode.setNodeName("My Input Node");
mqinNode.setQueueName("INPUTQ");
CollectorNode colNode = new CollectorNode();
colNode.getInputTerminal("NEWIN");
mf1.connect(mqinNode.OUTPUT_TERMINAL_OUT, colNode.getInputTerminal("NEWIN"));
```

To use a static terminal on a node, you must use the appropriate constant defined for it in the IBM Integration API. These constants are listed in the IBM Integration API javadoc, see IBM Integration API.

The following example shows you how to connect a subflow node to a built-in node. You must load the subflow message flow and link it to a subflow node. You must use the `getInputTerminal()`, `getInputTerminals()`, `getOutputTerminal()` or `getOutputTerminals()` method to access the terminal on the subflow node to which you want to connect. The example code completes the following steps:

1. The main message flow, `main.msgflow`, and a Compute node in the main message flow are loaded into memory.
2. The subflow message flow, subflow.msgflow, and the subflow node in the main message flow are loaded into memory.
3. The `setSubFlow()` method of the subflow node is used to link the subflow message flow *sub1* to the subflow node *sfNode*.
4. The `getOutputTerminal()` method is used to get the Process terminal of the subflow node. The `connect()` method of the message flow object is used to connect this terminal to the Input terminal of the Compute node.

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
ComputeNode compNode = (ComputeNode)mf1.getNodeByName("My Compute Node");
File subFlow = new File("subflow.msgflow");
MessageFlow sub1 = FlowRendererMSGFLOW.read(subFlow);
SubFlowNode sfNode = (SubFlowNode)mf1.getNodeByName("My Subflow Node");
sfNode.setSubFlow(sub1);
mf1.connect(sfNode.getOutputTerminal("Process"), compNode.INPUT_TERMINAL_IN);
```

The following example is the same as the previous example for connecting two build-in nodes, but for pattern authoring:

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
MQInputNode mqinNode = new MQInputNode();
mqinNode.setNodeName("My Input Node");
mqinNode.setQueueName("INPUTQ");
CollectorNode colNode = new CollectorNode();
colNode.getInputTerminal("NEWIN");
mf1.connect(mqinNode.OUTPUT_TERMINAL_OUT, colNode.getInputTerminal("NEWIN"));
```

The following example is the same as the previous example for using static terminals on a node, but for pattern authoring:

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
ComputeNode compNode = (ComputeNode)mf1.getNodeByName("My Compute Node");
MessageFlow sub1 = patternInstanceManager.getMessageFlow("MyFlowProject", "subflow.msgflow");
SubFlowNode sfNode = (SubFlowNode)mf1.getNodeByName("My Subflow Node");
sfNode.setSubFlow(sub1);
mf1.connect(sfNode.getOutputTerminal("Process"), compNode.INPUT_TERMINAL_IN);
```

Adding and connecting user-defined nodes

Use the IBM Integration API to add user-defined nodes and to connect user-defined nodes to other nodes.

The code required to add and connect user-defined node is different to the code required for built-in nodes and subflow nodes.

When you write Java code for user-defined nodes you must be aware of the following information:

- User-defined nodes are supported by instances of the `GenericNode` class. To add user-defined nodes to message flows, create instances of `GenericNode` and add them to the message flow instance.
- To retrieve existing instances of a user-defined node, call `getNodeByName()` and cast the returned object to a `GenericNode` object.
- The terminals defined on your user-defined nodes are not automatically available in the API. If you create an instance of a `GenericNode` class, it does not have any input or output terminals listed. The methods `getInputTerminals()` and `getOutputTerminals()` return empty lists.
- To get an input terminal for a `GenericNode`, call `getInputTerminal()` and pass the terminal name that exists on the generic node. This method returns the input terminal and makes it available in the message flow object that contains your generic node. After you have used `getInputTerminal()` with a known terminal name, this input terminal is returned if `getInputTerminals()` is used.
- To get an output terminal for a `GenericNode`, call `getOutputTerminal()` and pass the terminal name that exists on the generic node. This method returns the output terminal and makes it available in the message flow object that contains your generic node. After you have used `getOutputTerminal()` with a known terminal name, this output terminal is returned if `getOutputTerminals()` is used.

The following example shows how you can add a user-defined node to a message flow and connect it to a built-in node:

1. An MQInput node is created and added to the message flow.
2. A user-defined node is created by using the `GenericNode` class and is added to the message flow object.
3. The static output terminal of the MQInput is assigned to the variable *outputTerminal*.
4. The input terminal of the user-defined node is assigned to the variable *inputTerminal* by using the `getInputTerminal()` method with the known terminal name *In*.
5. The nodes are connected by using the `connect()` method.
6. The final section of code shows that the input node is now available for use in the message flow, by using the `getInputTerminals()` method of the user-defined node instance.

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);

MQInputNode mqinNode = new MQInputNode();
mqinNode.setNodeName("My Input Node");
mqinNode.setQueueName("IN");
mf1.addNode(mqinNode);

GenericNode myNode = new GenericNode("MyUserDefinedNode");
myNode.setNodeName("MyNode");
mf1.addNode(myNode);

OutputTerminal outputTerminal = mqinNode.OUTPUT_TERMINAL_OUT;
InputTerminal inputTerminal = myNode.getInputTerminal("In");
mf1.connect(outputTerminal, inputTerminal);

InputTerminal[] inputTerminals = myNode.getInputTerminals();
System.out.println("Input terminals on my node:");
for (int i = 0; i < inputTerminals.length; i++) {
   InputTerminal inputTerminal = inputTerminals[i];
   System.out.println(inputTerminal.getName());
}
```

Pattern authoring

The following example is the same as the previous example, but for pattern authoring:

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");

MQInputNode mqinNode = new MQInputNode();
mqinNode.setNodeName("My Input Node");
mqinNode.setQueueName("IN");
mf1.addNode(mqinNode);

GenericNode myNode = new GenericNode("MyUserDefinedNode");
myNode.setNodeName("MyNode");
mf1.addNode(myNode);

OutputTerminal outputTerminal = mqinNode.OUTPUT_TERMINAL_OUT;
InputTerminal inputTerminal = myNode.getInputTerminal("In");
mf1.connect(outputTerminal, inputTerminal);

InputTerminal[] inputTerminals = myNode.getInputTerminals();
System.out.println("Input terminals on my node:");
for (int i = 0; i < inputTerminals.length; i++) {
   InputTerminal inputTerminal = inputTerminals[i];
   System.out.println(inputTerminal.getName());
}
```

Removing connections between nodes

Use the IBM Integration API to remove connections between nodes.

You can disconnect two nodes by using the `disconnect()` method of the message flow object. You must provide this method with the names of the terminal instances that you want to disconnect.

The following example shows how you can disconnect two nodes:

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
MQInputNode mqinNode = (MQInputNode)mf1.getNodeByName("My Input Node");
MQOutputNode mqoutNode = (MQOutputNode)mf1.getNodeByName("My Output Node");
mf1.disconnect(mqinNode.OUTPUT_TERMINAL_OUT, mqoutNode.INPUT_TERMINAL_IN);
```

Pattern authoring

The following example is the same as the previous example, but for pattern authoring:

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
MQInputNode mqinNode = (MQInputNode)mf1.getNodeByName("My Input Node");
MQOutputNode mqoutNode = (MQOutputNode)mf1.getNodeByName("My Output Node");
mf1.disconnect(mqinNode.OUTPUT_TERMINAL_OUT, mqoutNode.INPUT_TERMINAL_IN);
```

Creating or changing user-defined properties

Use the IBM Integration API to create or change user-defined properties (UDPs).

You can create new UDPs and add them to the message flow, or you can discover existing UDPs and modify them.

The following example shows you how to create a UDP and add it to a message flow:

1. A UDP called `Property1` is created in parameter group `Group1`. The data type of the UDP is defined as a string, and the UDP is given the default value `Hello World!`
2. The UDP is then added to the message flow by using the `addFlowProperty()` method.

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
UserDefinedProperty udp = new UserDefinedProperty("Group1", "Property1",
 UserDefinedProperty.Usage.MANDATORY, UserDefinedProperty.Type.STRING, "Hello World!");
mf1.addFlowProperty(udp);
```

In the following example, the existing UDPs in a message flow are discovered by using the `getFlowProperties()` method on the message flow. The `setName()` method is then used to set the name of the first UDP to `Property3`:

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
Vector<FlowProperty> flowProperties = mf1.getFlowProperties();
flowProperties.get(0).setName("Property3");
```

You can also modify user-defined properties by using the administration REST API, as described in "Setting message flow user-defined properties at run time by using the administration REST API" on page 436.

Pattern authoring

The following examples are the same as the previous UDP examples, but for pattern authoring:

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
UserDefinedProperty udp = new UserDefinedProperty("Group1", "Property1",
 UserDefinedProperty.Usage.MANDATORY, UserDefinedProperty.Type.STRING, "Hello World!");
mf1.addFlowProperty(udp);
```

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
Vector<FlowProperty> flowProperties = mf1.getFlowProperties();
flowProperties.get(0).setName("Property3");
```

Changing pattern parameter values

Use the IBM Integration API to modify a pattern instance to change pattern parameter values.

You can change a pattern parameter value by using the `PatternInstanceManager` object.

The following example sets the value of the pattern parameter with the pattern parameter ID `pp1` to `true`:

```
patternInstanceManager.setParameterValue("pp1", "true");
```

Reading table values

Use the IBM Integration API to read table values by accessing and extracting table values.

To read table values, you must first access the table and then extract the data from each row. To read the table values, use one of the following examples:

Use this example to access and extract the table values by providing the name of the columns. In this example, *noRows* is the number of rows in the table, *value* is the parameter that stores the table value, *column* is the name of the column in the table, and *pp3* is the parameter ID.

```
PatternParameterTable paramtable = pim.getParameterTable("pp3");
int noRows = paramtable.getRowCount();
String value;
PatternParameterRow row;
for(int i=0; i<noRows; i++) {
    row = paramtable.getRow(i);
    value = row.getValue("column");
    //insert your code here
}
```

Alternatively, if you do not provide the name of the columns, you can use this example to access and extract the table values by using the `getColumns()` method. In this example, *noColumns* is the number of columns in the table, *value* is the parameter that stores the table value, *columns* is an array containing the names of the columns in the table, and *pp3* is the parameter ID.

```
PatternParameterTable paramtable = pim.getParameterTable("pp3");
int noRows = paramtable.getRowCount();
PatternParameterRow row;
```

```
String[] columns;
String value;
for(int i=0; i<noRows; i++) {
    row = paramtable.getRow(i);
    columns = row.getColumns();
    int noColumns = columns.length;
    for(int j=0; j<noColumns; j++) {
        value = row.getValue(columns[j]);
        //insert your code here
    }
```

Creating ESQL modules

Use the IBM Integration API when developing message flow applications to create ESQL modules. You can then associate ESQL modules with nodes that use ESQL. For example, if you create a Compute node, you can write Java code to create an ESQL module and then associate that module with the node.

Examples of nodes that use ESQL are Compute, Database, DatabaseInput, and Filter nodes. If you are using a non-default broker schema, you must set the schema by using the `setBrokerSchema()` method.

The following example shows you how to create an ESQL module in the `mqsi` schema. The module is then assigned to a new Compute node by using the `setComputeExpression()` method:

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
ESQLModule module = new ESQLModule();
module.setBrokerSchema("mqsi");
module.setEsqlMain("MyESQLMain");
ComputeNode compNode = new ComputeNode();
compNode.setNodeName("My Compute Node");
compNode.setComputeExpression(module);
mf1.addNode(compNode);
```

The following example shows you how to create an ESQL module in the default schema. The `setBrokerSchema()` method is not required.

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
File esql = new File("FileBatchProcessingSample_Branch.esql");
ESQLFile esqlFile = new ESQLFile(esql);
Vector<ESQLModule> esqlModules = esqlFile.getEsqlModules();
ComputeNode compNode = new ComputeNode();
compNode.setNodeName("My Compute Node");
compNode.setComputeExpression(esqlModules.get(0));
mf1.addNode(compNode);
```

The following example shows you how to discover an ESQL module from within an ESQL file by using the `getEsqlModules()` method. You can then use the ESQL module to set the compute expression on a Compute node by using the `setComputeExpression()` method.

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
File esql = new File("FileBatchProcessingSample_Branch.esql");
ESQLFile esqlFile = new ESQLFile(esql);
Vector<ESQLModule> esqlModules = esqlFile.getEsqlModules();
ComputeNode compNode = new ComputeNode();
compNode.setNodeName("My Compute Node");
compNode.setComputeExpression(esqlModules.get(0));
mf1.addNode(compNode);
```

Pattern authoring

The following examples are the same as the three previous examples, but tailored for pattern authoring:

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
ESQLModule module = new ESQLModule();
module.setBrokerSchema("mqsi");
module.setEsqlMain("MyESQLMain");
ComputeNode compNode = new ComputeNode();
compNode.setNodeName("My Compute Node");
compNode.setComputeExpression(module);
```

```
mf1.addNode(compNode);
```

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
ESQLModule module = new ESQLModule();
module.setEsqlMain("MyESQLMain");
ComputeNode compNode = new ComputeNode();
compNode.setNodeName("My Compute Node");
compNode.setComputeExpression(module);
mf1.addNode(compNode);
```

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
File esql = new File("FileBatchProcessingSample_Branch.esql");
ESQLFile esqlFile = new ESQLFile(esql);
Vector<ESQLModule> esqlModules = esqlFile.getEsqlModules();
ComputeNode compNode = new ComputeNode();
compNode.setNodeName("My Compute Node");
compNode.setComputeExpression(esqlModules.get(0));
mf1.addNode(compNode);
```

Renaming a message flow

Use the IBM Integration API when developing message flow applications to rename message flows.

You can write code to rename a message flow by using the `setName()` method. In the following example, a message flow file called `main.msgflow` is renamed to `mainGenerated.msgflow`.

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
mf1.setName(mf1.getName()+"Generated");
```

Pattern authoring

The following example is the same as the previous example, but for pattern authoring:

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
mf1.setName(mf1.getName()+"Generated");
```

Updating filter tables on Route nodes

Use the IBM Integration API to update filter tables on Route nodes.

You can add and update rows on the filter table of a Route node.

Adding a new row

The following example shows you how to add a new row to a filter table by using the `createRow()` method:

1. The message flow and the Route node are loaded into memory.
2. The filter table of the Route node is loaded into memory by using the `getFilterTable()` method of the RouteNode object.
3. A new filter table row is created by using the `createRow()` method.
4. The value of the `filter pattern` property on this new row is set to `value="123"` by using the `setFilterPattern()` method.
5. The `routing output terminal` property is set to NEWOUT by using the `setRoutingOutputTerminal()` method.
6. The new row is then added to the filter table by using the `addRow()` method.

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
RouteNode routeNode = (RouteNode)mf1.getNodeByName("My Route Node");
RouteNode.FilterTable filterTable = (RouteNode.FilterTable)routeNode.getFilterTable();
RouteNode.FilterTableRow newRow = filterTable.createRow();
newRow.setFilterPattern("value=\"123\"");
newRow.setRoutingOutputTerminal("NEWOUT");
filterTable.addRow(newRow);
```

Updating a row

The following example shows you how to update rows on the filter table of a Route node.

1. The message flow, Route node, and filter table of the Route node are loaded into memory.
2. The rows of the filter table are loaded into memory by using the `getRows()` method.
3. The `filter pattern` property of the first row of the filter table is set to `value2="456"`.
4. The `routing output terminal` property of the first row of the filter table is set to `NEWOUT2`.

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
RouteNode routeNode = (RouteNode)mf1.getNodeByName("My Route Node");
RouteNode.FilterTable filterTable = (RouteNode.FilterTable)routeNode.getFilterTable();
Vector<RouteNode.FilterTableRow> filterTableRows = filterTable.getRows();
filterTableRows.get(0).setFilterPattern("value2=\"456\"");
filterTableRows.get(0).setRoutingOutputTerminal("NEWOUT2");
```

Pattern authoring

The following examples are the same as the previously described examples, but for pattern authoring:

Adding a new row

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
RouteNode routeNode = (RouteNode)mf1.getNodeByName("My Route Node");
RouteNode.FilterTable filterTable = (RouteNode.FilterTable)routeNode.getFilterTable();
RouteNode.FilterTableRow newRow = filterTable.createRow();
newRow.setFilterPattern("value=\"123\"");
newRow.setRoutingOutputTerminal("NEWOUT");
filterTable.addRow(newRow);
```

Updating a row

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
RouteNode routeNode = (RouteNode)mf1.getNodeByName("My Route Node");
RouteNode.FilterTable filterTable = (RouteNode.FilterTable)routeNode.getFilterTable();
Vector<RouteNode.FilterTableRow> filterTableRows = filterTable.getRows();
filterTableRows.get(0).setFilterPattern("value2=\"456\"");
filterTableRows.get(0).setRoutingOutputTerminal("NEWOUT2");
```

Running PHP code

Use the IBM Integration API to modify a pattern instance to run PHP scripts from within your Java code.

You can run PHP scripts from within the IBM Integration API by using the `runScript()` method of the PatternInstanceManager object. In the following example, the IBM Integration API runs a PHP script in the `com.your.company.domain.code` plug-in, `templates/script.php`.

```
@Override
public void onGeneratePatternInstance (PatternInstanceManager patternInstanceManager) {
 patternInstanceManager.runScript("com.your.company.domain.code", "templates/script.php");
}
```

Saving a message flow file from memory

Use the IBM Integration API when developing message flow applications to save a message flow from memory.

Save a message flow to a message flow file to preserve additions and modifications that you have made. To save a message flow from memory, use the `write()` method of the `FlowRendererMSGFLOW` object. The `write()` method writes all the changes made using the IBM Integration API to the specified message flow file.

The schema for a message flow is stored in the message flow, and cannot be modified by using the IBM Integration API. When you save your message flow file by using the IBM Integration API, the file is saved to a directory that has the same name as the schema. If the directory does not exist, it is created. For

example, if your message flow is part of the `mqsi` schema, when you save the message flow file it is saved to the `mqsi` directory.

The following example shows how to save a message flow in the specified directory by using the `write()` method. On Windows, if the message flow is part of the `mqsi` schema, the message flow file is saved to `C:\MB\mqsi\main.msgflow`.

```
File msgFlow = new File("main.msgflow");
MessageFlow mf1 = FlowRendererMSGFLOW.read(msgFlow);
FlowRendererMSGFLOW.write(mf1,"C:\MB");
```

The IBM Integration API samples

Explore the samples to learn the basic features that are provided by the IBM Integration API.

Deploy BAR

The Deploy BAR sample deploys a BAR file to an integration server, and displays the outcome. Read about this sample in "Running the IBM Integration API Deploy BAR file sample" on page 467.

Modify IBM Integration API samples

You can modify the IBM Integration API samples, and change various parameters that affect how the samples run. Read "Modifying the IBM Integration API samples" on page 468 and follow the guidance given about possible changes.

Running the IBM Integration API Deploy BAR file sample

Run the IBM Integration API Deploy BAR file sample to deploy a BAR file to an integration server.

Before you begin

- You must have an integration node and an integration server that are started.
- You must have a BAR file.

About this task

Use the *Deploy BAR file* sample to deploy a BAR file to an integration server, and display the outcome. The *Deploy BARfile* sample consists of one file:

- Windows On Windows: *install_dir*`\server\sample\admin\IntegrationAPI\DeployBAR.java`
- Linux UNIX On other platforms: *install_dir*`/server/sample/admin/IntegrationAPI/DeployBAR.java`.

Procedure

1. Run the *Deploy BAR file* sample by compiling and then running `DeployBAR.java` for your platform, with the parameters *host_name*, *port_number*, *int_server_name*, and *bar_file_name*,

   where:

   host_name
   Specifies the host name of the integration node; for example `localhost`.

   port_number
   Specifies the port number of the integration node; for example 4414.

   int_server_name
   Specifies the name of the integration server; for example `default`.

   bar_file_name
   Specifies the name of the BAR file; for example `mybar.bar`.

   The IBM Integration API connects to the integration node by using the host name and port that are specified. Next, the IBM Integration API deploys the specified BAR file to the specified integration server. The following message is displayed to confirm the actions.

   ```
   Connecting to the integration node running at host_name:port_number...
   Discovering integration server 'int_server_name'...
   Deploying bar_file_name...
   Result = success
   ```

2. Check the results of the sample by viewing the integration node in the IBM App Connect Enterprise Toolkit.

Modifying the IBM Integration API samples

Modify the IBM Integration API samples to change the parameters that they use to complete their tasks.

About this task

If you change a sample, you must recompile the source code to implement those changes. For example, you might choose to change the default connection parameters. If you modify these and other values, you change the behavior of the sample.

To modify a sample, perform the following steps:

Procedure

1. Set up the environment by following the instructions provided in "Configuring an environment for developing and running custom integration applications" on page 444.
2. Locate the source file for the sample that you want to change.

   The source files for the samples are located in the following directories:

   Deploy BAR sample
   install_dir`/server/sample/admin/IntegrationAPI/DeployBar.java`

   Integration node info sample
   install_dir`/server/sample/admin/IntegrationAPI/IntegrationNodeInfo.java`

   Integration node operations sample
   install_dir`/server/sample/admin/IntegrationAPI/IntegrationNodeOperations.java`
3. Open the source file, and modify the appropriate parameters.
4. Save and recompile the source file.

What to do next

Run the modified sample by following the instructions in the appropriate link:

- “Running the IBM Integration API Deploy BAR file sample” on page 467

Managing resources by using the IBM App Connect Enterprise web user interface

Use the IBM App Connect Enterprise web user interface to manage resources.

Before you begin

Understand how you can access the IBM App Connect Enterprise web user interface. For more information, see “Accessing the web user interface” on page 89.

About this task

You can use the IBM App Connect Enterprise web user interface to manage resources. For more information, see the following topics:

- “Applying a user-defined property override in the IBM App Connect Enterprise web user interface” on page 469.
- “Removing a user-defined property override in the IBM App Connect Enterprise web user interface” on page 470.
- “Update the message flow thread pool by using the IBM App Connect Enterprise web user interface” on page 472.

Applying a user-defined property override in the IBM App Connect Enterprise web user interface

You can apply a user-defined property override by using the IBM App Connect Enterprise web user interface.

Before you begin

Read the following topics:

- “User-defined properties” on page 569
- “Setting message flow user-defined properties at run time by using the administration REST API” on page 436

About this task

User-defined property overrides are not persistent, which means that they must be reapplied after the integration node or integration server is restarted.

You can also remove a user-defined property override by using the IBM App Connect Enterprise administration REST API, as described in “Removing a user-defined property override in the IBM App Connect Enterprise web user interface” on page 470.

Procedure

1. Start the web user interface, by using one of the following methods:
   - **From the IBM App Connect Enterprise Toolkit:** In the toolkit, right-click the integration node or server and select **Start web user interface** from the menu.
   - **From a web browser:** Enter the URL for the web user interface into a web browser, in the following form:

     protocol`://`*hostname*`:`*port*

     where:

     – *protocol* is either `http` or `https`
     – *hostname* is the host that you specified in the **`host`** property in the `.yaml` configuration file for the integration node or server (for example, `localhost` or `127.0.0.1`)
     – *port* identifies the port that is to be used for the web user interface and the toolkit, and must match the value that you set for the **`port`** property in the `.yaml` configuration file. By default the port is set to 4414.

     Examples:

     ```
     https://localhost:4414
     ```

     or

     ```
     https://127.0.0.1:4414
     ```
2. In the web user interface, click the **Open List of Options** icon for the required integration server, and select **Open** from the drop-down menu.
   - If you are viewing all the available servers under the **Servers** tab, the **Open List of Options** icon appears within the tile for each integration server.
   - If you are viewing the content of an integration server under the **Contents** tab, the **Open List of Options** icon appears in the title bar for the integration server.
3. Click the **Open List of Options** icon for the required application, and select **Open** from the drop-down menu. The **Open List of Options** icon appears within the tile for each deployed application.
4. Click the **Open List of Options** icon for the required message flow, and select **Open** from the drop-down menu. The **Open List of Options** icon appears within the tile for each message flow.
5. Select the **Properties** tab for the message flow. The properties tab has a list of properties and a list of user-defined properties.
6. Click **Override user-defined-property** to open the **Override user-defined-property** wizard.
7. In the drop-down menu in the **Override user-defined-property** wizard, select the user-defined property that you want to override.
8. In the **Value** field, type in the new value for the user-defined property.
9. Click **Apply**.

   The new value appears in the list of user-defined properties. The **Remove override** button appears next to the **Override user-defined-property** button. The **Override user-defined-property** wizard closes.

Removing a user-defined property override in the IBM App Connect Enterprise web user interface

You can remove a user-defined property override by using the IBM App Connect Enterprise web user interface.

Before you begin

Read the following topics:

- "User-defined properties" on page 569
- "Setting message flow user-defined properties at run time by using the administration REST API" on page 436

About this task

You can also apply a user-defined property override by using the IBM App Connect Enterpriseweb user interface. For more information, see "Applying a user-defined property override in the IBM App Connect Enterprise web user interface" on page 469.

Procedure

1. Start the web user interface, by using one of the following methods:
   - **From the IBM App Connect Enterprise Toolkit:** In the toolkit, right-click the integration node or server and select **Start web user interface** from the menu.
   - **From a web browser:** Enter the URL for the web user interface into a web browser, in the following form:

     protocol`://`*hostname*`:`*port*

     where:

     – *protocol* is either `http` or `https`
     – *hostname* is the host that you specified in the **`host`** property in the `.yaml` configuration file for the integration node or server (for example, `localhost` or `127.0.0.1`)
     – *port* identifies the port that is to be used for the web user interface and the toolkit, and must match the value that you set for the **`port`** property in the `.yaml` configuration file. By default the port is set to 4414.

     Examples:

     ```
     https://localhost:4414
     ```

     or

     ```
     https://127.0.0.1:4414
     ```
2. In the web user interface, click the **Open List of Options** icon for the required integration server, and select **Open** from the drop-down menu.
   - If you are viewing all the available servers under the **Servers** tab, the **Open List of Options** icon appears within the tile for each integration server.
   - If you are viewing the content of an integration server under the **Contents** tab, the **Open List of Options** icon appears in the title bar for the integration server.
3. Click the **Open List of Options** icon for the required application, and select **Open** from the drop-down menu. The **Open List of Options** icon appears within the tile for each deployed application.
4. Click the **Open List of Options** icon for the required message flow, and select **Open** from the drop-down menu. The **Open List of Options** icon appears within the tile for each message flow.
5. Select the **Properties** tab for the message flow. The properties tab has a list of properties and a list of user-defined properties.
6. Click **Remove override** to open the **Remove user-defined property override** wizard.
7. In the drop-down menu in the **Remove user-defined property override** wizard, select the user-defined property override that you want to remove.
8. Click **Remove**.

   The original value of the user-defined property appears in the list of user-defined properties. The **Remove override** button continues to appear next to the **Override user-defined-property** button

unless all of the user-defined property overrides are removed. The **Remove user-defined property override** wizard closes.

Update the message flow thread pool by using the IBM App Connect Enterprise web user interface

You can change the number of threads for a message flow by using the IBM App Connect Enterprise web user interface to update the size of the thread pool for the message flow.

Before you begin

Read the following topic:

- "Workload management" on page 2873

Procedure

1. Start the web user interface, by using one of the following methods:
   - **From the IBM App Connect Enterprise Toolkit:** In the toolkit, right-click the integration node or server and select **Start web user interface** from the menu.
   - **From a web browser:** Enter the URL for the web user interface into a web browser, in the following form:

     protocol`://`*hostname*`:`*port*

     where:

     – *protocol* is either `http` or `https`
     – *hostname* is the host that you specified in the **`host`** property in the `.yaml` configuration file for the integration node or server (for example, `localhost` or `127.0.0.1`)
     – *port* identifies the port that is to be used for the web user interface and the toolkit, and must match the value that you set for the **`port`** property in the `.yaml` configuration file. By default the port is set to 4414.

     Examples:

     ```
     https://localhost:4414
     ```

     or

     ```
     https://127.0.0.1:4414
     ```
2. In the web user interface, click the **Open List of Options** icon for the required integration server, and select **Open** from the drop-down menu.
   - If you are viewing all the available servers under the **Servers** tab, the **Open List of Options** icon appears within the tile for each integration server.
   - If you are viewing the content of an integration server under the **Contents** tab, the **Open List of Options** icon appears in the title bar for the integration server.
3. Click the **Open List of Options** icon for the required application, and select **Open** from the drop-down menu. The **Open List of Options** icon appears within the tile for each deployed application.
4. Click the **Open List of Options** icon for the required message flow, and select **Open** from the drop-down menu. The **Open List of Options** icon appears within the tile for each message flow.
5. Select the **Properties** tab for the message flow.
6. Select the **Open List of Options** icon that appears in the title bar for the message flow.
7. Click **Update thread pool** to open the **Update thread pool** wizard.
8. In the **Thread pool size** field in the **Update thread pool** wizard, type in the new value, or use the up and down arrow keys to select the new value.

9. Optional: Select the checkbox for **Start all threads immediately on flow start**.
10. Optional: Select the checkbox for **Delete and recreate the thread pool**.
11. Click **Apply**.

    The new values appear for the following properties in the **Properties** tab for the message flow:

    - *Thread capacity*
    - *Thread instances start immediately*
    - *Threads*
    - *Threads in use*

    The **Update thread pool** wizard closes.

Administering Java applications

Manage the Java applications that are deployed to an integration node.

About this task

You can deploy message flows that contain Java applications to an integration node. The Java code is run within a JVM that is created by the integration server. The JVM runs in the same process as other integration node components such as message parsing and nodes that are not Java-based.

Administration of Java applications includes the following tasks:

- "Tuning JVM parameters" on page 473
- "Configuring class loaders for Java user-defined nodes" on page 473
- "Configuring class loaders for JavaCompute nodes" on page 473
- "Configuring class loaders for ESQL routines" on page 474

Tuning JVM parameters

About this task

Use the **mqsichangeproperties** command to tune the JVM parameters to ensure that there are sufficient resources for all the Java applications that are deployed to the integration server. For more details, see command and JVM parameter values.

Configuring class loaders for Java user-defined nodes

About this task

Java user-defined nodes are manually installed onto an integration node as either a PAR file or a JAR file. Because PAR and JAR files are only loaded by the integration node on startup, the integration node must be restarted. For more details, see "Packaging a Java user-defined node " on page 2450.

A PAR file is given its own Java class loader, ensuring that the node classes are isolated from any other node classes.

For more details, see "User-defined node class loading" on page 2451.

Configuring class loaders for JavaCompute nodes

About this task

A JavaCompute node is deployed to an integration server as part of a BAR file. A JavaCompute node can specify a Java Class Loader policy to be used by the node. A Java Class Loader policy defines the behavior of the class loaders that are used by the node (see "JavaCompute node class loading" on page 1754).

If a JavaCompute node specifies a Java Class Loader policy, you must define a policy with the name that is specified by the node (see "JavaCompute node class loading by using a policy" on page 1754).

Configuring class loaders for ESQL routines

About this task

You can identify Java methods to invoke from ESQL routines by using the CREATE FUNCTION statement or the CREATE PROCEDURE statement with a LANGUAGE clause of JAVA. You use the EXTERNAL NAME clause of the statement to specify the fully-qualified class and name of the method. To find the Java class that contains a method, the integration node uses the search algorithm that is described in Deploying Java classes. You can optionally specify a Java Class Loader policy when you identify a Java method in this way. The Java Class Loader policy defines the behavior of the class loader that is used to load the class specified in the EXTERNAL NAME clause. If you include a CLASSLOADER clause in a CREATE FUNCTION statement or a CREATE PROCEDURE statement, you must ensure that the corresponding policy is defined on the integration node. For more details, see Java Class Loader policy (JavaClassLoader).

ESQL Java routines and JavaCompute nodes that specify the same Java Class Loader policy share one instance of the class loader. Therefore, the nodes and the routines use the same in-memory version of Java classes, and have access to the same static variables. The class-loading mechanism for ESQL routines is the same as for JavaCompute nodes; for more details, see "JavaCompute node class loading by using a policy" on page 1754.

Changing the location of the IBM App Connect Enterprise working directory

The IBM App Connect Enterprise working directory is the location where components store internal data, such as installation logs, component details, and trace output. The shared-classes directory is also located in the work path directory and is used for deployed Java code. If the working directory does not have enough capacity, redirect the directory to another file system that has enough capacity.

About this task

The IBM App Connect Enterprise working directory[1] is fixed at installation time so that IBM App Connect Enterprise can always find the information that it needs, and always knows where to store new information.

If you need to change the location (for example, if you do not have enough capacity on the automatically-designated file system), do not change the path to the directory; instead, redirect the original working directory to a new location.

Note: When you create an integration node, you can specify a separate working directory for that integration node. For more information about this, see the -w *workPath* parameter of the command.

Procedure

- "Changing the location of the working directory on Windows systems" on page 474
- "Changing the location of the working directory on Linux " on page 475

Changing the location of the working directory on Windows systems

About this task

When you change the location of the IBM App Connect Enterprise working directory, you mount a new partition at the location of the original working directory.

[1] This working directory is sometimes referred to as the IBM App Connect Enterprise work path directory.

To change the location of the working directory on Windows, complete the following steps:

Procedure

1. Shut down all IBM App Connect Enterprise services and processes.
2. Create a new partition on the system.
   The new partition can be on the same drive as the original working directory, or on a different drive.
3. In the IBM App Connect Enterprise Console, locate the working directory for your installation on the local system by running the following command:

   ```
   echo %MQSI_WORKPATH%
   ```
4. Copy the contents of the working directory to the new partition.
5. Delete the contents of the original working directory.
6. Open the Computer Management dialog:
   Click **Start** > **Settings** > **Control Panel** > **Administrative Tools** > **Computer Management**.
   The Computer Management dialog opens.
7. In the left pane of the Computer Management dialog, click **Disk Management**.
   The new partition that you added, and any existing partitions, are listed in the right pane.
8. Right-click the new partition, then click **Change Drive Letter and Paths**.
   The Change Drive Letter and Paths dialog opens.
9. Click **Add**.
   The Add Drive Letter or Path dialog opens.
10. Ensure that **Mount in the following empty NTFS folder** is selected, then browse to the original working directory location.
11. Click **OK**, then click **OK** again.

Results

Any files that IBM App Connect Enterprise creates in the working directory location are stored on the new partition.

Changing the location of the working directory on Linux

About this task

When you change the location of the IBM App Connect Enterprise working directory, you can either mount a new partition at the location of the original working directory, or you can replace the original working directory with a soft link that points to a new working directory.

To change the location of the working directory on Linux, complete the following steps:

Procedure

1. Shut down all IBM App Connect Enterprise services and processes.
2. Create a new directory on a suitable file system.
3. Locate the working directory for your installation on the local system by running the following command:

   ```
   echo $MQSI_WORKPATH
   ```
4. Copy the contents of the working directory to the new partition.
5. Delete the contents of the original working directory.

6. Perform one of the following tasks so that the IBM App Connect Enterprise installation uses the new working directory location:
   - Use the **mount** command to mount the new working directory at the location of the original working directory.
   - Delete the original working directory and replace it with a soft link. Give the soft link the same name as the original working directory and point the link to the new working directory.

Results

Any files that IBM App Connect Enterprise creates in the working directory location are stored in the new location.

Backing up the IBM App Connect Enterprise Toolkit workspace

The IBM App Connect Enterprise Toolkit workspaces contain your personal settings and data, such as message flow and message set resources. You can have multiple workspaces in different locations, and you can also have references to projects that are in other locations, therefore consider all these locations when you back up your resources.

About this task

The default workspace directory for the IBM App Connect Enterprise Toolkit depends on the platform on which it is running:

- 

On Windows, the default workspace directory is created at `C:\Users\`*`user_name`*`\IBM\ACET12\workspace`.
- 

On Linux, the default workspace directory is created at `$HOME/IBM/ACET12/workspace`.

where *user_ID* is the user name with which you are logged on. Back up files in these locations, and in all other locations in which you have saved workspace files.

The IBM App Connect Enterprise Toolkit workspace directory contains a directory called `.metadata`, which contains your personal settings and preferences for the IBM App Connect Enterprise Toolkit. If the `.metadata` directory gets corrupted, you lose these settings, and the IBM App Connect Enterprise Toolkit reverts to the default layout and preferences. If you have not backed up the `.metadata` directory, you must manually set all preferences again, and import all projects, such as message flow projects, that were displayed in the Application Development view. To back up the `.metadata` directory, take a copy of the directory.

The IBM App Connect Enterprise Toolkit workspace also contains a directory for each project (for example, a message flow project) that you have created in the IBM App Connect Enterprise Toolkit. These directories contain your data, which you must back up.

Use one of the following methods to back up the data in your workspace.

Procedure

- Export your working projects.

  You can export the projects directly as a compressed file. For further information, see *Exporting* in the Eclipse Workbench User Guide.
- Copy the project directories from the workspace directory to another location.
- Copy all your BAR files to back up their contents.

  Include all the associated source files when you build your BAR files; you can then save all content by saving only the BAR file. To add resources to a BAR file that is ready for deployment, select **Include source files**, which adds the message flow and message set source files, and the compiled files.

What to do next

If you want to restore the resources, copy the directories back into your workspace directory and import the projects. For instructions, see *Importing* in the Eclipse Workbench User Guide.

Backing up resources

Back up your integration node components, and the working files associated with integration nodes and the IBM App Connect Enterprise Toolkit, so that you can restore these resources if required.

About this task

Back up your integration node components regularly to ensure that you can return to a known operational state if necessary. In addition to configuration and operation state, the integration node maintains additional resources in its work path, and you can request that these resources are also backed up.

Back up the workspaces you have created in the IBM App Connect Enterprise Toolkit; these resources contain your application development resources; for example message flows and message model schema files. If you use a development repository to store application resources, such as Rational ClearCase, see the documentation associated with that repository to check how you can back up this data.

The following topics tell you how to back up and restore integration nodes and the IBM App Connect Enterprise Toolkit workspace:

- “Backing up the integration node” on page 477
- “Restoring the integration node” on page 478
- “Backing up the IBM App Connect Enterprise Toolkit workspace” on page 476

On distributed systems, you can use the backed up components to restore the integration node only on an identical operating environment. The operating system must be at the same level, and the integration node and queue manager names must be identical.

Backing up the integration node

Back up the integration node configuration and all associated resources.

Before you begin

Create the integration node.

About this task

You can back up the integration node and its resources to preserve the current state of the integration node configuration. You can use the backup file that is created to restore an integration node in an identical operating environment: the operating system must be at the same level, and the integration node and queue manager names must be identical.

You can run this command for an integration node that is active. However, you must not take a backup while the integration node is processing configuration changes and deployments; the backup file created might contain incomplete information. If the file contains partial records, you cannot use it to restore the integration node at a later time.

To ensure that the backup is complete and correct, take a backup either when the integration node is not processing a configuration change (such as a deployment or change property) or when the integration node is stopped.

Procedure

1. If you want to back up an active integration node, check that no configuration change requests are in progress.

   For example, if you are changing integration node properties, or have initiated a deployment, wait for these actions to complete before you back up the integration node. Active message flows are unaffected by the backup process.

   If you prefer, you can stop the integration node before you take a backup by using the **mqsistop** command.
2. Back up the integration node.

   Specify the integration node name and the location in which the backup file is created. You can also optionally specify the name of the backup file, and the name of a file to which a detailed trace is written.

   - Linux Windows UNIX Run the **mqsibackupbroker** command, specifying the integration node name and the directory to which the backup file is written.

     For example, to back up an integration node on Windows, enter the following command:

     ```
     mqsibackupbroker INODE -d c:\MQSI\BACKUP
     ```
3. When the command has completed successfully, you can continue to use the integration node.

   If you stopped the integration node, restart it by using the **mqsistart** command.

Results

The current integration node configuration is saved in the backup file. Keep the file safe so that you can restore the integration node at a later date if required.

Restoring the integration node

Restore an integration node configuration that you backed up previously.

Before you begin

Back up the integration node.

About this task

You can restore an integration node on a computer that has an identical configuration by using the backup file that you created. The operating system must be at the same level, and the integration node and queue manager names must be identical.

Procedure

1. If you have deleted the integration node and it no longer exists, or if you are restoring it on a different computer, create it by using the **mqsicreatebroker** command.

   Use the same name and parameters that you used for the integration node that you backed up.
2. If the integration node is running, stop it by using the **mqsistop** command.

   If you intend to restore common configuration information from other integration nodes that you have configured on this computer, you must also stop all the integration nodes that share this common information. For example, you can restore profile information from common files.

3. Restore the integration node.

   Specify the integration node name and the name and location of the backup file. If you want to restore common configuration information, or if you want a trace of the actions that are taken, specify the appropriate parameters for your platform.

   - 
     Run the **mqsirestorebroker** command.

     For example, to restore an integration node on Windows, enter the following command:

     ```
     mqsirestorebroker WBRK_BROKER -d c:\MQSI\BACKUP -a mybroker.zip
     ```

4. When the command has completed successfully, start the integration node by using the **mqsistart** command. If the integration node has an associated queue manager, it must be running before you restart the integration node.

What to do next

The integration node configuration has been restored; you can continue your work with this integration node.

Chapter 6. Developing integration solutions

IBM App Connect Enterprise provides a flexible environment in which you can develop integration solutions to transform, enrich, route, and process your business messages and data. You can integrate client applications that use different protocols and message formats.

About this task

In IBM App Connect Enterprise, you develop an integration solution by using an application or an integration service.

- An *application* is a container for all the resources that are required to create an integration solution.
- An *integration service* is a specialized application with a defined interface that acts as a container for a web services solution.

You can use patterns to create integration solutions. *Patterns* provide reusable solutions that encapsulate a tested approach to solving a common architecture, design, or deployment task in a particular context.

An *integration solution* is the container for the resources that you develop to process your business messages and data. IBM App Connect Enterprise manages three sets of resources to integrate your applications, messages, and data:

- Message flows
- Message flow nodes
- Message models

A message flow is a sequence of processing steps that run in an integration node when an input message is received. An integration node is a set of execution processes that host one or more message flows to route, transform, and enrich in-flight messages.

You can configure message flows to use one or both of the supported communication models, point-to-point and publish/subscribe.

You can share the project for your integration solution with others by exporting and importing the project as a compressed file known as a *project interchange file*. For example, you can export a project interchange file from the IBM App Connect Enterprise Toolkit and others can import the file into their IBM App Connect Enterprise Toolkit to share the development of an integration solution or to otherwise use that solution as the starting point for a new integration solution.

You can also copy project directories from your workspace directory to another location; for example, to backup the project directory or to use in another workspace directory.

Procedure

Read the following sections to learn more about developing integration solutions. You can also use the Tutorials Gallery in the IBM App Connect Enterprise Toolkit to explore some pre-built integration solutions.

- Learn about the development resources that you require to build your integration solution. For more information, see “Resource management overview” on page 1942.
- Learn how to develop a message flow. A message flow is a sequence of processing steps that run in an integration node when an input message is received. For more information, see “Developing message flows” on page 482.
  - Learn how to connect your business process applications and data to your message flows. You can use a number of different protocols to communicate with the integration node. You can also interact

from your message flows with other products and services. For more information, see “Connecting client applications” on page 737.

  - Learn how to design your message flows to handle messages and data in different ways. You can choose from a range of message flow nodes that support:
    - “Routing messages” on page 1233
    - “Transforming and enriching messages” on page 1249
    - “Processing events” on page 1819
    - “Handling errors in message flows” on page 1883
  - Learn how to create a message flow by running Java code that uses the IBM Integration API. For more information, see “Managing resources by using the IBM Integration API” on page 444.
- Learn about different ways of creating your integration solutions.
  - “Developing integration solutions from scratch” on page 1941
  - “Developing integration solutions by using integration services” on page 1984
  - “Developing integration solutions by using patterns” on page 2056
  - “Developing integration solutions by using REST APIs” on page 2011

  If you have a project interchange file for an existing integration solution, you can import the project for that solution into your IBM App Connect Enterprise Toolkit. In your IBM App Connect Enterprise Toolkit:

  1. Click **File** > **Import...** > **IBM Integration / Project Interchange**
  2. In the Import wizard, select the zip file (project interchange file) and the project location root (workspace directory)
  3. Click **Finish**.
- Learn how to develop unit tests for your message flows and message flow nodes. For more information, see “Developing integration tests” on page 1891.
- Learn how to define your own message models. For more information, see “Constructing message models” on page 2133.

What to do next

When you create a project, it is recommended to avoid using spaces in the project name. Although using spaces in the name is valid, you might encounter problems. For example: A scenario where an XML schema file located in project X references an XML schema file project Y, either through import or include statements. If the referenced schema in the project contain spaces in project name, the name does not resolve, and you receive errors.

Developing message flows

Develop message flows to process your business messages and data. A message flow is a sequence of processing steps that run in an integration server when an input message is received.

About this task

A message flow is a sequence of processing steps that run in the integration server when an input message is received. To learn how to design, create, and configure a message flow and its associated resources, read the following sections:

- “Message flows overview” on page 483
- “Managing message flow resources” on page 572
- “Designing a message flow” on page 583
- “Defining message flow content” on page 614

When a message is received and processed by a message flow, the integration server handles both successful and failure processing.

Procedure

IBM App Connect Enterprise provides several ways in which you can develop the message flows that you require to support your business processes requirements.

Read the following sections to learn more about developing message flows:

- "Transforming and enriching messages" on page 1249: To exchange messages between multiple applications, you might find that the applications do not understand or expect messages in the same format. You must provide some processing between the sending and receiving applications that ensures that both can continue to work unchanged, but can exchange messages successfully.
- "Routing messages" on page 1233: To route messages through your message flow, you use nodes for decision making. Alternatively, you route your messages to applications by using the publish/subscribe method of messaging.
- "Connecting client applications" on page 737: To connect your client applications, you use one or more of the supported protocols from other resources and software servers in your network.
- "Managing resources by using the IBM Integration API" on page 444: To develop Java™ message flows, you use the IBM Integration API.
- "Processing events" on page 1819: To control the flow of complex messages through your message flows, you use event driven message processing.
- "Handling errors in message flows" on page 1883: To take a specific action in response to certain error conditions and situations, you enhance your message flows to provide your own error handling.

Message flows overview

A message flow is a sequence of processing steps that run in the integration node when an input message is received.

You define a message flow in the IBM App Connect Enterprise Toolkit by including a number of message flow nodes, each of which represents a set of actions that define a processing step. The way in which you join the message flow nodes together determine which processing steps are carried out, in which order, and under which conditions. The path that you create between one node and another is known as a connection.

A message flow must include an input node that provides the source of the messages that are processed. You can process the message in one or more ways, and optionally deliver it through one or more output nodes; see "Connecting client applications" on page 737. The message is received as a bit stream, and is converted by a parser into a tree structure that is used internally in the message flow. Before the message is delivered to a final destination, it is converted back into a bit stream. For more information about these conversions, see "Parsers" on page 520 and "The message tree" on page 500.

When you want to exchange messages between multiple applications, you might find that the applications do not understand or expect messages in the same format. You must provide some processing between the sending and receiving applications that ensures that both can continue to work unchanged, but can exchange messages successfully. For more information about the options available, see "Transforming and enriching messages" on page 1249.

You define the processing that is required when you create and configure a message flow. You can include built-in nodes, nodes that are supplied by a vendor, nodes that you have created yourself (user-defined nodes), or other message flows (known as subflows).

The processing that you set up determines what actions are completed on a message when it is received, the order in which the actions are completed, and the final destinations of the message. All these actions manage the route that a message takes through a message flow; more information about these actions is provided in "Routing messages" on page 1233. To complete more complex processing involving more than one message, you can use the nodes described in "Processing events" on page 1819.

You can configure additional properties to make your message flow transactional, or multithreaded. You can use a global cache to share data between message flows. You can also add error paths that ensure every message is handled in an appropriate way.

When you want to run a message flow to process messages, you deploy it to an integration node, where it is run in an integration server.

The mode in which IBM App Connect Enterprise is running can affect the number of integration servers and message flows that you can deploy. For more information, see "Restrictions that apply in each operation mode" on page 5.

The following topics describe the concepts that you must understand to design, create, and configure a message flow and its associated resources:

Message flow nodes

A message flow node is a processing step in a message flow. It can be a built-in node, a user-defined node, or a subflow node.

A message flow node receives a message, performs a set of actions against the message, and optionally passes the original message, and none or more other messages, to the next node in the message flow.

A message flow node has a fixed number of input and output points that are known as terminals. You can make connections between the terminals to define the routes that a message can take through a message flow. Message flow nodes are displayed in the node palette that is associated with the Message Flow editor. The palette is arranged in categories, which group together nodes that provide related processing; for example, transformation.

Input nodes do not have input terminals. The message flow starts when a message is retrieved from an input device; for example, an IBM MQ queue. The message flow ends when none or more output messages have been sent by one or more output nodes, and control returns back to the input node. The input node either commits or rolls back the transaction. Input and output nodes can be protocol-specific, to interact with particular systems such as web services.

Most nodes are processing nodes, that you can include between your input and output nodes and connect together to define the flow of control. These nodes typically transform a message from one format to another, or route a message along a particular path, or provide more complex options such as aggregation or filtering.

You can configure a node by setting or changing the values for its properties. Some nodes have *mandatory properties*, for which you must set a value. Other properties must have a value, but are assigned a default value that you can leave unchanged. The remaining properties are *optional properties*; no value is required.

When you develop a message flow, how you set the properties of the nodes in that flow influences how the messages are processed by that flow. For example, by setting properties that define input and output

IBM MQ queue names, you determine where the message flow receives the message from, and where it delivers the message.

You can also configure nodes by using *promoted properties*; promote one or more node properties to become properties of the message flow that contains those nodes. You can then change these properties at the flow level, rather than having to update one or more individual nodes. You can also promote equivalent properties from more than one node to the same message flow property; for example, you might use this technique to set, at the flow level, the name of the database that all the nodes in the message flow must connect to.

A subset of node properties is *configurable properties*; that is, you can change their values when you deploy the message flow to an integration node for execution. You might find this ability useful if you deploy a message flow to more than one integration node, and want it to behave in a slightly different way on each integration node. For example, when you deploy the message flow to a test integration node, you can set a configurable property to force the flow to interact with a test database. When you deploy the same message flow to a production integration node, you can set the same property to the value of a production database, without having to update the message flow itself.

Another subset of node properties is *operational properties*; that is, you can control their values by using a policy. A policy enables you to define a common approach to controlling certain aspects of message flow behavior, and particular node properties such as connection credentials. You can create and update a policy at any time in the solution lifecycle. For more information about operational policies, see “Overriding properties at run time with policies” on page 324.

The mode in which IBM App Connect Enterprise is running can affect the types of node that you can use; see “Restrictions that apply in each operation mode” on page 5.

You can add nodes of three types into your message flows:

Built-in node
A built-in node is a message flow node that is supplied by IBM App Connect Enterprise. The built-in nodes provide input and output, manipulation and transformation, decision making, collating requests, and error handling and reporting functions.

For information about all of the built-in nodes that are supplied by IBM App Connect Enterprise, see Built-in nodes.

For information about the nodes that you can use to connect IBM App Connect Enterprise to your applications, see “Nodes for connectivity” on page 487.

User-defined node
A user-defined node is an extension to the integration node that provides a new message flow node in addition to the nodes that are supplied with the product. A user-defined node must be written to the user-defined node API provided by IBM App Connect Enterprise for both C and Java languages.

Subflow
A subflow is a directed graph that is composed of message flow nodes and connectors and is designed to be embedded in a message flow or in another subflow. To connect your subflow to other nodes in the main flow, you can add Input and Output nodes to the subflow. You can define subflows in one of two resource types, either a `.subflow` file or a `.msgflow` file. A subflow that is defined in a `.subflow` file can be deployed as an individual resource. A subflow that is defined in a `.msgflow` file must be deployed with the main flow in which it is embedded.

A message is received by an Input node and processed according to the definition of the subflow. That definition might include being stored through a Database node, or delivered to another message target, for example through an MQOutput node. If required, the message can be passed through an Output node back to the main flow for further processing.

The subflow, when it is embedded in a main flow, is represented by a subflow node, which has a unique icon. The icon is displayed with the correct number of terminals to represent the Input and Output nodes that you included in the subflow definition.

The most common use of a subflow is to provide processing that is required in many places within a message flow, or is to be shared between several message flows. For example, you might code some

error processing in a subflow, or create a subflow to provide an audit trail (storing the entire message and writing a trace entry).

For more information, see "Subflows" on page 488.

A node does not always produce an output message for every output terminal: often it produces one output for a single terminal based on the message received or the result of the operation of the node. For example, a Filter node typically sends a message on either the True terminal or the False terminal, but not both.

If you connected more than one terminal to another node, the processing in the node determines the order in which the message is propagated to the nodes that it is connected to; you cannot change this order. The node sends the output message on each terminal, but sends on the next terminal only when the processing has completed for the current terminal.

Updates to a message are never propagated to nodes that have been previously executed, only to nodes that follow the node in which the update has been made. The order in which the message is propagated to the different output terminals is determined by the integration node; you cannot change this order. The only exception to this rule is the FlowOrder node, in which the terminals indicate the order in which the message is propagated to each.

All built-in nodes include error handling as part of their processing. If an error is detected within the node, the message is propagated to the failure terminal. What happens then depends on the structure of your message flow. You can use only the basic error handling that is provided by the integration node, or you can enhance your flow by adding error processing nodes and flows to provide more comprehensive failure processing. For more information about these options, see "Handling errors in message flows" on page 1883.

The message flow can accept a new message for processing only when all paths through the message flow (that is, all connected nodes from all output terminals) are complete, and control is returned to the input node that commits or rolls back the transaction.

Message flow node palette

The palette in the Message Flow editor contains all the built-in nodes, which are organized into categories, or drawers. A drawer is a container for a list of icons, such as the **Favorites** drawer.

When you first open the IBM App Connect Enterprise Toolkit, the default drawers contain built-in message flow nodes that are related in function. For example, one drawer contains all the nodes that handle input and output to IBM MQ queues. Another drawer, **Transformation**, groups the nodes that you can use to convert the input message into a different form, including the Compute and JavaCompute nodes.

You can drag the message flow nodes that you use most often into the **Favorites** drawer for easy access. If you create your own nodes, you can also add them to the palette. You can drag a node from the palette onto the canvas, and create a connection between two nodes. You can also use the palette to create an annotation on a message flow or node.

Right-click the palette to add a selected node to the canvas, or customize the appearance and behavior of the palette.

Use the Customize Palette dialog box to reorder node categories, set the drawer behavior for individual categories, and rename or hide nodes or categories.

You cannot move a category above the Favorites category. You can hide the Favorites category, but you cannot delete or rename it.

Use the Palette Settings dialog box to set the palette layout, determine the behavior of palette drawers, and choose a particular font.

The following topics explain how to change the palette layout and settings:

- "Changing the palette layout" on page 615
- "Changing the palette settings" on page 615
- "Customizing the palette" on page 616

- "Adding nodes to the Favorites category on the palette" on page 617

Nodes for connectivity

IBM App Connect Enterprise supports direct connections from applications, and can send direct requests to other application endpoints. IBM App Connect Enterprise can also connect to various subsystems including IBM MQ, files, and databases, to read and write existing application data.

You can connect IBM App Connect Enterprise to your applications by adding the appropriate nodes to your message flow. The nodes you use can be tailored to support the protocols and subsystems that your applications already use. IBM App Connect Enterprise supplies nodes to support different protocols and subsystems; you can also create your own nodes to support additional protocols and subsystems if required.

- Nodes are supplied to support the protocols that are described in "Connecting client applications" on page 737; for example, IBM MQ and HTTP.

Within your message flow, you can include the following types of nodes to communicate with your applications. The icons for the nodes in each group described are based on a common appearance, which is shown with that group.

Input nodes

The input node reads data from a subsystem or input application, which might be in the form of a message, or a record (for example, from a file). The input node calls a parser to interpret the data and create an internal message tree structure. The node can split the input message into records if required. When the message is ready, the input node sends it to the rest of the message flow for processing.

Input nodes are represented by icons that conform to this template: 

Output nodes

An output node takes data from the message tree, calls a parser to serialize the tree into the appropriate message or record format, and writes out the message or record to one or more specified end applications or subsystems. If appropriate, you can configure your message flow to continue processing a message after it has generated one or more output messages through output nodes.

Output nodes are represented by icons that conform to this template: 

Reply nodes

A reply node is a specialized form of an output node. Typically, the reply node is associated with an input node in the same flow, and uses context information from that input node to decide where to send the reply. Depending on the protocol of the input node, the context information might be created for you by that node; for other protocols, the context information might be contained within the message itself.

Reply nodes are represented by icons that conform to this template: 

Get and receive nodes

A get (receive) node reads extra data from a subsystem, and includes it in the current message tree, during message flow processing.

Get nodes are represented by icons that conform to this template: 

Request nodes

A request node writes a request to an external system, reads the response, and incorporates some or all that response data into the current message tree.

Request nodes are represented by icons that conform to this template: 

Asynchronous request and response nodes

These two nodes are specialized form of a request node, in which you can generate a request and handle the response in a second message flow. Typically, you use these nodes when you are making a request that might take some time to complete. By using this technique, you can have several outstanding requests, without suspending flow processing.

Asynchronous request nodes are represented by icons that conform to this template: 

Asynchronous response nodes are represented by icons that conform to this template: 

You can connect applications that use different protocols by choosing an appropriate mix of input and output nodes. You must also include nodes that can transform the input message into the appropriate output format between the input and output nodes.

Subflows

You define a subflow to provide a common sequence of actions to be used by several message flows, applications, or integration services. You can include subflows in your message flows in the same way as you include built-in or user-defined nodes. You can also connect subflows to other nodes in the same way.

A subflow provides the following benefits:

- Reusability and reduced development time
- Consistency and increased maintainability of your message flows (consider a subflow as analogous to a programming macro, or to inline code that is written once but used in many places)
- Flexibility to tailor a subflow to a specific context (for example, by updating the output queue or data source information)

Consider these examples of subflow use:

- You can define a subflow that provides a common sequence of actions that applies to several message flows if an error is encountered. For example, you might have a common error routine that writes the message to a database through the Database node, and puts it to a queue for processing by an error recovery routine. The use of this routine in multiple message flows, or in several places within one message flow, provides an efficient and consistent use of resources and avoids reinventing such routines every time an error is encountered.
- You might want to perform a common calculation on messages that pass through several different message flows; for example, you might access currency exchange rates from a database and apply them to calculate prices in several different currencies. You can include the currency calculator subflow in each of the message flows in which it is appropriate.

Note: You should not use a standard input node (a built-in input node such as MQInput, or a user-defined input node) in a subflow; instead use an Input node to provide the In terminal to a subflow. For more information, see node.

If you want to reuse subflows between multiple applications or integration services, store the subflows in a shared library. You can change those subflows and redeploy the shared library without the need to redploy the applications or integration services that reference the shared library.

Types of subflows

You define a subflow once, and use it in more than one message flow, application, integration service, and integration project. You define subflow content in the same way as you define message flow content, by adding, configuring, and connecting message flow nodes.

Note: At run time, each instance of a subflow creates a copy of all the message flow nodes that define that subflow. This behavior affects resource usage, which can affect your overall message flow performance.

You can create a subflow as a `.subflow` file or as a `.msgflow` file. Choose which type of subflow to use based on the following information:

A `.subflow` file subflow

A subflow that is defined in a `.subflow` file can be deployed in any of the following ways:

- The subflow is deployed separately from any of the message flows that use this subflow. The subflow and the message flows that include this subflow must be deployed in the same integration server. The subflow can be deployed directly to an integration server or as part of a library. If you update this type of subflow and redeploy it, all message flows that use this subflow, and are not part of an application or the integration service, are automatically updated. You do not need to redeploy these message flows. If you update a subflow in a shared library and redeploy it, all message flows in an application or integration service that use this subflow are updated automatically.
- The subflow is deployed as part of an application or integration service.

You cannot use the following nodes in this type of subflow:

- Nodes representing subflows that are defined in `.msgflow` files
- User-defined nodes created from subflows that are defined in `.msgflow` files

If you create a BAR file that contains both ESQL code and a subflow that is defined in a `.subflow` file, you cannot include the ESQL code directly in compiled message flow files.

A `.msgflow` file subflow

A subflow that is defined in a `.msgflow` file is embedded inside any parent message flows that use it when the message flow is placed in a BAR file. This type of subflow can only be deployed to an integration server with the message flow in which it is used. If you update this type of subflow, you must redeploy all message flows that use the subflow so that the updated subflow is used. This type of subflow can be packaged as a user-defined node.

Conditions that apply when you convert a subflow between `.msgflow` and `.subflow` and vice versa

You can convert a subflow created as a **`.msgflow`** file to a **`.subflow`** file.

- If the **`.msgflow`** file contains subflows that are defined as **`.msgflow`** files, these subflows must also be converted to **`.subflow`** files.
- If the **`.msgflow`** file is used as a subflow, the parent flow must be updated so that it references the new **`.subflow`** file.

You can convert a subflow created as a **`.subflow`** file to a **`.msgflow`** file.

- You cannot use the name of a file that already exists in that application, library, or integration project where you create your subflow as a **`.msgflow`** file. You must include **`.msgflow`** at the end of your subflow file name. An application or integration service can use subflows with the same name in one or more shared libraries if the subflows are in different broker schemas.

Conditions that apply when you want to add a subflow into a message flow

You can add subflows into a message flow if either of the following statements is true:

- The subflow that you want to add in a message flow is defined in a library, and you have specified the dependency of the current message flow container on that library. Applications and integration services can reference libraries. (A library is a logical grouping of related code, data, or both that typically contains reusable subflows, and other type of resources.)
- The subflow that you want to add in a message flow is defined in the same integration project, application, or integration service as the message flow.

When you store subflows in a shared library, you must place the subflows inside a schema that is not the default empty schema.

When an application or shared library references other shared libraries, all the subflows for a broker schema must be in a single container. Subflows for a broker schema must not be in both an application (or shared library) and a shared library that is referenced by that application (or shared library). Subflows for a broker schema must not be in two or more shared libraries that are referenced by a single application or shared library. All the subflows in a broker schema must be either in the main application or shared library, or in a single referenced shared library.

Conditions that apply when you want to add a subflow into a subflow

You can add subflows into a subflow in any of the following cases:

- You can add subflows that are defined in **.subflow** files into subflows that are defined in **.subflow** files and **.msgflow** files.
- You can add subflows that are defined in **.msgflow** files into subflows that are defined only in **.msgflow** files.
- A subflow in a shared library can contain another subflow in the same or a different shared library.

Conditions that apply when you deploy a subflow

You can deploy subflows in any of the following ways:

- Deploy a subflow as an independent resource that is defined in an integration project.
- Deploy a subflow in an application.
- Deploy a subflow as part of a service operation.
- Deploy a subflow in a library.

You deploy a subflow to an integration server by sending a BAR file to an integration server, which unpacks and stores the contents ready for when your message flows are started. You can also deploy a subflow directly to an integration server.

The following conditions apply when you deploy a subflow:

- If you deploy a message flow that contains a subflow that is defined in a **.subflow** file, the subflow is automatically included in the BAR file.
- If you deploy a subflow that is contained in an application, you must deploy the application to an integration server, which results in a complete deployment of the application.
- If you deploy a subflow that is contained in an integration service, you must deploy the service to an integration server, which results in a complete deployment of the integration service.
- If you deploy a subflow that is contained in a library, you can deploy the library to an integration server directly, outside of an application or an integration service. Then the subflow included in the library can be referenced by other message flows and subflows that are deployed directly to the same integration server as the library.
- A subflow that is created as a **.msgflow** file in an integration project can only be deployed as a separate resource if it contains at least one Input node.

Version control

Use the Passthrough node to enable version control of a subflow at run time.

By including a Passthrough node, you can add a label to your message flow or subflow. By combining this label with keyword replacement from your version control system, you can identify which version of a subflow is included in a deployed message flow. You can use this label for your own purposes. If you have included the correct version keywords in the label, you can see the value of the label in a any of the following ways:

- By using the **mqsireadbar** command to read the properties stored in the BAR file.

- In the IBM App Connect Enterprise Toolkit, on the properties of a deployed message flow when it was last deployed to a particular integration node.
- In the runtime environment, if you enable user trace for that message flow.

For subflows that are created as `.subflow` files, consider the following behavior when you deploy a new version of a subflow:

- If the subflow is deployed separately from any of the message flows that use this subflow, and you deploy a new version of the subflow, all the message flows are updated automatically.
- If the subflow is deployed as part of an application or an integration service, you need to update your applications and integration services to include the new subflow version, and redeploy them.

For subflows that are created as `.msgflow` files, consider the following behavior when you deploy a new version of a subflow:

- You must update your applications, integration services, and independent resources that use the subflow to include the new subflow version, and redeploy them.

To learn more about subflows, see the following scenario Scenario: Reusing common application logic in multiple integration solution.

Callable message flows

A message flow can call another flow directly. You can deploy both flows to IBM App Connect Enterprise or IBM App Connect on IBM Cloud, or you can deploy one flow to IBM App Connect Enterprise and one flow to IBM App Connect on IBM Cloud.

A message flow can complete many different actions. If any of those actions are labor-intensive, you can split them from the main flow and complete them somewhere else. Callable flows also facilitate reuse because they can be called by multiple message flows. You can split your flows between different applications in the same integration server, or between different integrations servers, which can also be in different integration nodes. Your callable flows must be in applications. You cannot deploy callable flows in libraries or integration projects.

Some parts of a message flow might logically belong in a specific location. For example, if your flow queries an on-premises database, performance is better if that part of the flow remains on premises. But if part of your flow queries a website multiple times, performance might be improved by running that part of the flow in the cloud. You can call the cloud-based flow from your on-premises flow, and the flow in the cloud does not use any of your on-premises resources.

If your callable flows are both deployed to IBM App Connect on IBM Cloud, they can communicate with each other as soon as you deploy them. You do not need to set up communication between them. You also do not need to set up communication if both flows are deployed to the same integration server on IBM App Connect Enterprise.

If you are splitting processing between different integration servers, or between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, your flows communicate by using a *Switch server* and *connectivity agents*. The Switch server is a special type of integration server that routes data. You cannot deploy anything to the Switch server. The connectivity agents contain the certificates that your flows require to communicate securely with the Switch server. The connectivity agents must be running in the integration servers where you have deployed your on-premises message flows.

You can split processing synchronously between message flows by using the CallableFlowInvoke node in the calling flow, and CallableInput and CallableReply nodes in the callable flow. Alternatively, you can split processing asynchronously between message flows, by using the CallableFlowAsyncInvoke node in the calling flow, CallableInput and CallableReply nodes in the callable flow, and the CallableFlowAsyncResponse node in the response flow. You can also choose to share data between the flows that contain these asynchronous nodes (the calling flow and the response flow) by storing and retrieving data in the `UserContext` folder in the environment tree. For more information about sharing data between flows, see “Sharing data between a calling flow and a response flow” on page 603.

Note: This topic is about using the callable flow technique between App Connect Enterprise message flows. You can also use the callable flows technique with on-cloud event-driven flows and API flows

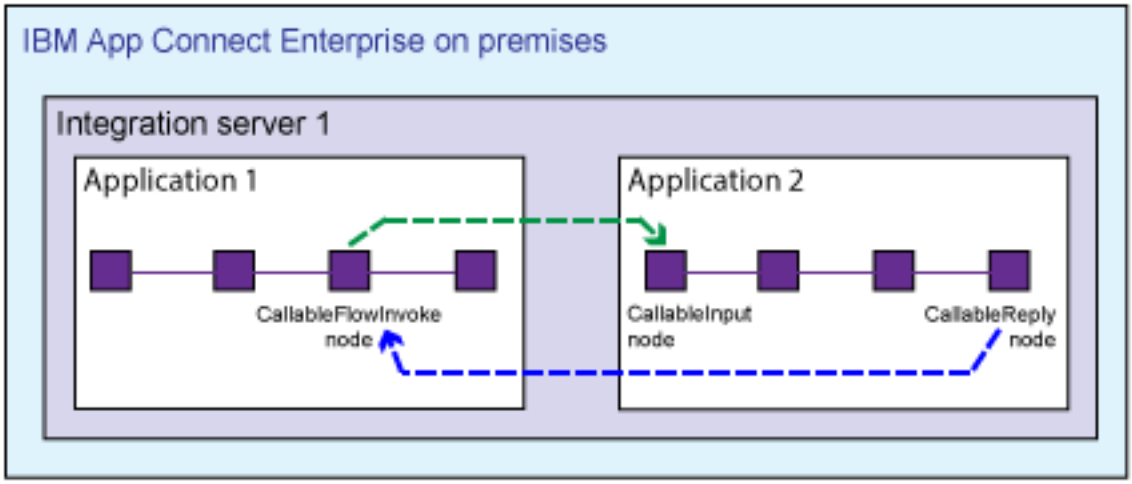
in IBM App Connect on IBM Cloud. Such on-cloud flows can be called by an App Connect Enterprise CallableFlowInvoke node, and such on-cloud flows can use the Invoke action node to call other on-cloud event-driven flows (that have the Input event node) or App Connect Enterprise message flows (that have the CallableInput node) either on cloud or on premises. For example, see the tutorial: Sharing data and processing from on-premises activities with on-cloud SaaS applications, by using an on-cloud callable flow.

You can split flows into multiple callable flows. However, for simplicity, the following scenarios assume that you are using two App Connect Enterprise message flows only: a calling flow and a callable flow.

Scenarios

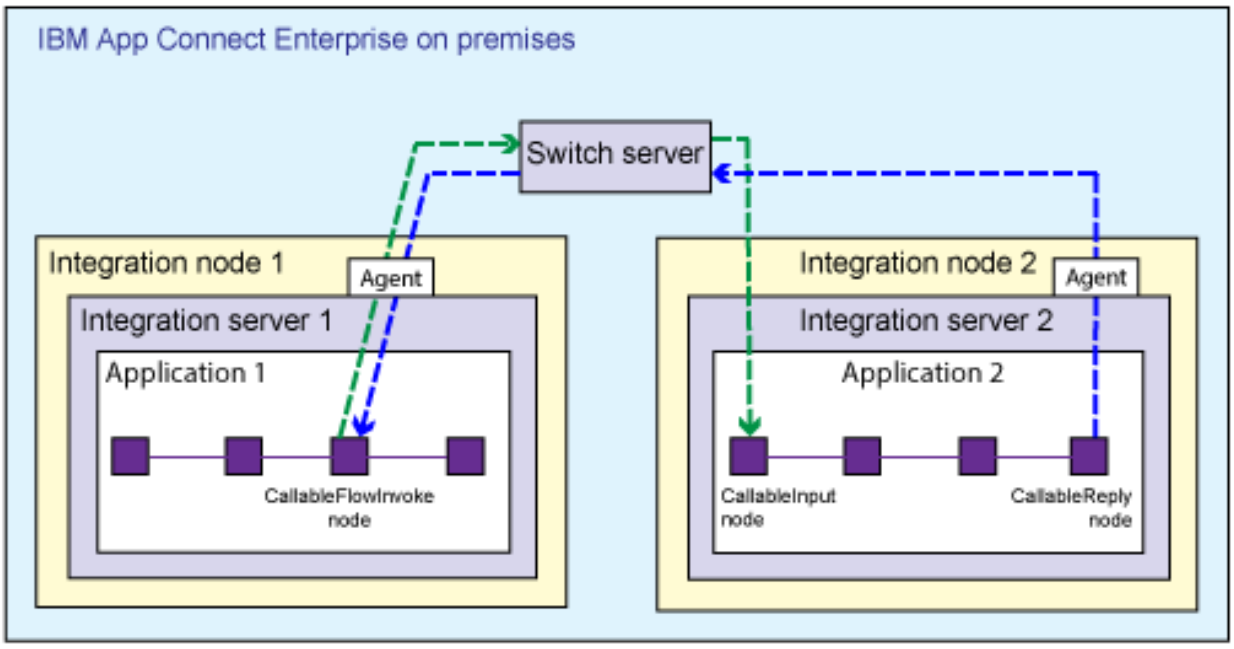
Splitting flows synchronously between applications on the same integration server

A message flow in an IBM App Connect Enterprise integration server calls a message flow in the same integration server, but in a different application. For this scenario, you do not need to set up a connection agent. This scenario is supported on all operating systems.



Splitting flows synchronously between applications on different integration servers

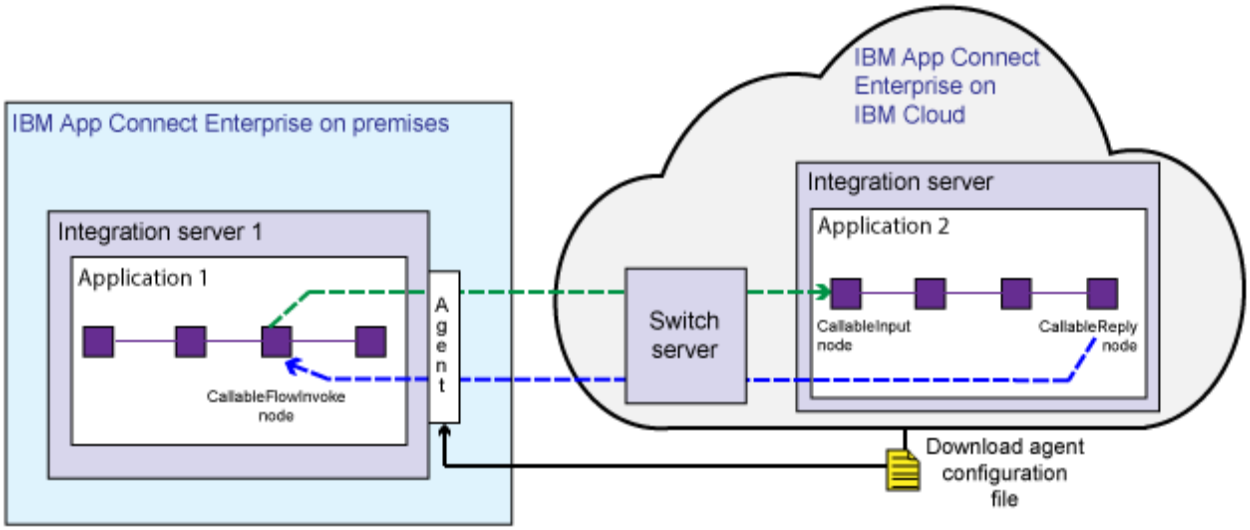
A message flow in an IBM App Connect Enterprise integration server calls a message flow in a different integration server.

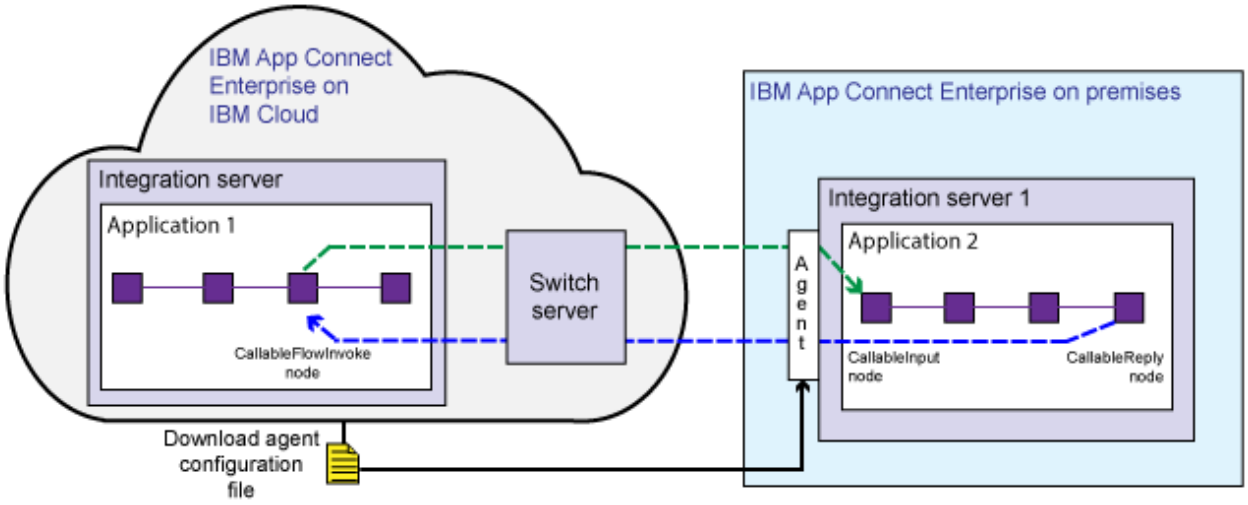


If your flows are split between different integration servers in IBM App Connect Enterprise, you must run a command that creates some configuration files. You use one of the configuration files to create the Switch server, and the other file to configure connectivity agents for each integration server. The integration servers can be in the same integration node or different integration nodes. This scenario is supported on Windows and Linux only.

Splitting flows synchronously between IBM App Connect Enterprise and IBM App Connect on IBM Cloud

A message flow in IBM App Connect Enterprise calls a message flow in IBM App Connect on IBM Cloud, or a message flow in IBM App Connect on IBM Cloud calls a message flow in IBM App Connect Enterprise.





If your flows are split between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, the Switch server is managed by IBM App Connect on IBM Cloud. You download a file from the cloud that configures an on-premises connectivity agent. This scenario is supported on Windows and Linux only.

Splitting flows asynchronously in IBM App Connect Enterprise, or between IBM App Connect Enterprise and IBM App Connect on IBM Cloud

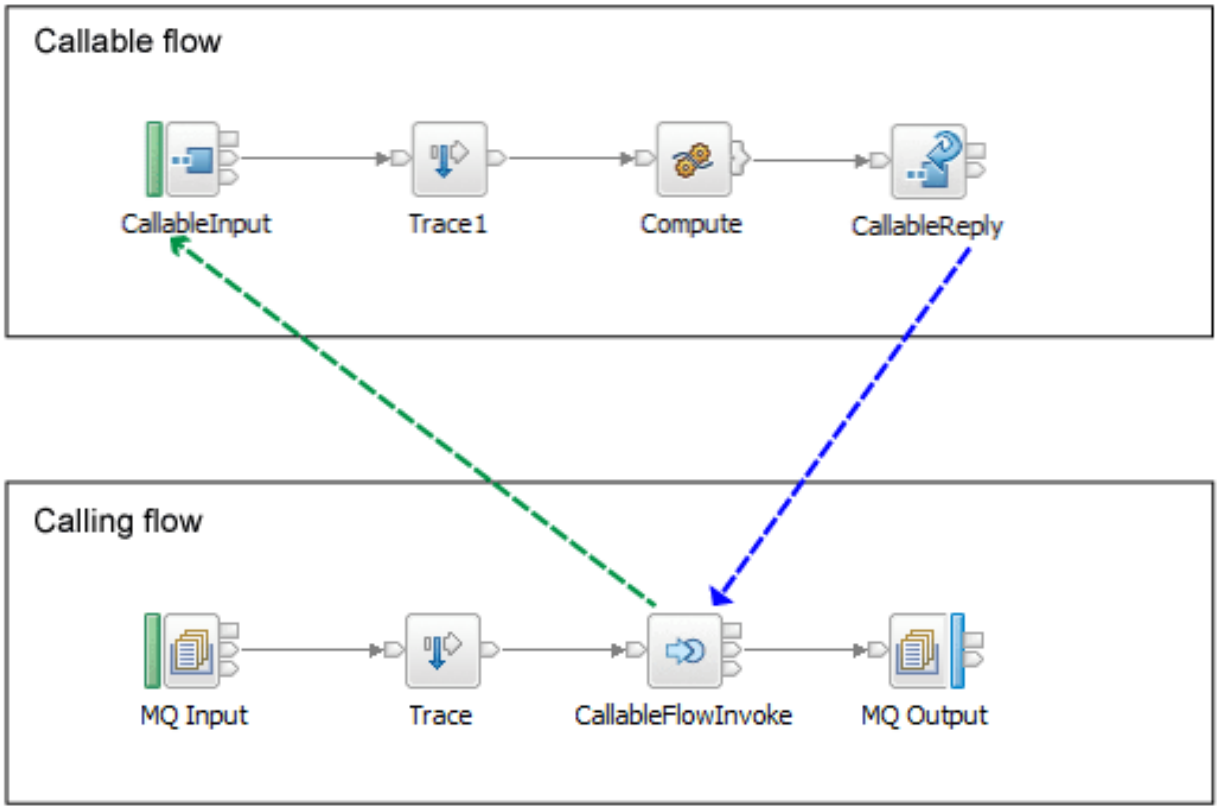
A message flow contains a CallableFlowAsyncInvoke node, which calls a second (*callable*) message flow containing a CallableInput node and a CallableReply node. A third (*response*) flow contains a CallableFlowAsyncResponse node.

When a message is passed into the calling message flow, the CallableFlowAsyncInvoke node sends the contents of the message body and environment folders to the CallableInput node of the callable flow, and then completes immediately. When the callable flow completes processing, the CallableReply node sends the message body and environment folder data to the CallableFlowAsyncResponse node in the response flow.

If your flows are split between different integration servers, you must create a Switch server (which routes data) and connectivity agents to allow the flows to communicate securely. For more information, see “Preparing the environment for callable flows” on page 222.

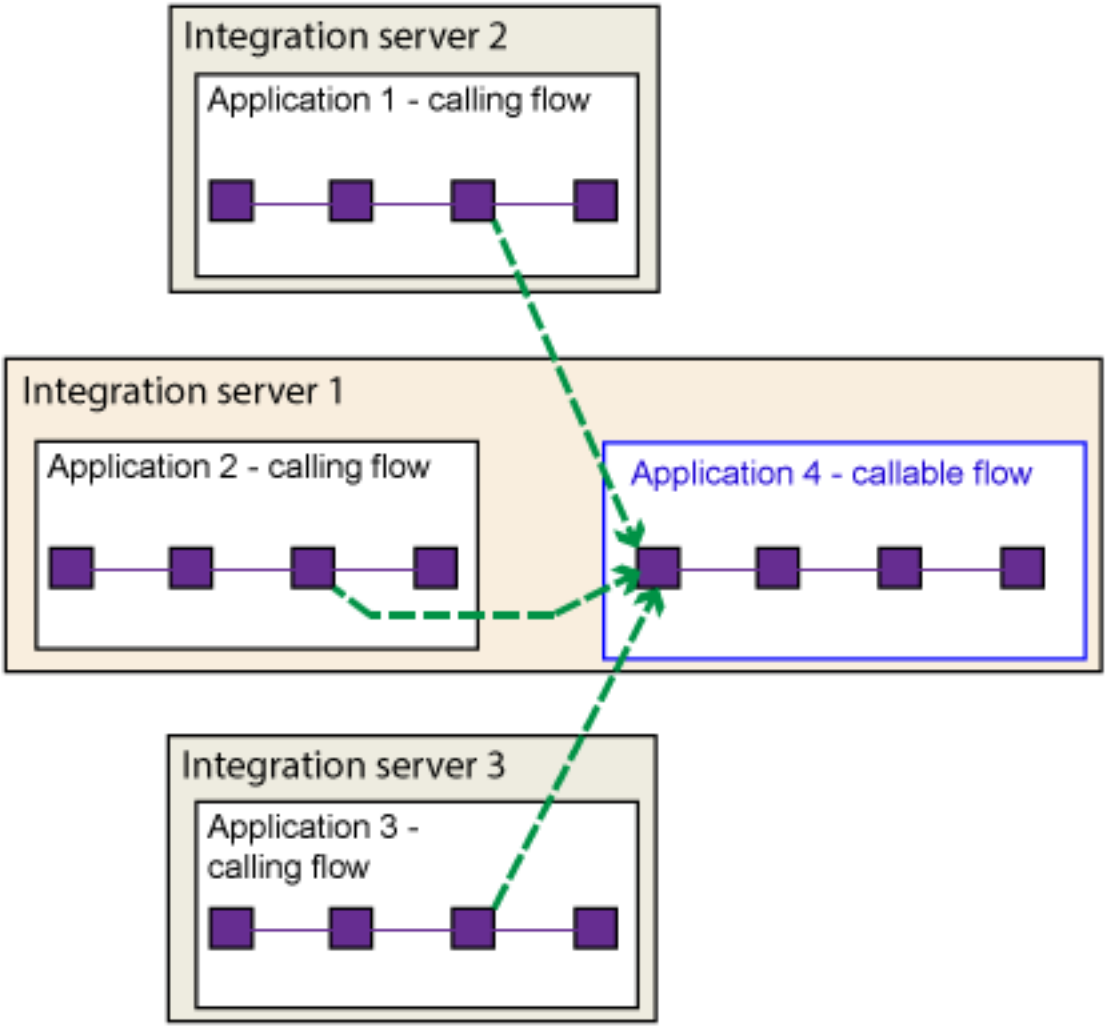
Flow configuration

When you decide how to split your message flow processing, create your message flows. The calling flow includes a CallableFlowInvoke or CallableFlowAsyncInvoke node, which calls a CallableInput node in a second (*callable*) flow. When the message is processed by the callable flow, a CallableReply node returns information to either the CallableFlowInvoke node in the calling flow (when flows that are split synchronously) or the CallableFlowAsyncResponse node (when flows that are split asynchronously). The calling flow uses a combination of the application name and the endpoint name of the CallableInput node to identify which callable flow to call.



In this example, the CallableFlowInvoke node parses the incoming message in full so that it is in a suitable format to send to the CallableInput node. Therefore, you should validate the message before it reaches the CallableFlowInvoke node. If the message fails validation at this point, it can be rolled back.

Multiple message flows can call the same callable flow. Therefore, your callable flow might complete a set of actions that are common to multiple flows.



You can add multiple CallableFlowInvoke or CallableFlowAsyncInvoke nodes to a message flow. You can also include CallableFlowInvoke or CallableFlowAsyncInvoke nodes in your callable flows. Application and endpoint name pairs must be unique on a single integration server. You can have multiple callable flows that have the same application and endpoint names, but they must be in different integration servers. In this case, the Switch server acts as a load balancer.

Deployment

After you develop your message flows, you package the containing applications into BAR files and deploy them to the appropriate locations. If the flow accesses on-premises resources, deploy its BAR file on premises. If the flow will run in the cloud, upload its BAR file to IBM App Connect on IBM Cloud.

When the calling flow receives an input message, the CallableFlowInvoke (or CallableFlowAsyncInvoke) node uses the application name and the **`Endpoint Name`** on the CallableInput node to identify and start the callable flow.

For detailed information about how to configure callable message flows, see “Splitting the processing of message flows” on page 599.

Message flow connections

A connection is an entity that connects an output terminal of one message flow node to an input terminal of another. The connection represents the flow of control and data between two message flow nodes.

Most nodes have one input terminal, and many have more than one output terminal. You can connect an output terminal to more than one target node, so that the same message can be processed in a number of different ways. For example, you might want to send the same information to more than one remote application for further processing.

The connections of the message flow, represented by black lines in the Message Flow editor, determine the path that a message takes through the message flow. You can add bend points to the connection to alter the way in which it is displayed.

Bend points

A bend point is added to a connection between two message flow nodes where the line that represents the connection changes direction.

Use bend points to change the visual path of a connection to display node alignment and processing logic more clearly and effectively. Bend points have no effect on the behavior of the message flow; they are visual modifications only.

A connection is initially made as a straight line between the two connected nodes or integration nodes. Use bend points to move the representation of the connection, without moving its start and end points.

Message flow node terminals

A terminal is the point at which one node in a message flow is connected to another node.

Use terminals to control the route that a message takes, depending on whether the operation that is performed by a node on that message is successful. Terminals are wired to other node terminals by using message flow node connections to indicate the flow of control.

Every built-in node has a number of terminals to which you can connect other nodes. Input nodes (for example, MQInput) do not have input terminals; all other nodes have at least one input terminal through which to receive messages to be processed.

Most built-in nodes have failure terminals that you can use to manage the handling of errors in the message flow. Use the failure terminal to handle errors within the node itself.

Most built-in nodes have a catch terminal. These nodes are typically at the start of a transaction, where an uncaught exception would cause a rollback. In these nodes, the catch terminal behaves as though a TryCatch node were wired directly to the Out terminal. Use the catch terminal to handle any exceptions that are thrown beyond the message flow node.

Most nodes have output terminals through which the message can flow to a subsequent node.

If you have any user-defined nodes, these might also have terminals that you can connect to other built-in or user-defined node terminals.

Dynamic terminals are terminals that you can add to certain nodes after you have added them to a message flow in the Message Flow editor. For example, you can add dynamic output terminals to the Route, and DatabaseRoute nodes, or you can add dynamic input terminals to the Collector node. You can also delete and rename dynamic terminals. If a node has five or more terminals, they are displayed in a group. For example, the following example shows a node with more than four output terminals. 

Broker schemas

A broker schema is a symbol space that defines the scope of uniqueness of the names of resources defined within it. The resources include message flows and other optional resources such as ESQL files, Java files, and mapping files.

The broker schema is defined as the relative path from the project source directory to the flow name.

You can create new broker schemas to provide separate symbol spaces within the same integration project. A broker schema is implemented as a folder, or subdirectory, within the project, and provides organization within that project. You can also use project references to spread the scope of a single broker schema across multiple projects to create an application symbol space that provides a scope for all resources associated with an application suite.

If you create a new broker schema while in category mode, the empty schema is not visible in the Application Development view. To show the empty schema in the Application Development view, click **Hide Categories**  on the toolbar.

A broker schema name must be a character string that starts with a Unicode character followed by zero or more Unicode characters or digits, and the underscore. You can use the period to provide a structure to the name, for example `Stock.Common`. A directory is created in the project directory to represent the schema, and if the schema is structured using periods, further subdirectories are defined. For example, the broker schema `Stock.Common` results in a directory `Common` within a directory `Stock` within the integration project directory.

If you create a resource (for example, a message flow) in the default broker schema within a project, the file or files associated with that resource are created in the directory that represents the project. If you create a resource in another broker schema, the files are created within the schema directory.

For example, if you create a message flow in the default schema in the integration project Project1, its associated files are stored in the Project1 directory. If you create another message flow in the `Stock.Common` broker schema within the project Project1, its associated files are created in the directory `Project1\Stock\Common`.

Because each broker schema represents a unique name scope, you can create two message flows that share the same name within two broker schemas. The broker schemas ensure that these two message flows are recognized as separate resources. The two message flows, despite having the same name, are considered unique.

If you move a message flow from one project to another, you can continue to use the message flow within the original project if you preserve the broker schema. If you do this, you must update the list of dependent projects for the original project by adding the target project. If, however, you do not preserve the broker schema, the flow becomes a different flow because the schema name is part of the fully qualified message flow name, and it is no longer recognized by other projects. This action results in broken links that you must manually correct. For further information about correcting errors after moving a message flow, see “Moving a message flow or subflow” on page 578.

Do not move resources by moving their associated files in the file system; you must use the IBM App Connect Enterprise Toolkit to move resources to ensure that all references are corrected to reflect the new organization.

The following scope and reuse conditions apply when you create functions, procedures, and constants in a broker schema:

Functions

- Functions are locally reusable and can be called by module-scope subroutines or mappings within the same schema.
- Functions are globally reusable and can be called by other functions or procedures in ESQL or mapping files within any schema defined in the same or another project.

Procedures

- Procedures are locally reusable and can be called from module-scope subroutines in ESQL files within the same schema.
- Procedures are globally reusable and can be called by other functions or procedures in ESQL files within any schema defined in the same or another project.

Procedures cannot be used in mapping files.

Constants

- Constants are locally reusable and can be used where they are defined in any ESQL or mapping file within the same broker schema.
- Constants are not globally reusable; you cannot use a constant that is declared in another schema.

If you want to reuse functions or procedures globally:

- Specify the path of the function or procedure:
  - If you want to reuse a function or procedure in an ESQL file, either provide a fully-qualified reference, or include a PATH statement that defines the path.

    If you define the path, code the PATH statement in the same ESQL file as that in which the function is coded, but not within any MODULE.
  - If you want to reuse a function in a mapping file, take one of the following steps:
    - Qualify the function in the Composition Expression editor.
    - Select **Organize Schema References** in the outline view. This detects dependent PATHs and automatically updates the reference.
    - Select **Modify Schema References** in the outline view. You can then select the schema in which the function is defined.

    (You cannot reuse a procedure in a mapping file.)
- Set up references between the projects in which the functions and procedures are defined and used.

Client application programming interfaces

You can configure the nodes in your message flows to customize the behavior of those nodes by using one or more of the supported programming interfaces.

You can use one of the following options for converting message formats in your message flows:

Mappings

The Graphical Data Mapping editor in the IBM App Connect Enterprise Toolkit is a graphical interface that displays a visual representation of messages. You can use this editor to:

- Drag fields from a source message to a target message
- Map data from databases to the message structure
- Apply functions

You can use mappings in the Mapping node.

ESQL

Use ESQL to manipulate data in both messages and database tables. ESQL is a programming language that is specific to IBM App Connect Enterprise, and based on SQL. You can code ESQL statements to create, reference, and update message fields and database content. ESQL provides a rich set of statements and functions that you can use to achieve sophisticated transformations.

You can use ESQL in the Compute, Database, and Filter nodes.

Java

Use the Java programming language to route or transform your messages. You can use XPath to create, reference, and update message fields. You can also use JDBC to access database tables.

You can use Java only in the JavaCompute node.

XSL style sheets
Use standard XSL style sheets to convert XML messages to other formats supported by the integration node.

You can use XSL only in theXSLTransform node.

Use this option if your message flows are processing XML messages, and your message flow designers are familiar with the XSL style sheets.

Windows .NET
Use the .NET framework to route or transform your messages. You can use .NET to create, reference, and update message fields.

You can use .NET in the .NETCompute node, and call .NET code from ESQL.

When you configure your message flows and nodes, you create a set of files that are stored in your workspace.

The files created are of the following types:

- A message flow definition file, *message_flow_name*`.msgflow`. This file is mandatory, and is created automatically for you. It contains details about the message flow characteristics and contents; for example, what nodes it includes and its promoted properties.
- One or more message mappings files, *message_flow_name_nodename*`.map`. A unique file is required for each node in the message flow that uses the Graphical Data Mapping editor. This file is required only if your message flow contains a Mapping node. You can create this file yourself, or you can cause it to be created for you by requesting specific actions against a node.
- One or more ESQL resources files, *message_flow_name*`.esql`. An ESQL file is required only if your message flow includes one or more of the nodes that must be customized by using ESQL modules, or contains functions that are called by your message mappings. You can create this file yourself, or you can cause it to be created for you by requesting specific actions against a node.

  You can customize the following built-in nodes by creating free-form ESQL statements that use the built-in ESQL statements and functions, and your own user-defined functions:

  – Compute
  – Database
  – Filter
- One or more Java programming files, *message_flow_name*`.java`. A Java file is required only if your message flow includes one or more JavaCompute nodes. You can create this file yourself, or you can cause it to be created for you by requesting specific actions against a node.
- One or more XSL stylesheets, *message_flow_name*`.xslt`. An XSLT file is required only if your message flow includes one or more XSLTransform nodes. You can create this file yourself, or you can cause it to be created for you by requesting specific actions against a node.

You can include other files in your integration project so that they are deployed to the integration node with your message flow. The integration node stores these extra files but does not process them in any way.

For details of how to create the files to support these transform options, and create their content, see “Transforming and enriching messages” on page 1249.

The message tree

A message tree is a structure that is created, either by one or more parsers when an input message bit stream is received by a message flow, or by the action of a message flow node.

A message is used to describe:

- A set of business data that is exchanged by applications

- A set of elements that are arranged in a predefined structure
- A structured sequence of bytes

IBM App Connect Enterprise routes and manipulates messages after converting them into a logical tree. The process of conversion, called parsing, makes obvious the content and structure of a message, and simplifies later operations. After the message has been processed, the parser converts it back into a bit stream.

IBM App Connect Enterprise supplies a range of parsers to handle the many different messaging standards in use.

After a message has been parsed, it can be processed in a message flow.

The logical tree has contents that are identical to the message, but the logical tree is easier to manipulate in the message flow. The message flow nodes provide an interface to query, update, or create the content of the tree.

Logical tree (message assembly)

The logical tree is the internal representation of a message, and is also known as the message assembly.

When a message arrives at IBM App Connect Enterprise, it is received by an input node that is configured in the message flow. Before the message can be processed, it must be interpreted by one or more parsers that create a logical tree representation from the bit stream of the message data.

The tree format contains identical content to the bit stream from which it is created, but it is easier to manipulate in the message flow. Many of the built-in message flow nodes provide an interface for you to query and update message content in the tree, and perform other actions against messages and databases to help you to provide the required function in each node.

Several interfaces are provided:

- ESQL, a programming language that you can code in the Compute, Database, and Filter nodes.
- Java, a programming language that you can code in the JavaCompute node.
- Mappings, a graphical method of achieving transformation from input to output structures, available in the Mapping node.
- XSL, a language for transforming XML that you can use in the XSLTransform node.

The tree structure that is created by the parsers is largely independent of any message format (for example, XML). The exception to this is the subtree that is created as part of the message tree to represent the message body. This subtree is message dependent, and its content is not further described here.

The input node creates this message assembly, which consists of four trees:

- “Message tree” on page 502
- “Environment tree” on page 508
- “Local environment tree” on page 509
- “Exception list tree” on page 516

The first of these trees is populated with the contents of the input message bit stream. The remaining three trees are initially empty.

Each of the four trees created has a root element (with a name that is specific to each tree). Each tree is made up of a number of discrete pieces of information called *elements*. The root element has no *parent* and no *siblings* (siblings are elements that share a single parent). The root is parent to a number of *child* elements. Each child must have a parent, can have zero or more siblings, and can have zero or more children.

The four trees are created for both built-in and user-defined input nodes and parsers.

The input node passes the message assembly that it has created to subsequent message processing nodes in the message flow:

- All message processing nodes can read the four trees.
- You can code ESQL in the Database and Filter nodes, or use mappings in the nodes that support that interface to modify the Environment and LocalEnvironment trees only.
- The Compute node differs from other nodes in that it has both an input message assembly and at least one output message assembly. Configure the Compute node to determine which trees are included in the output message assembly; the Environment tree is an exception in that it is always retained from input message assembly to output message assembly.

  To determine which of the other trees are included, you must specify a value for the `Compute mode` property of the node (displayed on the Advanced tab). The default action is for only the message to be created. You can specify any combination of message, LocalEnvironment, and ExceptionList trees to be created in the output message assembly.

  If you want the output message assembly to contain a complete copy of the input message tree, you can code a single ESQL SET statement to make the copy. If you want the output message to contain a subset of the input message tree, code ESQL to copy those parts that you want. In both cases, your choice of `Compute mode` must include `Message`.

  If you want the output message assembly to contain all or part of the input LocalEnvironment or ExceptionList tree contents, code the appropriate ESQL to copy information you want to retain in that tree. Your choice of `Compute mode` must include LocalEnvironment, or Exception, or both.

  You can also code ESQL to populate the output message, Environment, LocalEnvironment, or ExceptionList tree with information that is not copied from the input tree. For example, you can retrieve data from a database, or calculate content from the input message data.
- You can produce similar results in the JavaCompute node. See “Writing Java” on page 1755 for more information.

If messages are recorded as they pass through a message flow, you can view and edit the stored message assembly files by using the Message Assembly editor. You can also use the recorded message assemblies in unit tests for your message flows and message flow nodes. For more information, see “Developing integration tests” on page 1891 and #unique_720.

Message tree
The message tree is a part of the logical tree (message assembly) in which the internal representation of the message body is stored.

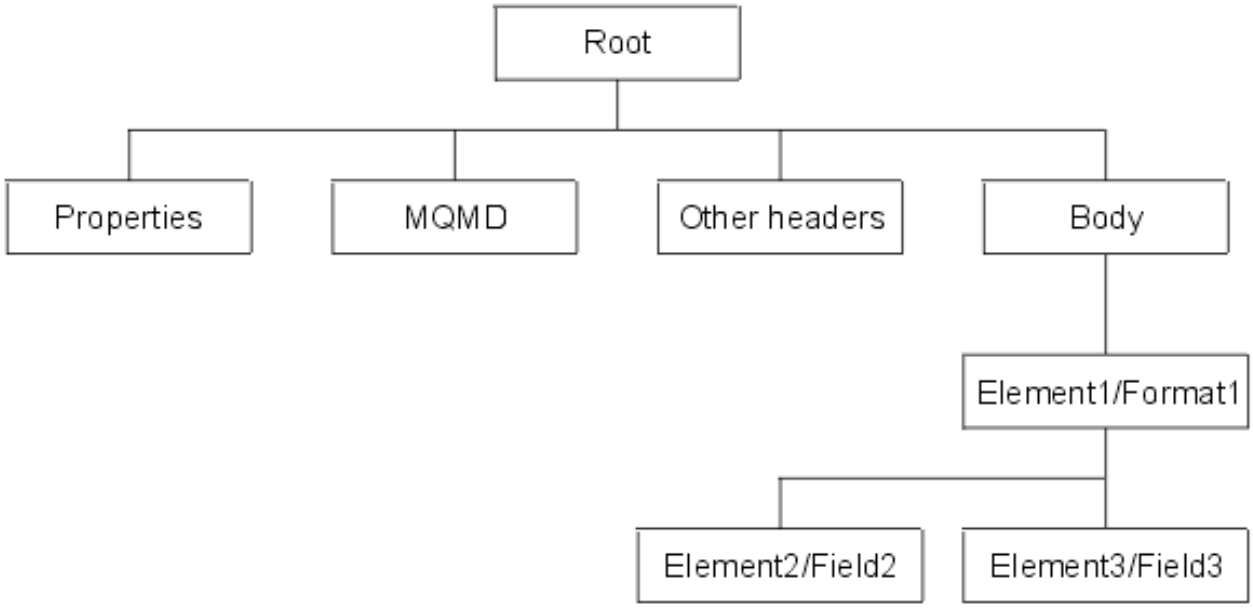
The root of a message tree is called Root. The message tree is always present, and is passed from node to node in a single instance of a message flow.

The message tree includes all the headers that are present in the message, in addition to the message body. The tree also includes the Properties subtree, if that is created by the parser. If a supplied parser has created the message tree, the element that represents the Properties subtree is followed by zero or more headers.

If the message has been received across the IBM MQ Enterprise Transport or IBM MQ Mobile Transport, the first header (the second element) must be the MQMD. Any additional headers that are included in the message appear in the tree in the same order as in the message. The last element beneath the root of the message tree is always the message body.

If a user-defined parser has created the message tree, the Properties tree, if present, is followed by the message body.

The message tree structure is shown in the following section. If the input message is not an IBM MQ message, the headers that are shown might not be present. If the parser that created this tree is a user-defined parser, the Properties tree might not be present.



The Body tree is a structure of child elements that represents the message content (data), and reflects the logical structure of that content. The Body tree is created by a body parser (either a supplied parser or a user-defined parser)

Each element in the parsed tree is one of three types:

Name element
A name element has a string associated with it, which is the name of the element. An example of a name element is `XMLElement`. A name element also has a second string associated with it, which is the namespace of the element; this string might be empty.

Value element
A value element has a value associated with it. An example of a value element is `XMLContent`.

Name-value element
A name-value element is an optimization of the case where a name element contains only a value element and nothing else. The element contains both a name and a value. An example of a name-value element is `XMLAttribute`.

Properties folder

The Properties folder is the first element of the message tree and holds information about the characteristics of the message.

The root of the Properties folder is called Properties. It is the first element under Root. All message trees that are generated by the built-in parsers include a Properties folder for the message. If you create your own user-defined parser, you can choose whether the parser creates a Properties folder. However, for consistency, you should include this action in the user-defined parser.

The Properties folder contains a set of standard properties that you can manipulate in the message flow nodes in the same way as any other property. Some of these fields map to fields in the supported IBM MQ headers, if present, and are passed to the appropriate parser when a message is delivered from one node to another.

For example, the MQRFH2 header contains information about the message model, message name, and message physical format. These values are stored in the Properties folder as MessageSet, MessageType, and MessageFormat. To access these values using ESQL or Java in the message processing nodes, refer to these values in the Properties folder; do not refer directly to the fields in the headers from which they are derived.

The Properties parser ensures that the values in the header fields match the values in the Properties folder on input to, and output from, every node. For any field, if only one header is changed (the Properties

header or a specific message header), that value is used. If both the Properties header and the specific message header are changed, the value from the Properties folder is used.

When the message flow processing is complete, the Properties folder is discarded.

How the message tree is populated
The message tree is initially populated by the input node of the message flow.

When the input node receives the input message, it creates and completes the Properties tree (the first subtree of the message tree).

The node then examines the contents of the input message bit stream and creates the remainder of the message tree to reflect those contents. This process depends to some extent on the input node itself, which is governed by the transport across which the message is received:

IBM MQ Enterprise Transport protocol
If your application communicates with the integration node across these protocols, and your message flow includes the corresponding MQInput node, all messages that are received must start with a Message Queue Message Descriptor (MQMD) header. If a valid MQMD is not present at the start of the message, the message is rejected, and no further processing takes place.

The input node first invokes the MQMD parser and creates the subtree for that header.

A message can have zero or more additional headers following the MQMD. These headers are chained together, with the **Format** field of one header defining the format of the following header, up to and including the last header, which defines the format of the message body. If an MQRFH and an MQRFH2 header exist in the chain, the name and value data in either of these two headers can also contain information about the format of the following data. If the value that is specified in **Format** is a recognized parser, this value always takes precedence over the name and value data.

The integration node invokes the appropriate parser to interpret each header, following the chain in the message. Each header is parsed independently. The fields in a single header are parsed in an order that is governed by the parser. You cannot predict the order that is chosen, but the order in which fields are parsed does not affect the order in which the fields are displayed in the header.

The integration node ensures that the integrity of the headers that precede a message body is maintained. The format of each part of the message is defined, either by the **Format** field in the immediately preceding header (if the following part is a recognized IBM MQ format), or by the values that are set in the MQRFH or MQRFH2 header:

- The format of the first header is known because it must be MQMD.
- The format of any subsequent header in the message is set in the **Format** field in the preceding header.
- The format of the body corresponds to the message domain and the parser that must be invoked for the message body (for example, XMLNSC). This information is set either in the MQRFH or MQRFH2 header, or in the *Message Domain* property of the input node that receives the message.

This process is repeated as many times as required by the number of headers that precede the message body. You do not need to populate these fields yourself; the integration node handles this sequence for you.

The integration node completes this process to ensure that **Format** fields in headers correctly identify each part of the message. If the integration node does not complete this process, IBM MQ might be unable to deliver the message. The message body parser is not a recognized IBM MQ header format, therefore the integration node replaces this value in the last headers **Format** field with the value MQFMT_NONE. The original value in that field is stored in the **Domain** field in the MQRFH or MQRFH2 header to retain the information about the contents of the message body.

For example, if the MQRFH2 header immediately precedes the message body, and its **Format** field is set to XMLNSC, which indicates that the message body must be parsed by the XMLNSC parser, the MQRFH2 **Domain** field is set to XMLNSC, and its **Format** field is reset to MQFMT_NONE.

These actions might result in information that is stored explicitly by an ESQL or Java expression being replaced by the integration node.

The **CodedCharSetId** and **Encoding** fields are not populated in the same way as the **Format** field. In particular, the message body is not used to determine the **CodedCharSetId** and **Encoding** values. Rather, these values affect the way in which the message body is written. This can cause unexpected results if an intermediate header (for example MQRFH2) is removed without updating the preceding header in the chain with the removed header values.

When all the headers have been parsed, and the corresponding sub-trees have been created in the message tree, the input node associates the specified parser with the message body. Specify the parser that is to be associated with the message body content, either in a header in the message (for example, the <mcd> folder in the MQRFH2 header), or in the input node properties (if the message does not include headers). The input node makes the association as described in the following list:

- If the message has an MQRFH or MQRFH2 header, the domain that is identified in the header (either in **Format** or the name and value data) determines the parser that is associated with this message.
- If the message does not have an MQRFH or MQRFH2 header, or if the header does not identify the domain, the *Message Domain* property of the input node indicates the domain of the message, and the parser that is to be used. You can specify a user-defined domain and parser.
- If the message domain cannot be identified by header values or by the *Message Domain* property of the input node, the message is handled as a binary object (BLOB). The BLOB parser is associated with the message. A BLOB can be interpreted as a string of hexadecimal characters, and can be modified or examined in the message flow by specifying the location of the subset of the string.

By default, the message body is not parsed straight away, for performance reasons. The message body might not need to be parsed during the message flow. It is parsed only when a reference is made to its contents.

For example, the message body is parsed when you refer to a field in the message body, for example: `Root.XMLNSC.MyDoc.MyField`. Depending on the paths that are taken in the message flow, this can take place at different points. This parsing when first needed approach is also referred to as "partial parsing" or "on-demand parsing", and in typical processing does not affect the logic of a message flow. However, there are some implications for error handling scenarios; see “Handling errors in message flows” on page 1883.

If you want a message flow to accept messages from more than one message domain, include an MQRFH2 header in your message from which the input nodes extract the message domain and related message definition information (message set, message type, and message format).

If you set up the message headers or the input node properties to identify a user-defined domain and parser, the way in which it interprets the message and constructs the logical tree might differ from that described here.

WebSphere Broker File Transport, WebSphere Broker Adapters Transport, IBM MQ Web Services Transport, and WebSphere Broker JMS Transport protocols

If your application communicates with the integration node across these supported protocols, and your message flow includes the corresponding input nodes, messages that are received do not have to include a particular header. If recognized headers are included, the input node invokes the appropriate parsers to interpret the headers and to build the relevant parts of the message tree, as described for the other supported protocols.

If there are no headers, or these headers do not specify the parser for the message body, set the input node properties to define the message body parser. If you do not set the node properties in this way, the message is treated as a BLOB. You can specify a user-defined parser.

The specified parser is associated with the message body by the input node (in the same way as it is for the IBM MQ Enterprise Transport protocol), and by default the message body is not parsed immediately.

If you set up the message headers or the input node properties to identify a user-defined domain and parser, the way in which it interprets the message and constructs the logical tree might differ from that described here.

All other protocols

If you want your message flow to accept messages from a transport protocol for which IBM App Connect Enterprise does not provide built-in support, or you want it to provide some specific processing on receipt of a message, use either the Java or the C language programming interface to create a new user-defined input node.

This interface does not automatically generate a Properties subtree for a message. A message does not need to have a Properties subtree, but you might find it useful to create one to provide a consistent message tree structure, regardless of input node. If you are using a user-defined input node, you must create a Properties subtree in the message tree yourself.

To process messages that do not conform to any of the defined message domains, use the C language programming interface to create a new user-defined parser.

Refer to the node interface to understand how it uses parsers, and whether you can configure it to modify its behavior. If the node uses a user-defined parser, the tree structure that is created for the message might differ slightly from that created for built-in parsers. A user-defined input node can parse an input message completely, or it can participate in partial parsing in which the message body is parsed only when it is required.

You can also create your own output and message processing nodes in C or Java.

Properties versus MQMD folder behavior for various transports

Differences exist in the way the Properties folder and the MQMD folder are treated with respect to which folder takes precedence for the same fields. This treatment is characterized by the transport type (for example, HTTP or WebSphere MQ) that you use.

When the message flow is sourced by an MQInput node, you have an MQMD to parse. In this case, the Properties folder is sourced by the MQMD values and so the MQMD folder takes precedence over the Properties folder in terms of value propagation between the folders. This scenario means that you can perform ESQL, for example, `SET OutputRoot.MQMD.CorrelId` and this command updates the Properties folder value.

When the message flow is sourced from an input node that is not the MQInput node (such as the HTTPInput node or a user-defined input node), no MQMD is parsed. In this scenario, the Properties folder is not sourced from an input MQMD; it is created and populated with transport values that come from other transport specific headers. When you create an MQMD folder in a message flow that was not sourced from the IBM MQ transport, the MQMD header does not take precedence over the Properties folder because the IBM MQ transport did not populate the Properties folder. Therefore, in this case, the Properties folder overwrites any values in MQMD.

The Properties folder is constructed and represents a message received on the transport. In this scenario two entirely different transports are being used which have different meanings and, therefore, different requirements of the Properties folder. When sourced from an HTTPInput node, the HTTP headers have control over the Properties folder for like fields. When sourced from an MQInput node the MQMD has control over the Properties folder for like fields.

Therefore, when you add an MQMD folder to a tree that was created by the HTTP Transport, this MQMD folder does not have control over the Properties folder, and the value propagation direction is not MQMD to Properties, it is Properties to MQMD. The correct approach is to set the **replyIdentifier** field of the Properties folder and to use it to populate the MQMD:

```
SET OutputRoot.Properties.ReplyIdentifier = X' ..... ';
```

The behavior is not unique to just the **CorrelId** to **ReplyIdentifier** fields, but applies to the following fields between the MQMD and Properties folder:

- **CorrelId**
- **Encoding**

- **CodedCharSetId** The `Properties.CodedCharSetId` represents the CodedCharSetId for the message payload, which matches the CodedCharSetId in any message header that immediately precedes the message payload.
- **Persistence**
- **Expiry**
- **Priority**

In summary:

1. When your message flow is sourced by an MQInput node, the MQMD takes precedence over the Properties folder in terms of value propagation between the folders.
2. When your message flow is sourced from an input node that is not the MQInput node (such as the HTTPInput node or a user-defined input node), the MQMD header does not take precedence over Properties folder .
3. When an MQMD folder is added in a tree that was created by the HTTP Transport, this MQMD does not have control over the Properties folder and the value propagation direction is not MQMD to Properties; it is Properties to MQMD.

Example

```
SET OutputRoot.Properties = InputRoot.Properties;
SET OutputRoot.MQMD.Version = 2;
SET OutputRoot.MQMD.CorrelId = X'4d454e53414a4533202020202020202020202020202020';
SET OutputRoot.MQMD.Encoding = 785;
SET OutputRoot.MQMD.CodedCharSetId = 500;
SET OutputRoot.MQMD.Persistence = 1;
SET OutputRoot.MQMD.Expiry = 10000;
SET OutputRoot.MQMD.Priority = 9;
SET OutputRoot.BLOB.BLOB = X'01';
```

When sourced from an HTTPInput node none of these changes take effect and the MQMD output from the Compute node is:

```
(0x01000000):MQMD       = (
    (0x03000000):Version        = 2
    (0x03000000):CorrelId       = X'000000000000000000000000000000000000000000000000'
    (0x03000000):Encoding       = 546
    (0x03000000):CodedCharSetId = 1208
    (0x03000000):Persistence    = FALSE
    (0x03000000):Expiry         = -1
    (0x03000000):Priority       = 0
```

Message tree contents after an exception
The contents of the message tree are updated if an exception is raised.

If no exception occurs while processing the message, the tree structure and content received by an individual message flow node is determined by the action of previous nodes in the flow. If an exception occurs in the message flow, the content of the four trees depends on the following factors:

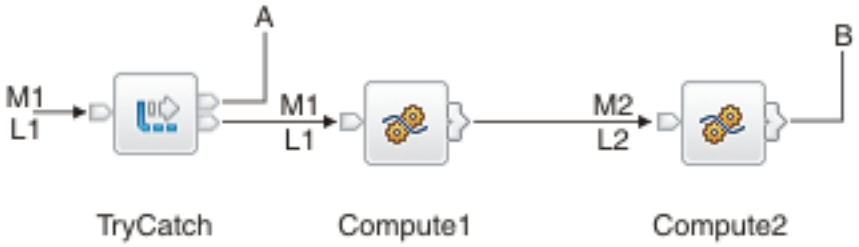
- If the exception is returned to the input node, and the input node Catch terminal is not connected, the trees are discarded. If the message is in a transaction, it is returned to the input queue for further processing. When the message is processed again, a new tree structure is created. If the message is not in a transaction, it is discarded.
- If the exception is returned to the input node and the Catch terminal is connected, the message and local environment trees that were created originally by the input node, and propagated through the Out terminal, are restored, and any updates that you made to their content in the nodes that followed the input node are lost. The environment tree is not restored, and its contents are preserved. If the nodes following the input node include a Compute node that creates a new local environment or message tree, those trees are lost. The exception list tree reflects the one or more exceptions that have been recorded.
- If the exception is caught in the message flow by a TryCatch node, the message and local environment trees that were previously propagated through the Try terminal of the TryCatch node are restored

and propagated through the Catch terminal. Any updates that you made to their content in the nodes that followed the TryCatch node are lost. The environment tree is not restored, and its contents are preserved. If the nodes following the TryCatch node include a Compute node that creates a new local environment or message tree, those trees are lost. The exception list tree reflects the one or more exceptions that have been recorded.

Exception handling paths in a message flow

Exception handling paths start at a failure terminal (most message processing nodes have these), the Catch terminal of an input node, a TryCatch node, or an AggregateReply node, but are no different in principle from a normal message flow path. Such a flow consists of a sequence of nodes connected together by the designer of the message flow. The exception handling paths differ in the kind of processing that they do to record or react to the exception. For example, they might examine the exception list to determine the nature of the error, and take appropriate action or log data from the message or exception.

The local environment and message tree that are propagated to the exception handling message flow path are those at the start of the exception path, not those at the point when the exception is thrown. The following figure illustrates this point:



- A message (M1) and local environment (L1) are being processed by a message flow. They are passed through the TryCatch node to Compute1.
- Compute1 updates the message and local environment and propagates a new message (M2) and local environment (L2) to the next node, Compute2.
- An exception is thrown in Compute2. If the failure terminal of Compute2 is not connected (point **B**), the exception is propagated back to the TryCatch node, but the message and local environment are not. The exception handling path starting at point **A** has access to the first message and local environment, M1 and L1. The environment tree is also available and retains the content it had when the exception occurred.
- If the failure terminal of Compute2 is connected (point **B**), the message and local environment M2 and L2 are propagated to the node connected to that failure terminal. The environment tree is also available and retains the content it had when the exception occurred.

Environment tree

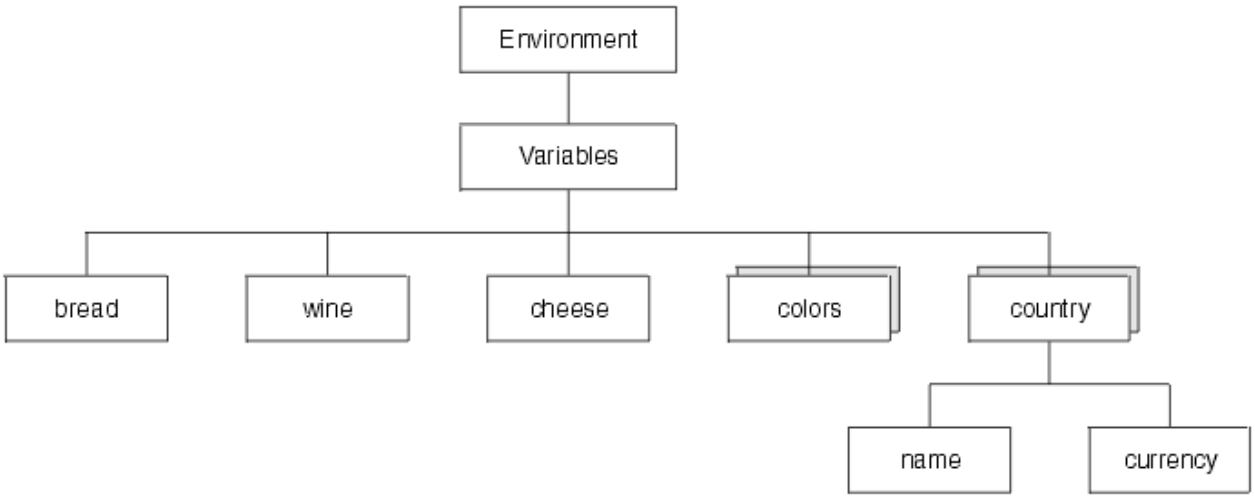
The environment tree is a part of the logical tree (message assembly) in which you can store information while the message passes through the message flow.

The root of the environment tree is called Environment. This tree is always present in the input message; an empty environment tree is created when a message is received and parsed by the input node. You can use this tree as you choose, and create both its content and structure.

The environment tree differs from the local environment tree in that a single instance of it is maintained throughout the message flow. If you include a Compute node, a Mapping node, or a JavaCompute node in your message flow, you do not have to specify whether you want the environment tree to be included in the output message. The environment tree is included automatically, and the entire contents of the input environment tree are retained in the output environment tree, subject to any modifications that you make in the node. Any changes that you make are available to subsequent nodes in the message flow, and to previous nodes if the message flows back (for example, to a FlowOrder or TryCatch node).

If you want to create your own information, create it in the environment tree in a subtree called Variables.

The following figure shown an example of an environment tree:



You could use the following ESQL statements to create the content shown above.

```
SET Environment.Variables =
      ROW('granary' AS bread, 'riesling' AS wine, 'stilton' AS cheese);
SET Environment.Variables.Colors[] =
      LIST{'yellow', 'green', 'blue', 'red', 'black'};
SET Environment.Variables.Country[] = LIST{ROW('UK' AS name, 'pound' AS currency),
     ROW('USA' AS name, 'dollar' AS currency)};
```

When the message flow processing is complete, the Environment tree is discarded.

Local environment tree
The local environment tree is a part of the logical tree (message assembly) in which you can store information while the message flow processes the message.

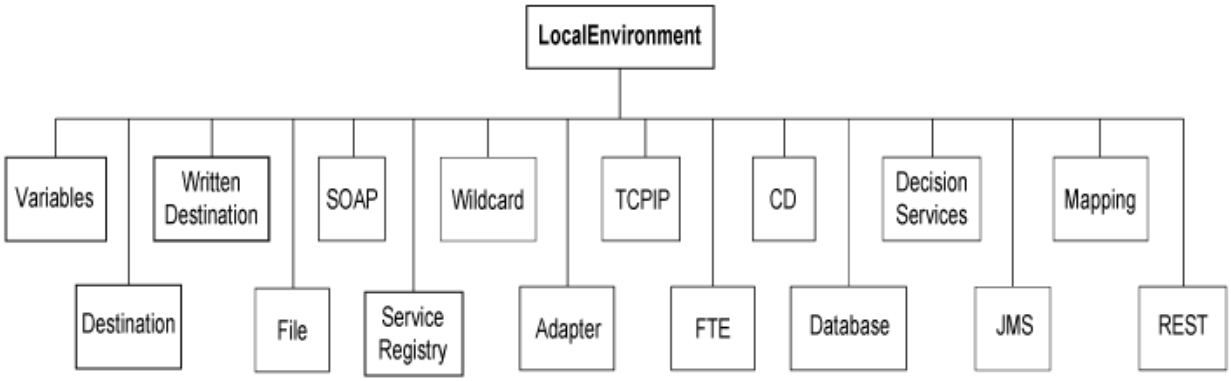
The root of the local environment tree is called `LocalEnvironment`. This tree is always present in the input message, and is created when a message is received by the input node. Some input nodes create local environment fields, other nodes leave the tree empty.

The local environment tree is made up of the following structure:

- Anything in the format of `LocalEnvironment.Destination.`*`output_or_request_node_name`*, for example; LocalEnvironment.Destination.Email, decides what happens when information is going into an output or request node.
- Anything in the format of `LocalEnvironment.WrittenDestination.`*`output_or_request_node_name`*, for example; LocalEnvironment.WrittenDestination.FTE, gives you information about the processed output of an output or a request node.
- Anything in the format of `LocalEnvironment.`*`input_node_name`*`.input`, for example; LocalEnvironment.Adapter.Input, contains information that has been stored by an input node.

Use the local environment tree to store variables that can be referred to and updated by message processing nodes that occur later in the message flow. You can also use the local environment tree to define destinations (that are internal and external to the message flow) to which a message is sent. IBM App Connect Enterprise also stores information in the local environment in some circumstances, and references it to access values that you might have set for destinations.

The following figure shows an example of the local environment tree structure. The children of Destination are protocol-dependent.



In the tree structure shown, LocalEnvironment has several children:

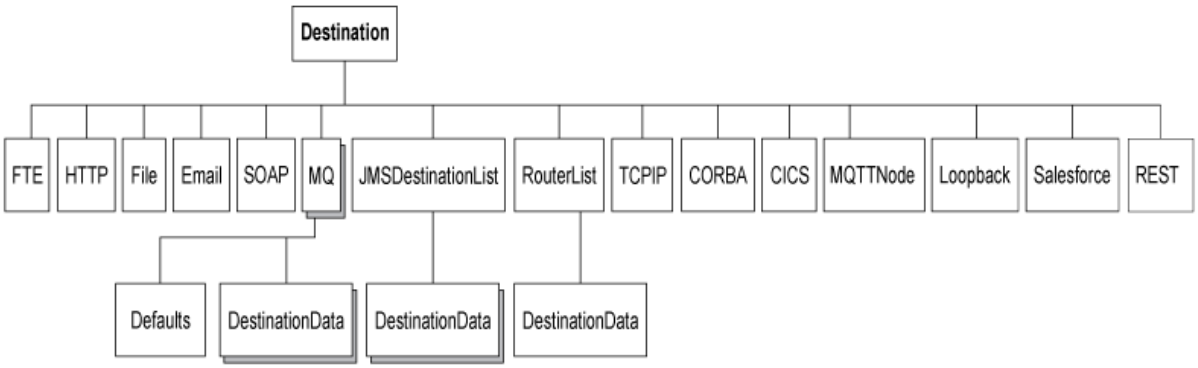
LocalEnvironment.Variables

This subtree is optional. If you create local environment variables, store them in a subtree called Variables. It provides a work area that you can use to pass information between nodes. This subtree is never inspected or modified by any supplied node.

Variables in the local environment can be changed by any subsequent message processing node, and the variables persist until the node that created them goes out of scope.

The variables in this subtree are persistent only within a single instance of a message flow. If you have multiple instances of a message passing through the message flow, and need to pass information between them, you must use an external database.

LocalEnvironment.Destination



This subtree consists of a number of children that indicate the transport types to which the message is directed (the Transport identifiers), or the target Label nodes that are used by a RouteToLabel node.

- Transport information

  Transport information is used by some input and output nodes, including FTE, HTTP, File, Email, SOAP, MQ, JMS, TCPIP, CORBA, CICS, and MQTT.

  LocalEnvironment.Destination.FTE

  If the message flow includes an FTEOutput node, you can override its properties with elements in this subtree. See “Using local environment variables with file nodes” on page 962.

  LocalEnvironment.Destination.HTTP

  If the message flow starts with an HTTPInput node, a single name element HTTP is added to Destination. The element HTTP.RequestIdentifier is created and initialized so that it can be used by an HTTPReply node. You can also create other fields in the HTTP structure for use by the HTTPRequest node; for example, the URL of the service to which the request is sent. For more

information, see *Local environment overrides* in the topic node, and examples in "Populating Destination in the local environment tree" on page 1656.

LocalEnvironment.Destination.File

If the message flow includes a FileOutput node, you can override its `directory` and `name` properties with elements in this subtree. See "Using local environment variables with file nodes" on page 962.

LocalEnvironment.Destination.Email

If the message flow includes an EmailOutput node, then information defined in this subtree will specify or override the SMTP server connection information and attachments associated with each email sent by the node. Multiple attachments can be specified for inclusion in the email sent, including the specification of the attachment name, content, and type. See node.

LocalEnvironment.Destination.SOAP

You can place outbound WS-Addressing header information in the local environment to override the defaults that are generated by the SOAPReply, SOAPRequest, or SOAPAsyncRequest nodes. See "WS-Addressing information in the local environment" on page 834.

If the message flow includes SOAPRequest or SOAPAsyncRequest nodes, you can override their HTTP Transport and JMS transport properties in this subtree. See node, node, or Local environment overrides for the node.

If the message flow includes a SOAPAsyncRequest node, you can use this subtree to pass state and correlation information to a SOAPAsyncResponse node in another message flow. See "WS-Addressing with the SOAPAsyncRequest and SOAPAsyncResponse nodes" on page 833.

If the message flow includes SOAPReply, SOAPRequest, or SOAPAsyncRequest nodes, you can override their use of outbound MTOM messages in this subtree. See "SOAP MTOM and the SOAPReply, SOAPRequest, and SOAPAsyncRequest nodes" on page 849.

LocalEnvironment.Destination.MQ

If the message flow includes an MQOutput node, each element is a name element, *MQ* (A deprecated alternative exists, called *MQDestinationList*. Use *MQ* for all new message flows). If more than one element exists, each is processed sequentially by the node. See the example in "Populating Destination in the local environment tree" on page 1656.

You can configure MQOutput nodes to examine the list of destinations and send the message to those destinations, by setting the property `Destination Mode` to Destination List. If you do so, you must create this subtree and its contents to define those destinations, giving it the name Destination. If you do not do so, the MQOutput node cannot deliver the messages.

If you prefer, you can configure the MQOutput node to send messages to a single fixed destination, by setting the property `Destination Mode` to Queue Name or Reply To Queue. If you select either of these fixed options, the destination list has no effect onintegration server operations and you do not have to create this subtree.

You can construct the MQ element to contain a single optional Defaults element. The Defaults element, if created, must be the first child and must contain a set of name-value elements that give default values for the message destination and its PUT options for that parent.

You can also create a number of elements called DestinationData within MQ. Each of these can be set up with a set of name-value elements that defines a message destination and its PUT options.

The set of elements that define a destination is described in Data types for elements in the MQ DestinationData subtree.

The content of each instance of DestinationData is the same as the content of Defaults for each protocol, and can be used to override the default values in Defaults. You can set up Defaults to contain values that are common to all destinations, and set only the unique values in each DestinationData subtree. If you do not set a value either in DestinationData or Defaults, the value that you have set for the corresponding node property is used. Similarly, if you specify a field

name or value with the wrong spelling or case, it is ignored, and the value that you have set for the corresponding node property is used.

The information that you insert into DestinationData depends on the characteristic of the corresponding node property: This information is described in “Accessing the local environment tree” on page 1654.

LocalEnvironment.Destination.JMSDestinationList

A JMSOutput node can be configured to send to multiple JMS Queues or to publish to multiple JMS Topics using a destination list created in the local environment by a transformation node.

The JMSOutput node searches the local environment for data elements called DestinationData under the folder Destination.JMSDestinationList. The node sends the JMS message to each

DestinationData entry found in that folder. See the example in “Populating Destination in the local environment tree” on page 1656.

LocalEnvironment.Destination.TCPIP

If the message flow includes a TCPIPClientOutput node or a TCPIPServerOutput node, you can override its TCPIP connection with elements in this subtree. See node and node.

LocalEnvironment.Destination.CORBA

If the message flow includes a CORBARequest node, you can override its `Operation name` property by specifying a value in the following location:

```
$LocalEnvironment/Destination/CORBA/Request/OperationName
```

For more information about the operation name, see node.

LocalEnvironment.Destination.CICS

If the message flow includes a CICSRequest node, you can override the following properties with elements in this subtree:

- `Program name`
- `Commarea length`
- `Mirror transaction ID`
- `Set EIBTRNID only`
- `Message domain`
- `Message set`
- `Message type`
- `Message format`
- `Message coded character set ID`
- `Message encoding`

For more information, see “Local environment overrides for the CICSRequest node” on page 1185.

You can also set LocalEnvironment values for CICS channels and containers. For more information, see “COMMAREA or channel data structures” on page 1171.

LocalEnvironment.Destination.MQTT.Output

If the message flow includes an MQTTPublish node, you can override the following properties with elements in this subtree:

- `Retained`
- `Topic name`
- `Quality of service`

For more information, see “Using local environment variables with MQTT nodes” on page 890.

LocalEnvironment.Destination.Loopback

If the message flow includes a LoopBackRequest node, you can override the properties of those nodes with elements in this subtree. For more information, see “Using local environment variables with LoopBackRequest nodes” on page 1226.

LocalEnvironment.Destination.Salesforce

If the message flow includes a SalesforceRequest node, you can override the properties of those nodes with elements in this subtree. For more information, see “Using local environment variables with Salesforce nodes” on page 1211.

LocalEnvironment.Destination.REST

If the message flow includes a RESTRequest or RESTAsyncRequest node, you can override the properties of those nodes with elements in this subtree. For more information, see "Using local environment variables with REST nodes" on page 1039.

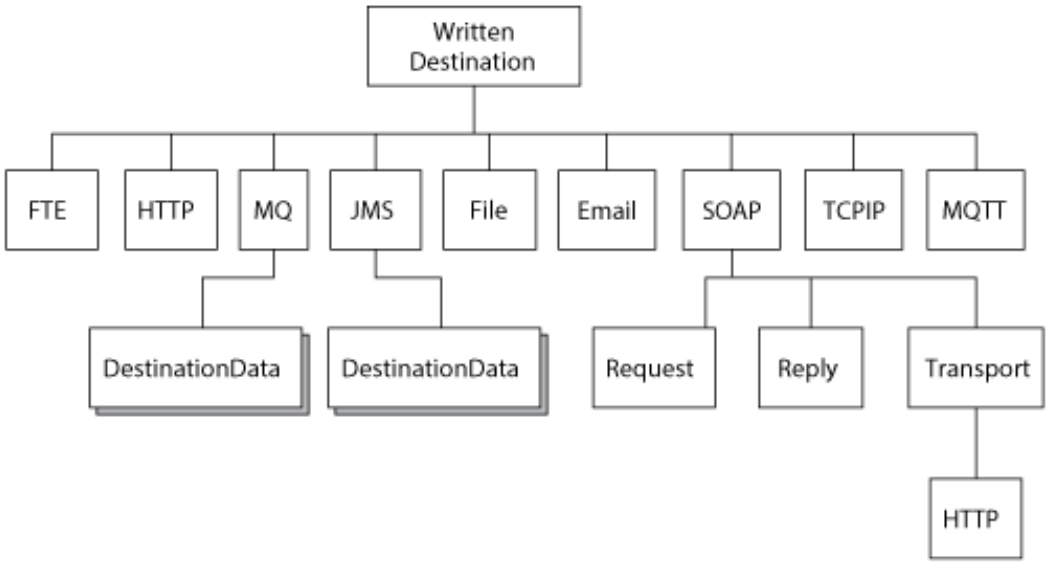
LocalEnvironment.Destination.Kafka

If the message flow includes a KafkaProducer node, you can override the properties of the node with elements in this subtree. For more information, see "Using local environment variables with Kafka nodes" on page 907.

- Routing information

The child of Destination is *RouterList*. It has a single child element called *DestinationData*, which has a single entry called labelName. If you are using a dynamic routing scenario involving the RouteToLabel and Label nodes, you must set up the Destination subtree with a RouterList that contains the reference labels.

LocalEnvironment.WrittenDestination



This subtree contains the addresses to which the message has been written. Its name is fixed and it is created by the message flow when a message is propagated through the Out terminal of a request, output, or reply node. The subtree includes transport-specific information (for example, if the output message has been put to an IBM MQ queue, it includes the queue manager and queue names).

You can use one of the following methods to obtain information about the details of a message after it has been sent by the nodes:

- Connect a transformation node to the Out terminal.

The topic for each node that supports WrittenDestination information contains details about the data that it contains.

LocalEnvironment.File

This subtree contains information that is stored by the FileInput node.

This information describes the file, and also contains data about the current record.

More details about the information that is stored in this subtree are in "Using local environment variables with file nodes" on page 962.

LocalEnvironment.SOAP
This subtree contains information that is stored by SOAPInput, SOAPAsyncResponse, or SOAPRequest nodes.

More details about the information that is stored in this subtree are in "WS-Addressing information in the local environment" on page 834.

If the message flow includes a SOAPAsyncResponse node, you can use this subtree to receive state and correlation information passed by a SOAPAsyncRequest node in another message flow.

More details about the information that is stored in this subtree are in "WS-Addressing with the SOAPAsyncRequest and SOAPAsyncResponse nodes" on page 833.

LocalEnvironment.Wildcard
This subtree contains information about the wildcard characters that are stored by the FileInput node.

On the FileInput node you can specify a file name pattern that contains wildcard characters.

More details about the information that is stored in this subtree are in "Using local environment variables with file nodes" on page 962.

LocalEnvironment.Adapter
This subtree contains information that is stored by the WebSphere Adapters nodes.

For a WebSphere Adapters input node:

- **MethodName** is the name of the business method that corresponds to the Enterprise Information System (EIS) event that triggered this message delivery.

  The bindings for EIS events or business methods are created by the Adapter Connection wizard.
- **Type** describes the type of adapter that is being used:
  - SAP
  - Siebel
  - PeopleSoft
  - JD Edwards

For a WebSphere Adapters request node:

MethodName is the name of the business method that the request node must use.

LocalEnvironment.TCPIP

If the message flow includes a TCPIPClientReceive node or a TCPIPServerReceive node, you can override its TCPIP connection with elements in this subtree. See node and node.

This subtree contains information that is stored by the TCPIPClientInput, TCPIPClientReceive, TCPIPServerInput, and TCPIPServerReceive nodes.

This information describes the connection that the node is using.

More details about the information that is stored in this subtree are in node, node, node, and node.

LocalEnvironment.FTE and LocalEnvironment.FTE.Transfer
These subtrees contain information that is stored by the FTEInput node. The LocalEnvironment.FTE subtree contains information about the current record. The LocalEnvironment.FTE.Transfer subtree contains information received from IBM MQ File Transfer Edition regarding the file.

More details about the information that is stored in these subtrees are in "Using local environment variables with file nodes" on page 962.

LocalEnvironment.CD and LocalEnvironment.CD.Transfer
These subtrees contain information that is stored by the CDInput node. The LocalEnvironment.CD subtree contains information about the current record. The LocalEnvironment.CD.Transfer subtree contains information received from IBM Sterling Connect:Direct regarding the file.

More details about the information that is stored in these subtrees are in "Using local environment variables with file nodes" on page 962.

LocalEnvironment.Database
This subtree contains information that is propagated from the DatabaseInput node.

The LocalEnvironment.Database.Input.Event.Usr subtree contains user-defined data associated with an event. It is initialized in the `ReadEvents` procedure of the ESQL module associated with the DatabaseInput node.

LocalEnvironment.Database.Input.Event.Key holds a unique key for an event. It is set in the `ReadEvents` procedure of the ESQL module associated with the DatabaseInput node.

LocalEnvironment.Database.Input.Event.FailureCount contains a value for the number of times an attempt to process an event has failed. This count includes all unhandled exceptions occurring either in the ESQL module or the message flow.

LocalEnvironment.JMS
This subtree contains information that is stored by the JMSReceive node.

If the message flow includes a JMSReceive node, you can override its JMS connection properties with elements in this subtree.

More details about this information that is stored in this subtree are in Local environment overrides for the node.

LocalEnvironment.Mapping
This subtree contains information that is stored by Mapping node.

If your message flow includes a Mapping node, you can override the mapping routine that is used to transform a message instance by specifying a new mapping routine in the **MappingRoutine** field. You must specify the new mapping routine in the LocalEnvironment.Mapping subtree that is upstream of the Mapping node that you need to modify.

LocalEnvironment.REST

This subtree contains information that is stored by a REST API when it receives a request and routes that request to a subflow that implements an operation in the REST API. For more information, see "Implementing REST API operation processing in the subflow by using message flow nodes" on page 2031.

This subtree also contains information that is stored by a RESTAsyncResponse node when it receives a response for a request initiated by a RESTAsyncRequest node. For more information, see "Using local environment variables with REST nodes" on page 1039.

LocalEnvironment.Kafka

This subtree contains information that is stored by the KafkaConsumer node, including information about the topic where the message was published. For more details about the information contained in this subtree, see "Using local environment variables with Kafka nodes" on page 907.

When the message flow processing is complete, the local environment tree is discarded.

Exception list tree
The exception list tree is a part of the logical tree (message assembly) in which the message flow writes information about exceptions that occur when a message is processed.

The root of the exception list tree is called ExceptionList, and the tree consists of a set of zero or more exception descriptions. The exception list tree is populated by the message flow if an exception occurs. If no exception conditions occur during message flow processing, the exception list that is associated with that message consists of a root element only. This list is, in effect, an empty list of exceptions.

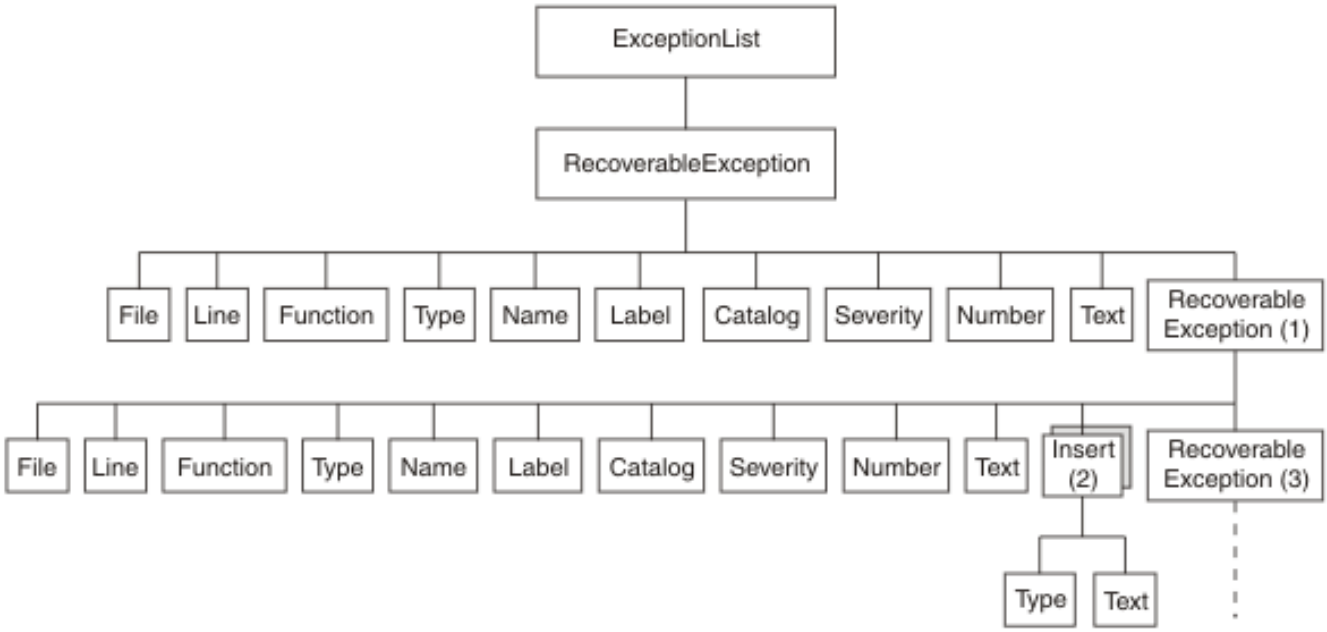
The exception list tree can be accessed by other nodes in the message flow that receive the message after the exception has occurred. You can modify the contents of the exception list tree only in a node that provides an interface to modify the outbound message tree; for example, the Compute node.

If an exception condition occurs, message processing is suspended and an exception is thrown. Control is passed back to a higher level; that is, an enclosing catch block. An exception list is built to describe the failure condition, and the whole message, together with the local environment tree, and the newly-populated exception list, is propagated through an exception-handling message flow path.

The child of ExceptionList may be any one of the exception types that is included in the following list. Typically, only one child of the root is created, although more than one might be generated in some circumstances. The child of ExceptionList contains a number of children, each of which may also be any one of the types in the following list. The last of these children provides further information specific to the type of exception.

- FatalException
- RecoverableException
- ConfigurationException
- SecurityException
- ParserException
- ConversionException
- DatabaseException
- UserException
- CastException
- MessageException
- SqlException
- SocketException
- SocketTimeoutException
- UnknownException

The following figure shows the structure of the exception list tree for a recoverable exception:



The exception description structure can be both repeated and nested to produce an exception list tree. In this tree:

- The depth (that is, the number of parent-child steps from the root) represents increasingly detailed information for the same exception.

- The width of the tree represents the number of separate exception conditions that occurred before processing was abandoned. This number is usually one, and results in an exception list tree that consists of a number of exception descriptions that are connected as children of each other.
- At the numbered points in the tree:
  1. This child can be any one of the exception types that are listed earlier in this topic. All of these elements have the children shown; if present, the last child is the same element as its parent.
  2. This element might be repeated.
  3. If present, this child contains the same children as its parent.

The children in the tree take the form of a number of name-value elements that give details of the exception, and zero or more name elements whose name is Insert. The NLS (National Language Support) message number identified in a name-value element identifies an IBM App Connect Enterprise error message. The Insert values are used to replace the variables in this message and provide further detail about the cause of the exception.

The name-value elements in the exception list shown in the figure above are described in the following table.

Name		Type	Description
File[1]		String	C++ source file name
Line[1]		Integer	C++ source file line number
Function[1]		String	C++ source function name
Type[2]		String	Source object type
Name[2]		String	Source object name
Label[2]		String	Source object label
Text[1]		String	Optional non-NLS text
Catalog[3]		String	NLS message catalog name[4]
Severity[3]		Integer	1 = information 2 = warning 3 = error
Number[3]		Integer	NLS message number[4]
Insert[3]	Type	Integer	The data type of the value: 0 = Unknown 1 = Boolean 2 = Integer 3 = Float 4 = Decimal 5 = Character 6 = Time 7 = GMT Time 8 = Date 9 = Timestamp 10 = GMT Timestamp 11 = Interval 12 = BLOB 13 = Bit Array 14 = Pointer
	Text	String	The data value

Notes:

1. Do not use the File, Line, Function, and Text elements for exception handling decision making. These elements ensure that information can be written to a log for use by IBM Service personnel, and are subject to change in both content and order.
2. The Type, Name, and Label elements define the object (usually a message flow node) that was processing the message when the exception condition occurred.
3. The Catalog, Severity, and Number elements define an NLS message: the Insert elements that contain the two name-value elements shown define the inserts into that NLS message.
4. NLS message catalog name and NLS message number refer to a translatable message catalog and message number.

When the message flow processing is complete, the exception list tree is discarded.

Correlation names

A correlation name is a field reference that identifies a well-defined starting point in the logical message tree and is used in field references to describe a standard part of the tree format.

When you access data in any of the four trees (message, environment, local environment, or exception list), the correlation names that you can use depend on the node for which you create ESQL or mappings, and whether the node creates an output message. For example, a Trace node does not alter the content of the message as it passes through the node, but a Compute node can construct a new output message.

You can introduce new correlation names with SELECT expressions, quantified predicates, and FOR statements. You can create non-correlation names in a node by using reference variables.

Correlation names in nodes that do not create an output message

Most message flow nodes do not create an output message; all ESQL expressions that you write in ESQL modules or in mappings in these nodes refer to just the input message. Use the following correlation names in the ESQL modules that you write for Database and Filter nodes:

Root
The root of the message passing through the node.

Body
The last child of the root of the message; that is, the body of the message. This name is an alias for `Root.*[<]`.

Properties
The standard properties of the input message.

Environment
The structure that contains the current global environment variables that are available to the node. Environment can be read and updated from any node for which you can create ESQL code or mappings.

LocalEnvironment
The structure that contains the current local environment variables that are available to the node. LocalEnvironment can be read and updated from any node for which you can create ESQL code or mappings.

DestinationList
The structure that contains the current local environment variables available to the node. Its preferred name is LocalEnvironment, although the DestinationList correlation name can be used for compatibility with earlier versions.

ExceptionList
The structure that contains the current exception list to which the node has access.

You cannot use these correlation names in the expression of any mapping for a Mapping node.

Correlation names in nodes that create an output message

If you are coding ESQL for a Compute node, the correlation names must distinguish between the two message trees involved: the input message and the output message. The correlation names in ESQL in these nodes are:

InputBody
The last child of the root of the input message. This name is an alias for `InputRoot.*[<]`.

InputRoot
The root of the input message.

InputProperties
The standard properties of the input message.

Environment
The structure that contains the current global environment variables that are available to the node. Environment can be read and updated.

InputLocalEnvironment
The structure that contains the local environment variables for the message passing through the node.

InputDestinationList
The structure that contains the local environment variables for the message passing through the node. Use the correlation name InputDestinationList for compatibility with earlier versions; if compatibility is not required, use the preferred name InputLocalEnvironment

InputExceptionList
The structure that contains the exception list for the message passing through the node.

OutputRoot
The root of the output message.

In a Compute node, the correlation name OutputBody is not valid.

OutputLocalEnvironment
The structure that contains the local environment variables that are sent out from the node.

While this correlation name is always valid, it has meaning only when the `Compute Mode` property of the Compute node indicates that the Compute node is propagating the LocalEnvironment.

OutputDestinationList
The structure that contains the local environment variables that are sent out from the node. Use the correlation name OutputDestinationList for compatibility with earlier versions; if compatibility is not required, use the preferred name OutputLocalEnvironment

OutputExceptionList
The structure that contains the exception list that the node is generating.

While this correlation name is always valid, it has meaning only when the `Compute Mode` property of the Compute node indicates that the Compute node is propagating the ExceptionList.

For a description of how to use *, see “Using anonymous field references” on page 1639.

Parsers

A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

A parser is called when the bit stream that represents an input message is converted to the internal form that can be handled by the integration node; this invocation of the parser is known as *parsing*. The internal form, a logical tree structure, is described in “Logical tree (message assembly)” on page 501. It is described as a tree because messages are typically hierarchical in structure; a good example of this structure is XML. The way in which the parser interprets the bit stream is unique to that parser; therefore, the logical message tree that is created from the bit stream varies from parser to parser.

The parser that is called depends on the structure of a message, referred to as the *message template*. Message template information comprises the message domain, message model, message type, and physical format of the message. Together, these values identify the structure of the data that the message contains.

A parser is also called when a logical tree that represents an output message is converted into a bit stream; this action by the parser is known as *writing*. Typically, an output message is generated by an output node at the end of the message flow. However, you can connect more nodes to an output node to continue processing of the message.

The message domain identifies the parser that is used to parse and write instances of the message. The remaining parts of the message template, message model, message type, and physical format, are optional, and are used by model-driven parsers such as the MRM parser.

The logical structure of the message typically maps to the business content of the message; for example, it contains a customer name, address, and account number. It is only when you send a message across a connection that the physical characteristics are important, and influence the construction of the bit stream.

The integration node requires access to a parser for every message domain to which your input messages and output messages belong. In addition, the integration node requires a parser for every identifiable message header that is included in the input or output message. Parsers are called when required by the message flow.

Body parsers

IBM App Connect Enterprise provides built-in support for messages in the following message domains by providing message body parsers:

- MRM (“MRM parser and domain” on page 545)
- XMLNSC, XMLNS, and XML (“XML parsers and domains” on page 528)
- SOAP (“SOAP parser and domain” on page 526)
- DataObject (“DataObject parser and domain” on page 546)
- JMSMap and JMSStream (“JMS parsers and domains” on page 547)
- MIME (“MIME parser and domain” on page 547)
- BLOB (“BLOB parser and domain” on page 552)
- IDOC (“IDOC parser and domain” on page 553)
- JSON (“JSON parser and domain” on page 553)
- DFDL (“DFDL parser and domain” on page 544)

See “Which body parser should you use?” on page 524 for a discussion about which message body parser to use under what circumstances.

You specify which message domain to use for your message at the place in the message flow where parsing or writing is initiated.

- To parse a message bit stream, typically you set the *Message Domain* property of the input node that receives the message. But, if you are initiating the parse operation in ESQL, use the **DOMAIN** clause of the **CREATE** statement.

  The message tree that is created is described in “Message tree” on page 502. Its exact form might change as it progresses through the message flow, depending on what the nodes are doing.

  The last child element of the Root element of the message tree takes the name of the body parser that created the tree. For example, if the *Message Domain* property was set to `MRM`, the last child element of Root is called MRM, which indicates that the message tree is owned by the MRM parser.
- To write a message, the integration node calls the owning body parser to create the message bit stream from the message tree.

Some body parsers are *model-driven*, which means that they use predefined messages from a message set when parsing and writing. The MRM, SOAP, DataObject, IDOC, and (optionally) XMLNSC parsers are model-driven parsers. To use these parsers, messages must be modeled in a message set and deployed to the integration node from the IBM App Connect Enterprise Toolkit.

Other body parsers are *programmatic*, which means that the messages that they parse and write are *self-defining* messages, and no message set is required. See "Predefined and self-defining messages" on page 523.

When you use a model-driven parser, you must also specify the message model and, optionally, the message type and message format so that the parser can locate the deployed message definition with which to guide the parsing or writing of the message.

To parse a message bit stream, typically you set the `Message model`, `Message `, and `Physical format` properties of the input node that receives the message. Or, if you are initiating the parse operation in ESQL, you use the **SETTYPE**, and **FORMAT** clauses of the **CREATE** statement. This information is copied into the *Properties* folder of the message tree.

To write a message, the integration node calls the owning body parser to create the message bit stream from the message tree. If the parser is a model-driven parser, it uses the *MessageSet*, *MessageType*, and *MessageFormat* fields in the Properties folder.

Whether the message type or message format are needed depends on the message domain.

Even if the body parser is not model-driven, it is good practice to create and use a message set in the IBM App Connect Enterprise Toolkit, because it simplifies the development of your message flow applications, even though the message set is not deployed in the IBM App Connect Enterprise runtime environment. See "Why model messages?" on page 2138 for information about the advantages of creating a message set.

Header parsers

IBM App Connect Enterprise also provides parsers for the following message headers, which your applications can include in input or output messages:

- WMQ MQMD (The MQMD parser)
- WMQ MQMDE (The MQMDE parser)
- WMQ MQCFH (The MQCFH parser)
- WMQ MQCIH (The MQCIH parser)
- WMQ MQDLH (The MQDLH parser)
- WMQ MQIIH (The MQIIH parser)
- WMQ MQRFH (The MQRFH parser)
- WMQ MQRFH2 and MQRFH2C (The MQRFH2 and MQRFH2C parsers)
- WMQ MQRMH (The MQRMH parser)
- WMQ MQSAPH (The MQSAPH parser)
- WMQ MQWIH (The MQWIH parser)
- WMQ SMQ_BMH (The SMQ_BMH parser)
- JMS header ("Representation of messages in the JMS Transport" on page 858)
- HTTP headers ("HTTP headers" on page 791)

All header parsers are programmatic and do not use a message set when parsing or writing.

User-defined parsers

To parse or write message body data or headers that the supplied parsers do not handle, you can create user-defined parsers that use the IBM App Connect Enterprise user-defined parser programming interface.

Tip: No parser is provided for messages, or parts of messages, in the WMQ format `MQFMT_IMS_VAR_STRING`. Data in this format is often preceded by an MQIIH header (format `MQFMT_IMS`). IBM App Connect Enterprise treats such data as a BLOB message. If you change the CodedCharSetId or the encoding of such a message in a message flow, the `MQFMT_IMS_VAR_STRING` data is not converted, and the message descriptor or preceding header does not correctly describe that part of the message. If you need the data in these messages to be converted, use the MRM domain and create a message set to model the message content, or provide a user-defined parser.

Root parsers

A root parser is the first parser in the Logical Tree structure built by the integration node. The root parser is defined by which input node you are using in your message flow, for example theSOAPInput Node uses a different root parser to the MQInput Node. Each root parser creates different properties parsers to work with the properties folder in the Logical Tree because different input nodes need to obtain and serialize these values in transport specific ways. The root parser that is assigned to different trees can cause different behavior when elements are copied between trees. The IBM MQ Root parser is used when you create new trees in ESQL.

Parser Copies

When you copy a tree between one parser and another, for example as a result of using ESQL then the behavior is different depending on the types of the parsers that are involved.

Like Parser Copies

When a tree is copied between two parsers that are the same, for example in ESQL:

```
SET OutputRoot.XMLNSC.myTesData.Data = InputRoot.XMLNSC.myInputData.myDarta
```

Then a "*Like Parser Copy*" is performed. In this instance, the integration node can be certain that the tree can be fully represented by the target parser and so all parser information is copied. The target parser has an identical copy of the tree that is taken from the source parser. All the parser structure under this element is retained and all attributes in the message are still represented as attributes in the target tree.

Unlike Parser Copies

When you copy a tree between two different parsers, for example in ESQL:

```
SET OutputRoot.DFDL.Data.Account = InputRoot.XMLNSC.Data.Account
```

In this instance, the integration node cannot know whether the source tree can be fully represented by the target parser. This behavior is because parsers do not all support the same type of structure and content information. In this instance instead of creating a copy of the source tree, the integration node must navigate down the logical structure, creating the elements using the target parser. Therefore, that parser structure is not maintained, and elements that were attributes in the source might not be attributes in the target tree. After an unlike parser copy, the target tree consists only of Name-Value pairs under the target parser with no other parser information.

Note that any parsers that were children of the root element of the source tree that are copied, are not preserved in the output tree. When serializing, you must ensure that trees created from unlike parser copies are constructed in such a way that a body parser can serialize the output message.

Predefined and self-defining messages

Both predefined and self-defining messages are supported.

Each message that flows through an integration node has a specific structure that is meaningful to the applications that send or receive that message.

You can use:

- Messages that you have modeled in the Integration Development perspective of the IBM App Connect Enterprise Toolkit; these messages are referred to as *predefined messages*. A model-driven parser requires predefined messages.
- Messages that can be parsed without a model; these are called *self-defining messages*.

Predefined messages

When you create a message in the IBM App Connect Enterprise Toolkit, you define the fields (*Elements*) in the message, along with special field types that you might need, and specific values (Value Constraints) to which the fields might be restricted.

When you deploy a message set to an integration node, the message model is sent to the integration node in a form appropriate to the parser that is used to parse and write the message.

For information about the benefits of predefining messages, see "Why model messages?" on page 2138

Self-defining messages

You can create and route messages that are self-defining. The best example of a self-defining message is an XML document.

You can also model self-defining messages in the IBM App Connect Enterprise Toolkit. However, you do not need to deploy these message sets to the integration nodes that support those message flows. For further information about why you might want to model these messages, see "Why model messages?" on page 2138.

Which body parser should you use?

The characteristics of the messages that your applications exchange indicate which body parser you must use.

WebSphere IBM Integration provides a range of message parsers. Each parser processes either message body data for messages in a particular message domain (for example, XML), or particular message headers (for example, the MQMD).

Review the messages that your applications send to the integration node, and determine to which message domain the message body data belongs, using the following criteria as a guide.

If your application data uses SOAP-based web services, including SOAP with Attachments (MIME) or MTOM
Use the SOAP domain. The SOAP domain has built-in support for WS-Addressing and WS-Security standards.

If your application data uses JSON format, as maybe used in RESTful web services
Use the JSON domain.

If your application data is in XML format other than SOAP
The domain that you use depends on the nature of the XML documents and the processing that you want to perform. See "Which XML parser should you use?" on page 525

If your application data comes from a C or COBOL application, or consists of fixed-format binary data
Use the DFDL domain. You can also use the MRM domain with a Custom Wire Format (CWF) physical format.

If your application data consists of formatted text, perhaps with field content that is identified by tags, or separated by specific delimiters, or both
Use the DFDL domain. You can also use the MRM domain with a Tagged/Delimited String (TDS) physical format.

If your application data is created using the JMS API
The domain that you use depends on the type of the JMS message. For a full description of JMS message processing, see "JMS message as input" on page 860.

If your application data is from a WebSphere Adapter such as the adapters for SAP, PeopleSoft, or Siebel
Use the DataObject domain.

If your application data is in SAP text IDoc format, such as those exported using the IBM MQ Link for R3

Use the DFDL domain. You can also use the MRM domain with a Tagged/Delimited String (TDS) physical format.

If your application data is in MIME format other than SOAP with Attachments (for example, RosettaNet)

Use the MIME domain. If the message is multipart MIME, you might have to parse specific parts of the message with other parsers. For example, you might use the XMLNSC parser to parse the XML content of a RosettaNet message.

If you do not know, or do not have to know, the content of your application data

Use the BLOB domain.

Which XML parser should you use?

If your messages are general-purpose XML documents, you can use one of the dedicated XML domains (XMLNSC or XMLNS) to parse the message, or you can use the MRM domain to parse the message.

Note: Although SOAP XML can be parsed using any namespace-aware XML parser, use the dedicated SOAP domain to parse SOAP XML because the SOAP domain provides full support for SOAP with Attachments, and standards such as WS-Addressing and WS-Security.

Note: The XML domain is deprecated. Do not use it for developing new message flows. The XML domain still works with existing message flows.

Which XML parser you choose depends on the nature of your XML messages, and the transformation logic that you want to use. The differentiating features of each domain are:

- The XMLNSC parser has a new architecture that gives significant performance improvements over the XMLNS and XML parsers.
- The XMLNSC parser can be used with or without an XML Schema that is generated from a message set. Using a message set with the XMLNSC parser allows the parser to operate in validating mode which provides the following capabilities:
  - XML Schema 1.0 compliant validation when parsing and writing.
  - The XML Schema indicates the real data type of a field in the message instead of always treating the field as a character string.
  - Base64 binary data can be automatically decoded.
- The MRM parser must be used with a message dictionary that is generated from a message set. This message dictionary enables the MRM parser to provide the following capabilities: For example:
  - Validation against the dictionary when parsing and writing. Note that validation is not XML Schema 1.0 compliant.
  - The dictionary indicates the real data type of a field in the message instead of always treating the field as a character string.
  - Base64 binary data can be automatically decoded.
- The XMLNS parser is programmatic and does not use a model when parsing.

  This means that:
  - All data in an XML message is treated as character strings.
  - Validation is not possible when parsing and writing.
- The MRM parser uses information from the XML physical format of a message set to simplify the task of creating transformation logic:
  - Date and time information can be extracted from a data value using a specified format string.
  - When creating output messages, the MRM parser can automatically generate the XML declaration, and other XML constraints.
- The XMLNSC and XMLNS parsers do not use XML physical format information from a message set. Transformation logic must explicitly create all constructs in an output message.

- The MRM parser discards some parts of an XML message when parsing; for example, white space formatting, XML comments, XML processing instructions, and inline DTDs. If you use this parser, you cannot create these constructs when building an output message.
- The XMLNSC parser, by default, discards white space formatting, XML comments, XML processing instructions, and inline DTDs. However, options are provided to preserve all of these constructs, except inline DTDs. You can create them all, except inline DTDs, when constructing an output message.
- The XMLNS parser preserves all parts of an XML document, including white space formatting. You can create all XML constructs when constructing an output message.
- The XMLNSC and MRM parsers build compact message trees that use fewer syntax elements than the XMLNS parser for attributes and simple elements. This makes these parsers more suitable than the XMLNS parser for parsing large XML messages.
- The XMLNS parser builds a message tree that conforms more closely than the XMLNSC or MRM parsers to the XML Data Model. You might want to use this parser if you are using certain XPath expressions to access the message tree, and the relative position of parent and child nodes is important, or if you are accessing text nodes directly.
- The XMLNS parser holds the text content of an element as a child of the element, whereas the XMLNSC parser builds a compact tree. To update a text value in the compact tree of the XMLNSC parser, use ESQL to set the VALUE of the target node. For example:

```
Set OutputRoot.XMLNSC.TestMsg.Value3 VALUE = InputRoot.XMLNSC.TestMsg.Value2;
```

Tip: If performance is critical, use the XMLNSC domain.

Tip: If you need to validate the content and values in XML messages, use the XMLNSC domain.

Tip: If you need to preserve formatting in XML messages on output, use the XMLNSC domain with the option to retain mixed content.

Tip: If you require the message tree to conform as closely as possible to the XML data model, perhaps because you are using certain XPath expressions to access the message tree, use the XMLNS domain.

Tip: If you are taking non-XML data that has been parsed by the DFDL domain, and merely transforming the data to the equivalent XML, use the XMLNSC domain.

Tip: If you are taking non-XML data that has been parsed by the CWF or TDS formats of the MRM domain, and merely transforming the data to the equivalent XML, use the MRM domain. You can achieve this by adding an XML physical format to the message set with default values, and changing the Message Format in the Properties folder of the message tree.

SOAP parser and domain

You can use the SOAP parser to create a common WSDL-based logical tree format for working with web services, independent of the physical bitstream format.

Use the SOAP parser in conjunction with the SOAP nodes in your message flow.

Messages in the SOAP domain are processed by the SOAP parser. The SOAP parser creates a common logical tree representation for all SOAP-based web services and validates the message against a WSDL definition. If a runtime message is not allowed by the WSDL, an exception is thrown; otherwise, the `portType` and `operation` names from the WSDL file are saved in the logical tree.

The SOAP domain offers `WS-*` processing, together with a canonical tree shape that is independent of the wire format (XML or MIME).

The following standards are supported:

- WSDL 1.1
- SOAP 1.1 and 1.2
- MIME 1.0
- Message Transmission Optimization Mechanism (MTOM) 1.0

A WSDL 1.1 definition must be deployed to describe the web service messages that the SOAP domain needs to parse and write at run time. Therefore, the SOAP parser is always model-driven. The bitstream format for these runtime messages can be SOAP 1.1 or SOAP 1.2, optionally wrapped by MIME as an SwA (SOAP with Attachments) or MTOM message.

When an application, library, or message set that supports the SOAP domain is added to a BAR file, XML schemas are created automatically. WSDL files in the application, library, or message set are added to the BAR file. The WSDL and XML schemas are deployed to the integration node and used by the SOAP parser.

If you want the SOAP domain to parse your SOAP web service, complete the steps in the following topic: "Using the SOAP domain to parse a SOAP web service" on page 527.

Tip: The SOAP parser invokes the XMLNSC parser to parse and validate the XML content of the SOAP web service. See "XMLNSC parser" on page 531.

SOAP message details
A SOAP message consists of an <Envelope>, which is the root element in every SOAP message, and this contains two child elements, an optional <Header> and a mandatory <Body>.

If the SOAP message has attachments, the 'envelope' is wrapped by MIME, or is encoded as MTOM.

For further information on the structure of a SOAP message, see "The structure of a SOAP message" on page 807.

Using the SOAP domain to parse a SOAP web service
Use the SOAP parser to create a common WSDL-based logical tree format for working with web services.

Before you begin

Read the concept information in "SOAP parser and domain" on page 526.

About this task

To use the SOAP domain to parse your SOAP web service, complete the following steps:

Procedure

1. Create an application or library. Alternatively, you can create a message set, or locate an existing message set.

   If you are likely to reuse your imported WSDL for multiple solutions, use a shared library.
2. If you are using a message set, indicate that the message set supports the SOAP domain by either setting the default message domain project to SOAP, or select the SOAP check box (under Supported message domains).
3. To create a message root (in an application or library) or a message definition file (in a message set), import your WSDL file into the application, library, or message set.

   Message roots or message definition files for the SOAP envelope and the SOAP logical tree are also added to the application, library, or message set automatically.
4. Add the application, library, or message set to a BAR file.

   If the WSDL file is in an application or library, the WSDL files and XSD files appear directly inside the `.appzip`, `.shlibzip`, or `.libzip` file inside the BAR file. If the WSDL file is in a message set, the required XML schema and WSDL files are generated in a file with the extension `.xsdzip`.
5. Deploy the BAR file.

Results

If you associate your WSDL with a SOAP node in your message flow, the `Message domain` property on the node is automatically set to SOAP and cannot be changed. If you are using a message set, the `Message model` property is automatically set to the name of the message set that contains the WSDL and cannot be changed. If you are using an application or library, the `Message model` property is empty and cannot be changed.

You can use a WSDL file in a shared library to configure a message flow in another container (an application, for example). However, that container must reference the shared library that contains the WSDL file. If you use a WSDL file from a shared library to configure a SOAP node, the `Message model` property contains the name of the shared library in braces, {}. The `WSDL file name` property also contains the name of the shared library.

XML parsers and domains

You can use XML domains to parse and write messages that conform to the W3C XML standard.

The term *XML domains* refers to a group of three domains that are used by IBM App Connect Enterprise to parse XML documents.

When reading an XML message, the parser that is associated with the domain builds a message tree from the input bit stream. The input bit stream must be a well-formed XML document that conforms to the W3C XML Specification (version 1.0 or 1.1).

When writing a message, the parser creates an XML bit stream from a message tree.

The domains have different characteristics, for guidance about which domain to choose, see "Which XML parser should you use?" on page 525.

XMLNSC domain

The XMLNSC domain is the preferred domain for parsing all general purpose XML messages, including those messages that use XML namespaces. This parser is the preferred parser for the following reasons:

- The XMLNSC parser has an architecture that results in ultra-high performance when parsing all kinds of XML.
- The XMLNSC parser reduces the amount of memory that is used by the logical message tree that is created from the parsed message. The default behavior of the parser is to discard non-significant white space and mixed content, comments, processing instructions, and embedded DTDs; however controls are provided to retain mixed content, comments, and processing instructions, if required.
- The XMLNSC parser can operate as a model-driven parser, and can validate XML messages against XML Schemas generated from a message set, to ensure that your XML messages are correct.

XMLNS domain

If the XMLNSC domain does not meet your requirements, use the alternative namespace-aware domain and parser.

XML domain

The XML domain is not namespace-aware. It is deprecated and must not be used to develop new message flows.

The MRM domain also provides XML parsing and writing facilities. For guidance on when you might use MRM XML instead of one of the XML parsers, see "Which XML parser should you use?" on page 525.

By default, the three XML parsers are *programmatic* parsers and do not use a message set at run time when parsing and writing. However, the XMLNSC parser can operate as a model-driven parser and can validate XML messages for correctness against XML Schemas generated from a message set.

When you use the XMLNS or XML parsers, or the XMLNSC parser without a message set, it is good practice to create and use a message set in the IBM App Connect Enterprise Toolkit; this action simplifies the development of your message flow applications, even though the message set is not deployed to the integration node run time.

For the advantages of creating a message set, see "Why model messages?" on page 2138.

The XML parsers are on-demand parsers. For more information, see Parsing on demand.

The topics in this product documentation provide a summary of XML terminology, concepts, and message constructs. These aspects are important when you use XML messages in your message flows.

Tip: For more detailed information about XML, see the World Wide Web Consortium (W3C) Web site.

Example XML message parsing

A simple XML message might take the following form:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE Envelope
PUBLIC "http://www.ibm.com/dtds" "example.dtd"
[<!ENTITY Example_ID "ST_TimeoutNodes Timeout Request Input Test Message">]
>
<Envelope version="1.0">
 <Header>
  <Example>&Example_ID;</Example>
  <!-- This is a comment  -->
 </Header>
 <Body  version="1.0">
  <Element01>Value01</Element01>
  <Element02/>
  <Element03>
   <Repeated>ValueA</Repeated>
   <Repeated>ValueB</Repeated>
  </Element03>
  <Element04><P>This is <B>bold</B> text</P></Element04>
 </Body>
</Envelope>
```

The following sections show the output that is created by the Trace node when this example message has been parsed in the XMLNS and XMLNSC parsers. They demonstrate the differences in the internal structures that are used to represent the data as it is processed by the integration node.

Example XML Message parsed in the XMLNS domain

In the following example, the white space elements within the tree are present because of the space, tab, and line breaks that format the original XML document; for clarity, the actual characters in the trace have been replaced with `'WhiteSpace'`. White space within an XML element does have business meaning, and is represented by using the Content syntax element. The XmlDecl, DTD, and comments, are represented in the XML domain using explicit syntax elements with specific field types.

```
(0x01000010):XMLNS        = (
    (0x05000018):XML      = (
      (0x06000011): = '1.0'
      (0x06000012): = 'UTF-8'
      (0x06000014): = 'no'
    )
    (0x06000002):         = 'WhiteSpace'
    (0x05000020):Envelope = (
      (0x06000004): = 'http://www.ibm.com/dtds'
      (0x06000008): = 'example.dtd'
      (0x05000021): = (
        (0x05000011):Example_ID = (
          (0x06000041): = 'ST_TimeoutNodes Timeout Request Input Test Message'
        )
      )
    )
    (0x06000002):         = 'WhiteSpace'
    (0x01000000):Envelope = (
      (0x03000000):version = '1.0'
      (0x02000000):         = 'WhiteSpace'
      (0x01000000):Header  = (
        (0x02000000):        = 'WhiteSpace'
        (0x01000000):Example = (
          (0x06000020): = 'Example_ID'
          (0x02000000): = 'ST_TimeoutNodes Timeout Request Input Test Message'
          (0x06000021): = 'Example_ID'
        )
        (0x02000000):        = 'WhiteSpace'
        (0x06000018):        = ' This is a comment  '
        (0x02000000):        = 'WhiteSpace'
      )
      (0x02000000):        = 'WhiteSpace'
      (0x01000000):Body    = (
        (0x03000000):version   = '1.0'
        (0x02000000):          = 'WhiteSpace'
        (0x01000000):Element01 = (
          (0x02000000): = 'Value01'
        )
        (0x02000000):          = 'WhiteSpace'
```

```
        (0x01000000):Element02 =
        (0x02000000):          = 'WhiteSpace'
        (0x01000000):Element03 = (
          (0x02000000):         = 'WhiteSpace'
          (0x01000000):Repeated = (
            (0x02000000): = 'ValueA'
          )
          (0x02000000):         = 'WhiteSpace'
          (0x01000000):Repeated = (
            (0x02000000): = 'ValueB'
          )
          (0x02000000):         = 'WhiteSpace'
        )
        (0x02000000):          = 'WhiteSpace'
        (0x01000000):Element04 = (
          (0x01000000):P = (
            (0x02000000):  = 'This is '
            (0x01000000):B = (
              (0x02000000): = 'bold'
            )
            (0x02000000):  = ' text'
          )
        )
        (0x02000000):          = 'WhiteSpace'
      )
      (0x02000000):        = 'WhiteSpace'
    )
```

Example XML Message parsed in the XMLNSC domain

The following trace shows the elements that are created to represent the same XML structure within the compact XMLNSC parser in its default mode. In this mode, the compact parser does not retain comments, processing instructions, or mixed text.

The example illustrates the significant saving in the number of syntax elements that are used to represent the same business content of the example XML message when using the compact parser.

By not retaining mixed text, all of the white space elements that have no business data content are no longer taking any space in the integration node message tree at run time. However, the mixed text in `Element04.P` is also discarded, and only the value of the child folder, `Element04.P.B`, is held in the tree; the text `This is` and `text` in P is discarded. This type of XML structure is not typically associated with business data formats; therefore, use of the compact XMLNSC parser is typically desirable. However, if you want to this type of processing, either do not use the XMLNSC parser, or use it with *Retain mixed text mode* enabled.

The handling of the XML declaration is also different in the XMLNSC parser. The version, encoding, and stand-alone attributes are held as child entities of the XmlDeclaration, rather than as elements with a particular field type.

```
(0x01000000):XMLNSC     = (
    (0x01000400):XmlDeclaration = (
      (0x03000100):Version    = '1.0'
      (0x03000100):Encoding   = 'UTF-8'
      (0x03000100):StandAlone = 'no'
    )
    (0x01000000):Envelope       = (
      (0x03000100):version = '1.0'
      (0x01000000):Header  = (
        (0x03000000):Example = 'ST_TimeoutNodes Timeout Request Input Test Message'
      )
      (0x01000000):Body    = (
        (0x03000100):version   = '1.0'
        (0x03000000):Element01 = 'Value01'
        (0x01000000):Element02 =
        (0x01000000):Element03 = (
          (0x03000000):Repeated = 'ValueA'
          (0x03000000):Repeated = 'ValueB'
        )
        (0x01000000):Element04 = (
          (0x01000000):P = (
            (0x03000000):B = 'bold'
          )
        )
   )
```

Some predefined message models are supplied with the IBM App Connect Enterprise Toolkit and can be imported by using the New Message Definition File wizard and selecting the IBM supplied message option. See Message Sets: IBM supplied messages that you can import.

XMLNSC parser
The XMLNSC parser is a flexible, general-purpose XML parser that offers high performance XML parsing and optional XML Schema validation.

The XMLNSC parser has a range of options that make it suitable for most XML processing requirements. Some of these options are only available in the XMLNSC parser.

Although the XMLNSC parser is capable of parsing XML documents without an XML Schema, extra features of the parser become available when it operates in model-driven mode. In model-driven mode, the XMLNSC parser is guided by an XML Schema, which describes the shape of the message tree (the logical model).

XML Schemas are created automatically from the content of a message set when the message set is added to a BAR file. The XML Schemas are deployed to the integration node and used by the XMLNSC parser to validate your XML messages. Validation is fully compliant with the XML Schema 1.0 specification.

For guidance on when to use the XMLNSC domain and parser, see "Which XML parser should you use?" on page 525.

If you want the XMLNSC domain to parse a message, select *Message Domain* as XMLNSC on the appropriate node in the message flow. Additionally, if you want the XMLNSC parser to validate your messages, perform the additional steps that are described in "XMLNSC validation" on page 537.

Features of the XMLNSC parser

Feature	Present	Description
Namespace support	Yes	Namespace information is used if it is present. No user configuration is required. See "XML parsers namespace support" on page 543.
On-demand parsing	Yes	See Parsing on demand.
Compact message tree	Yes	Less memory is used when building a message tree from an XML document. See "Manipulating messages in the XMLNSC domain" on page 1706.
Opaque parsing	Yes	One or more elements can be parsed opaquely. See "XMLNSC opaque parsing" on page 536.
Ultra high performance	Yes	The architecture of the XMLNSC parser means that the parser's use of processor resources is significantly less than that of the other XML parsers.
Validation	Yes	See the table that follows this one.
Inline DTD support	Partial	Inline DTDs are processed but discarded. See "XMLNSC DTD support" on page 540.

Feature	Present	Description
XML Data Model compliance	Partial	The compact nature of the message tree means that some XPath queries are not supported.

The following features are only available when message validation is enabled. See "XMLNSC validation" on page 537.

Feature	Description
Message validation	Validates compliance with the XML Schema 1.0 specification.
xsi:nil support	Sets the value of an element to NULL if it has xsi:nil="true" and the XML Schema indicates that it is nillable.
Default value support	Sets the value of an empty element, or missing attribute, to its default value, according to XML Schema rules.
Use correct simple types	Allows the use of the simple types that are defined in the XML Schema when building the message tree.
Base64 support	Converts base64 data to BLOB when parsing. Converts BLOB to base64 when writing.

If you specify the SOAP domain as the owner of a SOAP web services message, the SOAP parser invokes the XMLNSC parser in model-driven mode to parse the XML content of the SOAP message.

If you specify the DataObject domain as the owner of a WebSphere Adapter message, and the message is written to a destination other than a WebSphere Adapter, the DataObject parser invokes the XMLNSC parser to write the message as XML.

XMLNSC empty elements and null values
Empty elements and null values occur frequently in XML documents.

A robust message flow must be able to recognize and handle empty elements and null values. Similarly, elements in a message tree might have a NULL value, an empty value, or no value at all. This topic explains the parsing and writing of these values by the XMLNSC domain. For details on processing null values in Graphical Data Maps and ESQL, see "Handling null values" on page 566.

Parsing

Description	XML input parsed by XMLNSC	Value of 'element' in message tree
Empty element value	`<element/>`	Empty string
Empty element value	`<element></element>`	Empty string
Folder with child elements	`<element><childElement/ ></element>`	No value
Nil element value	`<element xsi:nil="true"/>`	No value and a child `xsi:nil` attribute with the value 'true'.

Both forms of an empty element result in the same value in the message tree.

Writing

Description	Value of 'element' in message tree	XML output from XMLNSC parser
Empty element value	Empty string	`<element/>`
Null element value	NULL	`<element/>`
Folder with child elements	No value	`<element><childElement/ ></element>`
Nil element value	Empty string, NULL, or Folder	`<element xsi:nil="true"/>` Note that the XMLNSC parser produces only `xsi:nil` attributes that are already in the message tree. It does not automatically produce `xsi:nil` attributes for all message tree elements that have a NULL value and are 'nillable'.

Empty elements

An empty element can take two forms in an XML document:

```
- <element/>
- <element></element>
```

The XMLNSC parser treats both forms in the same way. The element is added to the message tree with a value of "" (the empty string).

When a message tree is produced by the XMLNSC parser, it always uses the first form for elements that have a value of "" (the empty string) in the input XML message.

Elements with an `xsi:nil` attribute

If validation is enabled for the flow, the XMLNSC parser performs the following validations:

- The 'nillable' property of an element definition in the XML schema is set to 'true'.

  If the element in the document has an `xsi:nil` attribute with the value 'true', the element must not have a value, or contain any child elements.
- The 'nillable' property of an element definition in the XML schema is set to 'false'.

  The element in the input document must not have an `xsi:nil` attribute.

If an element in the input document has an `xsi:nil` attribute, the XMLNSC parser creates an element in the message tree with no value, and a child `xsi:nil` attribute with the value 'true' or 'false'.

When a message tree is written to a bit stream by the XMLNSC parser, if the value of the element is empty, NULL, or no value, and the element has no child elements, the element is written as `<element/>`. If the element has an `xsi:nil` attribute, it is written exactly like any other attribute.

Note that the XMLNSC parser produces only `xsi:nil` attributes that are already in the message tree. It does not automatically produce `xsi:nil` attributes for all message tree elements that have a NULL value and are 'nillable'.

XMLNSC: Using field types
The XMLNSC parser sets the field type on every syntax element that it creates.

The field type indicates the type of XML construct that the element represents. The XMLNSC parser uses the field type when writing a message tree. The field type can be set by using ESQL or Java to control the

output XML. The field types that are used by the XMLNSC parser must be referenced by using constants with names that are prefixed by 'XMLNSC.'

Tip: Field type constants that have the prefix 'XML.' are for use with the XMLNS and XML parsers only, and are not valid with the XMLNSC or MRM parsers.

Field types for creating syntax elements

Use the following field type constants to create syntax elements in the message tree. The XMLNSC parser uses these values when creating a message tree from an input message.

XML construct	XMLNSC Field Type constant	Value
Simple Element	XMLNSC.Field XMLNSC.CDataField	0x03000000 0x03000001
Attribute	XMLNSC.SingleAttribute XMLNSC.Attribute	0x03000101 0x03000100
Mixed content	XMLNSC.Value XMLNSC.CDataValue	0x02000000 0x02000001
Namespace Declaration	XMLNSC.SingleNamespaceDecl XMLNSC.NamespaceDecl	0x03000102 0x03000103
Complex element	XMLNSC.Folder	0x01000000
Inline DTD	XMLNSC.DocumentType	0x01000300
XML declaration	XMLNSC.XmlDeclaration	0x01000400
Entity reference	XMLNSC.EntityReference	0x02000100
Entity definition	XMLNSC.SingleEntityDefinition XMLNSC.EntityDefinition	0x03000301 0x03000300
Comment	XMLNSC.Comment	0x03000400
Processing Instruction	XMLNSC.ProcessingInstruction	0x03000401

Field types for path expressions (generic field types)

Use the following field type constants when querying the message tree by using a path expression; for example:

```
SET str = FIELDVALUE(InputRoot.e1.(XMLNSC.Attribute)attr1)
```

It is good practice to specify field types when querying a message tree built by the XMLNSC parser. This makes your ESQL code more specific and more readable, and it avoids incorrect results in some cases. However, care is required when choosing which field type constant to use. When you use the XMLNSC parser, use a generic field type constant when querying the message tree. This allows your path expression to tolerate variations in the input XML.

The generic field type constants are listed in the following table:

XML construct	XMLNSC Field Type constant	Purpose
Tag	XMLNSC.Element	Matches any tag, whether it contains child tags (XMLNSC.Folder) or a value (XMLNSC.Field)
Element	XMLNSC.Field	Matches a tag which contains normal text, CData, or a mixture of both. Does not match tags which contain child tags.
Attribute	XMLNSC.Attribute	Matches single-quoted and double-quoted attributes
Mixed content	XMLNSC.Value	Matches normal text, CData, or a mixture of both
XML Declaration	XMLNSC.NamespaceDecl	Matches single- and double-quoted declarations

If you write

```
InputRoot.e1.(XMLNSC.DoubleAttribute)attrName
```

your path expression does not match a single-quoted attribute. If you use the generic field type constant *XMLNSC.Attribute*, your message flow works with either single-quoted or double-quoted attributes.

Note that you should always use the field type constants and not their numeric values.

Field types for controlling output format

The following field types are provided for XML Schema and base64 support. Do not use these field type constants in path expressions; use them in conjunction with XMLNSC.Attribute and XMLNSC.Field to indicate the required output format for DATE and BLOB values. See "XMLNSC: XML Schema support" on page 1715 for further information.

XMLNSC Field Type constant	Purpose	Value
XMLNSC.gYear	The value must be a DATE. If the field type includes this value, the DATE value is produced by using the XML Schema gYear format.	0x00000010
XMLNSC.gYearMonth	The value must be a DATE. If the field type includes this value, the DATE value is produced by using the XML Schema gYearMonth format.	0x00000040
XMLNSC.gMonth	The value must be a DATE. If the field type includes this value, the DATE value is produced by using the XML Schema gMonth format.	0x00000020
XMLNSC.gMonthDay	The value must be a DATE. If the field type includes this value, the DATE value is produced by using the XML Schema gMonthDay format.	0x00000050
XMLNSC.gDay	The value must be a DATE. If the field type includes this value, the DATE value is produced by using the XML Schema gDay format.	0x00000030
XMLNSC.base64Binary	The value must be a BLOB. The value is produced with base64 encoding.	0x00000060

XMLNSC Field Type constant	Purpose	Value
XMLNSC.List	The element must be XMLNSC.Attribute or XMLNSC.Field. If the field type includes this value, the values of all child elements in the message tree are produced as a space-separated list.	0x00000070

Field types for direct output

Use the following field types to produce pre-constructed segments of an XML document. Character escaping is not done; therefore, take extra care not to construct a badly-formed output document. Use these constants only after carefully exploring alternative solutions.

XMLNSC Field Type constant	Purpose	Value
XMLNSC.BitStream	The value of this syntax element must be a BLOB. The value is written directly to the output bit stream. For more information about its usage, see "Working with large XML messages" on page 1703.	0x03000200
XMLNSC.AsisElementContent	The value of this syntax element must be CHARACTER. The value is written directly to the output bit stream. No character substitutions are performed. Use this element with care.	0x03000600

XMLNSC opaque parsing

Opaque parsing is a performance feature that is offered by the XMLNSC domain.

If you are designing a message flow and you know that certain elements in a message are never referenced by the message flow, you can specify that these elements are parsed opaquely. This reduces the costs of parsing and writing the message, and might improve performance in other parts of the message flow.

Use the property *Opaque Elements* on the *Parser options* page of the relevant message flow node to specify the elements that you want to be parsed opaquely. This property specifies a list of element names. If an element in the input XML message is named in this list, the element is parsed as a single string.

An opaque element cannot be queried like an ordinary element; its value is the segment of the XML bit stream that belongs to the element, and it has no child elements in the message tree, even though it can represent a large subtree in the XML document.

When an opaque element is serialized, the value of the element is copied directly into the output bit stream. The string is converted to the correct code page, but no other changes are made. Because this might produce a bit stream that is not valid XML, some care is required.

Do not parse an element opaquely in any of the following cases:

- The message flow must access one of its child elements.
- The message flow changes the namespace prefix in a way that affects the opaque element or one of its child elements **and** the element is to be copied to the output bit stream.
- The element, or any child element, contains a reference to an internal entity that is defined in an inline DTD **and** the element is to be copied to the output bit stream.
- The element contains child attributes that have default values that are defined in an inline DTD **and** the element is to be copied to the output bit stream.

Make sure that you check the above points before you specify an element for opaque parsing.

Using opaque parsing has some drawbacks. When opaque parsing is enabled, some parts of the message are never parsed, and XML that is either badly formed or not valid is allowed to pass through the message flow without being detected. For this reason, if you enable validation, you cannot use opaque parsing.

The XMLNS domain offers a more limited opaque parsing facility, but this is provided only to support existing applications. Use the XMLNSC domain in new message flows if you want to use opaque parsing.

Specifying opaque elements for the XMLNSC parser
Specify an element as an opaque element so that its content is ignored by the XMLNSC parser.

Before you begin

About this task

To specify the elements that are to be skipped by the XMLNSC parser:

Procedure

1. Right-click the selected message flow node, click **Properties** and select **Parser Options**.
2. At the bottom of the `XMLNSC Parser Options` panel is an area that lists the elements that have already been selected as opaque elements. Click **Add** to add an element to this list.

   A new pane **Add Opaque elements Entry** opens.
3. In the **Add Opaque elements Entry** pane, specify the new XML element that you want to be opaquely parsed.

   Each opaque element must be specified as an ESQL element name or an XPath expression of the form `//prefix:name` (or `//name`, if your input document does not contain namespaces).

   Note: A prefix is used rather than a full URI to identify the namespace; for further information, see "XPath namespace support" on page 1771.

What to do next

Click **Edit** or **Delete** to edit the list of opaque elements.

XMLNSC validation
The XMLNSC parser offers high-performance, standards-compliant XML Schema validation at any point in a message flow.

Validation of the input XML message or the message tree is performed against the XML Schemas that are deployed.

Validation is not the same as *parsing*. When parsing, the XMLNSC parser always checks that the input document is well-formed XML, according to the XML specification. If validation is enabled, the XMLNSC parser also checks that the XML document obeys the rules in the XML Schema.

Enabling XML Schema validation in a message flow

You must complete the following tasks to construct a message flow that validates an XML document in accordance with an XML Schema:

- Enable validation at the appropriate point in the message flow. This is typically achieved by setting the *Validate* property of the appropriate node to `Content and Value`. See "Validating messages" on page 610.
- Ensure that all required XML Schema files are deployed. See "Deploying XML Schemas" on page 538 later in this section.
- If the XML Schema files are deployed in a message set, you must also supply the name of the message set. Typically, you specify the message set by selecting the `Message model` property on a message flow node. If the parser is being invoked from a programming language such as ESQL or Java, the message set must be specified in the parameters of the function call.

Deploying XML Schemas

XML Schemas can be deployed within an application, in a library that is referenced by an application, or in a message set.

If the schemas are deployed as part of the application, they must be included in one of the projects that are referenced by the application.

If the schemas are deployed in a library, the application must reference that library, even if it will be deployed as part of a different application.

Tip: In IBM App Connect Enterprise, *message model schema* files contained in applications, integration services, and libraries are the preferred way to model messages for most data formats. Message sets are required if you use the MRM or IDOC domains. For more information about message modeling, see "Message modeling concepts" on page 2134.

If the schemas are deployed in a message set, you must complete the following steps.

All XML Schemas that are used by IBM App Connect Enterprise must be created as message definition files within a message set.

To create and deploy a message set for XML Schema validation:

1. Create a new message set or locate an existing message set.
2. Ensure that the message set has its *Default message domain* set to XMLNSC, or that the XMLNSC check box under *Supported message domains* is selected, to indicate that the message set supports the XMLNSC domain.
3. Create a message definition file in the message set to represent your message. If you have an existing XML Schema or DTD that describes your message, you can import it. You can repeat this step for each message that you want to validate.
4. Add the message set to a BAR file, which generates the required XML Schema in a file with extension .xsdzip, and deploy the BAR file to the integration node.

Standards compliant validation

XMLNSC validation complies fully with XML Schema v1.0 as defined in the specifications that are available at http://www.w3.org/TR/xmlschema-1/ and http://www.w3.org/TR/xmlschema-2/, with the following minor exceptions:

- Any floating point value that is smaller than 10E-43 is treated as zero.
- Any member of a group or complex type, that has both minOccurs > 1024 and maxOccurs > 1024, is validated as if minOccurs = 0 and maxOccurs is unbounded.

Validating XML v1.1 documents

You can validate documents that conform to the XML v1.1 specification, but support is limited by the fact that the XML Schema v1.0 documents must conform to XML v1.0.

As an example, you cannot always declare an XML v1.1 tag name in XML Schema v1.0. This limitation is not imposed by the XMLNSC parser implementation; it is a limitation of XML Schema v1.0.

Interpreting validation errors

A validation error is an error that results when the XML document breaks the rules that are defined in the XML schema. The XML Schema standard specifies exactly what these rules are, and how they should be applied. Validation errors that the XMLNSC parser issues contain information that links the error to the XML Schema rule that has been violated.

All validation errors are reported in BIP5025 or BIP5026 messages. Both messages begin with text in the following form:

```
XML schema validation error '[cvc-error key: error description]'
```

Examples:

```
'cvc-minInclusive-valid: The value "2" is not valid with respect to the minInclusive facet
with value "3" for type "po:itemCountType".'
```

```
'cvc-complex-type.2.4.a: Expecting element with local name "numItems" but saw "totalValue".'
```

To find the XML Schema rule that has been violated, open the XML Schema specification and search for the error key.

Example 1: Open http://www.w3.org/TR/xmlschema-1/ and search for ‘cvc-minInclusive-valid'. Follow the link to the XML Schema rules for the minInclusive facet.

Example 2: Open http://www.w3.org/TR/xmlschema-1/ and search for ‘cvc-complex-type'. Follow the link to the XML Schema rules for validating the content of a complex type. In this case, the error key contains extra information. The ‘2.4.a' refers to the exact sub-rule that was violated. It should not be included when searching for the rule.

If the XML Schema specification does not provide enough information, you can find more information using a search engine. The XML Schema standard is very widely used, and many online tutorials and other resources are available.

XMLNSC validation restriction

Do not use patterns that include an unbounded wildcard character followed by a negated character class to validate string elements because an error occurs and validation fails even if the input string is valid.

For example, validation of the input string `<StringWithXSDPattern>ADDDDDA</StringWithXSDPattern>` results in error `cvc-pattern-valid` if a pattern of the following format `<xs:pattern value="A.*[^D]"/>` is used in the schema. The unbounded wildcard character is `.*` and the negated character class is `[^D]`. You can replace the negated character class with a non-negated class to avoid this error: using a pattern of the following format `A.*[ABC]` in this example will result in correct validation.

XMLNSC message tree options
The XMLNSC options that are described in this section affect the parsing of an XML document by the XMLNSC parser. They have no effect on XML output.

Retain Mixed Content

Mixed content is XML text which occurs between elements.

```
<parent>
     <childElement1>Not mixed content</childElement1>
     This text is mixed content
     <childElement2>Not mixed content</childElement2>
</parent>
```

By default, the XMLNSC parser discards all mixed content. Mixed content is retained in the message tree if you select *Retain mixed content* in the Parser options page of the input node. For further information, see 'Element with mixed content' in “XMLNSC: Element values and mixed content” on page 1712 .

Retain Comments

By default, the XMLNSC parser discards all comments in the input XML. Comments are retained in the message tree if you select *Retain comments* in the Parser options page of the input node. For further information, see 'Comments' in “XMLNSC: Comments and Processing Instructions” on page 1715 .

Retain Processing Instructions

By default, the XMLNSC parser discards all processing instructions in the input XML. Processing instructions are retained in the message tree if you select *Retain processing instructions* in the Parser

options page of the input node. For further information, see 'Processing Instructions' in “XMLNSC: Comments and Processing Instructions” on page 1715 .

Build tree using XML Schema data types

By default, the XMLNSC parser uses the CHARACTER data type for all element and attribute values that the parser creates in the message tree. However, if you are using the XMLNSC parser to validate the XML document, you can select *Build tree using XML Schema data types* in the Parser options page of the input node. This causes element and attribute values to be cast to the IBM App Connect Enterprise data type that most closely matches their XML Schema simple type. The exact mapping between XML schema types and IBM App Connect Enterprise types can be found in “XMLNSC data types” on page 540.

XMLNSC data types
Mapping between XML Schema simple types and the data types that the XMLNSC parser uses in the message tree when `Build tree using XML Schema types` is specified.

For mapping details, see ESQL to XML Schema data type mapping. Base64 decoding is automatically performed by the XMLNSC parser.

List types

In the message tree, a list type is represented as a parent node with an anonymous child node for each list item. This allows repeating lists to be handled without any loss of information.

If a list element repeats, the occurrences appear as siblings of one another, and each occurrence has its own set of child nodes representing its own list items.

XMLNSC DTD support
The input XML message might contain an inline DTD.

Parsing

If the input XML document has an inline DTD, the XMLNSC parser reads and uses information in the DTD while parsing, but does not add the DTD information to the message tree.

Internal entity definitions in the DTD are used to automatically expand entity references that are encountered in the body of the document.

Attributes that are missing from the input document are automatically supplied with the default value specified in the DTD.

The XMLNSC parser never adds the DTD to the message tree because the information that it contains has already been used during the parse. This behavior keeps the message tree compact and reduces CPU usage, and means that the XMLNSC parser does not always produce exactly the same document as it parsed. However, the business meaning of the output document is not altered.

If these restrictions are a problem, the XMLNS domain and parser provide full support for parsing and writing of the DTD. See “XMLNS DTD support” on page 543.

Writing

The XMLNSC parser can produce a DTD that contains entity definitions only. This behavior allows the XMLNSC parser to be used for writing out XML documents that use internal entities (the most common reason for using a DTD). See “Manipulating messages in the XMLNSC domain” on page 1706 for further details.

External DTDs

No support is offered for external DTDs

XMLNS parser
The XMLNS parser is a flexible, general-purpose XML parser.

The XMLNS parser is not model-driven and does not use an XML Schema when parsing XML documents.

For guidance on when to use the XMLNS domain and parser, see "Which XML parser should you use?" on page 525.

If you want the XMLNS domain to parse a particular message, you must select *Message Domain* as XMLNS on the appropriate node in the message flow.

Features of the XMLNS parser

Feature	Present	Description
Namespace support	Yes	Namespace information is used if it is present. No user configuration is required. See "Namespace support" on page 628.
On-demand parsing	Yes	See Parsing on demand.
Compact message tree	No	
Opaque parsing	Partial	Limited support from ESQL only for parsing a single element opaquely. See "XMLNS opaque parsing" on page 542.
Ultra high performance	No	
Validation	No	
Inline DTD support	Yes	Inline DTDs are processed and retained in the message tree. See "XMLNS DTD support" on page 543.
XML Data Model compliance	Yes	The resultant message tree conforms to the XML Data Model.

XMLNS empty elements and null values
Empty elements and null values occur frequently in XML documents.

A robust message flow must be able to recognize and handle empty elements and null values. Similarly, elements in a message tree might have a NULL value, an empty value, or no value at all. This topic explains the parsing and writing of these values by the XMLNS domain. For advice on good ESQL or Java coding practices see "Handling null values" on page 566.

Parsing

Description	XML input parsed by XMLNS	Value of 'element' in message tree
Empty element value	<element/>	Empty string
Empty element value	<element></element>	Empty string
Folder with child elements	<element><childElement/></element>	No value
Nil element value	<element xsi:nil="true"/>	Empty string

Note that both forms of an empty element result in the same value in the message tree.

Note also that a NULL value is never put into the message tree by the XMLNS parser.

Writing

Description	Value of 'element' in message tree	XML output from XMLNS parser
Empty element value	Empty string	<element/>
Null element value	NULL	<element/>
Folder with child elements	No value	<element><childElement/></element>

Empty elements

An empty element can take two forms in an XML document:

```
- <element/>
- <element></element>
```

The XMLNS parser treats both forms in the same way. The element is added to the message tree with a value of "" (the empty string).

When a message tree is produced by the XMLNS parser, it always uses the first form for elements that have a value of "" (the empty string).

Elements with an xsi:nil attribute

The XMLNS parser treats the xsi:nil attribute exactly like any other attribute. When xsi:nil is encountered while parsing, it does not set the value of the parent element to NULL. If you require this behavior you should use the XMLNSC parser. When writing a message tree, if an xsi:nil attribute exists it will be produced in the same way as any other attribute.

XMLNS opaque parsing
Opaque parsing is a performance feature that is offered by the XMLNS domain.

XMLNS opaque parsing has been superseded by the opaque parsing feature of the XMLNSC domain. Do not use the XMLNS parser for opaque parsing unless your message flow requires features that are only offered by the XMLNS parser.

If you are designing a message flow, and you know that a particular element in a message is never referenced by the message flow, you can specify that that element is to be parsed opaquely. This reduces the costs of parsing and writing the message, and might improve performance in other parts of the message flow.

To specify that an XML element is to be parsed opaquely, use an **ESQL CREATE** statement with a PARSE clause to parse the XML document. Set the FORMAT qualifier of the PARSE clause to the constant, case-sensitive string 'XMLNS_OPAQUE' and set the TYPE qualifier of the PARSE clause to the name of the XML element that is to be parsed in an opaque manner.

The TYPE clause can specify the element name with no namespace (to match any namespace), or with a namespace prefix or full namespace URI (to match a specific namespace).

XMLNS opaque elements cannot be specified via the node properties.

Consider the following example:

```
DECLARE soap NAMESPACE 'http://schemas.xmlsoap.org/soap/envelope/';

DECLARE BitStream BLOB ASBITSTREAM(InputRoot.XMLNS
                  ENCODING InputRoot.Properties.Encoding
                  CCSID InputRoot.Properties.CodedCharSetId);
```

```
--No Namespace
  CREATE LASTCHILD OF OutputRoot
    DOMAIN('XMLNS')
          PARSE (BitStream
                 ENCODING InputRoot.Properties.Encoding
                 CCSID InputRoot.Properties.CodedCharSetId
                 FORMAT 'XMLNS_OPAQUE'
                 TYPE 'Body');

--Namespace Prefix
  CREATE LASTCHILD OF OutputRoot
    DOMAIN('XMLNS')
          PARSE (BitStream
                 ENCODING InputRoot.Properties.Encoding
                 CCSID InputRoot.Properties.CodedCharSetId
                 FORMAT 'XMLNS_OPAQUE'
                 TYPE 'soap:Body');

--Namespace URI
  CREATE LASTCHILD OF OutputRoot
    DOMAIN('XMLNS')
          PARSE (BitStream
                 ENCODING InputRoot.Properties.Encoding
                 CCSID InputRoot.Properties.CodedCharSetId
                 FORMAT 'XMLNS_OPAQUE'
                 TYPE '{http://schemas.xmlsoap.org/soap/envelope/}:Body');
```

XMLNS DTD support
The input XML might contain an inline DTD.

Parsing

If the input XML document has an inline DTD, the XMLNS parser reads and uses information in the DTD while parsing, and adds the DTD information to the message tree.

Internal entity definitions in the DTD are used to automatically expand entity references that are encountered in the body of the document.

Attributes that are missing from the input document are automatically supplied with the default value specified in the DTD.

Writing

The XMLNS parser can produce any inline DTD that has been constructed in the message tree.

External DTDs

No support is offered for external DTDs

XML parsers namespace support
Namespaces in XML messages are supported by the XMLNSC and XMLNS parsers. Namespaces are not supported by the XML parser.

Parsing

The XMLNS and XMLNSC parsers can parse any well-formed XML document, whether or not the document contains namespaces. If elements or attributes have namespaces, those namespaces are applied to the elements and attributes in the message tree. Namespace prefix mappings are also carried in the message tree, and are used when serializing the message tree back to XML.

- If an element or attribute in the input XML has a namespace, the corresponding node in the message tree also has that namespace.
- If an element contains a namespace declaration (an xmlns attribute), a child element that contains its prefix and namespace URI is created in the message tree.

While the message is passing through a message flow, namespaces and namespace mappings can be modified using ESQL or any of the other transformation technologies that are offered by IBM App Connect Enterprise.

Writing

Namespaces and their prefixes are preserved in the message tree when parsing, and are used when the XMLNS and XMLNSC parsers convert a message tree to an XML bit stream.

- When serializing a message tree, the parser scans for namespace declarations on each XML element. If any are found, it uses them to select the namespace prefixes in the output document.
- If an element in the message tree has a namespace, but there is no in-scope namespace declaration for its namespace URI, a valid namespace prefix is automatically generated and used in the output XML. Auto-generated prefixes have the form NS1, NS2, and so on.

Tip: If an element in the message tree has a child element that is a ‘default namespace' declaration, every child of that element (whether an XML element or an XML attribute, at any nesting depth) must have a namespace. If this rule is not enforced, IBM App Connect Enterprise cannot generate correct XML output for the message tree.

XML parser
The XML domain is very similar to the XMLNS domain, but the XML domain has no support for XML namespaces or opaque parsing.

The XML domain is deprecated, but existing message flows that use the XML domain continue to work. Use the XMLNSC domain when developing new message flows.

The XML parser is not model-driven and does not use an XML Schema when parsing XML documents.

If you want the XML domain to parse a particular message, you must select *Message Domain* as XML on the appropriate node in the message flow.

Tip: The XMLNSC and XMLNS parsers both support XML messages that do not use namespaces, with no extra configuration.

Features of the XML parser

Feature	Present	Description
Namespace support	No	
On-demand parsing	Yes	See Parsing on demand.
Compact message tree	No	
Opaque parsing	No	
Ultra high performance	No	
Validation	No	
Inline DTD support	Yes	Inline DTDs are processed and retained in the message tree.
XML Data Model compliance	Yes	The resultant message tree conforms to the XML Data Model.

DFDL parser and domain

Data Format Description Language (DFDL) is an XML-based language used to define the structure of formatted data in a way that is independent from the data format itself.

IBM App Connect Enterprise provides support for a DFDL domain. The DFDL domain can be used to parse and write a wide variety of message formats, and is intended for general text and binary message formats,

including industry standards. It is not intended for parsing and writing XML or JSON formatted messages, which have their own message domains.

IBM App Connect Enterprise uses the DFDL parser to read and write messages in the DFDL domain. When reading a message, the DFDL parser interprets a bit stream by using grammar defined in a DFDL schema file, and generates a corresponding DFDL domain logical message tree in the integration node. When writing a message, the DFDL serializer generates a DFDL formatted bit stream from a DFDL domain logical message tree.

Because the DFDL parser is model-driven, it can perform validation of messages against the message model that is defined in the DFDL schema file. The level of validation that is performed by the DFDL parser is the same as the level that is defined by XML Schema 1.0; see "Validating messages" on page 610.

The DFDL parser is an on-demand parser. See Parsing on demand.

To process messages with the DFDL parser, select DFDL as the *Message Domain* on the relevant node in the message flow.

MRM parser and domain

You can use the MRM domain to parse and write a wide range of message formats.

The MRM domain can be used to parse and write a wide variety of message formats. It is primarily intended for non-XML message formats, but it can also parse and write XML. For guidance on when to consider using the MRM parser, instead of one of the XML parsers, to parse XML, see "Which XML parser should you use?" on page 525

The key features of the MRM domain are:

- Support for messages from applications that are written in C, COBOL, PL/I and other languages, by using the Custom Wire Format (CWF) physical format. This support includes the ability to create a message model directly from a C header file or COBOL copybook.
- Support for text messages, perhaps with field content that is identified by tags, separated by specific delimiters, or both, by using the Tagged Delimited String (TDS) physical format. This includes industry standards such as CSV, HL7, SWIFT, EDIFACT, and X12.
- Support for XML messages, including those that use XML namespaces, by using the XML physical format.

IBM App Connect Enterprise uses the MRM parser to read and write messages that belong to the MRM domain. When reading a message, the MRM parser constructs a message tree from a bit stream. When writing a message, the MRM parser creates a bit stream from a message tree. The MRM parser is always model-driven, and it is guided by a message dictionary that describes the shape of the message tree (the logical model) and the physical layout of the bytes or characters in the bit stream (the physical format). A message dictionary is created automatically from the content of a message set when it is added to the BAR file. Therefore, when you create a message set for use with the MRM domain, you must define both the logical model and the appropriate physical format information.

The operation of the parser depends on the physical format that you have associated with the input or output message:

- For a binary message, the parser reads a set sequence of bytes according to information in the CWF physical format, and translates them into the fields and values in the message tree.
- For a text message, the parser uses a key piece of TDS physical format information called *Data Element Separation* to decide how to parse each portion of the message bit stream. This informs the parser whether the message uses delimiters, tags, fixed length elements, patterns, and so on. The parser then reads the data according to information in the TDS physical format, and translates it into the fields and values in the message tree.
- For an XML message, the parser reads the XML markup language (element tags and attributes), guided by information in the XML physical format, and translates them into the fields and values in the message tree.

Because the MRM parser is model-driven, it can perform validation of messages against the model that is defined in the deployed dictionary. The level of validation that is performed by the MRM parser is similar

to that defined by XML Schema 1.0, but is not fully compliant. If you use XML messages, and you want fully compliant XML Schema 1.0 validation, use the XMLNSC domain.

The MRM parser is an on-demand parser. See Parsing on demand.

If you want to use the MRM domain to parse a particular message:

1. Create a new message set with an appropriate CWF, TDS, or XML physical format; or locate an existing message set.
2. Ensure that the message set has its *Default message domain* set to `MRM`, or that the *MRM* check box under *Supported message domains* is selected to indicate that the message set supports the MRM domain.
3. Create a message definition file in the message set to represent your message, ensuring that both logical and physical format information is provided. If you have an existing C, COBOL, XML Schema, or DTD description of your message, you can import the description by using a wizard.
4. Add the message set to a BAR file which will generate a message dictionary for use by the MRM parser, and deploy the BAR file to the integration node.
5. Select `MRM` as *Message Domain* on the appropriate node in your message flow.
6. Additionally set values for the *Message model*, *Message*, and *Physical format* properties on the node. The *Message* property specifies the name of the message in the message definition file.

Some predefined message models are supplied with the IBM App Connect Enterprise Toolkit and can be imported by using the New Message Definition File From IBM supplied Message wizard. The CSV, ALE IDoc, and File IDoc models are specifically for use with the MRM domain. See Message Sets: IBM supplied messages that you can import.

IBM supplies predefined message sets for industry standard formats SWIFT, X12, EDIFACT, and FIX. For more information, contact Dublin Adapters at dubadapt@ie.ibm.com.

DataObject parser and domain

Use the DataObject domain to parse and write messages for WebSphere Adapters and CORBA applications.

- "Using the DataObject domain with WebSphere Adapters" on page 546
- "Using the DataObject domain with CORBA" on page 547

Using the DataObject domain with WebSphere Adapters

You must use the DataObject domain when you use WebSphere Adapter nodes in your message flow.

IBM App Connect Enterprise uses the DataObject parser to read and write message from Enterprise Information Systems (EIS) such as SAP, PeopleSoft, and Siebel. Such messages belong to the DataObject domain.

When it receives a message from an adapter, the DataObject parser constructs a message tree from the business object that it receives from the EIS. When it writes a message, the DataObject parser creates from the message tree the business object that it sends to the EIS. The DataObject parser is always *model-driven*, and it is guided by the XML Schemas that model the EIS business objects. The XML Schemas are created automatically from the content of a message set when the message set is added to the BAR file.

If you want to parse a message using the DataObject domain, you must:

1. Create a message set, or locate an existing message set.
2. Ensure that either the message set has its *Default message domain* project set to `DataObject`, or the *DataObject* check box (under *Supported message domains*) is selected, to indicate that the message set supports the DataObject domain.
3. Create a message definition file in the message set to represent your EIS business object. Use the *New adapter connection* wizard to connect to the EIS and retrieve the Business object metadata.

4. Add the message set to a BAR file, which generates XML Schema for the DataObject parser to use, and deploy the BAR file to the integration node.
5. If you associate your adapter inbound or outbound message with an adapter node in your message flow, the *Message model* property is automatically set in the node. The *Message domain* property is always pre-selected as `DataObject`.

Tip: If a message that belongs to the DataObject domain is written to a destination other than a WebSphere Adapter, the DataObject parser invokes the XMLNSC parser to write the message as XML.

Using the DataObject domain with CORBA

You must use the DataObject domain when you use CORBA nodes in your message flow.

IBM App Connect Enterprise uses the DataObject parser to read and write message from CORBA applications. Such messages belong to the DataObject domain.

For information about how to build the tree under the DataObject domain for use with CORBA, see "CORBA operation parameters" on page 1160 and "IDL data types" on page 1156.

JMS parsers and domains

The JMSMap and JMSStream domains can be used for modeling messages that are produced by the implementations of the Java Messaging Service standard, version 1.1 or 2.0.

Use the JMSMap domain when handling JMS messages of type MapMessage. Use the JMSStream domain when handling JMS messages of type StreamMessage.

These message types appear in the integration node in XML format, and are therefore supported in an identical way to XML domain messages.

For a full description of JMS MapMessage and StreamMessage processing, see "Using JMS in IBM App Connect Enterprise" on page 852.

MIME parser and domain

Use the MIME domain if your messages use the MIME standard for multipart messages.

The MIME (Multipurpose Internet Mail Extension) parser does not support the full MIME standard, but does support common uses of MIME. You can send the messages to the integration node over HTTP or over other transport types, such as IBM MQ. Use the MIME domain if your messages use the MIME standard for multipart messages.

The MIME domain does not support Content-Type values with a media type of *message*.

To specify that a message uses the MIME domain, select `MIME` as the *Message Domain* on the relevant message flow node.

Use the MIME domain and parser to parse and write MIME messages. The MIME parser creates a logical tree, and sets up the integration node ContentType property. You can use Compute nodes and JavaCompute nodes to manipulate the logical tree. Set the Content-Type value using the ContentType property in the MIME domain.

Example MIME message

The following example shows a simple multipart MIME message. The message shown is a SOAP with Attachments message with two parts: the root part and one attachment part. The boundary string *MIME_boundary* delimits the parts.

```
MIME-Version: 1.0
Content-Type: Multipart/Related; boundary=MIME_boundary; type=text/xml
Content-Description: Optional description of message.

Optional preamble text
--MIME_boundary
Content-Type: text/xml; charset=UTF-8
Content-Transfer-Encoding: 8bit
Content-ID: <rootpart@example.com>

<?xml version='1.0' ?>
<SOAP-ENV:Envelope
          xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">

    <SOAP-ENV:Header xmlns:ins="http://myInsurers.com">
       <ins:ClaimReference>abc-123</ins:ClaimReference>
    </SOAP-ENV:Header>

    <SOAP-ENV:Body xmlns:ins="http://myInsurers.com">
       <ins:SendClaim>
          <ins:ClaimDetail>myClaimDetails</ins:ClaimDetail>
          <ins:ClaimPhoto>
            <href>cid:claimphoto@example.com</href>
          </ins:ClaimPhoto>
       </ins:SendClaim>
    </SOAP-ENV:Body>

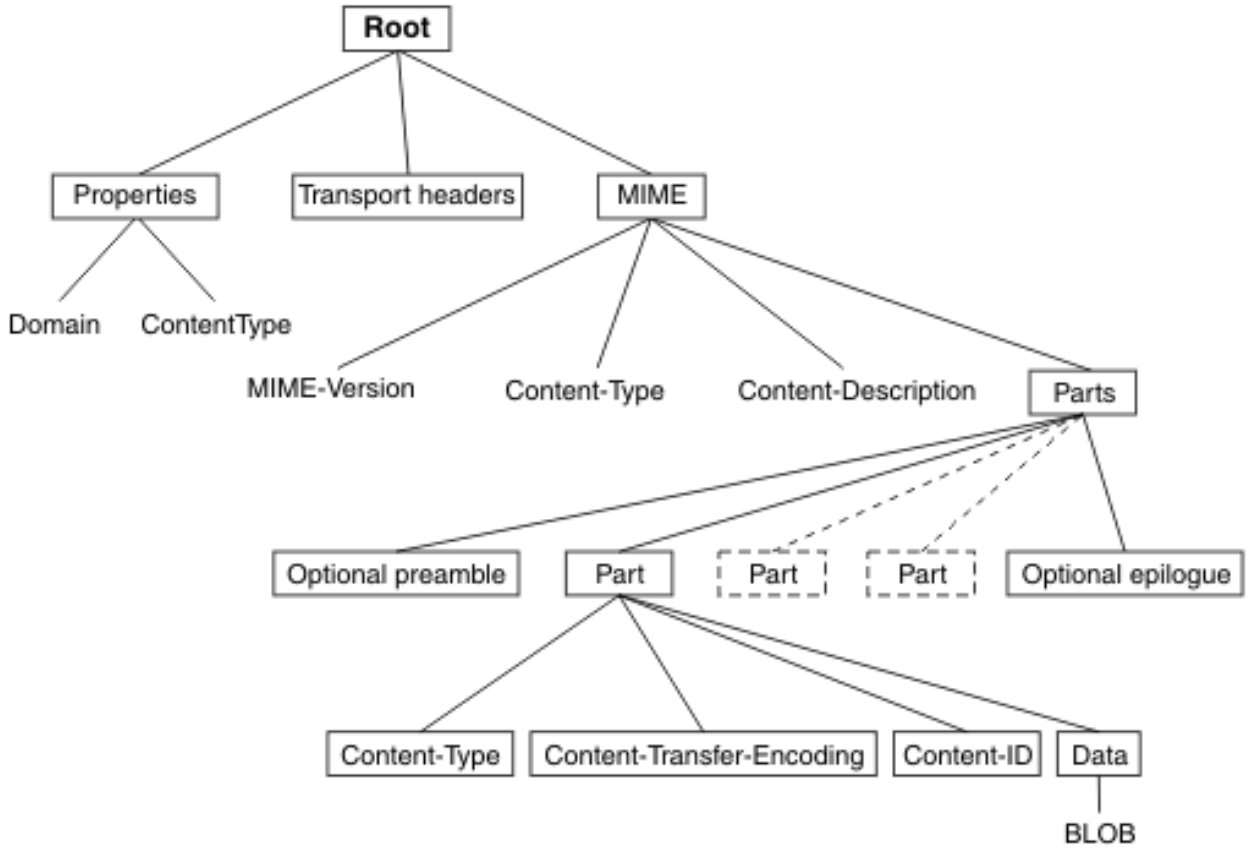
</SOAP-ENV:Envelope>

--MIME_boundary
Content-Type: application/octet-stream
Content-Transfer-Encoding: binary
Content-ID: <claimphoto@example.com>

myBinaryData
--MIME_boundary--
Optional epilogue text
```

Example MIME logical tree

The following diagram shows a MIME logical tree, which is described in “MIME tree details” on page 551. A MIME logical tree does not need to contain all of the children that are shown in the diagram. The value of the Content-Type header of a MIME message is the same as the ContentType field in the Properties subtree. The Transport-headers are headers from the transport that is used, such as an MQMD or HTTP.



You can further parse the BLOB data in the tree (for example, by using an ESQL CREATE statement) if you know about the format of that MIME part. You might be able to find information about the format from its Content-Type field in the logical tree. Alternatively, you might know the format that your MIME messages take, and be able to parse them appropriately. For example, you might know that the first MIME Part is always an XML message, and that the second MIME Part is a binary security signature.

When the EmailInput node receives an email from an email server that supports Post Office Protocol 3 (POP3) or Internet Message Access Protocol (IMAP), the body of the email message, and any attachments, are propagated in the MIME domain. All other information relating to the email is stored in the `Root.`*`Transport headers`* MIME logical tree; for example, `Root.EmailInputHeader.To`. Where To is the storage location of one of the email elements. For a complete list of the email elements that are propagated in the MIME logical tree when you use an EmailInput node, see node.

You must specify how to parse other message formats, such as tagged delimited or binary data, within your message flow, because the MIME parser does not do this. You must also specify how to handle encoded and signed message parts, because the MIME parser does not process these.

Some pre-defined MIME message models are supplied with the IBM App Connect Enterprise Toolkit and can be imported using the New Message Definition From IBM Supplied Message wizard.

MIME messages
A MIME message consists of both data and metadata. MIME metadata consists of HTTP-style headers and MIME boundary delimiters.

MIME headers

Each header is a colon-separated name-value pair on a line. The ASCII sequence <CR><LF> terminates the line. A sequence of these headers, called a header block, is terminated by a blank line: <CR><LF><CR><LF>. Any headers that are in this HTTP style can appear in a MIME document. Some common MIME headers are described in MIME standard header fields.

Content-Type

The only header that must be present is the *Content-Type* header. This header specifies the type of the data in the message. If the Content-Type value starts with "multipart", the message is a multipart MIME message. For multipart messages the Content-Type header must also include a boundary attribute that gives the text that is used to delimit the message parts. Each MIME part has its own Content-Type field that specifies the type of the data in the part. This can also be multipart, which allows multipart messages to be nested. MIME parts with any other Content-Type values are handled as BLOB data.

If a MIME document is sent over HTTP, the Content-Type header appears in the HTTP header block rather than in the MIME message body. For this reason, the integration node manages the value of the Content-Type header as the ContentType property in the *Properties* folder of the logical tree. This allows the MIME parser to obtain the Content-Type value for a MIME document that is received over HTTP. If you need to either create a new MIME tree or modify the value of the Content-Type, set the Content-Type value using the ContentType property in the MIME domain. If you set the Content-Type value directly in the MIME tree or HTTP tree, this value might be ignored or used inconsistently. The following ESQL is an example of how to set the integration node ContentType property:

```
SET OutputRoot.Properties.ContentType = 'text/plain';
```

Parsing

The MIME domain does not enforce the full MIME specification. Therefore, you can work with messages that might not be valid in other applications. For example, the MIME parser does not insist on a **`MIME-Version`** header. The MIME parser imposes the following constraints:

- The MIME headers must be properly formatted:
  - Each header is a colon-separated name-value pair, on a line of its own, terminated by the ASCII sequence <CR><LF>.
  - The header line must use 7-bit ASCII.
  - Semicolons are used to separate parameters:

    ```
    Content-Type: Multipart/Related; boundary=MIME_boundary; type=text/xml
    ```

  - A header might contain a comment in parentheses, for example:

    ```
    MIME-Version: 1.0 (Generated by XYZ)
    ```

- A line that starts with white space is treated as a continuation of the previous line. Therefore, a long header can be split across more than one line.
- If two or more headers in a header block have the same name, their values are concatenated into a comma-separated list.
- A top-level MIME Content-Type header must be available. The header is not case-sensitive. If the transport is HTTP, any Content-Type value in the HTTP header is used as the top-level Content-Type. If the transport is not HTTP, the Content-Type must appear in the initial header block of the MIME message.
- The Content-Type value is a media type followed by the `/` character and a subtype. Examples of this are `text/xml` and `multipart/related`. The parser does not validate subtypes. The Content-Type value can be followed by one or more parameters that are separated by semicolons.
- If the media type of a message is multipart, a boundary attribute must provide the text that is used to delimit the separate MIME parts.
- Each individual MIME part can have its own Content-Type header. The part header can have a media type of multipart, so that multipart messages can be nested. In this case, a valid boundary attribute must be provided, and its value must be different from any that has been previously defined in the message. MIME parts that have any other Content-Type value are handled as BLOB data.
- MIME multipart boundary delimiters are represented in 7-bit ASCII. The boundary delimiter consists of a line starting with a hyphen pair, followed by a boundary string. This sequence must not occur

within the MIME message at any point other than as a boundary. A MIME end-delimiter is a hyphen pair, followed by the MIME boundary string, followed by a further hyphen pair. All delimiter lines must end in the ASCII sequence <CR><LF>. An example of a delimited message is:

```
--MIME_boundary
message data
--MIME_boundary
message data
--MIME_boundary--
```

where *MIME_boundary* is the boundary delimiter string, and *message data* represents message data.

- The MIME media type *message* is not supported and results in an error at run time.
- Any preamble data (text between the initial MIME header block and the first boundary delimiter) or epilogue data (text after the final boundary delimiter) is stored in the logical tree as a value-only element. Preamble data and epilogue data can appear only as the first and last children, respectively, of a Parts node.
- The MIME parser does not support on-demand parsing and ignores the *Parse Timing* property. The parser does not validate MIME messages against a message model, and ignores the IBM App Connect Enterprise Toolkit *Validate* property.

Special cases of multipart MIME

The MIME parser is intended primarily for use with multipart MIME messages. However, the parser also handles some special cases:

- Multipart MIME with just one part. The logical tree for the MIME part saves the Content-Type and other information as usual, but the Data element for the attachment is empty.
- Single-part MIME. For single-part MIME, the logical tree has no Parts child. The last child of the MIME tree is the Data element. The Data element is the parent of the BLOB that contains the message data.
- MIME parts with no content.

Secure MIME (S/MIME)

S/MIME is a standard for sending secure email messages. S/MIME has an outer level Content-Type of *multipart/signed* with parameters **protocol** and **micalg** that define the algorithms that are used to encrypt the message. One or more MIME parts can have encoded content. These parts have Content-Type values such as *application/pkcs7-signature* and a Content-Transfer-Encoding of *base64*. The MIME domain does not attempt to interpret or verify whether the message is signed.

MIME tree details
A MIME message is represented in the integration node as a logical tree. When it writes a message, the MIME parser creates a message bit stream by using the logical message tree.

Logical tree elements

A MIME message is represented in the integration node as a logical tree with the following elements:

- The root of the tree is a node called MIME.
- All correctly formatted headers are stored in the logical tree, regardless of whether they conform to the MIME standard. The headers appear in the logical tree as name=value, as shown here:

```
Content-Type=text/xml
```

- A multipart MIME message is represented by a subtree with a root node called Parts.
- Any preamble or epilogue data associated with a multipart MIME message is represented by value-only elements appearing as the first and last children of Parts.
- In the special case of single-part MIME, the content is represented by a subtree with the root called Data.

- Each part of a multipart MIME message is represented by an element called Part with a child element for each MIME header, and a last child called Data.
- The Data element represents the content of a MIME part. This makes it easier to test for the presence of body content by using ESQL because the Data element is always the last child of its parent.

Writing MIME messages

When it writes a message, the MIME parser creates a message bit stream by using the logical message tree. The MIME domain does not enforce all of the constraints that the MIME specification requires, therefore it might generate MIME messages that do not conform to the MIME specification. The constraints that the MIME parser imposes are:

- The tree must have a root called MIME, and constituent Parts, Part, and Data elements, as described in "Logical tree elements" on page 551.
- Exactly one Content-Type header must be present at the top level of the tree, or be available by using the ContentType property. Media subtypes are not validated.
- If the media type is *multipart*, a valid boundary parameter must also exist.
- Any constituent MIME parts can have exactly one Content-Type header. If the value of this header starts with *multipart*, it must also include a valid boundary parameter. The value of this boundary parameter must not be the same as other boundary parameter values in the definition.
- The MIME Content-Type value "message" is not supported and results in an error at run time.
- All name-value elements in the tree are written as `name: value` followed by the ASCII sequence <CR><LF>.

If you have other elements in the tree, the parser behaves in the same way as the HTTP header parser:

- A name-only element or a NameValue element with a NULL value results in `Name: NULL` .
- Any children of a name-value element are ignored.

The message flow must serialize subtrees if they exist; you can use the ESQL command **ASBITSTREAM**.

BLOB parser and domain

The BLOB message domain includes all the messages with content that cannot be interpreted and subdivided into smaller sections of information.

Messages in this domain are processed by the BLOB parser. The BLOB parser is a program that interprets a bit stream or message tree that represents a message that belongs to the BLOB domain. The parser then generates the corresponding tree from the bit stream on input, or a bit stream from the tree on output.

A BLOB message is handled as a single string of bytes, and although you can manipulate it, you cannot identify specific pieces of the byte string using a field reference, in the way that you can with messages in other domains.

You can process messages in the BLOB domain in the following ways:

- You can refer to the message content if you know the location (offset) of particular information within the message. You can specify offset values in ESQL statements within nodes in a message flow to manipulate the information.
- You can store the message in an external database, in whole or in part (where the part is identified by the offset of the data that is to be stored).
- You can use the Mapping node to map to and from a predefined BLOB message, and to map to and from items of BLOB data. The BLOB message cannot be:
  - The message content in a message where `Content Validation` is defined as Open or Open Defined (for example, the message body of a SOAP envelope)
  - The message represented by a wildcard inside another message

  The UnknownParserName field is ignored.

The BLOB message body parser does not create a tree structure in the same way that other message body parsers do. It has a root element BLOB, which has a child element, also called BLOB, which contains the data.

For example, `InputBody.BLOB.BLOB[10]` identifies the tenth byte of the message body; `substring(InputBody.BLOB.BLOB from 10 for 10)` references 10 bytes of the message data starting at offset 10.

If you want to use the BLOB parser to parse a particular message, select `BLOB` as the `Message Domain` on the relevant node in your message flow.

IDOC parser and domain

The IDOC domain can be used to process messages that are sent to the integration node by SAP R3 clients across the IBM MQ link for R3. Such messages are known as SAP ALE IDocs.

Note: The IDOC domain is deprecated and is not recommended for developing new message flows. Instead use the MRM domain with a TDS physical format. See "MRM parser and domain" on page 545.

A typical ALE IDoc message that has been sent from SAP to the WebSphere MQ link for R3 consists of an MQMD header, an MQSAPH header, and the ALE IDoc itself. The IDoc is made up of fixed size structures:

- The first structure is the Control Structure (DC). This is a complex element 524 bytes long that contains a fixed set of SAP-defined simple elements.
- One or more Data Structures (DDs). Each DD is a complex element 1063 bytes long that contains a fixed set of SAP-defined simple elements that occupies 63 bytes, followed by 1000 bytes of user-defined segment data.

IBM App Connect Enterprise uses the IDOC parser to read and write ALE IDocs that belong to the IDOC domain. When reading a message, the IDOC parser constructs a message tree from a bit stream. When writing a message, the IDOC parser creates a bit stream from a message tree.

The IDOC parser processes the SAP-defined elements in the DC, then, for each DD, the IDOC parser processes the SAP-defined elements, then calls the MRM parser to process the user-defined segment data, using its CWF physical format. The IDOC parser is therefore a model-driven parser, and requires that you create a message model in which to model the IDoc message, and deploy it to the integration node.

If you want the IDOC domain to parse a particular message, you must:

1. Create a new message set with a CWF physical format, or locate an existing message set.
2. Ensure that either the message set has its *Default message domain* project set to `IDOC`, or the *IDOC* check box (under *Supported message domains*) is selected, to indicate that the message set supports the IDOC domain.
3. Create message definition files in the message set to represent your message. See Building the message model for the IDOC parser for the steps involved.
4. Add the message set to a BAR file which generates a message dictionary for use by the MRM parser, and deploy the BAR file to the integration node.
5. Select *Message Domain* as `IDOC` on the appropriate node in your message flow.
6. Additionally, select *Message model* and *Physical Format* on the node. (You do not need to select *Message*).

JSON parser and domain

JSON (JavaScript Object Notation) is a simple data-interchange format based on a subset of the JavaScript programming language.

IBM App Connect Enterprise supports a JSON domain. Messages in the JSON domain are processed by the JSON parser and serializer. The JSON parser interprets a bit stream by using the JSON grammar, and generates a corresponding JSON domain logical message tree. When processing data for output, the JSON serializer generates a JSON formatted bit stream from a JSON domain logical message tree.

JSON messages can be validated against a JSON schema file or OpenAPI definition during parsing. JSON message trees can be validated against a JSON schema file or OpenAPI definition during writing or mid-flow.

You can use the JSON editor in the IBM App Connect Enterprise Toolkit to edit JSON files; however, the validation capability of the editor has a number of limitations and should not be used to validate your JSON documents. For information about how to validate JSON documents, see "JSON validation" on page 561.

JSON is a language-independent text format, based on two structures:

- Objects (name-value pairs) with the following types:
  - String
  - Number
  - Boolean
  - Null
- Ordered collections of values (arrays)

Objects and arrays can be nested.

The JSON parser accepts only a JSON object or a JSON array as the top-level value type in both an input bit stream and an output bit stream. It is not possible to use the JSON parser to output a JSON string literal, number, Boolean, or null value without first embedding it in an object or array.

For more information about JSON message structure, see "JSON message details" on page 558. For more information about JSON parser parameters, see Parameter values for the JSON parser.

JSON data streams can be parsed from any coded character set ID (CCSID) that is supported by the integration node. The data stream is parsed according to the CCSID that is defined by the transport when the JSON parser is invoked from an input or request node, or defined by the CCSID parameter in a PARSE clause on a CREATE function call. If no CCSID is specified, or if a value of 0 is set, the parser attempts to detect (by examining the first few bytes of the data stream) whether one of the following Unicode encodings is being used:

- UTF-8
- UTF-16BE
- UTF-16LE
- UTF-32BE
- UTF-32LE

If a UTF-* CCSID is explicitly specified, the JSON parser tolerates the corresponding Byte Order Mark (BOM) at the beginning of the data stream.

JSON data streams are parsed into a logical message tree under the `Data` element below the `JSON` parser root. The logical tree structure is shown in the "Example JSON message" on page 555.

The `Data` element can be accessed and manipulated from ESQL as `JSON.Data`, from Java as `JSON/Data`, from the Graphical Data Mapping editor by using the Add User-Defined function to define `JSON->Data`, or from XPath as `$Body/Data`. The JSON parser issues an error if a bit stream is not formatted according to the JSON grammar.

The JSON serializer serializes message trees into a JSON format data stream. The CCSID can be defined by either the integration node properties tree, or by transport headers in the message assembly. If no CCSID is defined, the serializer defaults to the queue manager default CCSID for all nodes except HTTP nodes, which default to UTF-8 encoding.

When the JSON serializer is invoked through an `ASBITSTREAM` function call, the CCSID is defined by the CCSID parameter. If no CCSID parameter is provided, or if the value is set to 0, the JSON serializer defaults to using UTF-8 encoding.

If you code the ASBITSTREAM function with the parser mode option set to `FolderBitStream` to parse a JSON domain message tree to a bit stream, the generated bit stream is a JSON format that is built from the target element and its children.

To process messages with the JSON parser, select **JSON** as the *Message Domain* on the relevant node in the message flow. The XSLTransform node does not support the JSON domain.

The integration node sets the HTTP Content-Type header to `application/json` when it serializes a JSON message tree, unless an explicit value is set by the message flow.

JSON objects are modeled in the integration node message tree as a sequence of *NameValue* elements. The parser builds the message tree in the order in which it encounters the members in the bit stream. The serializer writes the object members into the bit stream in the tree order.

JSON arrays are modeled in the integration node message tree as a *Name* element with a JSON parser-specific type flag of *JSON.Array* and ordered children. The children can be any of the following types of array:

- An array that contains simple values; for example:

  ```
  "array1" : [ "thing1", 1 ]
  ```

  The following message tree is produced:

  ```
  (0x01001000:Array): array1 = (
      (0x03000000:NameValue):Item = 'thing1' (CHARACTER)
      (0x03000000:NameValue):Item = 1 (INTEGER)
   )
  ```

  The JSON parser assigns the name `Item` to the *NameValue* elements.
- An array that contains objects; for example:

  ```
  "array2" : [ {"a" : 1}, {"b" : 2} ]
  ```

  The following message tree is produced:

  ```
  (0x01001000:Array):array2 = (
    (0x01000000:Object):Item = (
      (0x03000000:NameValue):a = 1 (INTEGER)
    )
    (0x01000000:Object):Item = (
      (0x03000000:NameValue):b = 2 (INTEGER)
    )
  )
  ```

- A multidimensional array; for example:

  ```
  "array3" : [ [1.1], [2.1] ]
  ```

  The following message tree is produced:

  ```
  (0x01001000:Array):array3 = (
    (0x01001000:Array):Item = (
      (0x03000000:NameValue):Item = 1.1E+0 (FLOAT)
    )
    (0x01001000:Array):Item = (
      (0x03000000:NameValue):Item = 2.1E+0 (FLOAT)
    )
  )
  ```

Example JSON message

The following example shows a simple JSON message:

```
{
    "name" : "John Doe",
    "age" : -1.0,
    "known" : false,
```

```
    "address" : { "street" : null,
                  "city" : "unknown" },
    "belongings" : ["item1", "item2", "item3"]
}
```

This JSON input produces the following integration node logical message tree:

```
(0x01000000:Object):JSON            = ( ['json' : 0xd55fc8]
  (0x01000000:Object):Data = (
    (0x03000000:NameValue):name       = 'John Doe' (CHARACTER)
    (0x03000000:NameValue):age        = -1E+0 (FLOAT)
    (0x03000000:NameValue):known      = FALSE (BOOLEAN)
    (0x01000000:Object   ):address    = (
      (0x03000000:NameValue):street = NULL
      (0x03000000:NameValue):city   = 'unknown' (CHARACTER)
    )
    (0x01001000:Array    ):belongings = (
      (0x03000000:NameValue):Item = 'item1' (CHARACTER)
      (0x03000000:NameValue):Item = 'item2' (CHARACTER)
      (0x03000000:NameValue):Item = 'item3' (CHARACTER)
    )
  )
)
```

JSONP support in the JSON domain
JSONP (JavaScript Object Notation with Padding) is an extension of the JavaScript Object Notation (JSON) format.

IBM App Connect Enterprise provides support for JSONP services. A JSONP service, or Remote JSON Service, is a web service that returns JSON data padded with a user-defined JavaScript function call. The JSONP response message can be interpreted as an executable script, so this functionality can be used to create cross-domain function calls.

For example:

```
http://brokerhost:7080/flowUrlPathSuffix?jsonp=scriptFn
```

This URL includes a query string, where:

- **jsonp** tells the JSONP service that any response from the URL must be returned as a JSONP message
- **scriptFn** is the name of a client-side executable function

Responses to the URL would therefore be in the JSONP format:

```
scriptFn(response)
```

The JSON message tree provides a top level `Padding` element, into which the JSON parser places the name of the client-side JSONP function. Similarly, the JSON serializer pads a JSON message if the top-level element `Padding` is present in the tree.

For more information about JSON, see “JSON parser and domain” on page 553.

For information about how to use IBM App Connect Enterprise to provide a JSONP service, see “Providing a JSONP service” on page 557.

For information about how to use IBM App Connect Enterprise to consume a JSONP service response, see “Consuming a JSONP service response” on page 558.

Example JSONP message

The following example shows a simple JSONP message:

```
scriptFn (
    {
        "name" : "John Doe",
        "age" : -1.0,
        "known" : false,
        "address" : { "street" : null,
                      "city" : "unknown" },
```

```
        "belongings" : ["item1", "item2", "item3"]
    }
)
```

This JSONP input produces the following integration node logical message tree:

```
  (0x01000000:Object):JSON            = ( ['json' : 0xd55fc8]
    (0x03000000:NameValue):Padding = 'scriptFn' (CHARACTER)
    (0x01000000:Object   ):Data    = (
      (0x03000000:NameValue):name       = 'John Doe' (CHARACTER)
      (0x03000000:NameValue):age        = -1E+0 (FLOAT)
      (0x03000000:NameValue):known      = FALSE (BOOLEAN)
      (0x01000000:Object   ):address    = (
        (0x03000000:NameValue):street = NULL
        (0x03000000:NameValue):city   = 'unknown' (CHARACTER)
      )
      (0x01001000:Array    ):belongings = (
        (0x03000000:NameValue):Item = 'item1' (CHARACTER)
        (0x03000000:NameValue):Item = 'item2' (CHARACTER)
        (0x03000000:NameValue):Item = 'item3' (CHARACTER)
      )
    )
  )
```

Providing a JSONP service
Configure your IBM App Connect Enterprise message flow to provide a JSONP service response.

Before you begin

Before completing this task, read the following overview topics about JSON:

- "JSON parser and domain" on page 553
- "JSONP support in the JSON domain" on page 556

About this task

You can use ESQL or Java to configure your message flow to provide a JSONP response.

The code examples in this task assume that the client application provides a JavaScript call in the following format:

```
<script type="text/javascript"
 src="http://brokerhost:7080/flowUrlPathSuffix?jsonp=scriptFn">
</script>
```

Procedure

1. On the **Advanced** tab of your HTTPInput node, select `Parse Query String`.
   This option enables you to access the JSONP script prefix that is included in the incoming URL, for example `scriptFn`, from the local environment tree.
2. Insert the following code, as appropriate:
   - If your message flow uses a Compute node:

     ```
     SET OutputRoot.JSON.Padding = InputLocalEnvironment.HTTP.Input.QueryString.jsonp;
     SET OutputRoot.JSON.Data.objectName = 'thing1';
     ```

   - If your message flow uses a JavaCompute node:

     ```
     MbMessage outMessage = new MbMessage();
     MbElement outRoot = outMessage.getRootElement();
     MbElement outParser = outRoot.createElementAsLastChild(MbJSON.PARSER_NAME);
     String paddingString =
         assembly.getLocalEnvironment().getRootElement().getFirstElementByPath("HTTP/Input/
     QueryString/jsonp").getValueAsString();
     MbElement padding = outParser.createElementAsLastChild(MbElement.TYPE_NAME_VALUE,
      "Padding", paddingString);
     MbElement data = outParser.createElementAsLastChild(MbElement.TYPE_NAME, "Data", null);
     ```

```
data.createElementAsLastChild(MbElement.TYPE_NAME_VALUE,"objectName","thing1");
```

This code generates the following bit stream, sent as the HTTP reply:

```
scriptFn( {"objectName":"thing1"} )
```

This bit stream causes the JavaScript function `scriptFn` to be called with the JSON object as a parameter.

Consuming a JSONP service response
When a message flow is configured to use the JSON domain, the JSON parser automatically detects JSONP messages. The JSON parser puts the JSON padding in the top level `Padding` element, and the JSON data under the `Data` element.

Before you begin

Before completing this task, read the following overview topics about JSON:

- "JSON parser and domain" on page 553
- "JSONP support in the JSON domain" on page 556

About this task

You can process both JSON and JSONP messages in a single message flow, because the parser puts the JSON data under the `Data` element in the message tree. If JSONP padding is detected, the name of the client-side script is placed in the top level `Padding` element.

Follow these steps to test for the presence of padding:

Procedure

1. Create a message flow with an HTTPInput node, an HTTPReply node, and your choice of a Computeor JavaCompute node.
2. On the **Input Message Parsing** tab of your HTTPInput node, set the `Message domain` property to `JSON : For JavaScript Object Notation messages`.
3. Insert the following code, as appropriate:
   - If your message flow uses a Compute node:

     ```
     DECLARE PaddingRef REFERENCE TO InputRoot.JSON.Padding
     IF LASTMOVE(PaddingRef) THEN
        -- JSON Padding is present
     ELSE
         -- No JSON Padding present
     END IF;
     ```

   - If your message flow uses a JavaCompute node:

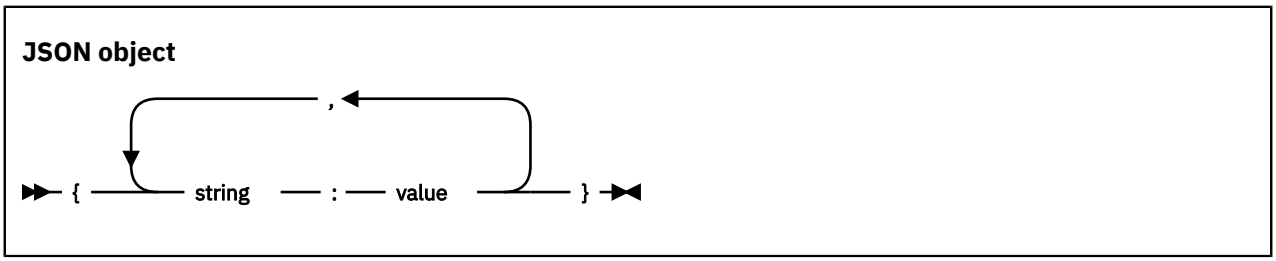
     ```
     if (message.getRootElement().getFirstElementByPath("JSON/Padding") != null){
         //JSON Padding is present
     }
     else{
         //No JSON Padding
     }
     ```

JSON message details
A JSON message consists of name-value pairs (objects), and ordered collections of values (arrays). Objects, arrays, or both structures can be nested.

For more detailed information about JSON, see the JavaScript Object Notation (JSON) web site.

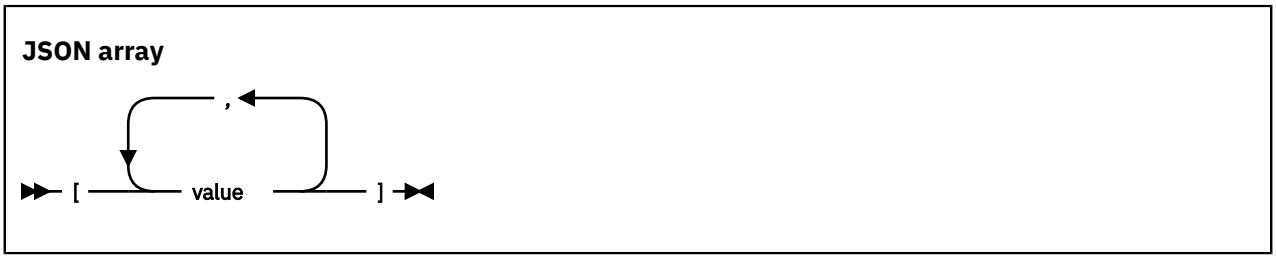
JSON object

In a JSON message, an object is an unordered set of comma-separated name-value pairs that begins with a left brace ({) and ends with a right brace (}). Each name is followed by a colon (:).



JSON array

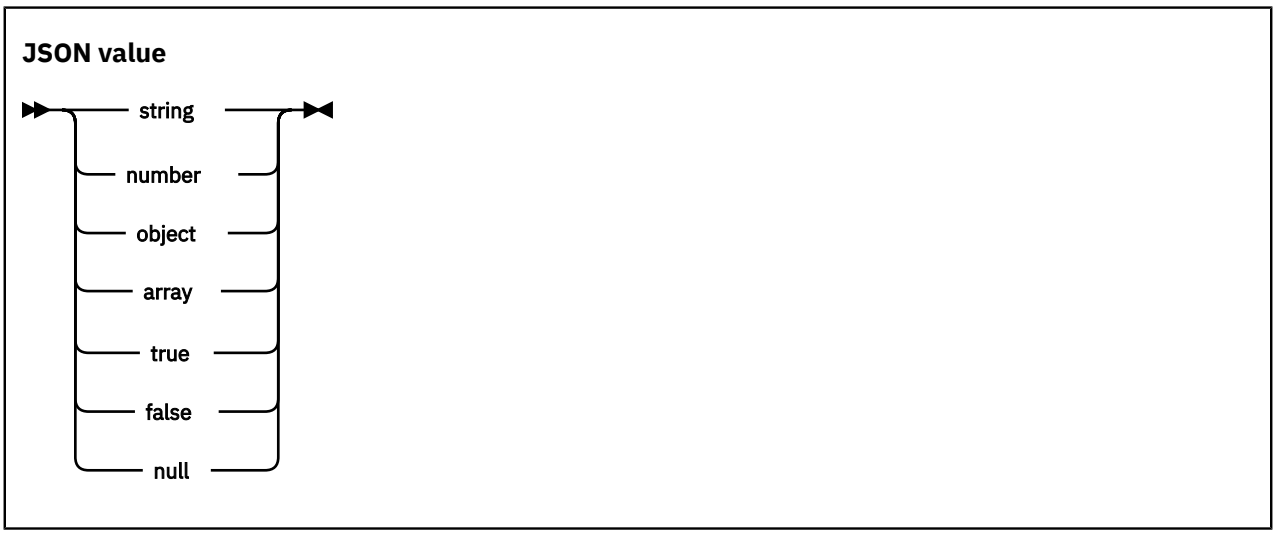
A JSON array is an ordered collection of comma-separated values that begins with left bracket ([) and ends with right bracket (]).



JSON value

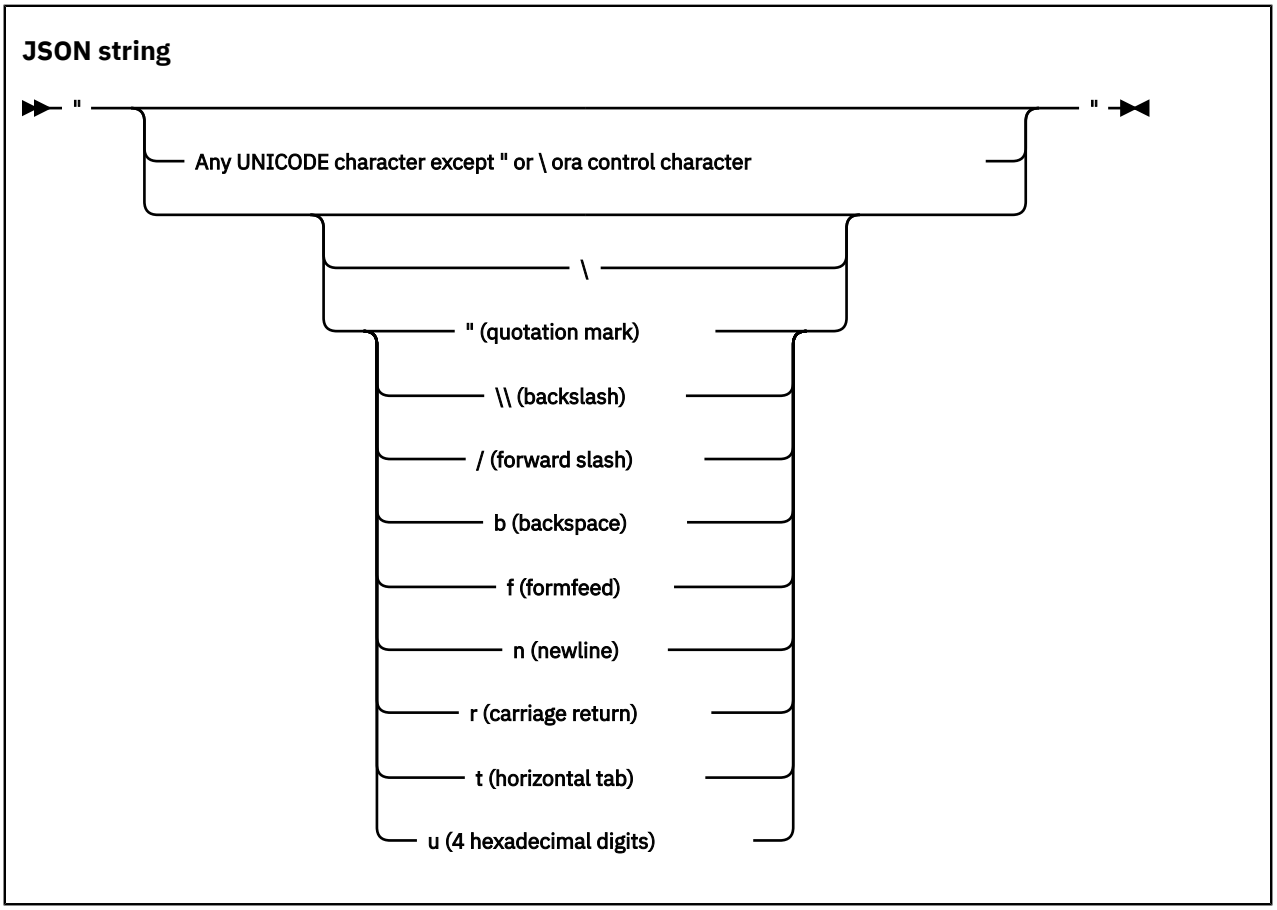
A JSON value can be any of the following structures, any of which can be nested:

- A string in double quotation marks
- A number
- Boolean
- Null
- An object
- An array



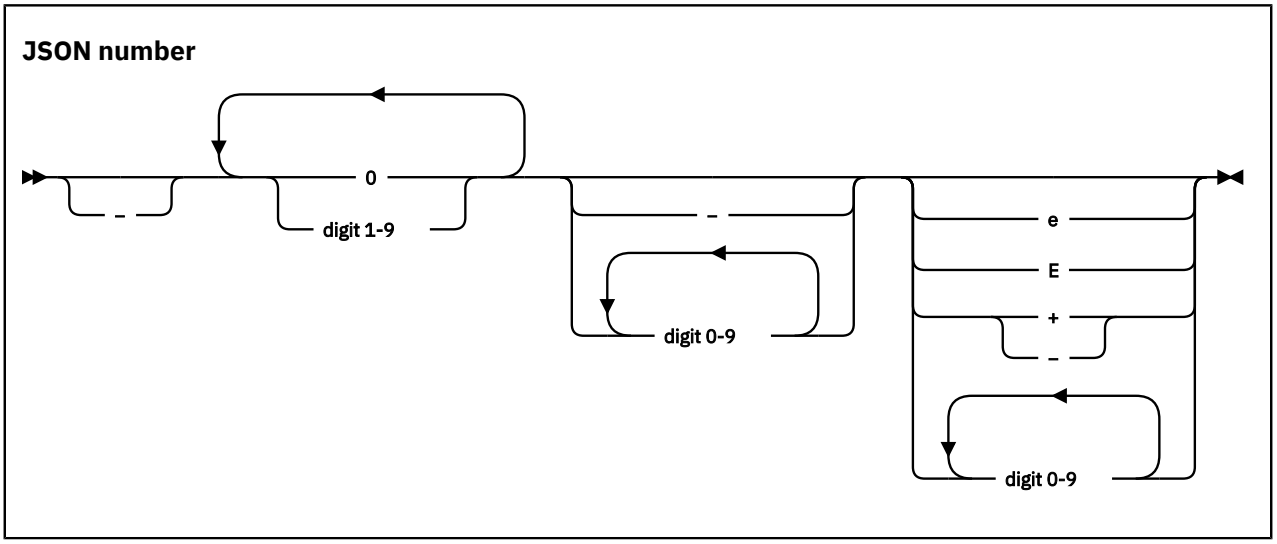
JSON string

A JSON string is very much like a C or Java string. A string is a collection of zero or more Unicode characters, wrapped in double quotation marks, using backslash escapes. A character is represented as a single character string.



JSON number

A JSON number is the same as a C or Java number, except that the octal and hexadecimal formats are not used.



Whitespace can be inserted between any pair of tokens.

JSON validation
The JSON parser offers high-performance, standards-compliant JSON schema validation at any point in a message flow.

Validation of the input JSON message or the message tree is performed against the JSON schema files or OpenAPI definition files that are deployed. JSON schema must be contained in a file with a `.json` file extension, and it must either contain schema in the name (for example, `.schema.json`) or the first line of the file must indicate that it is a schema (for example, `"$schema": "http://json-schema.org/draft-04/schema#"`).

In the following sections, the term *JSON schema* is used to refer to either a JSON schema file or an OpenAPI definition file.

Validation is not the same as *parsing*. When parsing, the JSON parser always checks that the input document is well-formed JSON, according to the JSON specification. If validation is enabled, the JSON parser also checks that the JSON document obeys the rules in the JSON schema.

You can use the JSON editor in the IBM App Connect Enterprise Toolkit to edit JSON files; however, the validation capability of the editor has a number of limitations and should not be used to validate your JSON documents.

Video: JSON Validation

This video demonstrates the capability to validate a JSON message using JSON Schema.

For more videos about JSON validation, see the IBM App Connect Enterprise playlist on YouTube.

Enabling JSON schema validation in a message flow

Complete the following tasks to construct a message flow that validates a JSON document in accordance with a JSON schema:

- Enable validation at the appropriate point in the message flow, by setting the *Validate* property of the appropriate node to `Content and Value`. For more information, see "Validating messages" on page 610. If the message flow is in a REST API project, enable validation by using the REST API editor.
- Ensure that all required JSON schema files are deployed, as described in "Deploying JSON schemas" on page 561.
- Supply the name of the JSON schema that contains the definition corresponding to the JSON document. Typically, you specify this by setting the `Message model` property on a message flow node. If the parser is being invoked from a programming language such as ESQL or Java, the message model must be specified in the parameters of the function call. If the message flow is in a REST API project, the JSON schema name is set automatically.

To ensure that misspelled and unwanted JSON objects and properties are detected by validation, set the **`"additionalProperties": "false"`** property in the JSON schemas.

Deploying JSON schemas

JSON schemas with a `.json` file extension can be deployed in an application or in a library that is referenced by an application.

If the schemas are deployed as part of the application, they must be included in one of the projects that are referenced by the application.

If the schemas are deployed in a library, the application must reference that library, even if it will be deployed as part of a different application.

Standards compliant validation

JSON validation complies with the JSON schema specifications shown in the following table, with the exception of the `default`, `format`, and `discriminator` properties, which are ignored:

Specification	Definition
JSON schema draft 04	https://datatracker.ietf.org/doc/html/draft-fge-json-schema-validation-00
JSON schema draft 05	https://datatracker.ietf.org/doc/html/draft-wright-json-schema-validation-00
Swagger 2.0	https://swagger.io/specification/v2/
OpenAPI 3.0.x	https://swagger.io/specification/

Other drafts are not supported, and any attempt to use a JSON schema that specifies an unsupported schema draft or OpenAPI version results in a BIP5754 message when the deployed schema is first used.

Interpreting validation errors

A validation error occurs when the JSON document does not conform to the rules that are defined in the JSON schema. The JSON schema specifications specify exactly what these rules are, and how they should be applied. Validation errors issued by the JSON parser contain information that links the error to the construct in the JSON schema that has been violated.

All validation errors are reported in BIP5751 (parsing) or BIP5752 (writing) messages. Each message contains the following information as inserts:

- The validation error
- The location of the error in the JSON message
- The matching location in the JSON schema file
- The error context

Both locations are in the form of a JSON pointer into the document (see https://datatracker.ietf.org/doc/html/rfc6901).

For the **oneOf**, **anyOf**, **allOf**, **not**, and **dependencies** JSON schema constructs, there is an initial BIP5751 or BIP5752 message, followed by one or more BIP5751 or BIP5752 messages with the error context set to the construct name. For example, if a validation error occurs because a JSON object in the message fails to match any of the items in a **oneOf** array in the schema, an initial BIP5751 message for the **oneOf** failure is followed by a BIP5751 message for each item in the **oneOf** array, explaining why the object failed to match the item, each with error context set to **oneOf**. Nested **oneOf**, **anyOf**, and **allOf** schema constructs can result in a large number of error messages, as the JSON parser attempts to validate against all the possibilities.

If the JSON schema file does not provide enough information, you can find more information using a search engine. The JSON schema draft standards are very widely used, and many online tutorials and other resources are available.

JSON schema correctness

Deployed JSON schema are checked for well-formedness and validity by parsing them and validating them against the JSON meta-schema file for the relevant JSON schema draft or OpenAPI version. Any violations are reported when the deployed JSON schema is first used by a message flow and causes an exception to occur. If this occurs, you must correct and redeploy the JSON schema.

OpenAPI considerations

When the JSON schema is part of an OpenAPI definition, the following additional considerations apply when validation is enabled and the message flow is **not** in a REST API project:

- When the schema model is defined in the top-level OpenAPI definition, the **Message** property of the node must be specified and must be a JSON pointer to the schema model in the definition. For example:

```
"/paths/~1customers/get/responses/200/content/application~1json/schema"
```

- When the schema model is defined by a JSON schema file or OpenAPI definition that is referenced by a top-level OpenAPI definition using the `$ref` schema construct, the **Message format** property must specify the OpenAPI version that applies. Valid values are `Swagger 2.0 definition` or `OpenAPI 3.0 definition`.

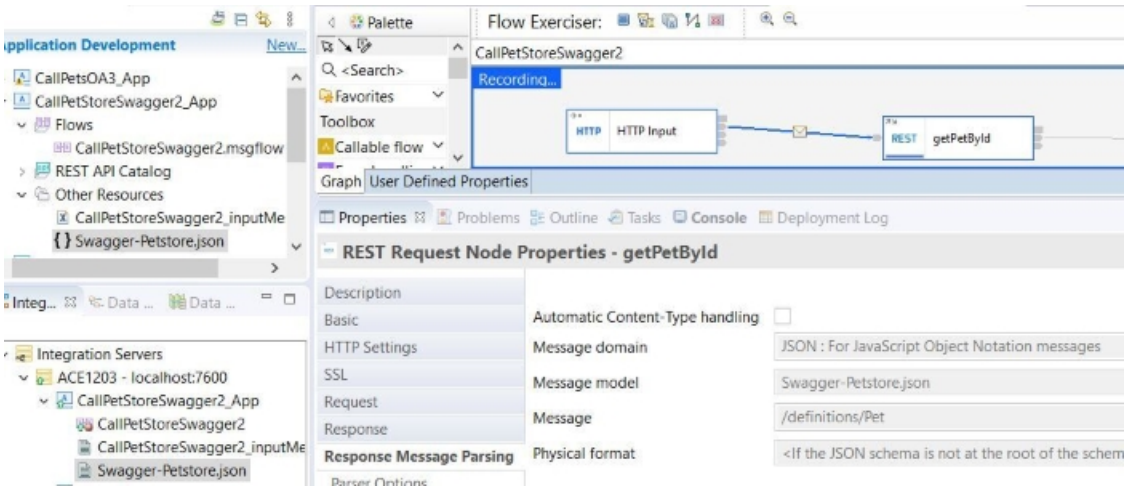
When the message flow is in a REST API project, these properties are set automatically.

The JSON models for REST API responses are typically provided in the Swagger `definitions` or OpenAPI 3 `components/schemas` section of the OpenAPI definition, and it is often simpler to specify the JSON path to that section directly. For example, the standard Pets Store Swagger 2 example operation `"getPetById"` defines its response as `"schema" : { "$ref" : "#/definitions/Pet" }`, so you can use the simple JSON pointer `"/definitions/Pet"` directly in the **Message** property on the RESTRequest node.

In the **Response Message Parsing** tab of the RESTRequest node, set the following properties:

- Deselect **Automatic Content type handling**
- Set **Message Domain** to JSON
- Set **Message model** to the OpenAPI document name
- Set **Message** to the JSON path for the relevant model

For example:



The more complex JSON pointer for this would be `"/paths/~1pet~1{petId}/get/responses/200/schema"`. When any part of the JSON path contains a `"/"`, it must be escaped as `"~1"`, which means that the `getPetById` operation's path `"/pet/{getId}"` would be `"~1pet~1{petId}"`.

Video: JSON Validation, using an OpenAPI document

This video demonstrates how you can configure a RESTRequest node to validate a JSON response message from a back-end REST API.

For more videos about JSON validation, see the IBM App Connect Enterprise playlist on YouTube.

Message tree mapping in the JSON domain
When reading a JSON message, the parser builds a message tree from the input bit stream by mapping JSON values to corresponding message tree element types. When serializing a message tree into the output bit stream, tree element types are mapped to JSON value types.

When you use the Graphical Data Mapping editor to transform a JSON message, ensure that the JSON element names that you define by using the **Add User Defined** function are valid according to the XML

element naming rules. JSON allows a wider range of characters than XML, for example a JSON object could include the @ character, however, the Graphical Data Mapping editor only allows element names that are valid in XML or XPath.

The following tables show how JSON message values are mapped to message tree element types:

- "JSON bit stream to message tree value mapping" on page 564
- "Message tree to JSON message value mapping" on page 564

JSON bit stream to message tree value mapping

The JSON parser maps JSON values to message tree element types according to the rules in the following table:

JSON value present in bit stream	Parsed as
String	CHARACTER
JSON Number value presented as: • A minus sign prefix if the value is negative • At least one digit, which can be zero • No dot fractional part • No exponent	INTEGER
JSON Number value presented as: • A minus sign prefix if the number is negative • At least one digit in the integer part, which can be zero • Either or both of: • A dot and at least one digit in the fractional part, which can be zero • An exponent using uppercase 'E' or lowercase 'e', an optional plus or minus sign, and at least one digit	FLOAT
Boolean	BOOLEAN
Null	NULL

Message tree to JSON message value mapping

The JSON serializer maps message tree elements to JSON value types according to the rules in the following table:

Message tree Element type	JSON Domain serializes as	
	JSON type	Format
BIT	String	Any number of 0 and 1s
BLOB	String	Even number of hexadecimal digits

Message tree Element type	JSON Domain serializes as	
CHARACTER	String	Char data with JSON string escaping for the characters that are listed below: • " - quotation mark (U+0022) • \ - reverse solidus (U+005C) • / - solidus (U+002F) • backspace (U+0008) • form feed (U+000C) • line feed (U+000A) • carriage return (U+000D) • tab (U+0009) See https://tools.ietf.org/html/rfc7159#section-7 for more details.
DATE	String	The standard ESQL string representation, 'yyyy-mm-dd'
TIME, GMTTIME	String	The standard ESQL string representation, 'hh:mm:ss.ffffff'
INTEGER	Number	• A minus sign prefix if the number is negative • At least one digit, which can be zero • No dot fractional • No exponent
FLOAT	Number	• A minus sign prefix if the number is negative • At least one digit in the integer part, which can be zero • At least one digit in the fractional part, which can be zero • An exponent part using uppercase 'E', a plus or minus sign, and at least one digit
DECIMAL	Number	• A minus sign prefix if the number is negative • At least one digit in the integer part, which can be zero • At least one digit in the fractional part, which can be zero Decimal literals ‘NAN', ‘INF', and so on, are not supported when serializing to JSON.
BOOLEAN	Boolean	true or false The serializer only serializes Boolean logical tree elements with true or false values; unknown is not supported
NULL	Null	Null

Message tree Element type	JSON Domain serializes as	

ROW	Object	Note: Assigning a ROW directly to a JSON Domain tree does not produce JSON arrays.
		`DECLARE myRow ROW;`
		`SET myRow.rowData[1].fieldOne = 'Row1Field1';`
		`SET myRow.rowData[1].fieldTwo = 'Row1Field2';`
		`SET myRow.rowData[2].fieldOne = 'Row2Field1';`
		`SET myRow.rowData[2].fieldTwo = 'Row2Field2';`
		`SET OutputRoot.JSON.Data.aRow = myRow;`
		Produces the following JSON bit stream
		`"aRow":{`
		`"rowData":`
		`{"fieldOne":"Row1Field1","fieldTwo":"Row1Field2"},"`
		`"rowData":`
		`{"fieldOne":"Row2Field1","fieldTwo":"Row2Field2"}`
		`}`

ROW	Array	To produce a JSON array from a ROW type the JSON.Array field would also be set.
		`SET OutputRoot.JSON.Data.aRow = myRow;`
		`SET OutputRoot.JSON.Data.aRow TYPE = JSON.Array;`
		Produces the following JSON bit stream
		`"aRow":[`
		`{"fieldOne":"Row1Field1","fieldTwo":"Row1Field2"},`
		`{"fieldOne":"Row2Field1","fieldTwo":"Row2Field2"}`
		`]`

Handling null values

A business message might contain fields that are either empty or have a specific out-of-range value. In these cases, the application that receives the message is expected to treat the field as if it did not have a value. The logical message tree supports this concept by enabling the value of any element to be set to NULL.

Ways to represent a null value

In an XML document, the usual way to represent a null value is to leave the element or attribute empty.

For example: `<price></price>` or `<element price=""/>`

The xsi:nil attribute provides a way to make this more explicit: `<price=xsi:nil="true"/>`

Some business messages use a special value to represent a null value: `<price>-999</price>`. This style of null representation is supported by the DFDL and MRM parsers.

DFDL parser support for null values

The DFDL parser can detect a null value that is represented by an out-of-range value. The null value must be specified in the DFDL schema, and can be the same or different for each element. In DFDL it is called a *nil value*. While parsing, the DFDL parser checks the nil value for each element in the message. If the value in the bit stream matches the nil value in the DFDL schema, the DFDL parser sets the value in the message tree to NULL. The same check is performed when converting a message tree to a bit stream. If the value in the message tree is NULL, the DFDL parser outputs the nil value from the DFDL schema.

For more information, see The DFDL 1.0 specification, section 13.15.

Graphical Data Mapper support for null values

In the Graphical Data Mapping editor, you can create an element in the message tree as NULL, you can set the value of a message tree element to NULL, and you can use XPath expressions in your graphical transformations to test if an input element is NULL.

When you map null values, consider the behavior of the Graphical Data Mapping editor. For more information, see Handling nulls in message maps.

When you test to check if an input element is NULL, you can use any of the following XPath expressions: **fn:empty**, **fn:nilled**, or **fn:exists**. For more information, see Choosing an XPath conditional expression that tests for a nil value in a transform .

ESQL support for null values

Using ESQL, you can set the value of a message tree element to NULL:

```
SET OutputRoot.XMLNSC.myField VALUE = NULL;
```

Note that this is different from `SET OutputRoot.XMLNSC.myField = NULL;` which would cause myField to be deleted from the message tree.

The same effect can be achieved using Java.

XMLNSC parser support for null values

Typically, the XML parsers (XMLNSC, XMLNS, and XML) do not create null values in the message tree; an empty element or an empty attribute value merely produces an empty string value in the message tree.

If validation is enabled, the XMLNSC parser detects and processes any xsi:nil attributes in the input document. If the xsi:nil attribute is set to 'true', and the element is nullable, the attribute's parent element in the message tree is given a null value.

For more information about XML parser support for empty elements and null values, see “XMLNSC empty elements and null values” on page 532 and “XMLNS empty elements and null values” on page 541.

JSON parser support for null values

The JSON format supports null as a JSON value type for an object.

When a JSON message includes an object with a null value, the JSON parser sets the value in the message tree to NULL.

When the JSON serializer includes an element in the message tree with a NULL value, the JSON bit stream is constructed as a JSON object with a value of null.

MRM parser support for null values

XML physical format

When parsing, the MRM XML parser can detect and process xsi:nil attributes in the input XML document. If the xsi:nil attribute is set to 'true', and the element is nullable, the attribute's parent element in the message tree is given a null value.

For information about enabling xsi:nil support in the MRM parser, see Message Sets: XML Null handling options.

The following topics provide more information about handling null values in the MRM parser:

- “MRM Custom wire format: NULL handling” on page 2182
- “MRM XML physical format: NULL handling” on page 2202
- “MRM TDS format: NULL handling” on page 2197

All physical formats

The MRM parser can detect a null value that is represented by an out-of-range value. The null value must be specified in the physical format of the message set.

While parsing, the MRM parser checks the null value for each element in the message. If the value in the bit stream matches the null value in the message set, the MRM parser sets the value in the message tree to NULL.

The same check is performed when converting a message tree to a bit stream. If the value in the message tree is NULL, the MRM parser outputs the null value from the message set.

Properties

You can view and change properties that define integration node characteristics, and those properties of associated resources such as message flows.

Integration node properties
Each integration node has a set of properties that define certain characteristics that you can control:

- You can set some integration node properties only at the time that you create the integration node by using the **mqsicreatebroker** command; for example, its associated queue manager.
- You can access some integration node properties from ESQL and Java programs that you run in message flow nodes.

Message flow node properties
Each built-in (supplied) node has at least one property that you can configure; some properties are mandatory, others are optional. In addition to setting these properties for each node when you add it to a message flow, you can also use the following configuration techniques:

- You can promote properties, so that you can set them at the message flow level. For information about how and why you might want to use this technique, see "Promoted properties" on page 568.
- You can configure properties when you add the message flow to a BAR file for deployment. In each node description, the subset of node properties that you can use in this way are identified.
- You can override some of the properties that are set on message flow nodes by using policies (see "Overriding properties at run time with policies" on page 324).

Node properties are discussed in "Message flow nodes" on page 484.

User-defined properties
You can create your own properties when you create a message flow, and access those properties from ESQL and Java programs in your message flow nodes. For further details, see "User-defined properties" on page 569

Promoted properties

A promoted property is a message flow node property that has been promoted to the level of the message flow in which it is included.

A message flow contains one or more message flow nodes. You can promote the properties of a message flow node to apply to the message flow to which it belongs. In this case, any user of the message flow can override these promoted properties at the message flow level, without being aware of the message flow's internal structure.

You can promote compatible properties (that is, properties that represent comparable values) from more than one node to the same promoted property; you can then set a single property that affects multiple nodes.

For example, you might want to set the name of a data source as a property of the message flow, rather than a property of each individual node in the message flow that references that data source. You create a message flow that accesses a database called SALESDATA. However, while you are testing the message flow, you want to use a test database called TESTDATA. If you set the data source properties of each individual node in the message flow to refer to SALESDATA, you can promote the data source property for each node in the flow that refers to it, and update the property to have the value TESTDATA; this value overrides the data source properties on the nodes while you test the message flow (the promoted property always takes precedence over the settings for the properties in any relevant nodes).

A subset of message flow node properties is also configurable (that is, the properties can be updated at deployment time). You can promote configurable properties: if you do so, the promoted property (which

can have a different name from the property or properties that it represents) is the one that is available to update at deployment time. Configurable properties are those associated with system resources; for example, queues and data sources. An administrator can set these properties at deployment time, without the need for a message flow developer.

User-defined properties

A user-defined property (UDP) is a property that is defined when you construct a message flow by using the Message Flow editor. This property can be used by the Compute, JavaCompute, .NETCompute, and Mapping nodes.

The advantage of UDPs is that their values can be changed by operational staff at deployment and run time. You do not need to change your application programs. For example, if you use the UDPs to hold data about your computer center, you can configure a message flow for a particular computer, task, or environment at deployment time, without having to change the code at the message node level.

When you launch the Message Flow editor to either create a message flow or modify an existing message flow, as well as deciding which nodes are required in the message flow, you also have the option (provided by the tab) of defining and giving initial values to some user-defined properties. Use the **User Defined Properties** tab at the bottom of the edit window. See Message Flow editor for more information. You can also define a UDP at the level of the integration server, by updating the `server.conf.yaml` configuration file.

You can access UDPs in the following ways:

- From a Mapping node within a Graphical Data Map. Use the `iib:getUserDefinedProperty("propertyname")` custom XPath function; see Accessing user-defined properties from a Mapping node. You can also access UDPs from custom ESQL that is invoked from a map.
- From a JavaCompute node, by calling the `getUserDefinedAttribute` method.
- From a Compute node, by using a DECLARE statement with the EXTERNAL keyword, which can also provide a default.
- From a .NETCompute node, by calling the `GetUserDefinedProperty` method.

See the DECLARE statement for details of the DECLARE statement, and see “Accessing message flow user-defined properties from a JavaCompute node” on page 1784 for more information about how to use a UDP in a JavaCompute node.

If you use ESQL to access your UDP, the value that you give to a UDP when you define it in a message flow overrides the value of that variable in your ESQL program.

You can also modify the value of a UDP at deployment time by using the Broker Archive editor to edit the BAR file. This value overrides the value that was set when you defined the message flow.

You can also change the behavior of a message flow at run time by using the administrative REST API to modify the values of user-defined properties on the message flow. For more information, see “Setting message flow user-defined properties at run time by using the administration REST API” on page 436.

The value of the UDP is set at the message flow level, and is the same for all eligible nodes that are contained in the flow. An *eligible node* is a node that supports UDPs and is within the scope of the declaration that declares the UDP to your application. For example, if you use the Message Flow editor to change the value of a user property called `timezone`, which is declared in a schema called *mySchema*, in a message flow called *myFlow*, the UDP is available at run time to all the nodes in *myFlow* that support UDPs and that fall within *mySchema*.

- If you use the Message Flow editor to change the value of a user-defined property in a subflow, the newly edited property is available to all the nodes in the subflow that support UDPs, and that are within the scope of the declaration. The property is not available, for example, to nodes in the parent flow.
- If a node within a subflow accesses a UDP and if the subflow does not define the UDP, the parent flow is searched for a definition of the UDP at run time. If the parent flow does not define the UDP and it is also a subflow, the parent of this subflow is searched for a definition of the UDP. The search process

continues in this recursive manner upwards through the chain of subflows and parent flows until the UDP definition is found, or until the top-level flow is reached.

To have a value that is available to both the main and subflow, define UDPs in one of the following ways:

- Define UDPs in the subflow and then promote them to the main flow. Set the value in the main flow.
- Define UDPs in the main flow only and allow the subflow to locate the UDP value in the main flow at run time.

Controlling user-defined properties at run time

User-defined properties can be queried, discovered, and set at run time to dynamically change the behavior of a message flow. You can use the administration REST API to manipulate these properties, which can be used by a systems monitoring tool to perform automated actions in response to situations that it detects in the monitored systems.

For example, a message flow contains a Route node, which is used to differentiate between the classes of customer that are defined in the message. The Route node has a user-defined property called `ProcessClasses`, which is set with an initial value of `All`. When `ProcessClasses` is set to `All`, the node routes messages from all classes of customer to its first terminal for immediate processing.

When certain conditions are detected (for example, the monitoring system detects that the request load is causing the service level agreement to fall below its target), the Route node must be set to pass requests from only "Gold" class customers for immediate processing, while other customer requests are sent to another output terminal, which queues them for later batch processing. Therefore, the monitoring application sets `ProcessClasses` to `Gold`, so that the Route node routes the less critical messages to the second terminal.

To make it easier to know what a user-defined property does, and what values it can have, adopt a suitable naming convention. For example, a user-defined property named `property01`, with an initial value of `valueA` is not as useful as a property named `RouteToAorB` with an initial value of `RouteA`.

For information about how to use the REST API to control user-defined properties at run time, see “Setting message flow user-defined properties at run time by using the administration REST API” on page 436. For more information about the administration REST API, see “Managing resources by using the administration REST API” on page 334.

Precedence of UDP value overriding

You can define a user-defined property in the following ways:

- In the ESQL code
- In the Message Flow editor
- Through a BAR file override before BAR file deployment
- By using the administration REST API

A BAR file override takes precedence over changes in the Message Flow editor, and changes in the Message Flow editor take precedence over changes in the ESQL code.

The precedence of the values for user-defined properties is shown in the following sequence:

1. The user-defined property `ProcessClasses` is set to `All` in a message flow BAR file. After deployment of the BAR file, the value of `ProcessClasses` is `All`.
2. A user-defined property override is set to `Gold` by using the administration REST API. After successful completion of this method, the value of `ProcessClasses` is `Gold`.
3. The integration node or server is shut down and restarted. The value of `ProcessClasses` reverts to `All` because the REST API update is not persistent.
4. A user-defined property override is set to `Gold` by using the administration REST API. After successful completion of this method, the value of `ProcessClasses` is `Gold`.
5. The original flow BAR file is redeployed. After deployment, the value of `ProcessClasses` is `All`.

Data conversion

Convert data that your message flows are transferring between different environments by using IBM MQ or IBM App Connect Enterprise facilities.

Data conversion is the process by which data is transformed from the format that is recognized by one operating system into the format that is recognized by a second operating system with different characteristics such as numeric order.

If you are using a network of systems that use different methods for storing numeric values, or you need to communicate between users who view data in different code pages, you must consider how to implement data conversion.

Code page conversions

Code page conversion might be required for one or more of the following reasons:

- ASCII versus EBCDIC
- Code pages that are specific to national language
- Code pages that are specific to operating systems

In IBM MQ, these factors are handled by the CCSID field in the MQMD header. For more information about the MQMD header, see "MQMD - Message descriptor" in the *Application Programming Reference* section of the IBM MQ product documentation online. For more information about code page support, see "Code page conversion", also in the *Application Programming Reference* section.

Encoding

Encoding (byte order) conversion might be required for one or both of the following reasons:

- Big endian versus little endian

  Endian is an attribute of data that describes whether it is stored in computer memory or transmitted with the most significant byte first (big endian) or last (little endian).
- Floating point number representations

In IBM MQ, these factors are handled by the Encoding field in the MQMD header. For more information about the MQMD header, see "MQMD - Message descriptor" in the *Application Programming Reference* section of the IBM MQ product documentation online. For more information about encoding, see "Machine encoding", also in the *Application Programming Reference* section.

If you are configuring a message flow to receive messages:

- Messages received across an IBM MQ protocol that uses IBM MQ headers, contain code page encoding characteristics in the MQMD header, and optionally in other IBM MQ headers.
- Messages received across protocols that do not use IBM MQ headers do not include these characteristics. Configure these characteristics by using properties on the nodes in your message flows. For example, set the Message coded character set ID and Message encoding properties on the FileInput node.

If you are configuring a message flow to send messages to other applications or systems:

- Messages sent across an IBM MQ protocol contain code page encoding characteristics in the MQMD header, and optionally in other IBM MQ headers.
- Messages sent across protocols that do not use IBM MQ headers must be modified to include these characteristics in the Properties folder in the logical message tree structure. The parser called by the output node uses these values to generate the correct bit stream.

When you use IBM App Connect Enterprise, you can use the data conversion facilities of IBM App Connect Enterprise, IBM MQ, or both.

IBM App Connect Enterprise facilities

You can model your messages in the MRM domain through the IBM App Connect Enterprise Toolkit. Predefined elements of the messages are converted according to their type and physical layer characteristics. For more information, see “Message Sets: Configuring physical properties” on page

2287. You can also use self-defining messages. You can then use the Compute, or JavaCompute node to configure encoding and CCSIDs. You do not need IBM MQ data conversion exits.

- String data is converted according to the CCSID setting.
- Decimal integer and float extended decimal types are converted according to the CCSID setting.
- Decimal integer and float (other physical data types) are converted according to the Encoding setting.
- Binary and Boolean data is not converted.

IBM App Connect Enterprise can also convert the IBM MQ headers for which parsers are provided.

When you use IBM App Connect Enterprise facilities, the whole message is not converted to the specified encoding and CCSID: you can specify a different encoding, or CCSID, or both, in each header to perform a different conversion for the following part of the message. The encoding and CCSID in the last header defines the values for the message body.

IBM MQ facilities

Headers and message body are converted according to the values set in the appropriate MQMD fields, and other header format names. You might need to set up data conversion exits to convert the body of your messages.

When you use IBM MQ facilities, the whole message is converted to the specified encoding and CCSID, according to the setting of the format in the IBM MQ header.

For more detail about data conversion using IBM MQ facilities, see "Data conversion" in the *Application Programming Reference* section of the IBM MQ product documentation online.

Managing message flow resources

You can use applications, libraries, and integration projects to organize your resources.

Before you begin

- To learn about the uses and benefits of applications and libraries, see “Benefits of using applications and libraries” on page 1959.
- To learn more about integration projects, see “Integration projects” on page 1959.

About this task

You can use applications, libraries, and integration projects to build your solution. An application is a container for everything that you need for your solution. A library contains a set of resources that you might want to reuse for other solutions. You can refer to one or more libraries from an application. You can deploy your solution by dragging the appropriate resources onto an integration server, or by adding them to a BAR file.

Message flow projects have been replaced by integration projects. When you import resources from WebSphere Message Broker Version 7.0, message flow projects are converted automatically to integration projects. You might want to convert your integration projects to applications or libraries, depending on the way in which you intend to use these resources.

You can choose the order in which you create your resources and their containers. For example, you can create a library before or after you create an application. The following section suggests a possible order in which to complete these tasks, depending on whether you are importing resources from a previous version or creating resources from scratch.

- “Starting by creating an application” on page 573
- “Converting existing resources to applications and libraries” on page 573
- “Organizing resources” on page 573

Starting by creating an application

About this task

The following steps describe how to build a solution by creating a container and filling it with resources.

Procedure

1. Create an application by following the instructions in "Creating an application" on page 1963.
2. Optional: Create a library by following the instructions in "Creating a library" on page 1964.
3. Create a message flow in your application by following the instructions in "Creating a message flow" on page 574.
4. You can create a default broker schema when you create the message flow, but to create another broker schema, follow the instructions in "Creating a broker schema" on page 1966.
5. Create other resources that you need in the application or library by following the instructions in "Creating resources in an application" on page 1964 or "Creating resources in a library" on page 1965.
6. Refer to one or more libraries of resources from the application, as described in "Referencing resources in other libraries" on page 1976.
7. Deploy your solution by using one of the following methods.
   - Add your applications, libraries, and other required resources to a BAR file, and deploy the BAR file.
   - Deploy your resources by dragging them from the Application Development view onto an integration server. If your solution includes shared libraries, deploy them to the integration server before you deploy the applications that refer to them.

   For more information, see Chapter 7, "Deploying integration solutions," on page 2463.

Converting existing resources to applications and libraries

About this task

You can import resources from previous versions of IBM App Connect Enterprise and use them as a basis for an application or library.

Procedure

1. Export a project from a previous version in a Project Interchange file.
2. Import the Project Interchange file to Version 12.0.
3. Convert or add the project to an application or library by following the instructions in the appropriate topic:
   - "Adding a project to an application, integration service, or library" on page 1979

Organizing resources

About this task

When you have created your resources, the following topics explain how to organize them.

- "Opening an existing message flow or subflow" on page 577
- "Copying a message flow or subflow by using copy" on page 580
- "Renaming a message flow or subflow" on page 578
- "Moving a message flow or subflow" on page 578
- "Deleting a message flow or subflow" on page 579
- "Deleting a schema" on page 1983
- "Adding version information and custom keyword values to your development resources" on page 2466

- "Saving a message flow or subflow" on page 581

Creating a message flow

Create a message flow to specify how to process messages in the integration node. You can create one or more message flows and deploy them to one or more integration nodes.

Before you begin

- You can create an application, library, or integration project at the same time as creating a message flow, or you can create it before you create a message flow. To create a container first, follow the instructions in the following topics:
  - "Creating an application" on page 1963
  - "Creating a library" on page 1964
  - "Creating an integration project" on page 1969
- One of the steps involved in creating a message flow is to select an existing broker schema, or create a new one. To use a particular broker schema with your message flow, create the schema by following the instructions in "Creating a broker schema" on page 1966.

About this task

The message flow and its resources are stored in a file system or in a shared repository. A file system can be on the local drive, or a shared drive. If you store files in a repository, you can use all the available repositories that are supported by Eclipse; for example, CVS.

Use this process to create a `.msgflow` file, in which you can define either a complete message flow that you can deploy, or a subflow that provides a subset of function (for example, a reusable error processing routine), that you cannot deploy on its own. To create a subflow that you can deploy as an individual resource, you must define the subflow in a `.subflow` file. For more information about subflows and the differences between subflows that are defined in `.subflow` files and subflows that are defined in `.msgflow` files, see "Subflows" on page 488.

The mode in which IBM App Connect Enterprise is running can affect the number of message flows that you can use; see "Restrictions that apply in each operation mode" on page 5.

To create a message flow, complete the following steps.

Procedure

1. To open the New Message Flow wizard, click **File** > **New** > **Message Flow**.

   Alternatively, in the Application Development view, right-click an application, library, or integration project and click **New** > **Message Flow**.
2. Specify the application, library, or integration project in which to create the message flow. Either select an existing container from the list, or create a container by clicking **New**.

   If you right-clicked a particular container in step "1" on page 574, the name of that container is selected automatically.
3. In the Message flow **Name** field, enter a name for the new message flow.

   You can use all valid characters for the name, but it is helpful to choose a name that reflects its function, for example, OrderProcessing.
4. Decide whether you want to create a default broker schema.

   By default, a default broker schema is created. If you do not want to create a default schema, clear the check box and select an existing schema from the list. However, if no schemas exist in the project, you must create a default schema at this point.
5. Click **Finish**.

Results

The new message flow (*message_flow_name*.msgflow) is displayed in the Application Development view, under the application, library, or integration project. The message flow opens in the Message Flow editor so that you can add some message flow nodes.

What to do next

Define the content of the message flow by following the instructions in "Defining message flow content" on page 614.

Creating a subflow

Create a .subflow file, in which you can define subflow content to include in your message flow applications. Use .subflow files to create subflows that you can deploy to an integration server as individual resources, independent of the message flows that use the subflow. You can create one or more subflows and deploy them to one or more integration servers.

Before you begin

- You can create an application, library, or integration project at the same time as creating a subflow, or you can create the container before you create the subflow. To create a container first, follow the instructions in the following topics:
  - "Creating an application" on page 1963
  - "Creating a library" on page 1964
  - "Creating an integration project" on page 1969

  When an application or shared library references other shared libraries, all the subflows for a broker schema must be in a single container. Subflows for a broker schema must not be in both an application (or shared library) and a shared library that is referenced by that application (or shared library). Subflows for a broker schema must not be in two or more shared libraries that are referenced by a single application or shared library. All the subflows in a broker schema must be either in the main application or shared library, or in a single referenced shared library.
- One of the steps involved in creating a subflow is to select an existing broker schema, or create a new one. Subflows in shared libraries cannot be in the default broker schema. To use a particular broker schema with your subflow, create the schema by following the instructions in "Creating a broker schema" on page 1966.

About this task

You can create subflows to define content that provides a subset of function (for example, a reusable error processing routine) that you can reuse in your message flow applications. You can create subflows either in .subflow files or in .msgflow files. For more information about subflows and the differences between subflows that are defined in .subflow files and subflows that are defined in .msgflow files, see "Subflows" on page 488. The information in this topic describes how to create a .subflow file.

The subflow and its resources are stored in a file system or in a shared repository. A file system can be on the local drive, or a shared drive. If you store files in a repository, you can use all the available repositories that are supported by Eclipse; for example, CVS.

The mode in which IBM App Connect Enterprise is running can affect the number of message flows that you can use; see "Restrictions that apply in each operation mode" on page 5.

To create a .subflow file, complete the following steps:

Procedure

1. To open the New Subflow wizard, click **File** > **New** > **Subflow**.

   Alternatively, right-click an application, library, or integration project and click **New** > **Subflow**.

2. Specify the application, library, or integration project in which to create the subflow. Either select an existing container from the list, or create a container by clicking **New**.

   If you right-clicked a particular container in step "1" on page 575, the name of that container is selected automatically.
3. In the **Subflow name** field, enter a name for the new subflow.

   You can use all valid characters for the name, but it is helpful to choose a name that reflects its function, for example, ErrorProcessing.
4. Decide whether you want to create a default broker schema.

   By default, a default broker schema is created. Subflows in shared libraries cannot be in the default broker schema. If you do not want to create a default schema, clear the check box and select an existing schema from the list. However, if no schemas exist in the project, you must create a schema at this point.
5. Click **Finish**.

Results

The new subflow file (*subflow_name*`.subflow`) is displayed in the Application Development view, under the application, library, or integration project. The subflow opens in the Message Flow editor so that you can define the subflow content by adding, configuring, and connecting message flow nodes. An Input node and an Output node are added to the subflow.

What to do next

1. Define the content of the subflow by following the instructions in "Defining message flow content" on page 614. Every Input node defined in the subflow represents an In terminal on the subflow node. Every Output node defined in the subflow represents an Out terminal on the subflow node. You can use these terminals to connect the subflow node to other nodes in the parent flow. You cannot add the following nodes to a subflow that is defined in a `.subflow` file:
   - Nodes representing subflows that are defined in `.msgflow` files
   - User-defined nodes created from subflows that are defined in `.msgflow` files
2. Add your subflow to a message flow; see "Adding a subflow" on page 623.

Converting between message flows and subflows

Convert a `.msgflow` file to a `.subflow` file, or a `.subflow` file to a `.msgflow` file.

Before you begin

This task assumes that you have already created a message flow or subflow; for more information, see "Creating a message flow" on page 574 or "Creating a subflow" on page 575.

About this task

You can convert `.msgflow` files to `.subflow` files, or `.subflow` files to `.msgflow` files.

When you convert `.msgflow` files to `.subflow` files, the following referenced files must be updated. You can complete these updates when you convert your `.msgflow` file.

- If the `.msgflow` file is used as a subflow, the parent flow must be updated so that it references the new `.subflow` file.
- If the `.msgflow` file contains subflows that are defined in `.msgflow` files, these subflows must also be converted to `.subflow` files.

Procedure

To convert a `.msgflow` file or a `.subflow` file, complete the following steps:

1. In the Application Development view, expand the appropriate application, library, or integration project.
2. To convert a `.msgflow` file to a `.subflow` file, complete the following steps:
   a) Right-click the message flow that you want to convert and click **Convert to subflow**.
   b) If the message flow is used as a subflow or contains subflows, the **Convert message flow to subflow** window opens and shows referenced files that must be updated. Select the files you want to update and click **OK**.

      The subflow is saved and its contents are validated. The editor provides a report of errors and warnings in the Problems view.
3. To convert a `.subflow` file to a `.msgflow` file, complete the following steps:
   a) Right-click the subflow that you want to convert and click **Convert to Message Flow**.
   b) Specify the name for the flow.

      You cannot use the name of a file that already exists in that application, library, or integration project. You must include `.msgflow` at the end of your file name.
   c) Click **OK**.

      The message flow is saved and its contents are validated. The editor provides a report of errors and warnings in the Problems view.

What to do next

For information about handling errors that occur when you save a message flow or subflow, see "Correcting errors from saving a message flow or subflow" on page 583.

Opening an existing message flow or subflow

Open an existing message flow or subflow to change or update its contents, or to add or remove nodes.

Before you begin

This task assumes that you have already created a message flow or subflow; for more information, see "Creating a message flow" on page 574 or "Creating a subflow" on page 575.

About this task

The Application Development view is populated with all the applications, libraries, and integration projects to which you have access. Message flows and subflows are contained in these containers. Message flow files are called *message_flow_name*`.msgflow`. Subflow files are called *subflow_name*`.subflow`.

Message flow projects have been replaced by integration projects in WebSphere Message Broker Version 8.0.

To open an existing message flow or subflow, complete the following steps.

Procedure

1. In the Application Development view, expand the appropriate application, library, or integration project.
2. Double-click the message flow or subflow that you want to open.

   The graphical view of the message flow is displayed in the Message Flow editor. You can now work with this message flow; for example, you can add or remove nodes, change connections between nodes, or modify node properties.
3. Some message flow nodes use data from associated files. For example, a Compute node has an associated ESQL file, a Mapping node has an associated map file, and a JavaCompute node has an associated Java file. You can open these associated files by double-clicking the node.

4. When you have completed your changes, save the message flow or subflow.

Renaming a message flow or subflow

You can rename a message flow or subflow. You might want to rename a flow if you have modified it to provide a different function, and you want the name of the flow to reflect this new function.

Before you begin

This task assumes that you have created a message flow or subflow. For more information, see “Creating a message flow” on page 574 or “Creating a subflow” on page 575.

About this task

To rename a message flow or subflow, complete the following steps.

Procedure

1. In the Application Development view, expand the appropriate application, library, or integration project.
2. To open the Rename Resource dialog box, select the flow that you want to rename (*message_flow_name*.msgflow or *subflow_name*.subflow), then click **File** > **Rename**.
3. Enter a new name for the file.
4. Click **OK** to rename the file, or **Cancel** to cancel the request.

   If you click **OK**, the file is renamed.

   After you have renamed the flow, any references that you have to this flow (for example, if it is embedded in another message flow) are no longer valid.

Moving a message flow or subflow

You can move a message flow or subflow from one application, library, or integration project to another. You might want to move a flow, for example, if you are reorganizing the resources in your projects.

Before you begin

This task assumes that you have already created a message flow or subflow; for more information about creating a message flow, see “Creating a message flow” on page 574. For more information about creating a subflow, see “Creating a subflow” on page 575.

About this task

The Application Development view is populated with all the applications, libraries, and integration projects to which you have access. Message flows and subflows are contained in these containers. Message flow files are called *message_flow_name*.msgflow. Subflow files are called *subflow_name*.subflow.

To move a message flow or subflow, complete the following steps.

Procedure

1. In the Application Development view, expand the appropriate application, library, or integration project, then expand the broker schema folder.

2. Right-click the message flow or subflow that you want to move, click **Move**, then select the destination application, library, or integration project.

   Alternatively, you can drag the flow to a new location.

   If the location to which you have dragged a flow is not valid, a no entry symbol is displayed, and the message flow or subflow is not moved.

   If you have created an empty broker schema for this purpose, it might not be visible in the Application Development view if category mode is selected. To see an empty schema in the Application Development view, click **Hide Categories**  .
3. Check the Problems view for errors or warnings that are generated by the move.

   Errors are indicated by the error icon  and warnings are indicated by the warning icon  . The Problems view includes errors that are caused by integration node references. When the move is complete, all references to this flow (for example, if this message flow is a reusable error routine that you have embedded in another message flow) are checked.
4. Double-click each error or warning to correct it.

   The message flow or subflow that contains the error is opened in the editor view and the node in error is highlighted.

Results

When you move a message flow or subflow, the associated files (for example, all ESQL or mapping files) are not automatically moved to the target broker schema. To move these files as well, you must follow the procedure in this topic for each file.

Deleting a message flow or subflow

Delete message flows or subflows from your application, library, or integration project when you no longer need them.

Before you begin

Deleting a message flow in the IBM App Connect Enterprise Toolkit deletes the project and its resources. If you are using a shared repository, the repository might retain a copy of a deleted resource.

This task assumes that you have created a message flow or subflow. For more information, see “Creating a message flow” on page 574 or “Creating a subflow” on page 575.

About this task

The Application Development view is populated with all the applications, libraries, and integration projects to which you have access. Message flows and subflows are contained in these containers. Message flow files are called *message_flow_name*`.msgflow`. Subflow files are called *subflow_name*`.subflow`. Applications and libraries are listed at the top level of the Application Development view; integration projects are listed in the Independent Resources folder.

To delete a message flow or subflow, complete the following steps.

Procedure

1. In the Application Development view, expand the appropriate application, library, or integration project.
2. Select the message flow or subflow that you want to delete, then click **Edit** > **Delete**.

   A confirmation dialog box is displayed.

3. Click **Yes** to delete the message flow or subflow, or **No** to cancel the delete request.

   When you click **Yes**, the requested objects are deleted.

   If you maintain resources in a shared repository, a copy is retained in that repository. You can follow the instructions provided by the repository supplier to retrieve the resource if required.

   If you are using the local file system or a shared file system to store your resources, no copy of the resource is retained. Be careful to select the correct resource when you complete this task.
4. Check the Problems view to see if errors have been returned to the delete request.

   Errors are generated if you delete a message flow or subflow that is embedded in another flow, because the reference is no longer valid.

   a) Click the error in the Problems view.

      The flow that now has a non-valid reference is displayed.

   b) Either remove the node that represents the deleted flow from the parent flow, or create another message flow or subflow with the same name to provide whatever processing is required.

Results

When you delete the message flow or subflow, the files that are associated with the flow (the ESQL and mapping files, if present) are not deleted by this action. If you want to delete these files also, you must do so explicitly.

Copying a message flow or subflow by using copy

Copy a message flow or subflow to use as a starting point for a new message flow or subflow that has similar function. For example, you might want to replace or remove one or two nodes to process messages in a different way.

Before you begin

To complete this task you must have already created a message flow or subflow; for more information, see "Creating a message flow" on page 574 or "Creating a subflow" on page 575.

About this task

The Application Development view is populated with all the applications, libraries, and integration projects to which you have access. Message flows and subflows are contained in these containers. Message flow files are called *message_flow_name*`.msgflow`. Subflow files are called *subflow_name*`.subflow`.

To copy a message flow, complete the following steps.

Procedure

1. In the Application Development view, expand the appropriate application, library, or integration project.
2. Select the message flow or subflow that you want to copy and click **Edit** > **Copy**.

3. Select the application, library, or integration project to which you want to copy the message flow or subflow, then click **Edit** > **Paste**.

   You can copy the flow to a different container, or to the same container. If the target container does not contain a broker schema, the schema is created automatically when you paste the message flow or subflow. If you copy a flow to the same container, you are prompted to rename the flow.

   When you copy a message flow or subflow, the associated files (ESQL and mapping, if present) are not automatically copied to the same target container. To copy these files as well, you must copy and paste each file.

   You might also need to update nodes that have associated ESQL or mappings, to ensure that modules are unique. For example, you have created a message flow Test1 that contains a single Compute node. You copy message flow Test1 and its associated `.esql` file to the same application, library, or integration project, and rename the copy Test2. However, two modules named Test1_Compute now exist in the same schema: one is in `Test1.esql` and the second is in `Test2.esql`.

   This duplication is not supported, and an error message is written to the Problems view when you have completed the copy action. You must rename the associated ESQL modules in the `.esql` file and update the matching node properties to ensure that every module in a broker schema is unique.

Results

When you have completed these steps, the flow is copied with all property settings intact. If you intend to use this copy of the message flow or subflow for another purpose (for example, to retrieve messages from a different input queue), you might have to modify its properties.

You can also copy a flow by clicking **File** > **Save As**. This task is described in "Saving a message flow or subflow" on page 581.

Saving a message flow or subflow

You might want to save your message flow or subflow when you close the IBM App Connect Enterprise Toolkit, work with another resource, or validate the contents of the flow.

Before you begin

This topic assumes that you have created or opened a message flow or subflow, as described in the following topics:

- "Creating a message flow" on page 574
- "Creating a subflow" on page 575
- "Opening an existing message flow or subflow" on page 577

About this task

To save a message flow or subflow, complete the following steps.

Procedure

1. To save the flow without closing it, click **File** > **Save**.

   You can also save everything by clicking **File** > **Save All**.

   The message flow or subflow is saved and the message flow validator validates the contents of the flow. The validator reports all errors that it finds in the Problems view. The flow remains open in the editor view. For example, if you save a message flow and have not set a mandatory property, an error message appears in the Problems view and the editor marks the node with the error icon  . The message flow in the Application Development view is also marked with the error icon. This error can

occur if you have not edited the properties of an MQInput node to define the queue from which the input node retrieves its input messages.

You might also get warnings when you save a message flow or subflow; warnings are also shown in the Problems view. Warnings indicate that, although the configuration of the message flow or subflow does not contain an explicit error, the configuration might result in unexpected results when the flow completes. For example, if you have included an input node in your message flow that you have not connected to another node, you get a warning.

2. If you save a message flow or subflow that includes a subflow, and the embedded subflow is no longer available, three error messages are added to the Problems view.

   These errors indicate that the input and output terminals and the embedded subflow itself cannot be located. This error can occur if the embedded subflow has been moved or renamed.

   To resolve this situation, right-click the subflow node in error and click **Locate Subflow**. The Locate Subflow dialog box is displayed, listing the available integration projects. Expand the list and explore the resources available to locate the required subflow. Select the correct subflow and click **OK**. All references in the current message flow or subflow are updated and the errors are removed from the Problems view.

3. You can also save a message flow or subflow when you close it. When you click **File** > **Close**, you are asked if you want to save the flow. Click **Yes** to save and close.

   Validation occurs and all errors and warnings are written to the Problems view.

What to do next

For information about using the **File** > **Save As** option to take a copy of the current flow, see "Copying a message flow or subflow by using the save option" on page 582.

For information about handling errors that occur when you save, see "Correcting errors from saving a message flow or subflow" on page 583.

Copying a message flow or subflow by using the save option

You can copy a message flow or subflow by using the **File** > **Save As** option.

Before you begin

This topic assumes that you have created or opened a message flow or subflow, as described in the following topics:

- "Creating a message flow" on page 574
- "Creating a subflow" on page 575
- "Opening an existing message flow or subflow" on page 577

Procedure

1. Click **File** > **Save As**.
2. Specify the application, library, or integration project in which you want to save a copy of the message flow or subflow.

   By default, the current project is selected; you can accept this name, or choose another name from the list.

3. Specify the name for the new copy of the flow.

   To save this message flow or subflow in the same project, you must either give it another name, or confirm that you want to overwrite the current copy.

   To save the message flow or subflow in another project, the project must already exist. You can save the flow with the same name or another name in another project.

4. Click **OK**.

   The message flow or subflow is saved and its contents are validated. The editor provides a report of errors and warnings in the Problems view.

What to do next

For information about handling errors that occur when you save a message flow, see "Correcting errors from saving a message flow or subflow" on page 583.

Correcting errors from saving a message flow or subflow

Correct the errors that are reported when you save a message flow or subflow.

About this task

When you save a message flow or subflow, as described in "Saving a message flow or subflow" on page 581, the flow is validated. Errors and warnings are shown in the Problems view. The following steps describe how to correct errors that occur when you save a flow.

Procedure

1. Examine the list of errors and warnings in the Problems view.
2. Double-click each entry in turn.

   The message flow or subflow is opened in the editor view (if it is not already open), and the editor selects the node in which the error was detected. If the error has been generated because you have not set a mandatory property, the editor also opens the Properties view, or dialog box, for that node.

   If you have included a user-defined node in your message flow, and have defined one or more of its properties as configurable, you might get a warning about a custom property editor. If you define a property as a configurable property, and you have specified that it uses a custom property editor, the BAR editor cannot handle the custom property editor, and handles the property as if it is type string. This action restricts your ability change this property at deployment time.
3. Correct the error that is indicated by the message.
   For example, provide a value for a mandatory property.
4. When you have corrected all the errors, save the message flow or subflow again.

   The editor validates all the resources that you have changed, and removes the corresponding graphical indication from the nodes that you have modified successfully. Corrected errors are also removed from the Problems view.

Results

You do not have to correct every error to save your work. The editor saves your resources even if it detects errors or warnings, so that you can continue to work with them at a later date. However, you cannot deploy a resource that has a validation error. You must correct every error before you deploy a resource. Warnings do not prevent successful deployment.

Designing a message flow

A message flow can perform a wide range of operations, depending on your business and operational requirements. For best performance and capability, you must design it to include the most appropriate nodes.

Before you begin

Read the following concept topic: "Message flow nodes" on page 484.

About this task

When you design a message flow, consider the following questions and options:

- The mode that your integration node is working in can affect the types of message flow node that you can use and the number of message flows you can deploy. For more information, see “Restrictions that apply in each operation mode” on page 5.
- Which message flow nodes provide the function that you require. In many cases, you can choose between several nodes that provide a suitable function. You might have to consider other factors listed here to determine which message flow node is best for your overall needs. You can include built-in nodes, user-defined nodes, and subflow nodes. For more information, see “Deciding which nodes to use” on page 585.
- Whether it is appropriate to include more than one input node. For more information, see “Using more than one input node” on page 597.
- How to specify the characteristics of the input message. For more information, see “Defining input message characteristics” on page 598.
- Whether to determine the path that a message follows through the message flow, based on the content or the characteristics of the message. Several message flow nodes provide checks or examination of the message, and have output terminals that can be connected to direct certain messages to different message flow nodes. For more information, see “Using nodes for decision making” on page 1233.
- Whether it is appropriate to split message flow processing between different locations. A message flow can call another flow directly. You can deploy both flows to IBM App Connect Enterprise or IBM App Connect on IBM Cloud. You can also deploy one flow to IBM App Connect Enterprise and one flow to IBM App Connect on IBM Cloud. Callable flows also facilitate reuse because they can be called by multiple message flows. For more information, see “Splitting the processing of message flows” on page 599.
- Whether you can use subflows that provide a well-defined subset of processing. You might be able to reuse subflows that were created for another project (for example, an error processing routine), or you might create a subflow in your current project, and reuse it in several places in the same message flow. For more information, see “Subflows” on page 488.
- What response times your applications expect from the message flow. This factor is influenced by several aspects of how you configure your nodes and the message flow. For more information, see “Optimizing message flow response times” on page 2765.
- Whether you can use the destination list in the local environment that is associated with the message to determine the processing in the message flow (for example, by using RouteToLabel and Label nodes), or the target for the output messages (for example, by setting the `Destination Mode` property of the MQOutput node to Destination List). For more information, see “Creating destination lists” on page 610.
- Whether to use IBM MQ cluster queues. For more information, see “Using IBM MQ cluster queues for input and output” on page 780.
- Whether to validate input messages that are received by the input node, or output messages that are generated by the Compute node, or both. For more information, see “Validating messages” on page 610.
- Whether to view or record message structure in Trace node output. For more information, see “Viewing the logical message tree in trace output” on page 685.
- Whether your message flows access data in databases. You must configure integration nodes, databases, and database connections to enable this function, as described in “Working with databases” on page 1130. You must also configure your message flows; see “Accessing databases from message flows” on page 1134.

  If you include message flow nodes that use ESQL, for information about how to code the appropriate statements, see “Accessing databases from ESQL” on page 1135. If you want to access databases from Java nodes by using JDBC, see “Interacting with databases by using the JavaCompute node” on page 1785 or “Extending the capability of a Java message processing or output node” on page 2415.

- Whether your message flows access data in files. By using the FileInput and FileOutput nodes, your message flows can read messages from files and write messages to files in the local file system, or on a network file system that appears local to the integration node. For more information, see “Connecting client applications” on page 737.
- Whether your messages must be handled in a transaction. You can set the properties of some built-in message flow nodes to control how transactions are managed, and how messages are processed in a transaction. For more information, see “Configuring transactionality for message flows” on page 698.

  If you want to include JMSInput and JMSOutput nodes in your message flow transactions, you must consider the additional information in “Configuring JMS and SOAP nodes to support globally coordinated transactions” on page 721.
- Whether you want your messages to go through data conversion. For information about the available options, see “Configuring message flows for data conversion” on page 727.
- Whether you want to use the MQGet node. For more information about how messages are processed by the MQGet node, and a description of request-reply scenarios that uses this node, see “Working with IBM MQ” on page 753.
- How your message flows can benefit from user exits. For more information, see “Exploiting user exits” on page 2329.
- What steps to take to ensure that messages are not lost. For more information, see “Ensuring that messages are not lost” on page 786.
- How errors are handled in the message flow. You can use the facilities provided by the integration node to handle any errors that arise during message flow execution (for example, if the input node fails to retrieve an input message, or if writing to a database results in an error). However, you might prefer to design your message flow to handle errors in a specific way. For more information, see “Handling errors in message flows” on page 1883.

Deciding which nodes to use

IBM App Connect Enterprise includes many message processing nodes that you can use in your message flows.

Before you begin

Read the concept topic, “Message flow nodes” on page 484.

About this task

IBM App Connect Enterprise also provides an interface that you can use to define your own nodes, which are known as user-defined nodes.

The mode in which IBM App Connect Enterprise is running can affect the types of node that you can use; see “Restrictions that apply in each operation mode” on page 5.

Your decision about which nodes to use depends on the processing that you want to perform on your messages.

Input, output, and request nodes

Input and output nodes define points in the message flow to which client applications send messages (input nodes, such as MQInput), and from which client applications receive messages (output nodes, such as MQOutput). Client applications interact with these nodes by putting messages to, or getting messages from, the I/O resource that is specified by the node as the source or target of the messages. Although a message flow must include at least one input node, it does not have to include an output or request node.

An input node is different from other nodes because it controls when the rest of the message flow is triggered to do its processing. The input node is designed to check when there is data for the message flow to process, read that data from the transport or server, and present that data to the rest of the flow for processing. The other nodes do processing, but do not control when the flow gets invoked.

You can also use reply, request, and response nodes to interact with other applications from within a message flow; these types of node are supplied for a subset of protocols only.

- If you are creating a message flow for deployment to an integration node, you must include at least one input node to receive messages. The input node that you select depends on the source of the input messages, and where in the flow you want to receive the messages.
- If you want to send the messages that are produced by the message flow to a target application, you can include one or more output nodes. The output node that you select depends on the transport across which the target application expects to receive those messages.
- If you want to make a request, in the middle of your flow, to an external system, and put the result into the message tree, use a request node.

Nodes for manipulating, enhancing, and transforming messages

Most enterprises have applications that have been developed over many years, on different systems, using different programming languages, and different methods of communication. IBM App Connect Enterprise removes the need for applications to understand these differences by providing the ability to configure message flows that transform messages from one format to another.

For example, personal names are held in many forms in different applications. Surname first or last, with or without middle initials, uppercase or lowercase, are just some of the permutations. Because you can configure your message flow to know the requirements of each application, each message can be transformed to the correct format without modifying the sending or receiving application.

You can work with the content of the message to update it in several ways. Your choices here might depend on whether the message flow must handle predefined (modeled) messages, self-defining messages (for example, XML), or both.

A message flow can completely rebuild a message, convert it from one format to another (for example, changing order of fields, byte order, or language), remove content from the message, or introduce specific data into it. For example, a node can interact with a database to retrieve additional information, or to store a copy of the message (whole or part) in the database for offline processing.

The following examples show the importance of message transformation:

- An order entry application has a part ID in the body of the message, but its associated stock application expects it in the message header. The message is directed to a message flow that knows the two different formats, and can therefore reformat the information as it is needed.
- A data-entry application creates messages containing stock trade information. Some applications that receive this message need the information as provided, but others need additional information added to the message about the price to earnings (PE) ratio. The stock trade messages are directed to a message flow that passes the message unchanged to some output nodes, but calculates and adds the extra information for the others. The message flow does this calculation by looking up the current stock price in a database, and uses this value and the trade information in the original message to calculate the PE value before passing on the updated message.

You can also create message flows that use these nodes to interact with each other. Although the default operation of one message flow does not influence the operation of another message flow, you can force this action by configuring your message flows to store and retrieve information in an external source, such as a database.

These nodes are supplied to transform messages.

Nodes for making decisions

You can use nodes that determine the order and flow of control in the message flow in various ways to decide how messages are processed by the flow. You can also use nodes (TimeoutControl and TimeoutNotification) that determine the time, and frequency of occurrence, of events in the message flow. Routing is independent of message transformation, although the route that a message takes might determine exactly what transformation is performed on it.

For example, a money transfer application always sends messages to one other application. You might decide that every message with a transfer value of more than $10,000 must also be sent to a second application, to enable all high-value transactions to be recorded.

In another example, a national auto club offers a premier service to specific members for orders above a threshold value. Most orders are routed through the typical channels, but, if the membership number and order value meet certain criteria, the order gets special treatment.

You can also establish a more dynamic routing option by building additional routing information into the message when it is processed. Optional sets of rules are set up to receive messages according to values (destinations) set into the message. You can establish these rules such that a message is processed by one or more of the optional sets of rules, in an order that is determined by the added message content.

These nodes are provided to decide about the route that a message follows through the message flow.

Nodes for controlling time-sensitive operations
You might want a batch application process to run every day at a specific time, or you might want information to be processed and published at fixed intervals (for example, currency exchange rates are calculated and sent to banks), or you might want to take a specified recovery action if certain transactions are not completed within a defined time. For all these cases, two timeout nodes (TimeoutControl and TimeoutNotification) are provided; see “Nodes for controlling time-sensitive operations” on page 595.

Miscellaneous nodes
Other nodes exist to do the following tasks:

- Collate requests
- Create message collections
- Control the sequence of messages
- Handle and report errors
- Invoke the message flow security manager

See “Miscellaneous nodes” on page 596 for details.

Input nodes
You must include at least one input node in your message flow.

An input node is different from other nodes because it controls when the rest of the message flow is triggered to do its processing. The input node is designed to check when there is data for the message flow to process, read that data from the transport or server, and present that data to the rest of the flow for processing. The other nodes do processing, but do not control when the flow gets invoked.

CallableInput node
Use the CallableInput node in a callable flow so that you can split message flow processing between different locations. The CallableFlowInvoke node in a calling flow calls the CallableInput node of a callable flow.

DatabaseInput node
Use the DatabaseInput node to respond to events in a database. For example, the integration node can keep an external system synchronized with a database by sending updates to the target system whenever data is changed in the database.

EmailInput node
Use the EmailInput node to retrieve an email, with or without attachments, from an email server that supports Post Office Protocol 3 (POP3) or Internet Message Access Protocol (IMAP).

FileInput node
Use a FileInput node if the messages are contents of files.

FTEInput node
Use the FTEInput node to receive files using IBM MQ File Transfer Edition.

HTTP input node
Use an HTTPInput node if the messages are sent by a web services client.

Input node
If you are creating a message flow that you want to embed in another message flow (a subflow) that you will not deploy as a stand-alone message flow, you must include at least one Input node to receive messages into the subflow.

An instance of the Input node represents an In terminal. For example, if you have included one instance of the Input node, the subflow icon shows one In terminal, which you can connect to other nodes in the main flow in the same way that you connect any other node.

To deploy a message flow, it must have at least one input node. If your message flow does not contain an input node, you are prevented from adding it to the BAR file. The input node can be in the main flow, or in a message flow that is embedded in the main flow.

You can use more than one input node in a message flow. For more information, see "Using more than one input node" on page 597.

JMSInput node
Use a JMSInput node if the messages are sent by a JMS application.

KafkaConsumer node
Use the KafkaConsumer node to connect to the Kafka messaging system and to receive messages that are published on a Kafka topic.

MQInput node
Use an MQInput node if the messages arrive at the integration node on an IBM MQ queue, and the node is to be at the start of a message flow.

MQTTSubscribe node
Use the MQTTSubscribe node to receive messages that are published by applications and devices to a topic that is hosted on an MQ Telemetry Transport (MQTT) server.

.NETInput node
Use the .NETInput node to create inputs for the .NETCompute node using C#, F#, and VB templates.

SOAP input node
Use the SOAPInput node to process client SOAP messages and to configure the message flow to behave like a SOAP web services provider.

TCPIPClientInput or TCPIPServerInput node
Use a TCPIPClientInput node or a TCPIPServerInput node to create a TCP/IP connection when messages are sent through raw TCP/IP sockets.

TCPIPClientReceive or TCPIPServerReceive node
Use a TCPIPClientReceive node or a TCPIPServerReceive node to read the messages that arrive in the message flow through a TCP/IP connection.

User-defined input node
Use a user-defined input node if the message source is a client or application that uses a different protocol or transport.

WebSphere Adapters nodes
Use the WebSphere Adapters nodes to interact with Enterprise Information Systems (EIS) such as SAP, Siebel, and PeopleSoft. The following input nodes are available:

- SAPInput node
- SiebelInput node
- PeopleSoftInput node
- JDEdwardsInput

The WebSphere Adapters input nodes monitor an EIS for a particular event. When that event occurs, business objects are sent to the input node. The node constructs a tree representation of the business objects and propagates it to the Out terminal so that the data can be used by the rest of the message flow.

The WebSphere Adapters request nodes can send and receive business data. They request information from an EIS and propagate the data to the rest of the message flow.

Output nodes

If you want to send the messages that are produced by the message flow to a target application, include one or more output nodes in the flow.

CallableReply node
Use a CallableReply in a callable flow to return a response to the CallableFlowInvoke node in the message flow that called the callable flow.

EmailOutput node
Use the EmailOutput node to send an email message to one or more recipients.

FileOutput node
Use a FileOutput node if a file is the target of the output messages.

FTEOutput node
Use the FTEOutput node to write messages to files using the IBM MQ File Transfer Edition.

HTTPReply node
Use an HTTPReply node if the messages are in response to a web services client request.

JMSOutput and JMSReply nodes
Use a JMSOutput node if the messages are for a JMS destination.

The JMSReply node has a similar function to the JMSOutput node, but the JMSReply node sends JMS messages only to the reply destination that is supplied in the JMSReplyTo header field of the JMS message tree. Use the JMSReply node to treat a JMS message that is produced from a message flow as a reply to a JMS input message, and when you have no other routing requirements.

KafkaProducer node
Use the KafkaProducer node to connect to the Apache Kafka messaging system, and to publish messages from a message flow to a topic on a Kafka server.

MQOutput and MQReply nodes
Use an MQOutput node if the target application expects to receive messages on an IBM MQ queue, or on the IBM MQ reply-to queue that is specified in the input message MQMD.

Use an MQReply node if the target application expects to receive messages on the IBM MQ reply-to queue that is specified in the input message MQMD.

MQTTPublish node
Use the MQTTPublish node to publish an output message from a message flow to a topic that you specify on an MQ Telemetry Transport (MQTT) server.

Output node
If you are creating a message flow that you want to embed in another message flow (a subflow) that you will not deploy as a stand-alone message flow, you must include at least one Output node to propagate messages to subsequent nodes that you connect to the subflow.

An instance of the Output node represents an Out terminal. For example, if you have included two instances of the Output node, the subflow icon shows two Out terminals, which you can connect to other nodes in the main flow in the same way that you connect any other node.

Publication node
Use a Publication node to distribute the messages using the publish/subscribe network for applications that subscribe to the integration node across all supported protocols. A Publication node is an output node that uses output destinations that are identified by subscribers whose subscriptions match the characteristics of the current message.

SAPReply node
Use this node with the SAPInput node to respond to an incoming SAP event.

SOAPReply node
Use a SOAPReply node if the target application expects to receive SOAP messages in response to a message sent to the SOAPInput node.

SCAReply node
Use the SCAReply node to send a message from the integration node to the originating client in response to a message received by a SCAInput node.

TCPIPClientOutput or TCPIPServerOutput node
Use a TCPIPClientOutput node or a TCPIPServerOutput node if the messages are to be sent to the target application through raw TCP/IP sockets.

User-defined output node
Use a user-defined output node if the target is a client or application that uses a different protocol or transport.

Request nodes

If you want to make a request, in the middle of your flow, to an external system, and put the result into the message tree, use a request node.

AppConnectRESTRequest node
Use the AppConnectRESTRequest node to interact with an IBM App Connect REST API. The AppConnectRESTRequest node uses an imported Swagger document (in either JSON or YAML format), which defines the REST API and the operations that you can invoke.

CallableFlowInvoke node
Use the CallableFlowInvoke node to call a callable flow, so that you can split message flow processing between different locations. The CallableFlowInvoke node calls the CallableInput node of a callable flow. A CallableReply node in the callable flow sends a response to the CallableFlowInvoke of the calling flow.

CICSRequest node
Use the CICSRequest node to call an external CICS Transaction Server for z/OS application over TCP/IP-based IP InterCommunications (IPIC) protocol. You can create a message flow that contains a CICSRequest node, which calls an application on CICS. By using the CICS support that is provided in IBM App Connect Enterprise you can deploy CICS applications into a service-oriented architecture (SOA).

CORBARequest node
Use the CORBARequest node to call an external CORBA application over Internet Inter-Orb Protocol (IIOP). You can create a message flow that contains a CORBARequest node, which calls a CORBA server. The message flow uses an IDL file to call methods on a remote CORBA object. You can then give existing CORBA applications a new external interface; for example, a SOAP interface.

Database node
Use the Database node to interact with a database that is identified by the node properties. The Database node handles both predefined and self-defining messages. Use the ESQL editor to code ESQL functions to update database content from the message, insert new information into the database, and delete information from the database, using information in the message. Do not use the ESQL code that you develop for use in a Database node in any other type of node.

This node provides a flexible interface with a wide range of functions. It also has properties that you can use to control the way in which the interaction participates in transactions.

You can control the way in which the database is accessed by this node by specifying user and password information for the data source that you specify in the node properties. Use the **mqsisetdbparms** command to initialize and maintain these values.

You can update only databases from this node; you cannot update message content. If you want to update message content, use the Compute or Mapping node.

DatabaseRetrieve node
Use the DatabaseRetrieve node to ensure that information in a message is up to date. Use the node to modify a message using information from a database. For example, you can add information to a message using a key, such as an account number, that is contained in a message. Use the DatabaseRetrieve node to implement message routing with minimal programming logic. For more advanced routing scenarios, use a Compute node or a JavaCompute node.

FileRead node
Use the FileRead node to read a file from the middle of a message flow. The node can:

- Read the entire contents of the file.
- Read a single record.
- Rename or delete the file without reading any data.

HTTPRequest node
Use an HTTPRequest node if your message flow interacts with a web service after it has started.

IMSRequest node
Use the IMSRequest node to send a request to run a transaction on a local or remote IBM Information Management System (IMS) system, and wait for a response. IMS Connect must be configured and running on the IMS system.

JMSReceive node
Use the JMSReceive node to consume or browse messages from a JMS queue in the middle of a message flow. The node can augment the input message with result data from the received message.

LoopBackRequest node
Use the LoopBackRequest node in a message flow to create, retrieve, update, and delete data through a LoopBack connector such as MongoDB, Cloudant, or PostgreSQL.

MQGet node
Use an MQGet node to retrieve a message from an IBM MQ queue, if you want to get the message later in the message flow.

SalesforceRequest node
Use the SalesforceRequest node to make synchronous requests to Salesforce.com, to create, retrieve, update, and delete Salesforce records.

SOAP nodes
Use the SOAP nodes to process client SOAP messages and to configure the message flow to behave like a SOAP web services provider:

- SOAPRequest
- SOAPAsyncRequest
- SOAPAsyncResponse

WebSphere Adapters nodes
Use the WebSphere Adapters nodes to interact with Enterprise Information Systems (EIS) such as SAP, Siebel, and PeopleSoft. The following request nodes are available:

- SAPRequest node
- SiebelRequest node
- PeopleSoftRequest node
- JDEdwardsRequest node

WebSphere Service Registry and Repository (WSRR) nodes
Use the WebSphere Service Registry and Repository nodes to retrieve web services information:

- Use the EndpointLookup node to retrieve service endpoint information held in the WebSphere Service Registry and Repository.
- Use the RegistryLookup node to retrieve any type of entity held in the WebSphere Service Registry and Repository.

Nodes for manipulating, enhancing, and transforming messages
Optionally, include nodes to change messages.

Compute node
Use the Compute node to:

- Manipulate message content

- Transform the message in some way
- Interact with a database to modify the content of the message or the database and pass on one or more new messages

You can use this node to manipulate predefined and self-defining messages.

Use the ESQL editor to create an ESQL module, specific to this node, that contains the statements that define the actions to perform against the message or database. Do not use the ESQL code that you develop for use in a Compute node in any other type of node.

You can control the way in which the database is accessed by this node by specifying user and password information for the data source that you specify in the node property. Use the **mqsisetdbparms** command to initialize and maintain these values.

If possible, perform your message manipulation requirements in a single Compute node. Fewer, more complex Compute nodes perform better than a larger number of simpler nodes because the integration node parses the message on entry to each Compute node.

.NETCompute node

Use the .NETCompute node to:

- Build messages.
- Interact with Microsoft .NET Framework (.NET) or Component Object Model (COM) applications.
- Transform messages from one format to another.
- Copy messages between parsers.
- Use a .NET programming language to examine an incoming message and, depending on the message content, propagate it unchanged to one of the .NETCompute node output terminals. The node behaves in a similar way to a Filter node, but uses .NET languages instead of ESQL to determine which output terminal to use.
- Use .NET to change part of an incoming message and propagate the changed message to one of the output terminals.
- Use .NET to create and build an output message that is independent of the input message.

JavaCompute node

Use the JavaCompute node to:

- Examine an incoming message and, depending on its content, propagate it unchanged to one of the node's output terminals. The node behaves in a similar way to a Filter node, but uses Java instead of ESQL to determine which output terminal to use.
- Change part of an incoming message and propagate the changed message to one of the output terminals.
- Interact with a database through a JDBC type 4 connection to modify the content of the message or the database and pass on one or more new messages
- Create and build a new output message that is independent of the input message.

Mapping node

Use the Mapping node to:

- Manipulate graphically message content
- Enrich a message with data from a database
- Interact with a database to modify the content of the message or the database and pass on one or more new messages

You can use this node to manipulate predefined and self-defining messages.

Use the Graphical Data Mapping editor to create a message map, specific to this node, that contain the data transforms that define the actions to perform against the message or database.

XSLTransform node

Use the XSLTransform node (formerly known as the XMLTransformation node) to transform an input XML message into another format using XSLT style sheets and to set the message domain, message set, message type, and message format for the generated message. It is imperative that the data can be parsed into an XML message. The style sheet, using the rules that are defined in it, can perform the following actions:

- Sort the data
- Select data elements to include or exclude based on some criteria
- Transform the data into another format

The Xalan-Java transformation engine (Apache Xalan-java XSLT processor) is used as the underlying transformation engine. For more information about XML Transformations, the W3C specification of the syntax, and semantics of the XSL Transformations language for transforming XML documents into other XML documents, see W3C XSL Transformations.

You can deploy style sheets and XML files to integration node integration servers, to help with style sheet and XML file maintenance.

JMSMQTransform node

Use the JMSMQTransform node to transform a message with a JMS message tree into a message that has a tree structure that is compatible with the format of messages that are produced by the IBM MQ JMS provider.

The JMSMQTransform node can be used to send messages to existing message flows and to interoperate with IBM MQ JMS and IBM MQ Publish/Subscribe.

MQJMSTransform node

Use the MQJMSTransform node to receive messages that have an IBM MQ JMS provider message tree format, and transform them into a format that is compatible with messages that are to be sent to JMS destinations.

You can use the MQJMSTransform node to send messages to existing message flows and to interoperate with IBM MQ JMS and IBM MQ Publish/Subscribe.

SOAPEnvelope and SOAPExtract nodes

Use the SOAPEnvelope and SOAPExtract nodes to add or remove SOAP envelopes from the SOAP message body. You can use the SOAPExtract node both to extract the envelope, and to route the message based on the message content to a Label node.

Header nodes

Use the HTTPHeader, JMSHeader, or MQHeader nodes to manipulate HTTP, JMS, and IBM MQ transport headers and their properties without writing compute nodes. You cannot use these nodes to change the message body.

- Use the HTTPHeader node to add, modify, or delete HTTP headers such as HTTPInput, HTTPResponse, HTTPRequest and HTTPReply.
- Use the JMSHeader node to modify contents of the JMS Header_Values and Application properties so that you can control the node's output without programming.
- Use the MQHeader node to add, modify, or delete MQ Message Descriptor (MQMD) and MQ Dead Letter Header (MQDLH) headers.

User-defined processing node

Use a user-defined node processing node to handle specific requirements that are not met by the built-in nodes.

For example, if your node accesses a database, include a user-defined node to interact with the database. You can control the way in which the database is accessed by this node by specifying user and password information for the data source that you specify in the node property. Use the **mqsisetdbparms** command to initialize and maintain these values.

Cloned node

Use a Cloned node to create reusable templates from .NETInput nodes that you have created and customized in your message flow.

Cloned nodes have no special properties, and you cannot select a new Cloned node from a palette drawer. You must create it from an existing node in your message flow, and then save it into the palette drawer. For more information about using the Cloned node type, see "Cloning a .NETInput node" on page 1810.

When saved in a palette drawer, you can create an instance of your saved Cloned node by dragging into your message flow. You can therefore use a Cloned node to be able to reproduce your customized parameters and values without manually configuring a new node instance each time. You can save multiple templates in the palette, if each Cloned node you create has a unique name.

Nodes for making decisions

Optionally, use nodes that determine the order and flow of control in the message flow to decide how messages are processed by the flow.

Nodes for making decisions

Validate node

Use the Validate node to check that the message that arrives on its input terminal is as expected. You can check that the message has the expected message template properties (message domain, message set, and message type) and that the content of the message is correct. You can check the message against one or more of the message domain, message set, or message type values.

The Validate node replaces the Check node, which is deprecated. The Validate node works in the same way as the Check node, but it has more Validation properties to enable the validation of message content by parsers that support that capability.

Filter node

Use the Filter node with an ESQL statement to determine the next node to which the message is sent by this node. Do not use the ESQL code that you develop for use in a Filter node in any other type of node.

The node terminals are True, False, Unknown, and Failure. The message is propagated to the True terminal if the test succeeds, and to the False terminal if it fails. If the statement cannot be resolved (for example, it tests the value of a field that is not in the input message), the message is propagated to the Unknown terminal. If any other error is detected, the message is propagated to the Failure terminal.

The test in the ESQL statement can depend on message content, database content, or a combination of the two.

If you refer to a database, you can control how it is accessed by this node by specifying user and password information for each data source that is defined in the registry on the integration node system. Use the **mqsisetdbparms** command to initialize and maintain these values.

Use this node in preference to the Compute node to provide message selection and routing; the Filter node is more efficient for this task.

FlowOrder node

You can connect the terminals of this node to force the message to be processed by one sequence of nodes, followed by a second sequence of nodes.

Passthrough node

Use the Passthrough node to enable version control of a subflow at run time. Use this node to add a label to your subflow. By combining this label with a reserved word replacement from your version control system, you can identify which version of a subflow is included in a deployed message flow. You can use this label for your own purposes. If you include the correct version keywords in the label, you can see the value of the label:

- Stored in the BAR file, by using the **mqsireadbar** command

- As last deployed to a particular integration node, on the properties of a deployed message flow in the IBM App Connect Enterprise Toolkit
- In the integration node, if you enable user trace for that message flow

Route node
Use the Route node to direct messages that meet certain criteria down different paths of a message flow. For example, you can forward a message to different service providers based on the request details. You can also use the Route node to bypass unnecessary steps. For example, you can check to see whether certain data is in a message, and run a database lookup operation only if the data is missing. If you set the `Distribution Mode` property to `All`, you can trigger multiple events that each require different conditions. For example, you can log requests that relate to a particular account identifier, and send requests that relate to a particular product to be audited.

Use the Route node to implement message routing with minimal programming logic. For more advanced routing scenarios, use a Compute node or a JavaCompute node.

RouteToLabel node
Use the RouteToLabel node after a Compute node or a JavaCompute node for complex routing. Define a list of destinations in a Compute or JavaCompute node that are acted on by the RouteToLabel node. The RouteToLabel node interrogates the destinations and passes the message on to the corresponding Label node.

DatabaseRoute node
Use the DatabaseRoute node to route a message by using information from a database with applied XPath routing expressions. The node looks up a collection of named column values from a located database row and synchronously applies one or more XPath expressions to these acquired values. Use the DatabaseRoute node to implement message routing with minimal programming logic. For more advanced routing scenarios, use a Compute node or a JavaCompute node.

Label node
Use the Label node as a target for the next sequence of one or more nodes that are to process a message. Use this node in combination with the RouteToLabel node for all types of messages, or with the SOAPExtract node for SOAP messages.

The Label node routes the message to the next node in the flow and completes no processing.

ResetContentDescriptor node
Use the ResetContentDescriptor node to set new message properties that are used when the message bit stream is next parsed by a subsequent node in the message flow.

Mapping node
Use the Mapping node to route a message.

Nodes for controlling time-sensitive operations
Run processes at specific times, or at fixed intervals, and take action if transactions are not completed within a defined time.

TimeoutControl node
Use a TimeoutControl node and a TimeoutNotification node together in a message flow to control events that occur at a specific time or at defined time intervals. The TimeoutControl node receives an input message that contains a timeout request. All or part of this input message is validated and stored to be propagated by an associated TimeoutNotification node in the message flow. The input message is also propagated unchanged to the next node in the message flow.

More than one TimeoutControl node can be associated with each TimeoutNotification node.

TimeoutNotification node
Use a stand-alone TimeoutNotification node to generate messages that are propagated at configured times or time intervals to the next node in the message flow for further processing.

Miscellaneous nodes

Nodes to perform a variety of tasks.

Nodes for collating requests

Group nodes and aggregation nodes provide alternative ways to collate related requests and responses. Use these nodes to generate several requests in response to one input message, to control and coordinate the responses that are received in response to those requests, and to combine the information that is provided by the responses to continue processing.

- Group nodes: GroupScatter, GroupGather, and GroupComplete.
- Aggregate nodes: AggregateControl, AggregateReply, and AggregateRequest

For more information about these nodes, see "Group nodes and aggregation nodes" on page 596.

Node for creating message collections

Use the Collector node to generate collections of messages and make multiple synchronous or asynchronous requests in parallel. The Collector node does not need an initial fan-out stage, and can group unrelated input messages by correlating their content. You can configure dynamic input terminals on a Collector node to receive messages from different sources. You can also configure properties on the Collector node, known as event handlers, to determine how messages are added to a message collection, and when a message collection has completed.

Nodes for controlling the sequence of messages

Use the Sequence node to apply a sequence number to a message received from an input source, and the Resequence node to change the sequence of messages that contain a sequence number. You can divide messages into sequence groups and use the Sequence and Resequence nodes to control the sequences in groups of messages that arrive at the nodes.

Nodes for handling and reporting errors

Use the following nodes to affect error handling and reporting:

Trace node
Include a Trace node to generate one or more trace entries to record what is happening in the message flow at this point.

TryCatch node
Include a TryCatch node to control the error processing when exceptions are thrown.

Throw node
Include a Throw node to force an exception to be thrown, and specify the identity of the exception, to make it easier to diagnose the problem.

Node for invoking the message flow security manager

Use the SecurityPEP node to invoke the message flow security manager at any point in the message flow between an input node and an output (or request) node. The SecurityPEP node enables you to invoke the security manager even if your input nodes do not support message flow security. You can also use the SecurityPEP node to invoke different aspects of security (for example, authentication and authorization) at different points in the message flow.

Group nodes and aggregation nodes

Group nodes and aggregation nodes provide alternative ways to collate related requests and responses. Use these nodes to generate several requests in response to one input message, to control and coordinate the responses that are received in response to those requests, and to combine the information that is provided by the responses to continue processing.

The Group nodes provide the ability to create fan-out/fan-in style static and dynamic aggregation scenarios that are stateless and highly performant without requiring an IBM MQ queue manager to be available for the integration server. The node is responsible for creating a new group, and enables downstream nodes to send requests that are marked as part of the group. (The list of currently supported downstream nodes for a group is: MQOutput node (the node must have the "Request" attribute set), HTTPAsyncRequest node, CallableFlowAsyncInvoke node, and RESTAsyncRequest node.)

The Aggregation nodes provide a similar capability, but make use of storage queues that are controlled by IBM MQ so you must install IBM MQ on the same computer as your integration server if you want to use the capabilities that are provided by the aggregation nodes. For more information about the queues that are required by aggregation nodes, see “Configuring the storage of events for aggregation nodes ” on page 229.

Note: The group nodes are not a drop-in replacement for the aggregate nodes, therefore customers who wish to migrate from using the aggregate nodes to the group nodes will need to redesign their flows.

There is no group node that is equivalent to the AggregateRequest node, rather supported output nodes now directly specify whether they are participating in a group or not by their node properties. Custom transports can still be enabled using Environment overrides.

Testing has shown that the group nodes provide better overall performance when compared to the aggregate nodes, with reduced message processing times and CPU costs.

You should use the group nodes if you have the following requirements:

- You want a stateless integration server
- You want highly performant aggregations that scales to high numbers of branches
- You do not have access to, or do not want to use, IBM MQ
- You will deploy all flows responsible for orchestrating the aggregations to a single integration server (note this does not include the backend services)

You should use the Aggregate nodes if you have the following requirements:

- You require that all parts of the aggregation, including control data, received replies and sent requests, are recoverable if the integration server shuts down
- You want to deploy the flows responsible for orchestrating the aggregations across multiple integration servers within the same integration node
- Your backend replies are large, which may cause excessive memory consumption if not stored on disk while waiting for the aggregation to complete

Using more than one input node

You can include more than one input node in a single message flow.

Before you begin

Read the following concept topic:

- “Message flow nodes” on page 484

About this task

You might find this useful in the following situations:

- The message flow provides common processing for messages that are received from multiple transports. For example, a single message flow might handle:
  - Data in messages received from IBM MQ, and therefore through an IBM MQ queue and an MQInput node
  - Messages that are received from native IP connections (a Real-timeInput node)

- You need to set standard properties on the MQInput node if input messages:
  - are predefined, and
  - are all received from IBM MQ, and
  - do not include an MQRFH2 header.

  If the required standard properties are not always the same for every message, you can include more than one input node and configure each to handle a particular set of properties.

  This requirement is not necessary for self-defining messages.
- Each input node in a message flow causes the integration node to start a separate thread of execution. Including more than one input node might improve the message flow performance. However, if you include multiple input nodes that access the same input source (for example, an IBM MQ queue), the order in which the messages are processed cannot be guaranteed. If you want the message flow to process messages in the order in which they are received, this option is not appropriate.

  If you are not concerned about message order, consider using additional instances of the same message flow rather than multiple input nodes. If you set the `Additional Instances` property of the message flow when you deploy it to the integration node, multiple copies of the message flow are started in the integration server. This is the most efficient way of handling multiple instances.

Defining input message characteristics

When a message is received by an input node in a message flow, the node detects how to interpret that message by determining the domain in which the message is defined and starting the appropriate parser.

Before you begin

Read the following concept topic:

- "Parsers" on page 520

About this task

You can provide message domain information to the input node in one of two ways:

- You can configure the built-in input nodes to indicate the message domain, and therefore the parser to be started, for each message that is received.
- You can set values in the input message itself that specify this information. Include an MQRFH2 header, which contains a folder that defines the message characteristics. This approach is more flexible because it means that the input node can start the appropriate parser based on the content of each message.

If the input message is defined in the MRM domain, and is therefore interpreted by the MRM parser, you must specify the following additional properties:

- The `Message model`, which is the message model in which the message is defined
- The `Message type`, which is defined by the message model
- The `Message format`, which defines the physical characteristics of the message

The way that these properties are set depends upon the type of message, or node, that you want to use:

- If the message is an IBM MQ message, these properties can be set either in the input node or in the MQRFH2 header of the incoming message. If the properties are set in both, the properties of the MQRFH2 header take precedence. If the properties are not found in either the node or the MQRFH2 header, the default value is empty and the BLOB parser is used.
- If the message is a JMS message, the property that is set on the node takes precedence. If the `Message domain` is empty, the `Message domain` is, by default, derived according to certain criteria following a predetermined order of precedence; see "JMS message payload and appropriate parser" on page 863.

- If the input message belongs to a `Message domain` other than those for which a parser is supplied, you must provide a user-defined parser to handle it, and a user-defined input node to accept it for processing in the message flow. Check the documentation provided with the user-defined parser and node for further information.
- If the `Message domain` is in a TimeoutControl node, an empty `Message domain` has either of the following results:
  - If the `Stored message location` property is also empty, the full message is stored. When the message comes back at TimeoutNotification, it is parsed in the same way as the original message.
  - If the `Stored message location` property is not empty, a partial message is stored and no parser is associated, therefore, by default, it is treated as BLOB.
- If the `Message domain` is in a ResetContentDescriptor node, an empty `Message domain` has either of the following results:
  - If `Reset message domain` is cleared, the domain is not reset.
  - If `Reset message domain` is selected, the default is BLOB.
- If the input node cannot determine the message characteristics, the default value is empty and the message is considered to be in the BLOB domain, and the BLOB parser is started.

Splitting the processing of message flows

Process parts of your message flow in different locations by creating one message flow that calls another message flow.

Before you begin

Read the concept information in "Callable message flows" on page 491.

About this task

Callable flows allow you to split your message flow processing between different locations. Callable message flows also facilitate reuse because they can be called by multiple message flows. You can split your processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, or between different locations in IBM App Connect Enterprise.

In App Connect Enterprise message flows, the calling flow uses a CallableFlowInvoke node to call a CallableInput node in the callable flow. The callable flow then uses a CallableReply node to return information to the CallableFlowInvoke node in the original flow.

Note: This topic is about using the callable flow technique between App Connect Enterprise message flows. You can also use the callable flows technique with on-cloud event-driven flows and API flows in IBM App Connect on IBM Cloud; for example, see the tutorial: Sharing data and processing from on-premises activities with on-cloud SaaS applications, by using an on-cloud callable flow.

If your initial and callable flows are in the same integration server, they can communicate with each other as soon as you deploy them. If your flows are in different integration servers, or one is in IBM App Connect Enterprise while the other is in IBM App Connect on IBM Cloud, you must configure communication between them. The flows use a Switch server to route data, and connectivity agents to connect securely to the Switch server.

You can split flows into multiple callable flows. However, for simplicity, the following tasks describe how to create two flows only: a calling flow and a callable flow.

Procedure

To split the processing of your message flows, complete the following steps.

- Create your initial and callable flows. For more information, see "Developing synchronously callable message flows" on page 600 and "Developing asynchronously callable message flows" on page 602.

- If your flows are split between different integration servers in IBM App Connect Enterprise, configure connectivity between the flows. For more information, see “Preparing the environment to split processing between different integration servers” on page 222.
- If your flows are split between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, configure connectivity between the flows. For more information, see “Preparing the environment to split processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud” on page 225.

Developing synchronously callable message flows

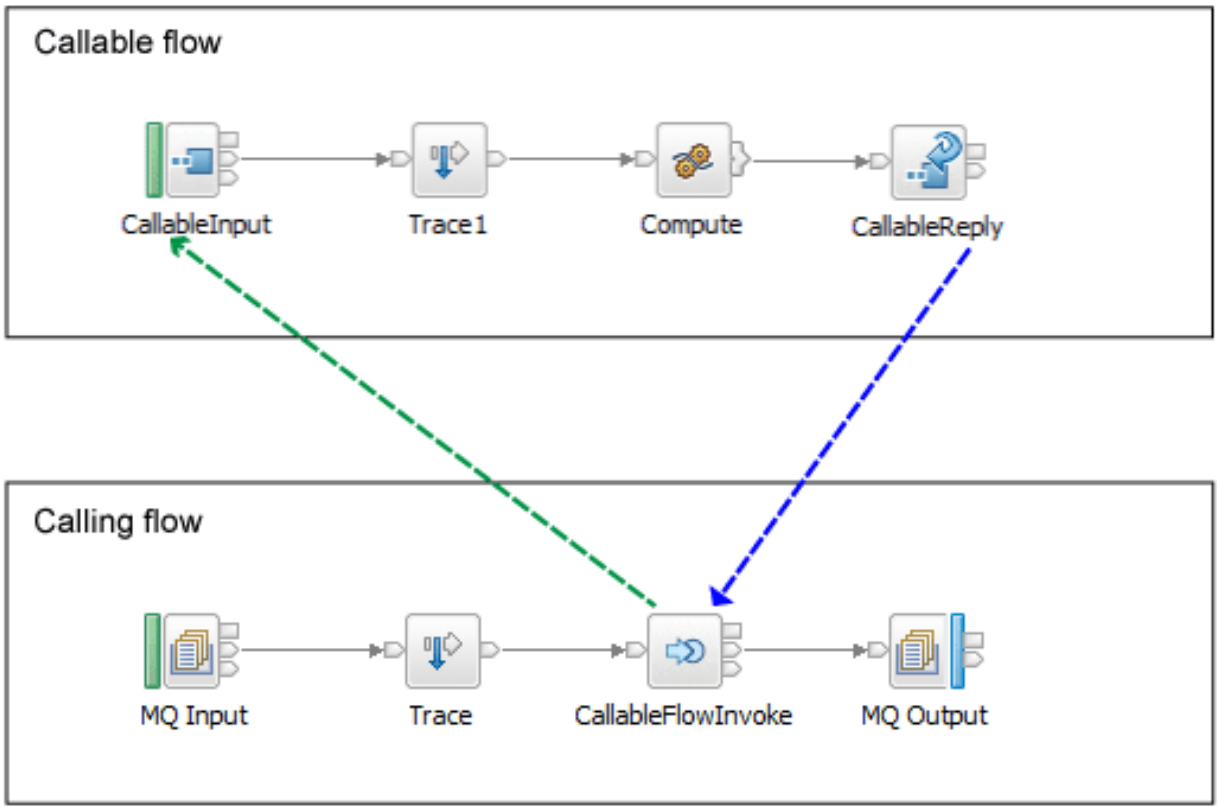
Create a calling message flow that contains a CallableFlowInvoke node. Create a callable message flow that contains CallableInput and CallableReply nodes.

Before you begin

Read the concept information in “Callable message flows” on page 491.

About this task

The following steps describe how to create a calling flow and a callable flow that can send information to each other.



For information about calling a flow asynchronously, see “Developing asynchronously callable message flows” on page 602.

Procedure

1. In the IBM App Connect Enterprise Toolkit, create the calling message flow, which must include a CallableFlowInvoke node.

   The CallableFlowInvoke node parses the incoming message in full so that it is in a suitable format to send to the CallableInput node. Therefore, you should validate the message before it reaches the CallableFlowInvoke node. If the message fails validation at this point, it can be rolled back.

2. In a different application, create a callable message flow, which must begin with a CallableInput node, and contain a CallableReply node.

   A CallableFlowInvoke node calls a callable flow by referring to the endpoint name on the CallableInput node, and the application that contains the callable flow. Therefore, you must include all callable flows in applications.
3. On the CallableInput node of the callable flow, use the `Endpoint Name` property to provide a name for the callable flow.

   Application and endpoint name pairs must be unique on a single integration server. You can have multiple callable flows that share the same application and endpoint names, but they must be in different integration servers. In this case, the Switch server acts as a load balancer.
4. On the CallableFlowInvoke node of the calling flow, set the following properties.

Table 11. CallableFlowInvoke node properties

Property	Value
Target Application	Set this property to the name of the application that contains the callable flow.
Target Endpoint Name	Enter the name of the `Endpoint Name` property of the CallableInput node. This name is case sensitive. The `Target Endpoint Name` must match the `Endpoint Name` of the CallableInput node exactly.
Request timeout (sec)	Set the time within which the callable flow must be called, in seconds. If the callable flow is not called within the specified time, an error message is issued.
Call Preference	• If your main and callable flows are in the same integration server, set this property to **`Prefer local calls`**. • If your flows are split between different integration servers, or between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, set this property to **`Remote calls only`**.

5. Package the applications that contain your message flows into BAR files.
6. Deploy the BAR files to the appropriate integration servers.

   If you are splitting processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, deploy one BAR file on premises and upload the other to the cloud. For more information about deploying BAR files to IBM App Connect on IBM Cloud, see Running enterprise integration solutions in App Connect on IBM Cloud in the IBM Integration community.

Results

When you pass a message into the main message flow, the CallableFlowInvoke node sends the contents of the message body and local environment folders to the CallableInput node of the callable flow. When the callable flow completes processing, the CallableReply node returns the message body and local environment folder data to the CallableFlowInvoke node of the main flow.

What to do next

If your callable flows are in different integration servers, you need to create a Switch server (which routes data) and connectivity agents to allow the flows to communicate securely. For more information, see “Preparing the environment for callable flows” on page 222.

Developing asynchronously callable message flows

Create a calling message flow that contains a CallableFlowAsyncInvoke node. Create a callable message flow that contains CallableInput and CallableReply nodes. Create a response message flow that contains a CallableFlowAsyncResponse node.

Before you begin

Read the concept information in "Callable message flows" on page 491.

About this task

This topic explains how to split processing between asynchronously callable message flows, by using the CallableFlowAsyncInvoke and CallableFlowAsyncResponse nodes. You can also choose to share data between the flows that contain these nodes (the calling flow and the response flow) by storing and retrieving data in the `UserContext` folder in the Environment. For information about sharing data between the calling flow and the response flow, see "Sharing data between a calling flow and a response flow" on page 603.

Procedure

The following steps describe how to create a calling flow, a callable flow, and a response flow that can send information to each other.

1. In the IBM App Connect Enterprise Toolkit, create the calling message flow, which must include a CallableFlowAsyncInvoke node.

   The CallableFlowAsyncInvoke node parses the incoming message in full so that it is in a suitable format to send to the CallableInput node. Therefore, you should validate the message before it reaches the CallableFlowAsyncInvoke node. If the message fails validation at this point, it can be rolled back.
2. In a different application, create a callable message flow, which must begin with a CallableInput node, and contain a CallableReply node.

   A CallableFlowAsyncInvoke node calls a callable flow by referring to the endpoint name on the CallableInput node, and the application that contains the callable flow. Therefore, you must include all callable flows in applications.
3. On the CallableInput node of the callable flow, use the `Endpoint Name` property to provide a name for the callable flow.

   Application and endpoint name pairs must be unique on a single integration server. You can have multiple callable flows that share the same application and endpoint names, but they must be in different integration servers. In this case, the Switch server acts as a load balancer.
4. On the CallableFlowAsyncInvoke node of the calling flow, set the following properties:

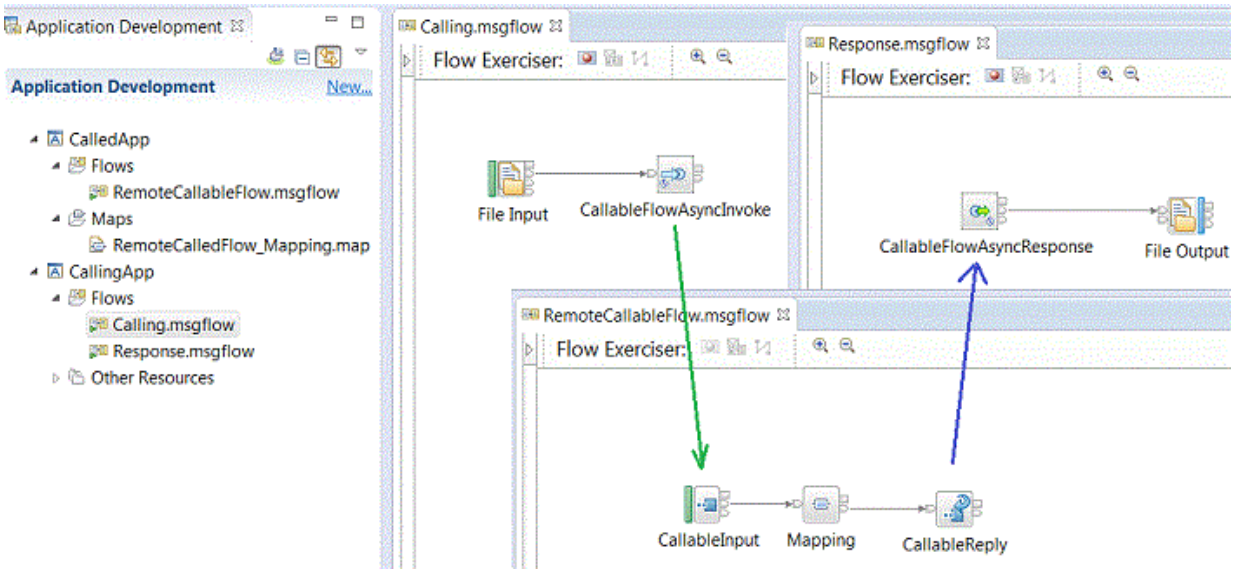
Table 12. CallableFlowAsyncInvoke node properties

Property	Value
Target Application	Set this property to the name of the application that contains the callable flow.
Target Endpoint Name	Enter the name of the `Endpoint Name` property of the CallableInput node. This name is case sensitive. The `Target Endpoint Name` must match the `Endpoint Name` of the CallableInput node exactly.
Request timeout (sec)	Set the time within which the callable flow must be called, in seconds. If the callable flow is not called within the specified time, an error message is issued.

Table 12. CallableFlowAsyncInvoke node properties (continued)	
Property	**Value**
Call Preference	• If your main and callable flows are in the same integration server, set this property to **`Prefer local calls`**. • If your flows are split between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, set this property to **`Remote calls only`**.

5. In a different application, or in the same application that was used in step 1, create a response message flow that starts with a CallableFlowAsyncResponse node.
6. Set the **`Unique identifier`** property of the CallableFlowAsyncResponse node to match the value set in the CallableFlowAsyncInvoke node that was created in step 1.

   You now have three separate message flows: a calling flow, a callable flow, and a response flow:



7. Package the applications that contain your calling and response message flows into a BAR file, and package the called message flow into a separate BAR file.
8. Deploy the BAR files to the appropriate integration servers.

   If you are splitting processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, deploy one BAR file on premises and upload the other to the cloud. For more information about deploying BAR files to the cloud, see "Deploying integration solutions to a production environment" on page 2480.

Results

When you pass a message into the main message flow, the CallableFlowAsyncInvoke node sends the contents of the message body and local environment folders to the CallableInput node of the callable flow and then completes. When the callable flow completes processing, the CallableReply node sends the message body and local environment folder data to the CallableFlowAsyncResponse node in the separate response flow.

Sharing data between a calling flow and a response flow

You can share data between a flow that contains a CallableFlowAsyncInvoke node (the calling flow) and a flow that contains a CallableFlowAsyncResponse node (the response flow), by storing and retrieving data in the `UserContext` folder in the Environment.

Before you begin

- Read the concept information in "Callable message flows" on page 491.

- Create a calling flow, a callable flow, and a response flow, as described in “Developing asynchronously callable message flows” on page 602.

About this task

The user context is a storage area that is used to pass data that is not part of the message between nodes in a message flow. For example, by using the user context, you can pass state from the CallableFlowAsyncInvoke node in the calling message flow to the CallableFlowAsyncResponse node in the response message flow. However, this user context data is not accessible to the called message flow.

To store user context data, you can either set a value in the `Environment.CallableFlow.UserContext` environment variable, or create and populate child folders below it in the message tree. For example, you can use the following command to specify context data to be stored the environment:

```
SET Environment.CallableFlow.UserContext = 'myData';
```

The specified context data is shown in the `UserContext` element in the message tree:

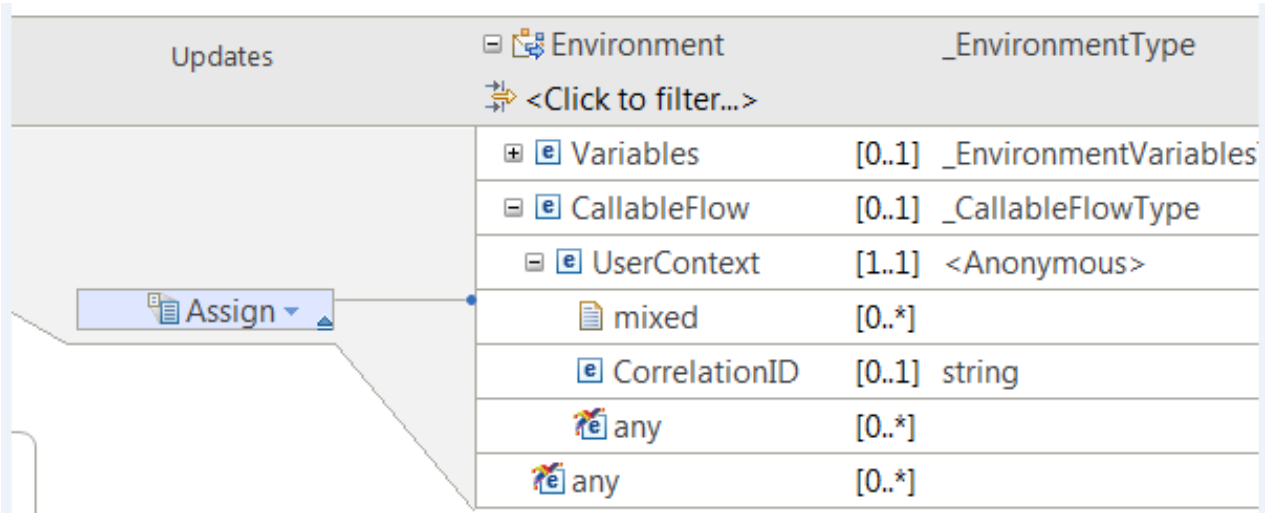
```
<environment>
  <CallableFlow>
     <CorrelationID>43414c4c0100000000000000f3264f744805000000000000</CorrelationID>
     <UserContext>myData</UserContext>
```

Alternatively, the user context can be a folder with a subtree, which is preserved and re-created:

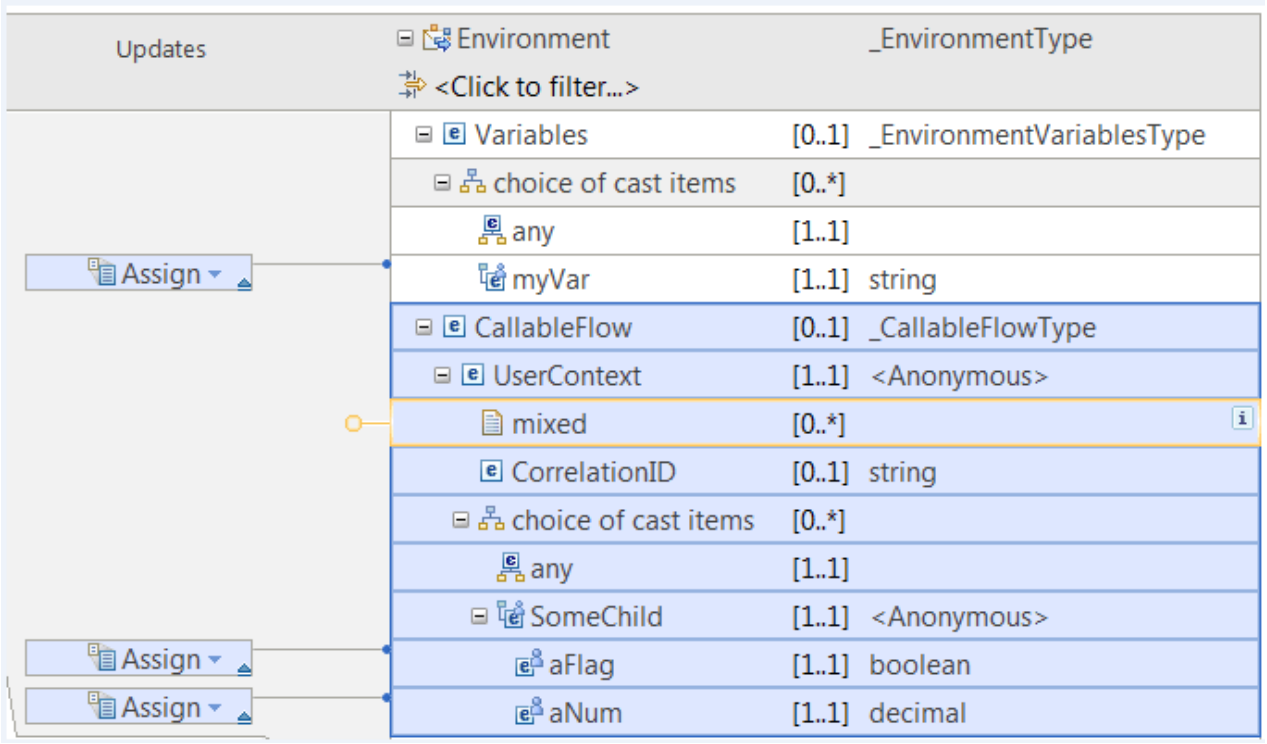
```
<environment>
    <CallableFlow>
      <CorrelationID>43414c4c0100000001000000603a527418280000000000000</CorrelationID>
      <UserContext>
        <c1>
           <c2>myData</c2>
```

When the user context data has been specified, the CallableFlowAsyncResponse node can subsequently retrieve it.

You can use a Mapping node to set a value, by mapping to the `mixed` child element `Environment.CallableFlow.UserContext.mixed`, as shown in the following diagram:



To use a mapping node to create sub-elements, use user-defined elements or cast the `xsd:any` and map to them, as shown in the following diagram:



To access the user context data after a CallableFlowAsyncResponse node, read the value or children of the `Environment.CallableFlow.UserContext` environment variable.

Preparing the environment to split processing between different integration servers

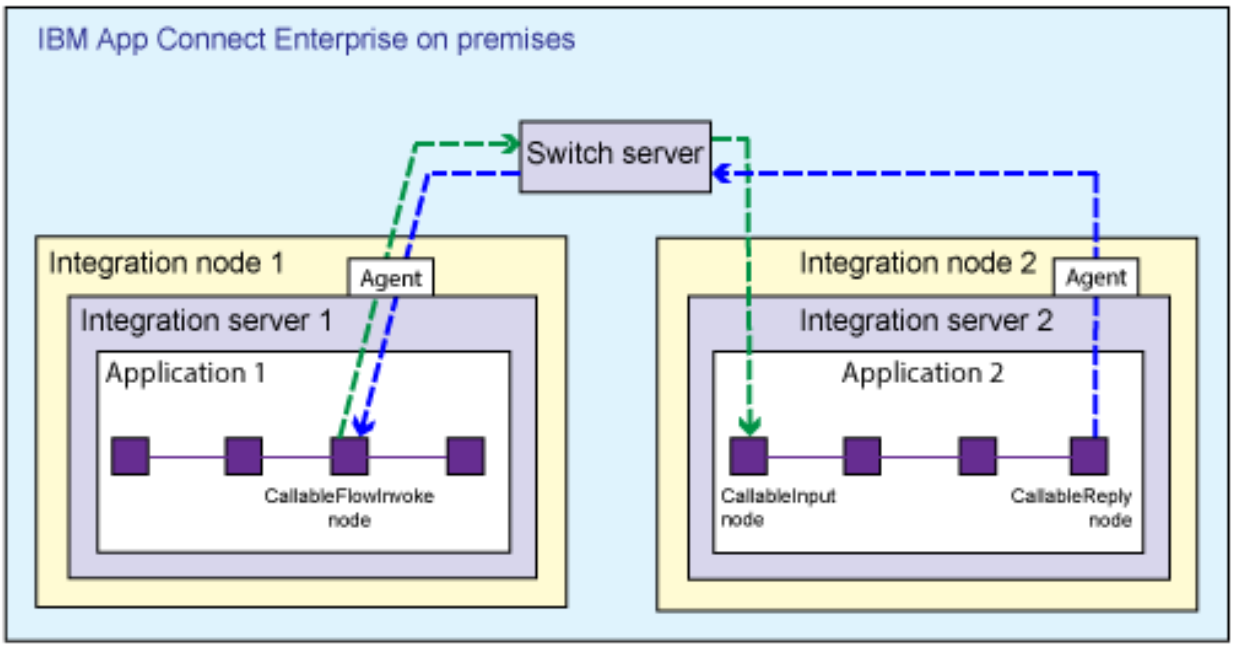
When you split message flow processing between different integration servers, you must configure a data router and a connectivity agent. The integration servers can be running on different integration nodes.

Before you begin

Read the concept information in "Callable message flows" on page 491.

About this task

When you split processing between different integration servers, your flows communicate securely by using a Switch server and connectivity agents. The Switch server is a special kind of integration server that routes data. The connectivity agents contain the certificates that your flows require to communicate securely with the Switch server. A connectivity agent must be running in each integration server where you have deployed message flows.



If your callable flows and the flows that call them are ***all*** deployed on premises, you must create and configure the Switch server on premises. You must run a command that creates some configuration files. You use one of the configuration files to create the Switch server, and the other file to configure connectivity agents for each integration server where you have deployed callable flows or flows that call them. The steps for this procedure are given in this topic.

This on-premises scenario is supported on Windows and Linux only.

If you are splitting processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, the Switch server is created and managed for you in the cloud. You must download an agent configuration file from the cloud, and use it to configure the on-premises connectivity agent for each integration server. For more information about configuring connectivity agents for use with IBM App Connect on IBM Cloud, see "Preparing the environment to split processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud" on page 225.

Procedure

To prepare the environment to split processing between integration servers on premises, complete the following steps.

1. Start an IBM App Connect Enterprise command environment.
2. Create the required configuration files, by running the **iibcreateswitchcfg** command.
   You need to run the command in a directory for which you have permission to write. Alternatively, you can specify an output directory. For example, the following command creates the configuration files and saves them in the `temp` directory.

   Windows On Windows:

   ```
   iibcreateswitchcfg /output c:\temp
   ```

   Linux On Linux:

   ```
   iibcreateswitchcfg -output /temp
   ```

   If this command is successful, you see the following responses:

   ```
   Generated self signed certificate file 'c:\temp\adminClient.p12'
   Generated switch configuration file 'c:\temp\switch.json'
   ```

```
Generated agentx configuration file 'c:\temp\agentx.json'
```

This command creates two JSON configuration files, and a certificate, which is reserved for future use. One file (`switch.json`) is used to create the Switch server. The other file (`agentx.json`) is used to configure the agent for each integration server where your flows are deployed.

3. Create the Switch server, by running the **iibswitch** command to use the configuration file (`switch.json`) that you created in step 2.

   Windows For example, on Windows:

   ```
   iibswitch create switch /config c:\temp\switch.json
   ```

   Linux On Linux:

   ```
   iibswitch create switch -c /temp/switch.json
   ```

   If the command is successful, you see a "Successful command completion" response. The Switch server is created in a special integration node called ACESWITCH_NODE_V11.

4. Optional: To test that the Switch server is created and running, run the following command: **mqsilist** ACESWITCH_NODE_V11.

   If the Switch server is running, you see the following response:

   ```
   BIP1286I: Integration server 'IIBSWITCH_SERVER' on integration node 'ACESWITCH_NODE_V11' is
    running.
   ```

5. Configure a connectivity agent for each integration server where you have deployed callable flows or flows that call them.

   You can configure the agent by copying the configuration file, `agentx.json` (that you created in step 2), to the server's `iibswitch/agentx` directory.

   - For an independent integration server: *work directory*`/config/iibswitch/agentx`
   - For an integration server under an integration node: *$MQSI_WORKPATH*`/config/`*Node_name*`/`*Server_name*`/iibswitch/agentx`

   For each affected integration server, the agent should automatically establish a connection to the Switch server. For example, in the App Connect Enterprise console for an independent integration server you should see the following messages:

   ```
   The connection agent for remote callable flows has established a connection to the Switch
    server with URL 'wss://localhost:9011'.
   The integration server component 'agentx' has been started.
   ```

   Similarly, in the Windows Application log, you should see the following messages for an integration server (N101ISAA) under an integration node (NODEIPL01):

   ```
   ( NODEIPL01.N101ISAA ) The connection agent for remote callable flows has established a
    connection to the Switch server with URL ''wss://localhost:9011''.

   A connection agent for remote callable flows has been configured on this integration server.
    The connection agent has successfully connected to the Switch server.

   No response required.
   ----------------------------------------------------------------------------------------------
   ( NODEIPL01.N101ISAA ) The integration server component ''agentx'' has been started.

   The specified component has been started and is available for use.

   No response required.
   ```

Results

A message flow that is deployed to one configured integration server can now communicate securely with a message flow on another configured integration server. For more information about developing these message flows, see “Developing synchronously callable message flows” on page 600.

Preparing the environment to split processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud

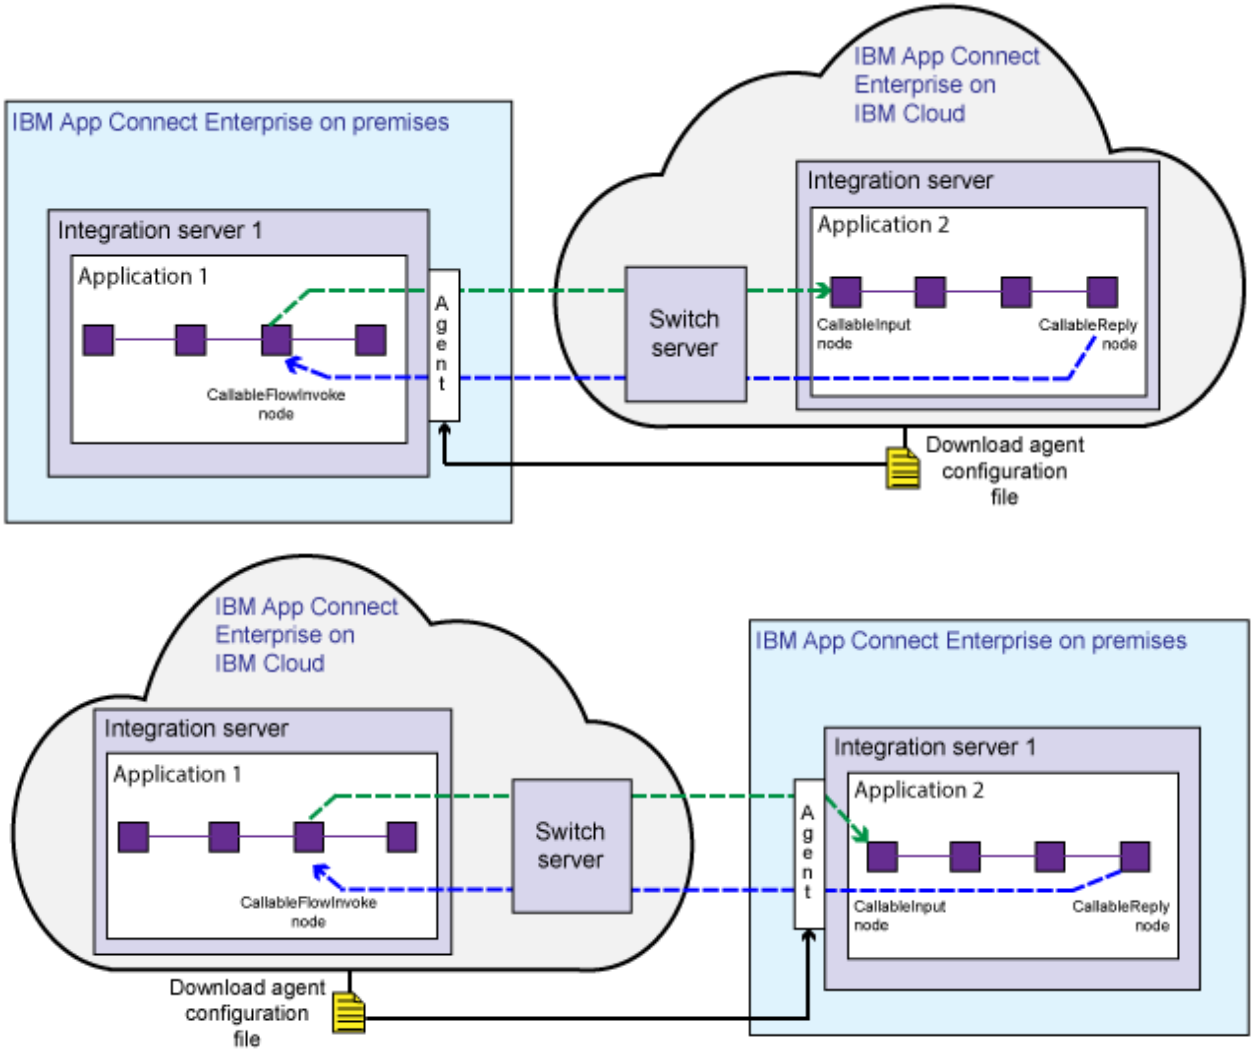
When you split message flow processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, you must configure a connectivity agent.

Before you begin

These instructions assume that you have IBM App Connect Enterprise installed on premises, and that you have created an App Connect service in IBM Cloud.

About this task

When you split processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, your flows communicate by using a Switch server and connectivity agent. The Switch server, which routes data, is managed for you by IBM App Connect on IBM Cloud. The connectivity agent contains the certificates that your flows require to communicate securely with the Switch server. A connectivity agent must be running in the IBM App Connect Enterprise integration server where you have deployed your on-premises message flows.



The Switch server is already created in IBM App Connect on IBM Cloud. You must download an agent configuration file from the cloud, and use it to configure the on-premises connectivity agent. Your callable flows use this agent to communicate with each other securely, through the Switch server.

Procedure

To prepare the environment to split processing between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, complete the following steps.

1. In IBM App Connect on IBM Cloud, click **Callable flows**  .

   If you have not configured callable flows before, the list will be empty.
2. Click **Connect callable flows**.

   A dialog box opens to set up your agent.
3. Click **Download the configuration** and save the agent configuration file (`agentx.json`) to convenient location, and then use it to configure the on-premises integration servers.

   Copying the `agentx.json` file, to the on-premises server's `iibswitch/agentx` directory.

   - For an independent integration server: *work directory*`/config/iibswitch/agentx`
   - For an integration server under an integration node: *$MQSI_WORKPATH*`/config/`*Node_name*`/`*Server_name*`/iibswitch/agentx`

   For each affected integration server, the agent should automatically establish a connection to the Switch server. For example, in the App Connect Enterprise console for an independent integration server you should see the following messages:

   ```
   The connection agent for remote callable flows has established a connection to the Switch
    server with URL 'wss://ibm-sw-lfcxnlolwumbamsnq.eu-gb.ace.ibm.com:443/'.
   The integration server component 'agentx' has been started.
   ```

   Similarly, in the Windows Application log, you should see the following messages for an integration server (N101ISAA) under an integration node (NODEIPL01):

   ```
   ( NODEIPL01.N101ISAA ) The connection agent for remote callable flows has established
    a connection to the Switch server with URL ''wss://ibm-sw-lfcxnlolwumbamsnq.eu-
   gb.ace.ibm.com:443/''.

   A connection agent for remote callable flows has been configured on this integration server.
    The connection agent has successfully connected to the Switch server.

   No response required.
   ----------------------------------------------------------------------------------------------
   ( NODEIPL01.N101ISAA ) The integration server component ''agentx'' has been started.

   The specified component has been started and is available for use.

   No response required.
   ```

   Note: If a message flow on one on-premises integration server calls a message flow on other on-premises integration servers, and one of those integration servers also uses the callable flows technique to interact with flows in IBM App Connect on IBM Cloud, you need to copy the downloaded `agentx.json` file to all those on-premises integration servers (so that they all continue to use the same Switch server, now on cloud). For example, consider the initial on-premises scenario where a flow on server A calls a flow on server B, with both servers configured with the local `agentx.json` (to use the on-premises Switch server). Later, a flow in IBM App Connect on IBM Cloud is added to call the flow on server B, so server B needs to be configured with the `agentx.json` downloaded from the cloud (to use the on-cloud Switch server). Also, to continue to use the same Switch server as server B, server A needs to be configured with the `agentx.json` downloaded from the cloud (to use the on-cloud Switch server)

4. In IBM App Connect on IBM Cloud, you can check that the on-premises agent can connect to the Switch server in the cloud.

   You can perform the following checks:

   - Refresh the Callable flows page. This should list all the callable and calling flows on premises and on cloud; for example:
   - In the **Connect callable flows** dialog, click **Test your agent**. This should return the number of on-premises agents found.

   If the test is successful, close the dialog box.

Results

The callable flows technique can be used between IBM App Connect Enterprise and IBM App Connect on IBM Cloud, and between integration servers in IBM App Connect Enterprise configured to use the on-cloud Switch server.

For more information about developing these message flows, see "Developing synchronously callable message flows" on page 600.

Creating destination lists

Create a list of destinations to indicate where a message is sent.

Before you begin

Read the concept topic "Message flow nodes" on page 484.

About this task

You can include a Compute node in your message flow, and configure it to create a destination list in the local environment subtree. You can then use the destination list in the following nodes:

- The MQOutput and JMSOutput nodes, to put output messages to a specified list of destinations.
- The RouteToLabel node, to pass messages to Label nodes.

For more information about accessing the LocalEnvironment subtree, destination list contents, and example procedures for setting values for each of these scenarios, see "Accessing the local environment tree" on page 1654.

For more information about how to populate destination in the LocalEnvironment subtree, and how to build JMS destination lists, see "Populating Destination in the local environment tree" on page 1656.

You might find it useful to create the contents of the destination list from an external database that is accessed by the Compute node. You can then update the destinations without needing to update and redeploy the message flow.

The use of the destination list to define which applications receive the output messages is in contrast to the publish/subscribe application model, in which the recipients of the publications are those subscribers that are currently registered with the integration node. The processing that is completed by the message flow does not have any effect on the current list of subscribers.

Validating messages

The integration node or server provides validation based on the message model for predefined messages.

Before you begin

Read the concept topics about message flows and parsers, especially "DFDL parser and domain" on page 544, "JSON parser and domain" on page 553, and "XMLNSC parser" on page 531.

About this task

Validation applies only to messages that you have modeled and deployed to the integration node or server. Specifically, the message domains that support validation are DFDL, XMLNSC, JSON, SOAP, IDOC, and MRM.

Integration nodes and servers do not provide any validation for self-defining messages. The DFDL, XMLNSC, and SOAP domains validate predefined messages directly against message model schema files. The JSON domain validates predefined messages directly against JSON schema files or OpenAPI definitions. The IDOC and MRM parsers validate predefined messages against the message dictionary generated from a message set.

Message flows are designed to transform and route messages that conform to certain rules. By default, parsers perform some validity checking on a message, but only to ensure the integrity of the parsing operation. However, you can validate a message more stringently against the message model contained in the message set by specifying validation options on certain nodes in your message flow.

You can use validation options to validate the following messages:

- Input messages that are received by an input node
- Output messages that are created, for example, by a Compute, Mapping, or JavaCompute node

These validation options can ensure the validity of data entering and leaving the message flow. The options provide you with some degree of control over the validation performed to:

- Maintain a balance between performance requirements and security requirements
- Validate at different stages of message flow completion; for example, on input of a message, before a message is propagated, or at any point in between
- Cope with messages that your message model does not fully describe

You can also specify what action to take when validation fails.

Message validation involves navigating a message tree, and checking the validity of the tree. Message validation is an extension of tree creation when the input message is parsed, and of bit stream creation when the output message is written.

Validation options are available on the following nodes:

Node type	Nodes with validation options
Input node	FileInput, FTEInput, HTTPInput, JMSInput, KafkaConsumer, MQInput, MQTTSubscribe, .NETInput, SOAPInput,TCPIPClientInput, TCPIPClientReceive, TCPIPServerInput, TCPIPServerReceiveTimeoutNotification
Output node	EmailOutput, FileOutput, FTEOutput, HTTPReply, JMSOutput, JMSReply, KafkaProducer, MQOutput, MQReply, MQTTPublish, SOAPReply, TCPIPClientOutput, TCPIPServerOutput
Other nodes	Compute, CICSRequest, DatabaseRetrieve, HTTPRequest, FileRead, JavaCompute, Mapping, MQGet, ResetContentDescriptor, SOAPRequest, SOAPAsyncResponse, Validate, XSLTransform

Validation options can also be specified on the ESQL CREATE statement and the ASBITSTREAM function. The equivalent Java API methods, **`createElementAsLastChildFromBitstream()`** and **`toBitstream()`** in MBElement, also provide validation options.

To validate input messages that are received on an input node, you can specify validation properties on the input node. The input message is then validated when the message bit stream is parsed to form the message tree.

You can also use the `Parse Timing` property of the input node to control whether the entire message is parsed and validated at this time, or whether individual fields in the message are parsed and validated only when referenced.

To validate output messages that are created by a transformation node, specify validation properties either on the node itself, or on the output node that sends the message. The validation takes place when the message bit stream is created from the message tree by the output node.

Alternatively, use a Validate node to validate a message tree at a particular place in your message flow, or use the ESQL ASBITSTREAM function in a Compute, Filter, or Database node.

A limited amount of validation occurs by default if you leave the validation settings unaltered. At this default level, an exception is thrown if one of the following statements is true:

- A data mismatch occurs; for example, the parser cannot interpret the data that is provided for the field type specified.
- The order of elements in the output message does not match the order of elements in the logical message tree (DFDL, MRM CWF, and MRM TDS fixed-length models only).

Additionally, the DFDL parser performs limited remedial action under the following circumstances:

- If mandatory content is missing, default values are supplied, if available in the schema, on output.
- If the data type of an element in the tree is CHARACTER and does not match that specified in the schema, the data type is converted on output to match the schema, if possible.

Additionally, the MRM parser performs limited remedial action under the following circumstances:

- Extraneous fields are discarded on output for fixed formats (CWF and TDS fixed-length models only).
- If mandatory content is missing, default values are supplied, if available, on output for fixed formats (CWF and TDS fixed-length models only).
- If the data type of an element in the tree does not match that specified in the dictionary, the data type is converted on output to match the dictionary definition, if possible, for all formats.

However, by using validation options you can request more thorough validation of messages. For example, you might want to validate one or more of the following conditions, and throw an exception, or log the errors:

- The whole message at the start of the message flow
- That complex elements have the correct `Composition` and `Content Validation`
- That all data fields contain the correct type of data
- That data fields conform to the value constraints in the message model
- That all mandatory fields are present in the message
- That only the expected fields are present in the message
- That message elements are in the correct order

When using validation options, it is important to understand the following behavior.

- The `Parse Timing` property, which controls whether *on-demand* parsing (sometimes called partial parsing) takes place, affects the timing of the validation of input messages, including message headers.

  For more information about the `Parse Timing` property, see Parsing on demand.
- If a message tree is passed to an output node, by default the output node inherits the validation options in force for the message tree. You can override these options by specifying a new set of validation options on the output node.
- If a message tree is passed as input to a Compute, Mapping, XSLTransform, DatabaseRetrieve, or JavaCompute node, any new output message trees that the node creates have the validation options specified by the node itself (even if the whole message is copied). You can override this behavior and specify that the messages that are created by the node inherit the validation options of the input message tree.
- (DFDL and MRM domains only) When the bit stream is written, and validation options are applied, the entire message is validated. The message tree might contain an unresolved type (for example, if a Compute node copied an unresolved type from an input message to an output message without resolving it). If such a type is encountered, a validation error occurs because it is not possible to validate

the type. To prevent this error, ensure that all unresolved types are resolved before they are copied to output messages.

- (MRM domain only) Do not select the `Truncate fixed length strings` check box because validation is done before truncation, and a fixed-length field fails validation if its length exceeds the length that is defined in the message set. For more information about the `Truncate fixed length strings` property, see Message Sets: Custom Wire Format message set properties and Message Sets: TDS Format message set properties.

For information about how you can control validation by using different properties, see Validation properties.

Changing the parser used in a message flow

If you need to change the parser that is used in a message flow, use the ResetContentDescriptor node to request that the message is reparsed by a different parser.

About this task

Use the ResetContentDescriptor node to set new message properties that are used when the message bit stream is next parsed by a subsequent node in the message flow.

For example, if the format of an incoming message is unknown when it enters a message flow, the BLOB parser is started. Later on in the message flow, you might decide that the message is predefined as a message in the MRM domain, and you can use the ResetContentDescriptor node to set the correct values to use when the message is parsed by a subsequent node in the message flow.

You can select from the following parsers:

- DFDL
- XMLNSC
- JSON
- DataObject
- XMLNS
- JMSMap
- JMSStream
- MIME
- BLOB
- XML (this domain is deprecated; use XMLNSC)
- IDOC (this domain is deprecated; use MRM)
- MRM

If you specify MRM, XMLNSC, DataObject, or IDOC as the new parser, you can also specify a different message template (message set, message type, and message format).

Whether or not the node reparses the message straight away depends on the settings of the `Parse timing` option in the node properties. `Parse timing` is, by default, set to `On Demand`, which causes parsing of the message to be delayed. For more details on controlling when the message is parsed, see Parsing on demand.

Providing user-defined properties to control behavior

User-defined properties can be set at design time, deployment time, or run time.

About this task

For example, user-defined properties can be queried, discovered, and set at run time to dynamically change the behavior of a message flow. You can use the administration REST API or IBM Integration API

to manipulate these properties, which can be used by a systems monitoring tool to perform automated actions in response to situations that it detects in the monitored systems.

Procedure

- You can use the Message Flow editor to define a user-defined property when you construct a message flow. For more information, see Message Flow editor.
- You can set user-defined properties at deployment time to configure a message flow, as described in “Configuring a message flow at deployment time with user-defined properties” on page 1749.
- You can use the administration REST API to modify user-defined properties on a message flow dynamically at run time, as described in “Setting message flow user-defined properties at run time by using the administration REST API” on page 436.
-

Defining message flow content

You can define message flow content by adding and configuring message flow nodes and connecting them to form flows.

About this task

When you create a message flow, the editor view is initially empty. You must create the contents of the message flow by using a combination of the following tasks:

- “Adding a message flow node” on page 618
- “Adding a subflow” on page 623
- “Renaming a message flow node” on page 624
- “Configuring a message flow node” on page 624
- “Connecting message flow nodes” on page 636
- “Inserting nodes into existing message flows” on page 639
- “Adding a bend point” on page 640
- “Aligning and arranging nodes” on page 642

While you are developing message flows, you might want to record notes about flow development or particular nodes in the flow:

- “Adding annotations to a message flow or node” on page 643
- “Editing annotations on a message flow or node” on page 644
- “Copying annotations on a message flow or node” on page 645
- “Showing and hiding annotations on a message flow or node” on page 646
- “Deleting annotations from a message flow or node” on page 646

When you finalize the contents of the message flow, you might also need to complete the following tasks:

- “Removing a message flow node” on page 636
- “Removing a node connection” on page 639
- “Removing a bend point” on page 641

Using the node palette

The node palette contains all the built-in nodes, which are organized into categories.

Before you begin

Read the following concept topic “Message flow node palette” on page 486.

About this task

You can add the nodes that you use most often to the Favorites category by following the instructions in “Adding nodes to the Favorites category on the palette” on page 617.

You can change the palette preferences in the IBM App Connect Enterprise Toolkit. The changes that you can make are described in the following topics.

Procedure

Changing the palette layout

You can change the layout of the palette in the Message Flow editor.

Procedure

1. Switch to the Integration Development perspective
2. Right-click the palette to display the pop-up menu.
3. Click **Layout**.
4. Click one of the available views:

   Columns
   Displays named icons in one or more columns. Change the number of columns by clicking on the right edge of the palette and dragging.

   List
   Displays named icons in a single-column list. The list view is the default layout.

   Icons Only
   Displays a list of icons only.

   Details
   Displays descriptions of the icons.

Changing the palette settings

How to use the **Palette Settings** dialog box.

About this task

Change the palette settings in the Message Flow editor using the **Palette Settings** dialog box.

Procedure

1. Switch to the Integration Development perspective.
2. Right-click the palette to display the pop-up menu.
3. Click **Settings**.
   The **Palette Settings** dialog box opens.

4. Use the dialog to change the appropriate setting:
   - Click **Change** to change the font on the palette.
   - Click **Restore Default** to restore the default palette settings.
   - In the **Layout** list, click the appropriate radio button to change the palette layout. (See "Changing the palette layout" on page 615 for more information.)
   - Select **User large icons** to toggle between large and small icons in the palette.
   - In the **Drawer options** list, click the appropriate radio button to change the way that drawers are handled in the palette. A drawer is a container for a list of icons, such as the **Favorites** drawer on the Message Flow editor's palette, or the **Entity** drawer on the Integration node Topology editor's palette.

Customizing the palette

If you customize the message flow node palette, you can make it easier to find the nodes that you use most often.

About this task

This saves time and on-screen space. For example:

- Change the order of the drawers in the palette so that the ones that you use most often are at the top.
- Hide any drawers that you do not use, to save on-screen space.
- Pin open the drawers that contain the nodes that you use most often.
- Create your own drawers to hold user-defined nodes that you create.

Customize the palette for the Message Flow editor using the Customize Palette dialog box:

Procedure

1. Switch to the Integration Development perspective.
2. Right-click the palette, then click **Customize**. The Customize Palette dialog box opens.
   - To change the order of entries and drawers in the palette, click the appropriate item in the list to highlight it, then click **Move Down** or **Move Up**. You cannot move any category above the Favorites category.
   - To hide an entry or drawer, click the appropriate item in the list to highlight it, then select the **Hide** check box.
   - To create a new separator, click **New** > **Separator**.
   - To create a new drawer:
     a. Click **New** > **Drawer**.
     b. Type a name and description for the drawer.
     c. If required, select the **Open drawer at start-up** check box.
     d. If required, select the **Pin drawer open at start-up** check box.
3. Click **OK** or **Apply** to save your changes.

Results

You have customized the message flow node palette.

Adding nodes to the Favorites category on the palette

The nodes on the palette are organized in categories. The first category is Favorites, which is usually empty. You can drag the nodes that you use most often to the Favorites category.

Before you begin

Read the concept topic about the message flow node palette.

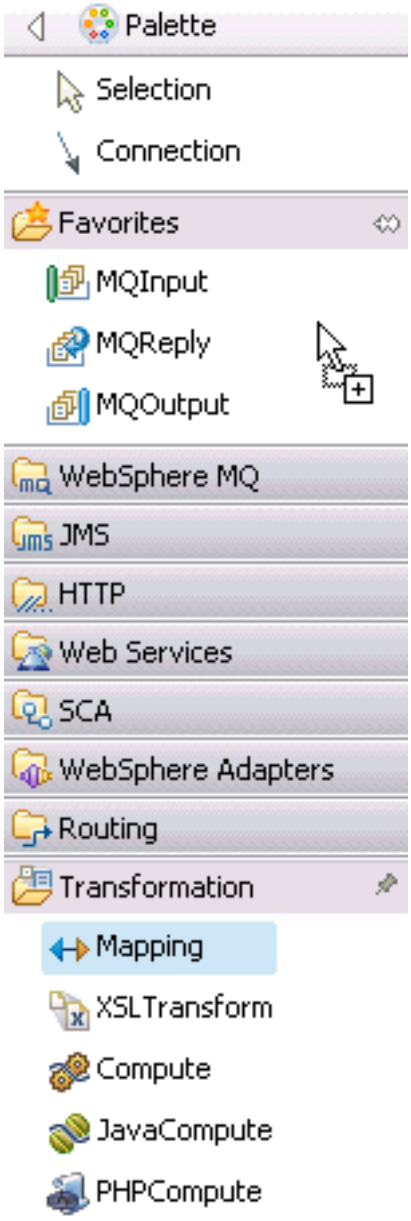
About this task

The following steps describe how to drag nodes into the Favorites category.

Procedure

1. Switch to the Integration Development perspective.
2. On the palette, open the Favorites category.
3. On the palette, open the category that contains the node that you want to add to the Favorites category.

4. Use the mouse to drag the node into the Favorites category, as shown in the following example:



Results

Alternatively, right-click the palette and choose the appropriate option to add or remove nodes from the Favorites category.

Adding a message flow node

When you have created a message flow, add nodes to define its function.

Before you begin

- Read the concept topic about message flow nodes, see "Message flow nodes" on page 484.
- Create a message flow or open an existing message flow; see "Creating a message flow" on page 574 and "Opening an existing message flow or subflow" on page 577.
- If you want to use a user-defined node or connector in your message flow, you need to install it in the IBM App Connect Enterprise Toolkit. For more information, see "Installing a user-defined node" on page 620 or "Using a connector in a message flow" on page 620.

About this task

To add a node to a message flow:

Procedure

1. Open the message flow with which you want to work.
2. Open the Palette.
   - Hold the mouse pointer over the palette bar while it is in collapsed mode. The palette bar expands. When you move the mouse pointer away from the palette bar, it collapses again.
   - Click the **Show Palette** icon at the top of the palette bar. The palette bar expands and it remains expanded when the mouse is moved away from the palette bar. To collapse the palette bar again, click the **Hide Palette** icon at the top of the palette bar while it is in expanded mode.
3. Click **Selection** above the palette of nodes.
4. Decide which node you want to add: a built-in node or a user-defined node.

   You can select any of the nodes that are displayed in the node palette, but you can add only one node at a time.

   Nodes are grouped in categories according to the function that they provide. To see descriptions of the nodes in the palette, either hold the mouse pointer over a node in the palette, or switch to the Details view by following the instructions in "Changing the palette layout" on page 615.
5. Drag the node from the node palette onto the canvas.

   When you add a node to the canvas, the editor automatically assigns a name to the node, but the name is highlighted and you can change it by entering a name of your choice. If you rename the node, the name that you choose must be unique in the message flow. If you do not change the default name at this time, you can change it later, see "Renaming a message flow node" on page 624. The default name is set to the type of node for the first instance. For example, if you add an MQInput node to the canvas, it is given the name MQInput; if you add a second MQInput node, the default name is MQInput1; the third is MQInput2, and so on.
6. Repeat steps "4" on page 619 and "5" on page 619 to add further nodes.
7. You can also add nodes from other flows into this flow:
   a) Open the other message flow.
   b) Select the node or nodes that you want to copy from the editor or outline views, and press Ctrl+C or click **Edit** > **Copy**.
   c) Return to the flow with which you are currently working.
   d) Press Ctrl+V or click **Edit** > **Paste**.

      This action copies the node or nodes into your current flow. The node names and properties are preserved in the new copy.

Results

When you have added the nodes that you want in this message flow, you can connect them to specify the flow of control through the message flow, and you can configure their properties.

What to do next

Now you can configure the nodes, see "Configuring a message flow node" on page 624.

Installing a user-defined node

Install a user-defined node for use to develop message flows.

About this task

You can develop message flows by using the user-defined node in the same way as the built-in nodes. Before you can use a user-defined node, you must install it into your IBM App Connect Enterprise Toolkit. A user-defined node is installed differently depending on how it was packaged.

Procedure

1. Install the user-defined node project:
   - If the user-defined node was packaged as plug-in JAR files, copy your JAR files into the dropins folder in your IBM App Connect Enterprise Toolkit installation location, and run the **`ace toolkit -clean -initialize`** command to pick up the new files.
   - If the user-defined node was packaged as an update site, install the plug-ins from the update site.
2. Restart your IBM App Connect Enterprise Toolkit. The user-defined nodes are displayed in the palette in the Message Flow editor under the category that you specified for the user-defined node project.

What to do next

If you have created a user-defined node in Java or C that uses a custom property compiler, you must also install the user-defined node plug-in on the integration nodes or independent integration servers onto which you want to deploy the user-defined node; see the following topics:

- "Installing user-defined extension runtime files on an integration server" on page 2456
- "Installing user-defined extension runtime files on an integration node" on page 2455

Message sets packaged with a user-defined node

Adding message sets to an update site.

About this task

Message sets are automatically packaged into user-defined node JAR files and update sites. If you drag a user-defined node from the palette onto the canvas, the IBM App Connect Enterprise Toolkit detects whether the required message sets are available in the current workspace.

Procedure

1. If the required message sets are unavailable in the current workspace, a warning is displayed in the **Problems** tab, and the **Import Required Message Sets** window opens.
2. To import the message set from the user-defined node plug-in, click **Import selected message sets**, or you can import the message sets from another source.

   If the message set is available in the same integration server at execution time, you do not have to import the message sets.

Using a connector in a message flow

The capabilities of a connector are exposed to a message flow in a user-defined node. Before you can use that user-defined node, you must install it into your IBM App Connect Enterprise Toolkit.

About this task

Connectors can be used in IBM App Connect Enterprise to interact with applications or data sources. A connector developer creates a connector for the runtime environment and a user-defined node for the IBM App Connect Enterprise Toolkit. The connector developer provides this user-defined node in a plug-in JAR file. You can develop message flows by using the user-defined node in the same way as the built-in nodes.

Procedure

To install the user-defined node into your IBM App Connect Enterprise Toolkit, complete the following steps:

1. Copy the user-defined node plug-in JAR file into the `dropins` folder in your IBM App Connect Enterprise Toolkit installation location: *`install_dir`*`/tools/dropins`.

   For example, the default installation directory on Windows is `C:\Program Files\IBM\IIB\`*`version`*`\`.
2. To ensure that the new files are available to the IBM App Connect Enterprise Toolkit, restart the Toolkit.

Results

The user-defined node for your connector is displayed in the palette in the Message Flow editor. If the connector developer specified a category in the user-defined node project, the user-defined node is displayed beneath that category.

What to do next

Add the user-defined node to a message flow by following the instructions in "Adding a message flow node" on page 618.

Adding a message flow node by using the keyboard

You can use the keyboard to perform tasks in the Message Flow editor, such as adding a node to the canvas.

Before you begin

- Ensure that you have created or opened a message flow. For more information, see "Creating a message flow" on page 574 or "Opening an existing message flow or subflow" on page 577.
- Read the concept topic, "Message flow nodes" on page 484.

Procedure

1. Open the message flow to which you want to add a node.
2. Open the Palette view or the Palette bar.
3. Select a node in the Palette view or Palette bar by using the up and down arrows to highlight the node that you want to add to the canvas.
4. Add the node to the canvas by using one of the following methods:
   - Press **Alt + L**, then press **N**.
   - Press **Shift + F10** to open the pop-up menu for the Palette, and press **N**.

   The node that you selected in the Palette bar or Palette view is placed on the canvas in the Editor view.

   When you add a node to the canvas, the editor automatically assigns a name to the node, but the name is highlighted and you can change it by entering a name of your choice. If you do not change the default name at this time, you can change it later by following the instructions in "Renaming a message flow node" on page 624. The default name is set to the type of node for the first instance. For example, if you add an MQInput node to the canvas, it is given the name MQInput. If you add a second MQInput node, the default name is MQInput1; the third is MQInput2, and so on.

Dragging a resource from the Application Development view

Drag a node or a related resource into the Message Flow editor.

Before you begin

Complete the following tasks:

- Create or open a message flow, as described in “Creating a message flow” on page 574“Creating a message flow” on page 574 and “Opening an existing message flow or subflow” on page 577.
- Read concept information in “Message flow nodes” on page 484.

About this task

To create a node, drag a resource from the Application Development view to an empty canvas. To modify an existing node, drag a resource onto that node. The following resources are supported:

- An Adapter file
- An IBM Integration Bus SCA definition file
- A database service
- An ESQL file
- A Java file
- An MQ service
- A subflow
- A WSDL file
- An XSL file

Procedure

1. Open the message flow with which you want to work.
2. Drag one of the supported resources from the Application Development view onto the canvas.
   - If you drop the resource on an empty canvas, a node is created and configured automatically.

     The following table shows the results when you drag a resource from the Application Development view onto an empty canvas:

Resource	Node created	Property set
Adapter file	A PeopleSoftInput node, SAPInput node, or SiebelInput node is created.	`Adapter component`
CORBA IDL file	A CORBARequest node is created.	`IDL file`
ESQL file	A Compute node is created.	`ESQL Module`
Java file	A JavaCompute node is created.	`Java Class`
WSDL file	A SOAPInput node, SOAPRequest node, or SOAPAsyncRequest node is created.	`WSDL file name`
XSL file	An XSLTransform node is created.	`Stylesheet`

   - If you drop the resource onto an existing node, the relevant node property is updated with the name of the resource file. For example, if you drop a Java file onto a JavaCompute node, the `Java Class` property is set to the class name of the Java file that you are dropping. If you drop an ESQL file over any node that uses ESQL, such as a Database node, the `ESQL Module` property is set. Further examples include dropping an MQ Service onto an MQ node to configure it, or dropping a database service onto a Compute node to configure it.

Adding a subflow

In a message flow, you can include an embedded message flow, also known as a *subflow*. For example, you might define a subflow that provides error handling, and include it in a message flow connected to a failure terminal on a node that can generate an error in some situations.

Before you begin

To complete this task, you must have created your subflow in either a `.subflow` file, or in a `.msgflow` file. You must also have created a message flow in which to insert the subflow.

- For more information about creating a `.subflow` file, see "Creating a subflow" on page 575.
- For more information about creating a `.msgflow` file, see "Creating a message flow" on page 574.
- For more information about the differences between subflows defined in `.subflow` files and subflows defined in `.msgflow` files, see "Subflows" on page 488.

About this task

You can embed subflows into your message flow if either of the following statements is true:

- The subflow that you want to embed is defined in the same application, library, or integration project as the message flow.
- The subflow is defined in a different library, and you have specified the dependency of the current application, library, or integration project on that other library.

If you want to embed subflows into other subflows, be aware of the following information:

- You can embed subflows that are defined in `.subflow` files into subflows that are defined in `.subflow` files and `.msgflow` files.
- You can embed subflows that are defined in `.msgflow` files into subflows that are defined only in `.msgflow` files.
- A subflow in a shared library can contain another subflow in the same library or in another shared library.

Subflows in shared libraries cannot be in the default broker schema.

When an application or shared library references other shared libraries, all the subflows for a broker schema must be in a single container. Subflows for a broker schema must not be in both an application (or shared library) and a shared library that is referenced by that application (or shared library). Subflows for a broker schema must not be in two or more shared libraries that are referenced by a single application or shared library. All the subflows in a broker schema must be either in the main application or shared library, or in a single referenced shared library.

Procedure

To add a subflow to a message flow or subflow, complete the following steps:

1. Open the message flow or subflow in which you want to embed the subflow.
2. To add a subflow, drag the message flow or subflow that you want to add from the Application Development view to the editor.

   Alternatively, click **Flow** > **Add subflow**, then select the flow that you want to add from the list.

   The embedded subflow is shown in the Message Flow editor as a single node with the terminals that represent the Input and Output nodes that you have included in the subflow.
3. Connect the subflow node to one or more of the nodes in the main message flow or subflow.

   For more details, see "Connecting message flow nodes" on page 636.
4. To add and connect further subflow nodes, repeat steps "2" on page 623 and "3" on page 623.
5. To work with the contents of the subflow, double-click the subflow icon.

   The subflow opens in the Message Flow editor.

What to do next

Renaming a message flow node

You can change the name of any type of message flow node (a built-in node, user-defined node, or subflow node) to reflect its purpose.

Before you begin

Complete the following tasks:

- Create a message flow, as described in "Creating a message flow" on page 574.
- Read the concept topic, "Message flow nodes" on page 484.

About this task

When you first add a message flow node to the canvas, the editor automatically assigns a name to the node; the name is highlighted, and you can change it by entering a name of your choice. If you do not change the default name at this time, you can change it later, as described in this topic. For example, you might include a Compute node to calculate the price of a specific part in an order; you could change the name of the node to Calculate_Price.

When you rename a node, use only the supported characters for this entity. The editor prevents you from entering unsupported characters.

To rename a node:

Procedure

1. Switch to the Integration Development perspective.
2. Open the message flow with which you want to work.
3. You can rename a message flow node in three ways:
   - Right-click the node and click **Rename**. The name is highlighted; enter a name of your choice and press **Enter**.
   - Click the node to select it, then click the name of the node so that it is highlighted; enter a name of your choice and press **Enter**.
   - Click the node to select it, then on the Description tab of the Properties view, enter a name of your choice in the Node name field.

   The name that you enter must be unique in the message flow.

What to do next

If you generate ESQL code for a Compute, Database, or Filter node, the code is contained in a module that is associated with the node. The name of the module in the ESQL file must match the name specified for the module in the *ESQL Module* property of the corresponding node. You can modify the module name, and change it from its default value (which is the name of the message flow, concatenated with the name of the node with which the module is associated). However, ensure that the module in the ESQL file matches the node property.

Configuring a message flow node

When you have included an instance of a node in your message flow, you can configure its properties to customize how it works.

Before you begin

- Read the concept topic about message flow nodes

- Add a node

Viewing the properties of a node

About this task

To view a node's properties:

Procedure

1. In the Message Flow editor, open the message flow with which you want to work.
2. To open the Properties view, right-click a node and click **Properties**.

   The selected node's properties are displayed. You can edit the properties.

Editing the properties of a node

About this task

Properties are organized into related groups and displayed on tabs. Each tab is listed on the left of the Properties view. Click each tab to view the properties that you can edit.

Procedure

- Every node has at least one tab, **Description**, where you can change the name of the node and enter short and long descriptions. The description fields are optional because they are used only for documentation purposes.
- If a property is mandatory (that is, one for which you must enter a value), the property name is marked with an asterisk, as shown in the following example:

  ```
  Queue Name* _______________________________
  ```

- Many nodes have properties that require XPath expressions, typically to identify the location of a particular resource.

  For example, for the MQInput node, you can specify the location of the security token and password by using either ESQL or XPath expressions. For help in constructing an XPath expression, you can open the XPath Expression Builder by clicking **Edit** next to each XPath property. For more information about using XPath expressions, see “Using XPath” on page 626.

What to do next

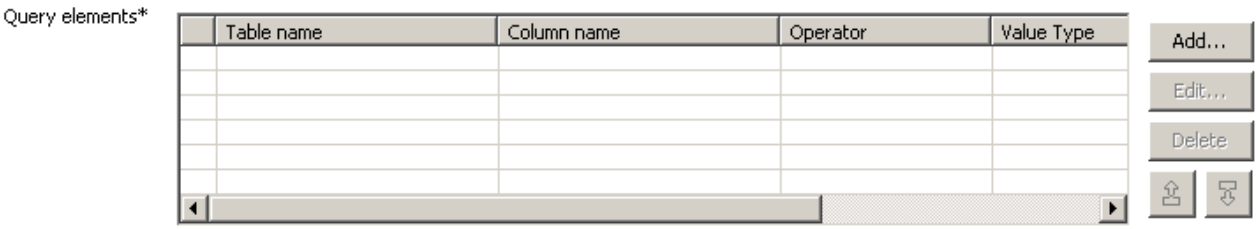
For detailed information about how to configure individual built-in nodes, see the reference topic for the relevant node (see Built-in nodes).

If you have included a user-defined node, refer to the documentation that came with the node to understand if, and how, you can configure its properties.

Editing complex properties

About this task

A complex property is a property to which you can assign multiple values. Complex properties are displayed in a table in the Properties view, where you can add, edit, and delete values, and change the order of the values in the table. This example shows the `Query elements` complex property of the DatabaseRoute node.



Procedure

- To add a value to a complex property, click **Add**, enter the required fields in the dialog box that opens, then click **OK**.

  The values appear in the table. Repeat this step to enter as many values as are required.
- To edit a value, click any element in a row, click **Edit**, edit any of the values in the dialog box, then click **OK**.
- To delete a value, click any element in a row and click **Delete**.

  The entire row is deleted.
- To change the order of values in the table, click any element in a row and click the up icon  or down icon  to move the row.

Overriding properties at deployment time

About this task

You can override some node property values when you deploy a message flow. These property values are known as configurable properties, and you can use them to modify some characteristics of a deployed message flow without changing the message flow definitions. For example, you can update queue manager and data source information.

Even though you can set values for configurable properties at deployment time, you must set values for these properties within the message flow if they are mandatory. Each built-in node reference topic contains a table of properties, which identifies the configurable and mandatory properties.

You can override message flow node properties at run time by deploying policies, either directly to an integration server or in a BAR file with your message flows. Alternatively, you can put policies in the `overrides` sub-directory of the integration server work directory. For more information, see "Overriding properties at run time with policies" on page 324.

What to do next

Next: connect the nodes.

Using XPath

XPath provides an alternative method to ESQL for entering expressions in the property fields of specific built-in nodes.

About this task

In addition to ESQL as a message transformation language, IBM App Connect Enterprise supports an alternative expression grammar in property fields. For more information, see ESQL-to-XPath mapping table.

You can use ESQL or XPath expressions in built-in nodes, within your message flows, to query or update message trees that are specified as accessible, and that you expect to be processed by a given node.

This section provides information on:

XPath overview

The XML Path Language (XPath) is used to uniquely identify or address parts of an XML document. An XPath expression can be used to search through an XML document, and extract information from any part of the document, such as an element or attribute (referred to as a *node* in XML) in it. XPath can be used alone or in conjunction with XSLT.

Some of the built-in nodes provided in the IBM App Connect Enterprise Toolkit can use XPath expressions to specify the part of a message that is processed by the node. For example, you can use an XPath expression to identify fields in a message and determine if they match a specified value, or to set the field value by updating it with the results of a database query.

You can use XPath 1.0 path expressions in your flow to access specific parts of an incoming message, create or locate parts of an outgoing message, and perform complex message processing that might involve values present in message trees accessible by a node so that you can transform, filter, or retrieve values from a message.

For example, the Route node applies XPath 1.0 general expressions to the content of message trees associated with the incoming message assembly for this node. Following evaluation of an expression the result is cast as a Boolean (true or false) result, and this in turn is used to determine if a copy of the incoming message is routed down an output terminal associated with the processed expression.

If you have XML schema or DFDL message definition files (.xsd), or Message Sets (.mxsd) present in your workspace, any elements, attributes or data types defined in such definitions can be loaded into the Data types viewer and selected to automatically generate a path expressions mapping to the definition concerned.

Equally, depending on the XPath expressions supported by the property concerned, you can select XPath functions and operators to include in an expression, or you can build your own expressions manually.

The **Data types viewer** contains a list of variables relating to trees that can be accessed by expressions for the node property concerned.

For example, `$InputRoot` gives access to the incoming message tree. The fixed format of standard folders you can expect to exist under this tree, for example, `Properties` and `MQMD` are described without the need to import an `.mxsd` definition for them. These structures can be navigated in the viewer and, on selection of an element within them, a path expression that maps to the element in question is built automatically through the XPath 1.0 language.

For further information on XPath 1.0 see W3C XPath 1.0 Specification.

You can use the XPath Expression Builder to visually build XPath expressions to set the relevant properties in your nodes. You launch the XPath Expression Builder from buttons located along side property fields present in the Properties viewer, for those nodes that support the use of XPath expressions as property values.

The XPath files in IBM App Connect Enterprise are supplied in three property editors; see XPath property editors for more details.

The XPath editor supports both content-assist directly on the text field and also an **Edit...** button that launches the XPath builder dialog. The dialog gives you a larger area in which to build your XPath expressions.

The content assist based control contains two different proposal lists in the following order:

1. Nodes and Variables

2. Functions and Operators

The node and variable proposals are displayed the first time that you use the XPath editor. In this view, the status bar reads `Press` **`Ctrl+Space`** `to show Function and Operation Proposals`.

Pressing **`Ctrl+Space`** when you are in the function and operator level proposals selects the Node and Variable proposals.

Note: In the Graphical Data Mapping editor, you can use XPath 2.0 functions and expressions. You can use XPath functions to define graphical transformations in your message. You can use XPath expressions to define conditions for your transformations.

Namespace support
The XPath Expression builder provides qualified support for namespaces.

The XPath Expression builder dialog contains a namespace settings table that:

- Supports simplified expressions that enable qualified namespace matching at run time
- Can be auto-generated based on imported schema definitions and generated expressions (based on selections made in the dialog when you build an expression)
- Allows you to add your own entries to the table

The table encapsulates deployable data passed to the runtime environment, as part of the nodes attribute data, and is used by the node to modify expressions through prefix-to-URI substitution. The final expressions support namespace matching, because they are processed against a target tree when employed by their associated message processing engine, that is, the XPath 1.0 runtime engine or ESQL runtime engine.

When you enter an ESQL field reference expression in a read-only or read-write path field, or an XPath 1.0 path expression in a read-only or read-write path field, or a general expression field (general expressions can contain zero or more path expressions), IBM App Connect Enterprise understands the language from the syntax you use.

XPath is the default for general expression fields that are validated by ensuring they conform to the XPath 1.0 grammar. For path expression fields XPath is assumed if the expression is valid and begins with a $ sign.

The language you can use is dictated by the property editor currently in use for a node's property field.

Namespace prefixes are used in an XPath or ESQL expression to make the statements shorter and easier to understand, while still supporting the ability to qualify an element name match by also matching on its associated namespace URI.

For example, consider the following message, where namespace prefix b is overridden through an inner declaration:

```
<b:a xmlns:b='xyz'>
 <!-- the namespace of elements 'a' and 'c' using prefix 'b'  is xyz -->
 <b:c>
  <b:d  xmlns:b='qrs'>
   <!-- the namespace of elements 'd' and 'e' using prefix 'b' is now qrs -->
   <b:e>100</b:e>
  </b:d>
 </b:c>
</b:a>
```

Note that the scope of a namespace declaration declaring a prefix extends from the beginning of the start tag in which it appears to the end of the corresponding end tag, excluding the scope of any inner declarations with the same namespace prefix. In the case of an empty tag, the scope is the tag itself: >.

To navigate to element e in the above message use the following human-readable XPath expression:

```
/b:a/b:c/b2:d/b2:e
```

Note, that to prevent the auto-generated prefix to the URI map produced in the expression dialog overloading the same prefix (in this case b), the inner b prefix is appended with a numeric value to distinguish it from the outer b prefix. This strategy is repeated for each prefix name clash.

This notation is similar to the equivalent human-readable ESQL expression:

```
Root.b:a.b:c.b2:d.b2:e
```

To support namespace prefixes within expressions, the XPath Expression Builder Dialog automatically generates a prefix to a URI namespace settings table (based on the content of imported schema definitions, through which expressions are generated) .

Without the use of namespace prefixes to URI mapping data in this table, the runtime environment would be forced to take a less efficient approach, where portable but verbose XPath expressions would be required by it to provide namespace matching support.

The previous expression:

```
/b:a/b:c/b2:d/b2:e
```

would take the form:

```
/*[namespace-uri()='xyz' and local-name()='a']/*[namespace-uri()='xyz'
   and local-name()='c']/*[namespace-uri()='qrs' and
   local-name()='d']/*[namespace-uri()='qrs' and local-name()='e']
```

XPath Expression Builder
You can launch the XPath Expression Builder from most property fields that support, or expect, XPath expressions as a value that can be entered into the field.

The use of the XPath Expression Builder is optional, in that it is an aid to you in developing message flow applications. The XPath Expression Builder helps you to construct message processing expressions in either XPath or ESQL. You are free to enter expressions by hand, or use the XPath Expression Builder to help construct such expressions.

The XPath Expression Builder does not support use of the $Body variable. You can use the $Body variable when you enter an expression by hand, but the XPath Expression Builder and associated validation in the IBM App Connect Enterprise Toolkit do not support it. Use the $Root variable instead.

You can populate the fields, regardless of the state of the node; that is, whether the node is detached or connected, or fully, partially, or completely unconfigured.

You launch the XPath Expression Builder from a button in the following locations:

- Table cells, located to the right of the text entry field within the cell.
- **Add** or **Edit** dialog boxes used to construct rows in tables, located to right of the property field concerned.
- Tabs in the property viewer for a node, to the right of a property field.

Variables (or in ESQL terminology, correlation names) provide a list of all message tree start points that are applicable to the property field from which the dialog was launched.

If a field is a read-only or a read-write path field, expressions must start with such a variable to indicate which tree in which message assembly the path expression is mapping to.

XPath variable names map to existing correlation names found in ESQL field reference expressions, but to conform to the ESQL grammar they are designated as variable references by prefixing them with the dollar ($) character.

For example:

ESQL
```
Root.XMLNSC.CUST_DETAILS.NAME
```

XPATH
```
$Root/XMLNSC/CUST_DETAILS/NAME
```

The variable indicates to which tree and where in that tree the expression is anchored.

The XPath Expression Builder dialog box supports validation, which you can turn off on the XPath preferences page by clearing the **Validate when creating XPath expressions** check box.

If you select the `$Root` or `$Body` variables and create an expression that refers to the body of the message, the XPath expression contains the message element. This expression is correct for message bodies owned by the XMLNSC, XMLNS, XML, and DataObject domains.

For message bodies that are owned by the SOAP, MIME, MRM, and IDOC domains, you must remove the message element from the expression.

For example, the XPath expression `$Body/my_message/my_field` is correct for XMLNSC, but must be changed to `$Body/my_field` to be correct for MRM.

Views

There are three main views when functions are supported.

Whether a view is displayed, and what is displayed in it, depends on what type of property editor you have used to launch the dialog, and its tailored settings; for example, for path type fields you do not see a functions pane. The operators that are supported can change as can the list of applicable variables.

Data Types Viewer
This view shows the different schema types, elements, and attributes that you can use within the XPath expression that you are creating, as well as the allowable variable references.

XPath Function
This view shows four main top level categories, which are:

String
This category corresponds to the description in the XPath 1.0 specification of `section-String-Functions`.

Boolean
This category corresponds to the description in the XPath 1.0 specification of `section-Boolean-Functions`.

Numeric
This category corresponds to the description in the XPath 1.0 specification of `section-Number-Functions`.

Nodeset
This category corresponds to the description in the XPath 1.0 specification of `section-Node-Set-Functions`.

For information on the format of XPath 1.0 expressions see the W3C XPath 1.0 Specification.

Operators
This view shows a list of all of the available operators that you can use within the given XPath expression.

Namespace settings

If you expand **Namespace settings** in the XPath Expression Builder dialog you see a table of Prefix and Namespace pair strings. This table is automatically updated when XPath expressions are created. If the default prefix generated is not what you want, you can change it by clicking **Change Prefix**.

To add a prefix and namespace map entry click **Add** and complete the fields in the dialog.

To edit or delete an entry in the table, select the item and click **Edit** or **Delete** respectively.

Edit opens another field dialog allowing you to change the prefix and namespace.

For information about the preferences supplied with the XPath editor, see “XPath editor preferences” on page 631.

XPath editor preferences
This topic describes the possible options available to you when you use the XPath editor.

The following lists describe the custom preferences used in the XPath editor.

- Validation option:

  Validation when building XPath expressions
  Default: checked.

  This option is used to perform validation each time you update the XPath expression. As validation requires re-parsing the expression against the XML Schema document you can turn this option off, for example, if you are dealing with very large complex XPath expressions.

- Content Assist display options:

  Show XML Schema model groups
  Default: not checked.

  This option allows you to view XML schema model groups, or not.

  Show type in XML Schema tree
  Default: checked.

  This option allows you to view the `<type name>` in both the Content Assist view and the XPath expression builder, or not.

  Show function parameters
  Default: checked.

  This option allows you to have function parameters shown, or not.

  Show function return type
  Default: checked.

  This option allows you to have function return types shown, or not.

  Show content assist description
  Default: checked.

  This option allows you to view the description of a given selected entry in the Content Assist view, or not..

- Auto-Activation option:

  Enable auto activation
  Default: checked.

  When this option is active, the Content Assist field appears whenever the cursor is after one of the following characters:

  – / - Forward slash character
  – [- left bracket character
  – (- Left parentheses character
  – , - Comma character

  You set the delay time, before the Content Assist field appears, in the **Auto activation delay** field. The time is in milliseconds and the range is a positive number between zero and 9999.

- Content assist color options:

  This preference allows you to customize the background and foreground colors for the Content Assist fields. The default background color is (red, green, blue - 254, 241, 233) and the default foreground color is (red, green, blue - 0, 0, 0) - black.

XPath expressions supported by default
XPath supports a number of expressions by default.

The following expressions are supported:

Read-only fields

$Root, $Body, $Properties, $LocalEnvironment, $DestinationList, $ExceptionList, $InputRoot , $InputBody, $InputProperties, $InputLocalEnvironment, $InputDestinationList, $InputExceptionList, $Environment.

To exclude variables for a node property from the default list, specify a comma separated string of variables. For example, specifying:

```
"com.ibm.etools.mft.ibmnodes.editors.xpath.XPathReadOnlyPropertyEditor", "InputRoot ,
 InputBody, InputProperties, InputLocalEnvironment, InputDestinationList,
 InputExceptionList"
```

restricts the XPath field to support only:

```
$Root, $Body, $Properties, $LocalEnvironment,  $DestinationList, $ExceptionList'
$Environment
```

Read-write fields

$InputRoot , $InputBody, $InputProperties, $InputLocalEnvironment, $InputDestinationList, $InputExceptionList, $OutputRoot , $OutputLocalEnvironment, $OutputDestinationList, $OutputExceptionList, $Environment.

To exclude variables for a node property from the default list, specify a comma separated string of variables. For example, specifying:

```
"com.ibm.etools.mft.ibmnodes.editors.xpath.XPathReadWritePropertyEditor", "InputRoot ,
 InputBody, InputProperties, InputLocalEnvironment, InputDestinationList,
 InputExceptionList"
```

restricts the XPath field to support only:

```
$OutputRoot, $OutputLocalEnvironment, $OutputDestinationList, $OutputExceptionList,
 $Environment
```

Expression fields

$Root, $Body, $Properties, $LocalEnvironment, $DestinationList, $ExceptionList, $InputRoot , $InputBody, $InputProperties, $InputLocalEnvironment, $InputDestinationList, $InputExceptionList, $OutputRoot , $OutputLocalEnvironment, $OutputDestinationList, $OutputExceptionList, $Environment.

To exclude variables for a node property from the default list, specify a comma separated string of variables. For example, specifying:

```
"com.ibm.etools.mft.ibmnodes.editors.xpath.XPathPropertyEditor", "InputRoot ,
InputBody, InputProperties, InputLocalEnvironment, InputDestinationList,
InputExceptionList, OutputRoot , OutputLocalEnvironment, OutputDestinationList,
OutputExceptionList"
```

restricts the XPath field to support only:

```
$Root, $Body, $Properties, $LocalEnvironment,  $DestinationList, $ExceptionList,
 $Environment.
```

Creating XPath expressions

Many message flow nodes provide properties that can be specified using an XPath 1.0 expression, for example properties to set data locations for Monitoring or Security where this language is used to form

a path expression to locate incoming message body elements. The Mapping node supports XPath 2.0 functions and expressions.

About this task

Other less common node property fields support the entry of general XPath 1.0 expressions that support a wider range of the language to perform more complex evaluations in the integration node's XPath 1.0 runtime engine.

Note: In the Graphical Data Mapping editor, you can use XPath 2.0 functions and expressions. You can use XPath functions to define graphical transformations in your message. You can use XPath expressions to define conditions for your transformations.

The XPath Expression builder provides a tree view of a message, and supports the automatic generation of an XPath 1.0 path expression, through the selection of an element within the tree.

The **Schema Viewer** section provides a tree view of the input message. To visually build your XPath expression follow these steps:

Procedure

1. Add the relevant node to your message flow
2. In the Properties viewer, enter the correlation name, or press Ctrl + Space to use content assist, or press Edit to use the Expression editor.

   Content assist is also invoked by simply typing $ in cell-based property fields. See "Correlation names" on page 519 for further information on correlation names.
3. Expand the tree, navigate to the field for which you want to build an expression, and click to select it.

   A field is either an element, or an attribute.

   Double-click the field to add it to the XPath expression. You can also drag fields, functions, and operators to the desired location in the XPath expression when using the XPath Expression builder.
4. To set conditions, enter them as you would a normal XPath Expression.

Results

The complete XPath expression is shown either:

- In the XPath Expression pane if you are using the XPath Expression builder.

  The Expression builder dialog is an optional aid for generating expressions that, when complete, form the value in a node's property field.

  If you do not use the Expression builder dialog, the expressions entered manually are validated using the property editor.
- In the Property field if it is in the node itself.

Messages are displayed at the top of the XPath Editor window to alert you to the fact that a path or expression you have entered is not valid.

Note: The editor does not prevent you from entering, and saving, an expression that is not valid.

Example

Here is the XPath expression built in the XPath Expression Builder to filter the Employee business objects for all employees who are managers: `$Root/XMLNSC/getEmployeeInfo/Emp[isManager=true()]`.

- `$Root/XMLNSC/`: The body section of the message; that is, the last child of root. This example assumes that the XMLNSC domain is being used.
- `/getEmployeeInfo`: The name of the operation in the interface.
- `/Emp`: The name of the input message type.
- `[isManager=true()]`: Checks whether the `isManager` field is set to true.

In this case the same expression works for both request and response flows, because the input and output messages for the operation are identical.

For more information on XPath 1.0, see W3C XPath 1.0 Specification.

Selecting the grammar mode
The grammar mode allows you to use only a restricted set of expressions, in either XPath or ESQL, and checks whether the syntax you have entered is valid.

About this task

IBM App Connect Enterprise supports the following field categories:

- Read-only path field
- Read-write path field
- Expression field

Each of these field types can be either fixed or mixed language, that is, ESQL, XPath, or either.

If you use XPath syntax, and the expressions are not supported for the property you are using, the syntax is rejected during the validation process.

ESQL and XPath have similar restrictions on the syntax that is permitted for the first two of these field types. There are restrictions to the expression fields as well, but as this type of field supports general expressions that can be used in either language, the range of syntax available is greater than in the first two.

IBM App Connect Enterprise uses code assistance in the grammar management of XPath 1.0 to validate the syntax of expressions you enter. This assistance is always available, regardless of the grammar mode you are using.

By default, you are operating in the restricted grammar mode.

Code assistance enables you to construct syntactically correct expressions but it does not validate those expressions. Validation is performed by property editors in which such expressions are entered.

If you attempt to use an expression that is not valid, the property editor marks it as such, either from a syntax or schema validation perspective.

You receive error or warning messages depending on the preference choices you set in **Windows>Preferences>Broker Development>XPath>Validation** .

If, under the above validation settings, particular checks are to be marked as errors, error markers are shown in the problems viewer. This behavior results in a message flow being marked as broken, and it cannot then be imported into, or compiled in, a deployable BAR file using the BAR editor.

If you want to use the appropriate unrestricted grammar to input a specific field type, property editors do not force restricted forms of ESQL or XPath 1.0 expressions for such fields that expect them. Instead, you can enter the full range of syntax in the context of the field category concerned, namely, path or general expression, without the validation checks being applied. This means that if you need to, you can deploy the full range of syntax supported by the ESQL or XPath 1.0 runtime environment. Note, however, that such expressions might not be in a form that can be converted to the other language.

To use unrestricted grammar, carry out the following procedure:

Procedure

1. Click **Window -> Preferences** and expand Integration Development.
2. Expand **XPath** and click **Grammar**.
3. Clear the **Use XPath and ESQL equivalent grammar** check box.

What to do next

Note that expressions are still checked for valid syntax appropriate in the context of the field type, but you can now use the full range of grammar supported by the runtime environment.

Using dynamic terminals

You can add, rename, and remove dynamic terminals on a node in the Message Flow editor.

Before you begin

- Add a node that supports dynamic terminals; for more details, see "Adding a message flow node" on page 618 and "Message flow node terminals" on page 497.

About this task

Some message flow nodes support dynamic input or output terminals, including the Collector, Route, and DatabaseRoute nodes. When you have added a node to the flow editor, you can add, remove, or change dynamic terminals.

Procedure

- **Adding a dynamic terminal**
  a) Right-click the node and click **Add Input Terminal** or **Add Output Terminal**.
  b) Enter a name for the new terminal and click **OK**.

     The name must be unique for the terminal type. For example, if an input terminal called *In* already exists, you cannot create a dynamic input terminal with the name *In*.

     The new terminal is displayed on the node. If a node has five or more terminals, they are displayed as a terminal group. The following example shows a Route node with more than four output terminals.  To connect a particular output terminal, click the terminal group to open the Terminal Selection dialog box, or right-click the node and select **Create Connection**.
- **Renaming a dynamic terminal**
  a) Right-click the node and click **Rename Input Terminal** or **Rename Output Terminal**.

     These options are available only if you have added one or more appropriate terminals to this node.
  b) Select from the list the name of the terminal that you want to change.

     Only dynamic terminals are listed because you cannot change the name of a static terminal.
  c) Enter a new name for the terminal and click **OK**.

     Do not rename a dynamic terminal if one of the node properties is configured to use that name.
- **Removing a dynamic terminal**
  a) Right-click the node and click **Remove Input Terminal** or **Remove Output Terminal**,

     These options are available only if you have added one or more appropriate terminals to this node.
  b) Select from the list the name of the terminal that you want to remove and click **OK**.

     Only dynamic terminals are listed because you cannot remove a static terminal. Do not remove a dynamic terminal if one of the node properties is configured to use that terminal.

What to do next

When you have added dynamic terminals to a node, connect them to other nodes in the message flow; for more information, see "Connecting message flow nodes" on page 636.

Removing a message flow node

When you have created and populated a message flow, you might need to remove a node to change the function of the flow, or to replace it with another more appropriate node. The node can be a built-in node, a user-defined node, or a subflow node.

Before you begin

This topic assumes that you have completed one or more of the following tasks.

- Create a message flow, or open an existing message flow, as described in "Creating a message flow" on page 574 and "Opening an existing message flow or subflow" on page 577.
- Add a node to the message flow, as described in "Adding a message flow node" on page 618.
- Add a subflow, as described in "Adding a subflow" on page 623.
- Read background information about nodes in "Message flow nodes" on page 484.

About this task

To remove a node from a message flow, complete the following steps.

Procedure

1. Open the message flow with which you want to work.
2. Highlight the node that you want to remove and click **Edit** > **Delete**.

   The node is removed from the flow. If you have created any connections between that node and any other node, those connections are also deleted when you delete the node.
3. If you delete a node in error, you can restore it by clicking **Edit** > **Undo Delete** or pressing Ctrl+Z. The node and its connections, if any, are restored.
4. If you undo the deletion, but decide that it is correct to delete the node, click **Edit** > **Redo Delete**.

Connecting message flow nodes

When you include more than one node in your message flow, you must connect the nodes to indicate how the flow of control passes from input to output. The nodes can be built-in nodes, user-defined nodes, or subflow nodes.

Before you begin

Complete the following tasks.

- Add a note to your message flow, as described in "Adding a message flow node" on page 618.
- Add a subflow to your message flow, as described in "Adding a subflow" on page 623.
- Read the concept topic, "Message flow connections" on page 497.

About this task

Your message flow might contain just one MQInput node, one Compute node, and one MQOutput node. Or it might involve a large number of nodes, and perhaps embedded message flows, that provide a number of paths through which a message can travel depending on its content. You might also have some error processing routines included in the flow. You might also need to control the order of processing.

You can connect a single output terminal of one node to the input terminal of more than one node (this is known as fan-out). If you do this, the same message is propagated to all target nodes, but you have no control over the order in which the subsequent paths through the message flow are executed (except with the FlowOrder node).

You can also connect the output terminal of several nodes to a single node input terminal (this is known as fan-in). Again, the messages that are received by the target node are not received in any guaranteed order.

When you have completed a connection, it is displayed as a black line, and is drawn as close as possible to a straight line between the connected terminals. This behavior might result in the connection passing across other nodes. To avoid this problem, you can add bend points to the connection.

To view metadata information for a node, subflow, or connection:

1. Switch to the Integration Development perspective.
2. Open a message flow.
3. In the Message Flow editor, hold the mouse pointer over a node, a subflow, or a node connection in the open message flow by placing the mouse over the element.

A custom tooltip is displayed below the element.

- To turn the pop-up window into a scrollable window, press **F2**.
- To hide the pop-up window, either press Esc or move the mouse away from the node.

If you define a complex message flow, you might have to create a large number of connections. The principle is the same for every connection. You create connections either by using the mouse, or by using the Terminal Selection dialog. See "Creating node connections with the mouse" on page 637 and "Creating node connections with the Terminal Selection dialog box" on page 638 for more information.

Creating node connections with the mouse

Use the mouse to connect one node to another.

Before you begin

Read the concept topic about connections.

About this task

Procedure

1. Switch to the Integration Development perspective.
2. Open the message flow with which you want to work.
3. Click the terminal from which the connection is to be made; that is, the terminal from which the message is propagated from the current node.

   For example, you can click the Failure, Out, or Catch terminal of the MQInput node. Hold the mouse pointer over each terminal to see the name of the terminal. You do not need to keep the mouse button pressed.

   Alternatively, click **Connection** on the palette, then click the node from which the connection is to be made. The Terminal Selection dialog box opens for you to choose the terminal from which to make a connection. Click **OK**. If a node has five or more input or output terminals (for example, if you have added dynamic terminals), they are displayed in a group. The following example shows a node with more than four output nodes.  To select a particular output terminal, click the grouped output terminal to open the Terminal Selection dialog box.
4. Click the input terminal of the next node in the message flow (to which the message passes for further processing).

   The connection is made when you click a valid input terminal. The connection appears as a black line between the two terminals.

Results

To view metadata information for a node, subflow, or connection:

1. Switch to the Integration Development perspective.
2. Open a message flow.
3. In the Message Flow editor, hold the mouse pointer over a node, a subflow, or a node connection in the open message flow by placing the mouse over the element.

A custom tooltip is displayed below the element.

- To turn the pop-up window into a scrollable window, press **F2**.
- To hide the pop-up window, either press Esc or move the mouse away from the node.

What to do next

Next: add a bend point, as described in "Adding a bend point" on page 640.

Creating node connections with the Terminal Selection dialog box

Use the Terminal Selection dialog box to connect one node to another.

Before you begin

Read the concept topic about connections.

About this task

1. Switch to the Integration Development perspective.
2. Open the message flow with which you want to work.
3. Click **Connection** above the node palette.
4. Click the node from which you want the connection to be made. The Terminal Selection dialog box is displayed.
5. Select the terminal from the list of valid terminals on this node. Click **OK**. The dialog box closes.
6. Click the node to which to make the connection. If this node has only one input terminal, the connection is made immediately. If this node has more than one input terminal, the Terminal Selection dialog box is displayed again, listing the input terminals of the selected node. Click the correct terminal and click **OK**.

Alternatively, you can make a connection in the following way:

Procedure

1. Click **Selection** above the node palette.
2. Right-click the node from which you want to make the connection and click **Create Connection**. The Terminal Selection dialog box is displayed.
3. Select the terminal from the list of valid terminals on this node. Click **OK**. The dialog box closes.
4. Click the node to which to make the connection. If this node has only one input terminal, the connection is made immediately. If this node has more than one input terminal, the Terminal Selection dialog box is displayed again, listing the input terminals of the selected node. Click the correct terminal and click **OK**.

Results

To view metadata information for a node, subflow, or connection:

1. Switch to the Integration Development perspective.
2. Open a message flow.

3. In the Message Flow editor, hold the mouse pointer over a node, a subflow, or a node connection in the open message flow by placing the mouse over the element.

A custom tooltip is displayed below the element.

- To turn the pop-up window into a scrollable window, press **F2**.
- To hide the pop-up window, either press Esc or move the mouse away from the node.

What to do next

Next: add a bend point, as described in "Adding a bend point" on page 640.

Inserting nodes into existing message flows

You can insert a node into an existing message flow without having to delete existing connections and create connections for the new node.

Before you begin

The following instructions assume that you have created a message flow, as described in "Creating a message flow" on page 574.

About this task

In earlier versions of IBM App Connect Enterprise, to insert a new node into a message flow, you had to delete the existing connection between two nodes, insert the new node, then create new connections between the existing nodes and the new node. From WebSphere Message Broker Version 7.0 onwards, you can insert a new node in one step by dropping it onto an existing connection, as described by the following steps.

Procedure

1. In the Message Flow editor, open the message flow into which you want to insert a new node.
2. Choose the node that you want to insert from the message flow node palette.
3. Drag the node onto the connection between the two nodes where you want the new node to be added.

   When the mouse pointer is over the connection, a label is displayed saying "Add a node here". When you release the mouse button, the node is inserted in the message flow and is automatically connected to the preceding and succeeding nodes.

Removing a node connection

The message flow editor displays the nodes and connections in the editor view. You can remove connections to change the way in which the message flow processes messages.

Before you begin

Complete the following tasks:

- "Connecting message flow nodes" on page 636.
- Read the concept topic, "Message flow connections" on page 497.

About this task

To remove a connection that you have created between two nodes:

Procedure

1. Open the message flow that you want to work with.
2. Click **Selection** above the node palette.

3. Select the connection that you want to delete.

   When you hold the mouse pointer over the connection, the editor highlights the connection that you have selected by thickening its line, adding an arrowhead at the target terminal end, and annotating the connection with the name of the two terminals connected, for example Out->In.

   When you select the connection, the editor appends a small black square at each end and at every bend point of the connection, and a small arrowhead at the target terminal end. The annotation disappears when you select the connection.
4. Check that the selected connection is the one that you want to delete.
5. Right-click the connection and click **Delete**, press the Delete key, or click **Edit** > **Delete**.

   If you want to delete further connections, repeat these actions from step "3" on page 640.
6. If you delete a connection in error, you can restore it by right-clicking in the editor view and clicking **Undo Delete**.

   The connection is restored.
7. If you undo the delete, but decide that it is the correct delete action, you can right-click in the editor view and click **Redo Delete**.

   You can also delete a connection by selecting it in the Outline view and pressing the Delete key.

Results

If you delete a node, its connections are automatically removed; you do not have to do this as a separate task.

Adding a bend point

When you are working with a message flow, and connecting your chosen nodes together to determine the flow of control, you might find that a connection that you have made crosses over an intervening node and makes the flow of control difficult to follow. To help you to display the message flow nodes and their connections in a clear way, you can add bend points to the connections that you have made to improve the organization of the display. The addition of bend points has no effect on the execution of the nodes or the operation of the message flow.

Before you begin

- Connect the nodes
- Read the concept topic about bend points

About this task

To add a bend point:

Procedure

1. Switch to the Integration Development perspective.
2. Open the message flow that you want to work with.
3. Click **Selection** above the node palette.
4. Select the connection to which you want to add a bend point.

   The editor appends a small black square to each end of the connection to highlight it.

   a) Check that this is the correct connection.

      The editor also adds a small point (a handle) in the connection halfway between the in and out terminals that are joined by this connection.

5. Hold the mouse pointer over this point until the editor displays a black cross to indicate that you now have control of this bend point.
   a) Hold down the left mouse button and move your mouse to move the black cross and bend point across the editor view.
6. As you drag your mouse, the connection is updated, retaining its start and end points with a bend point at the drag point.

   You can move the bend point anywhere in the editor view to improve the layout of your message flow.
7. Release the mouse button when the connection is in the correct place.

   The editor now displays the bend point that you have created with a small square (such as those at the ends of the connection), and displays another two small points in the connection, one between your newly-created bend point and the out terminal, the other between the new bend point and the in terminal.

Results

If you want to add more than one bend point to the same connection, repeat these actions from step "4" on page 640 using the additional small points inserted into the connection.

What to do next

Next: align and arrange the nodes.

Removing a bend point

When you are working with a message flow in the editor view, you might want to simplify the display of the message flow by removing a bend point that you previously added to a connection between two nodes.

Before you begin

- Add a bend point
- Read the concept topic about bend points

About this task

To remove a bend point:

Procedure

1. Switch to the Integration Development perspective.
2. Open the message flow that you want to work with.
3. Click **Selection** above the node palette.
4. Select the connection from which you want to remove the bend point.

   The editor highlights the connection and its current bend points by thickening its line and appending a small black square to each end of the connection, and by indicating each bend point with a small black square. Check that this is the correct connection.
5. Right-click over the selected connection, if you added this bend point in the current edit session.
   a) Click **Undo Create Bend Point**.

   The editor removes the selected bend point.

   If you right-click in the editor view without a connection being selected, you can also click **Undo Create Bend Point** from the menu. However, this removes the last bend point that you created in any connection, which might not be the one that you want to remove.

6. Move the bend point to straighten the line if you added this bend point in a previous edit session, because you cannot use the undo action.

   When the line is straight, the bend point is removed automatically.

   When the bend point has been removed, the connection remains highlighted. Both ends of the connection, and any remaining bend points, remain displayed as small black squares.

   The editor also inserts small points (handles) into the connection between each bend point and between each terminal and its adjacent bend point, which you can use to add more bend points.
7. If you want to remove another bend point from the same connection, repeat these actions from step "4" on page 641.

Aligning and arranging nodes

When you are working in the Message Flow editor, you can decide how your nodes are aligned in the editor view.

Before you begin

This option is closely linked to the way in which your nodes are arranged. The default for both alignment and arrangement is left to right, which means that the in terminal of a node appears on its left edge, and its out terminals appear on its right edge. You can also change this characteristic of a node by rotating the icon display to right to left, top to bottom, and bottom to top.

To complete this task, you must have completed the following task:

- "Adding a message flow node" on page 618

About this task

To modify the way in which nodes and connections are displayed in the editor:

Procedure

1. Switch to the Integration Development perspective.
2. Open the message flow that you want to work with.
3. Click **Selection** above the node palette.
4. Right-click in the editor window and select **Manhattan Layout** if you want the connections between the nodes to be displayed in Manhattan style; that is with horizontal and vertical lines joined at right angles.
5. If you want to change the layout of the complete message flow:
   a) Right-click in the editor view and click **Layout**.

      The default for the alignment is left to right, such that your message flow starts (with an input node) on the left and control passes to the right.

   b) From the four further options displayed, **Left to Right**, **Right to Left**, **Top to Bottom**, and **Bottom to Top**, click the option that you want for this message flow.

      The message flow display is updated to reflect your choice. As a result of the change in alignment, all the nodes in the message flow are also realigned.

      For example, if you have changed from a left to right display (the default) to a right to left display, each node in the flow has now also changed to right to left (that is, the in terminal now appears on the right edge, the out terminals appear on the left edge).

6. You might want to arrange an individual node in a different direction from that in which the remaining nodes are arranged in the message flow:
   a) Right-click the node that you want to change and click **Rotate**.
      Four further options are displayed: **Left to Right**, **Right to Left**, **Top to Bottom**, and **Bottom to Top**. The option that represents the current arrangement of the node is not available for selection.
   b) Click the option that you want for this node.

Results

If you change the alignment of the message flow, or the arrangement of an individual node, or both, these settings are saved when you save the message flow. They are applied when another user accesses this same message flow, either through a shared repository or through shared files or import and export. When you reopen the message flow, you see these changed characteristics. The alignment and arrangement that you have selected for this message flow have no effect on the alignment and arrangement of any other message flow.

You can also access the editor toolbar to select other options related to the display and arrangement of nodes, for example, snap to grid. These options are defined in Message Flow editor.

Adding annotations to a message flow or node

You can add annotations to a message flow, a node, or multiple nodes. You can use these annotations to record reminders, issues arising during the development of a message flow, or informal documentation to facilitate team development.

Before you begin

The following instructions assume that you have created a message flow, as described in “Creating a message flow” on page 574.

About this task

Procedure

- **Adding an annotation to a message flow**
  a) Open the message flow that you want to annotate in the Message Flow editor.
  b) In the message flow node palette, click **Note**, then click the canvas of the Message Flow editor.
     A blank note, in editing mode, is added to the canvas.
  c) Enter your comments to the note.
  d) To exit editing mode, click the canvas outside the note.
     The note resizes according to the amount of text that you enter.
  e) To save the contents of the note, save the message flow.

- **Associating an annotation with a node**

  a) Add a note to the canvas, as described in the preceding steps.

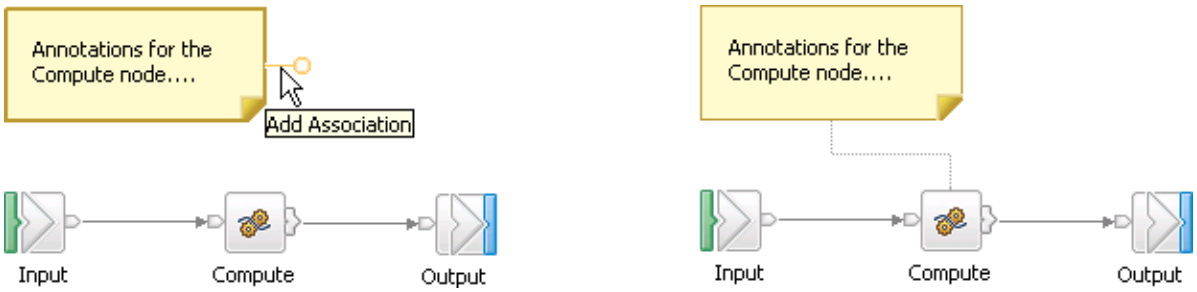
  b) To associate a note with a node in the message flow, move the mouse pointer over the edge of the note until a connector appears.

  c) Click the connector, then click the node with which you want to associate the note.

  The sticky note is associated with the selected node. This association is shown in the Message Flow editor by a dotted line.

  You can repeat these steps to associate an annotation with more than one node.

  The following diagram shows that a connector appears when you move the mouse cursor over the edge of a note, and that a dotted line represents the association between a node and a note.



What to do next

After you have added an annotation to a message flow or node, you can modify the annotation in the following ways:

- “Editing annotations on a message flow or node” on page 644
- “Copying annotations on a message flow or node” on page 645
- “Showing and hiding annotations on a message flow or node” on page 646
- “Deleting annotations from a message flow or node” on page 646

Editing annotations on a message flow or node

After you have added an annotation to a message flow or node, in the form of a sticky note, you can edit the contents of that note.

Before you begin

The following instructions assume that you have added an annotation to a message flow or node, as described in “Adding annotations to a message flow or node” on page 643.

About this task

You can add annotations to message flows or nodes to create reminders, or record details about message flow development. For example, you might want to add a list of modifications that need to be made to a message flow. As you complete the modifications, you might want to edit the annotation to reflect progress. The following steps describe how to edit an annotation.

Procedure

- **Editing the content of a note**
  a) In the Message Flow editor, open the message flow that contains the note that you want to edit.
  b) To put the note into editing mode, click the text of the note.
     The note changes color, acquires a blue border, and a cursor appears.
  c) Edit the content of the note.
     You can use standard cut, copy, and paste operations.
  d) To exit editing mode, click the canvas outside the note.
     The note resizes according to the amount of text that you enter.
  e) To save the contents of the note, save the message flow.
- **Moving a sticky note**
  – To move a sticky note, click inside the note (not on the text) so that black dots appear at each corner. You can now drag the note to a new position on the canvas. If the note is associated with one or more nodes, the association line also moves.
  – You can also move a sticky note by using cut and paste operations. Right-click the note, click **Cut**, right-click the canvas where you want the note to appear, and click **Paste**.
- **Changing the association of a sticky note**
  – To associate a sticky note with a different node, move the mouse pointer over the old node, click the end of the association line, hold down the mouse button, then drag the association line to the new node. When you release the mouse button, the sticky note is associated with the new node, as indicated by a dotted line.
  – To associate a node with a different sticky note, move the mouse pointer over the old sticky note, click the end of the association line, hold down the mouse button, then drag the association line to the new sticky note. When you release the mouse button, the node is associated with the new sticky note, as indicated by a dotted line.

Copying annotations on a message flow or node

You can copy annotations that you have added to a message flow or node to the same instance of the Message Flow editor, or to a different instance of the editor.

Before you begin

The following instructions assume that you have added an annotation to a message flow or node, as described in “Adding annotations to a message flow or node” on page 643.

Procedure

- In the Message Flow editor, open the message flow that contains the annotation that you want to copy.
  A copy of the note appears in the new location. If the original note is associated with one or more message flow nodes, those associations are not copied. You can also cut and paste a note in the same way.
- Right-click the note that you want to copy, then click **Copy**.
- Optional: If you want to copy annotations to a different Message Flow editor, switch to the Message Flow editor to which you want to copy the note.
- Right-click the Message Flow editor canvas where you want the copy of the note to appear, then click **Paste**.

Showing and hiding annotations on a message flow or node

After you have added an annotation to a message flow or node, you can hide it without having to delete it.

Before you begin

The following instructions assume that you have added an annotation to a message flow or node, as described in “Adding annotations to a message flow or node” on page 643.

About this task

Procedure

1. Open a message flow that contains notes.
2. Right-click a note, then click **Hide Notes**.

   All notes in the message flow are hidden.
3. To show all sticky notes, right-click the Message Flow editor canvas, then click **Show Notes**.

Deleting annotations from a message flow or node

Typically an annotation on a message flow or node contains temporary information, therefore you can delete it when you no longer need it.

Before you begin

The following instructions assume that you have added an annotation to a message flow or node, as described in “Adding annotations to a message flow or node” on page 643.

Procedure

- **Deleting a single annotation from a message flow**
  a) In the Message Flow editor, open the message flow that contains the note that you want to delete.
  b) Right-click the note that you want to delete, then click **Delete**.

     The note is deleted. If the note was associated with any nodes, those associations are also deleted.
- **Deleting multiple annotations from a message flow**
  a) In the Message Flow editor, open the message flow that contains the notes that you want to delete.
  b) Hold down Ctrl, highlight all the notes that you want to delete by clicking them (not on the text), then press **Delete**.

     The selected notes are deleted. If any of the notes are associated with nodes, those associations are also deleted.
- **Deleting an association between a note and a message flow node**
  a) In the Message Flow editor, open the message flow that contains the note association that you want to delete.
  b) Right-click the dotted association line between the note and the node, then click **Delete**.

     The association is deleted, but the note and node remain.
- **Deleting multiple associations between a note and message flow nodes**
  a) In the Message Flow editor, open the message flow that contains the note associations that you want to delete.
  b) Hold down Ctrl, select all the dotted association lines that you want to delete by clicking them, then press **Delete**.

     The selected associations are deleted, but the notes and nodes remain.

Testing and troubleshooting message flows

You can test your message flows in a development environment to identify issues before you deploy them to a production environment, and you can use Trace nodes to help you troubleshoot a message flow after it has been deployed. You can also create unit tests for your message flows and message flow nodes, and you can run these tests either during development or after the message flows have been deployed.

Before you begin

You must have a basic understanding of message flows and their representation in the IBM App Connect Enterprise Toolkit. See “Message flows overview” on page 483.

About this task

You can test and troubleshoot your message flows by using the following methods:

Use the Flow Exerciser

You can use the Flow Exerciser to deploy your message flow and then create and send messages to the flow. After the messages are processed, the paths that the messages took are highlighted. You can then view the structure and content of the logical message tree on any highlighted connection in the message flow. See “Testing your message flow by using the Flow Exerciser” on page 648. You might use the Flow Exerciser when you want to check the operation of a message flow.

Develop unit tests for your message flows

You can create and run unit tests to validate the operation of your App Connect Enterprise flows and message flow nodes. You can create and run the tests for flows and nodes that you are developing or for flows that have already been deployed. For more information, see “Developing integration tests” on page 1891.

Use the Flow debugger

You can use the Flow debugger to track messages through your message flow in real time. You can set breakpoints in a message flow, then step through the flow. While you are stepping through, you can examine and change the message variables and the variables used by ESQL code and Java code. See “Testing your message flow by using the flow debugger” on page 659. You might use the Flow debugger when you know that there is a problem with a message flow and you want to troubleshoot the problem.

Note: It is not possible to use the Flow debugger with the Flow Exerciser. When you use the Flow debugger, you must use a third-party tool or the Test Client to send a message to the flow; see #unique_955.

Enable user trace

You can enable user trace to show the history of processing that is carried out in a particular message flow. Built-in nodes write messages to user trace when they are processing work. You can use these messages to review the activity in a message flow and show information such as which message flow nodes were invoked, what code the nodes ran, and through which terminals the messages were sent. See Testing your message flow by enabling user trace.

Use Trace nodes

You can use Trace nodes to write out your own debugging information at specific points in the message flow. The debugging information is written to a file, to user trace, or to the system log. You can review the information after the message flow processes one or more messages. See “Testing your message flow by adding Trace nodes” on page 685. You might add Trace nodes to your message flow during development so that, when your flow is deployed in production, you can get additional information if you use user trace to troubleshoot your flow.

Enable exception log

You can enable the exception log to record data relating to issues and errors in your message flows. See “Enabling the exception log” on page 688.

Testing your message flow by using the Flow Exerciser

To check that a message flow or integration service is processing messages as expected, you can send messages to the flow by using the Flow Exerciser or an external client. You can then use the Flow Exerciser to show the path that each message took. You can also view the structure and content of the message assembly at any point in a message flow.

Before you begin

You must have the following components:

- A resource (integration service, stand-alone message flow, application that includes a message flow, or REST API).
- An integration node and associated integration server, or an independent integration server that is accessible from the IBM App Connect Enterprise Toolkit.
- If your message flow uses MQInput nodes to connect to a remote queue manager, you must have either an IBM MQ client or an IBM MQ server on the same machine as the IBM App Connect Enterprise Toolkit. To install IBM MQ components, see the IBM MQ product documentation: https://www.ibm.com/docs/en/ibm-mq.

About this task

The Flow Exerciser is a tool that is available from the flow editor and the integration service editor, but not from the REST API Editor. If you want to use the Flow Exerciser with a REST API, you must locate and open the main message flow of the REST API.

You can use the Flow Exerciser to complete the following set of tasks:

1. Create and start an integration server to use for testing your message flow.
2. Deploy the resource to an integration server and set the message flow to Record mode.
3. a. Create and send an input message to the input node of the message flow.
   b. Send a previously saved recorded message to the input node of the message flow.

   For more information, see Messages that you can use.

   You can also send messages to the message flow by using an external client.
4. Highlight and view the message path on the message flow and any subflows that are associated with the message flow.
5. View the recorded message assembly for a message that passed through a connection in the message flow.
6. Save the content of the recorded message assembly as a recorded message that you can send to the message flow later.
7. Save the content of all message assemblies in the message path as recorded messages that you can send to the message flow later.

The following videos show examples of how to use the Flow Exerciser:

- Understanding a message assembly shows how to use the Flow Exerciser to record and save a message assembly to be used as an input message to the flow.
- Creating an input message shows how to use the Flow Exerciser by creating an input message to send to the flow.
- Using an external client shows how to use the Flow Exerciser by using an external client to send a message to the flow, and how to save the message for future use.

Procedure

To check that a message flow or integration service is processing messages as expected, complete the following steps:

1. In the IBM App Connect Enterprise Toolkit, open the message flow by completing one of the following steps:
   - If the message flow is a stand-alone message flow or a message flow that is part of an application, open the flow with the flow editor.
   - If the message flow is part of an integration service, open the integration service description with the service editor.
   - If the message flow is part of a REST API, use the message flow editor to open the main message flow of the REST API, which is located under **Resources**.
2. Create or start an integration server. In the editor, click the **Start Flow Exerciser** icon () in the Flow Exerciser toolbar so that the flow recording can start.

   Before you send a message to the message flow, you must have an integration server that is connected to the IBM App Connect Enterprise Toolkit, and the integration server must be started. If you do not have a started integration server connected to the IBM App Connect Enterprise Toolkit, a message notifies you that an integration server is required. Click **OK** to use the wizard that helps you create and start an integration server. For more information, see "Creating and starting a local, independent integration server by using the Toolkit" on page 170.

   Alternatively, you can click **Cancel** and then create and start an integration server by using one of the methods described in "Creating an integration server" on page 168.

   When the integration server has been created and started, it is available to use for testing the message flow.
3. Deploy the message flow. When you have one or more started integration servers that are connected to the IBM App Connect Enterprise Toolkit, click the **Start Flow Exerciser** icon () again. The flow recording starts.

   If you have more than one started integration server that is connected to the IBM App Connect Enterprise Toolkit, you are prompted to select the integration server where you want to deploy the resource. If the message flow receives messages on an MQInput node that is configured to use a local queue manager, you can use the Flow Exerciser to send messages to that MQInput node. However, you can deploy the flow only to an integration server that is managed by a local integration node. Select the integration server where you want to deploy the message flow and click **Finish**.

   A window is presented where you are advised that a message flow cannot be deployed individually, and the owning application or library is deployed instead. Click **OK** to deploy the owning application or library to your selected integration server.

   If the resource was previously deployed to the integration server, a window is presented where you are advised that the resource is already deployed. Click **Yes** to confirm that you want to redeploy the resource or click **No** to skip the redeployment step.

   The resource is deployed to the integration server. A window is presented where you are advised that the message flow is ready to record messages. Click **OK** to close the window and return to the message flow editor. The flow editor is now surrounded by a blue border, and the text "Recording" appears. The red **Record** button is now replaced with a blue **Return flow to edit mode** button, and the message flow is set to Record mode. You cannot edit the message flow when it is in Record mode. If you want to stop the recording and return the flow to edit mode, press the blue **Return flow to edit mode** button.
4. Send messages to the message flow by using one of the following options:
   - If you are using an integration service, or if your message flow contains MQInput, HTTPInput, or SOAPInput nodes, click the **Send message** icon () in the Flow Exerciser toolbar. You can then use the **Send Message** dialog to create an input message (or select an existing input message or recorded message) and send it to the flow. For more information about creating messages or

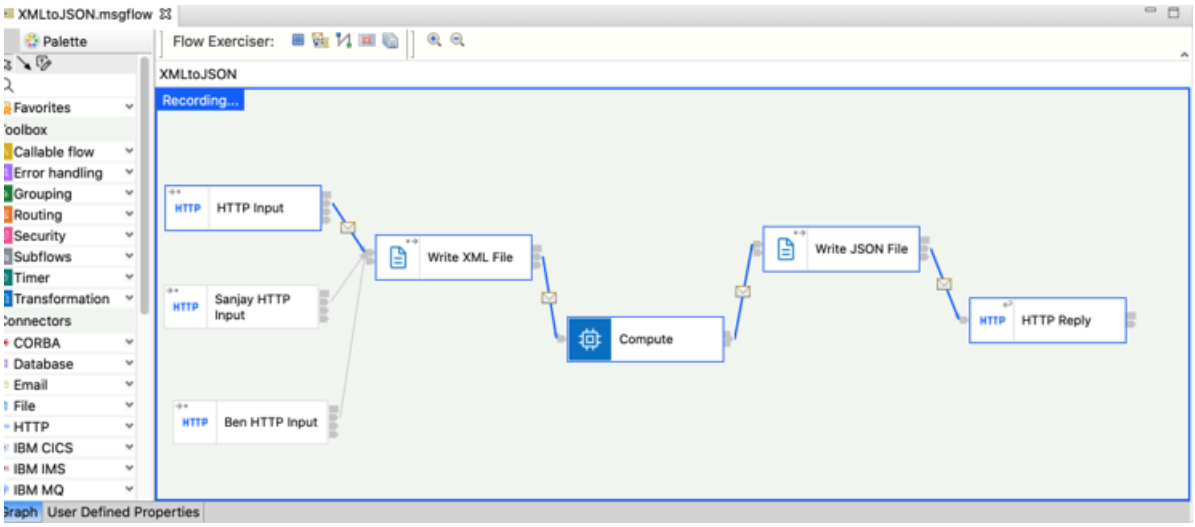
using recorded messages, see Creating input messages and Using recorded messages. The **Send message** function is not available for flows in a REST API.

- If your message flow uses input nodes that the Flow Exerciser cannot send messages to directly, use an external tool or client to form and send one or more input messages to the flow.

Click **Close** to close to the Send Message dialog.

5. View the path through the flow by using one of the following methods:
   - After you click **Close** to close to the Send Message dialog, the message paths are automatically highlighted in blue on the flow.
   - In an integration service, click the operation name in the **Integration Service Description** page to see the message paths highlighted on the subflow.
   - If your message flow uses input nodes that the Flow Exerciser cannot send messages to directly, and you used an external tool or client to form and send one or more input messages to the flow,

you must click the **View path** icon ( ) in the Flow Exerciser toolbar to highlight message paths on the flow.



The diagram shows a flow where the message paths are highlighted. At least one message passed through each highlighted connection.

- The highlighted connections do not distinguish between the paths that are taken by different messages. If you send more than one message to the flow, you must inspect each highlighted connection to see which messages passed through that connection.
- If you send a single message to the flow and the message passes through a connection multiple times, the logical message tree is captured as a separate message instance each time the message passes through a connection.
- By default, a maximum of 200 message instances are displayed in the message flow, but you can change this value in the preferences (**Windows** > **Preferences** > **Integration Development** > **Flow Exerciser**).
- If the number of message instances that are captured exceeds the number that is configured in the preferences, you are prompted to choose whether to view the configured number of recorded messages, or whether to view all the recorded messages:
  - If you opt to view the configured maximum number of recorded messages, you might not see whole sequences of messages.
  - If you opt to view all the messages, performance can be impacted.

When you finish viewing the path through the flow, choose one of the following options:

- Click **Clear Recorded Messages** to clear the recorded messages. The blue line that highlights the path taken through the flow is no longer shown.
- Click **Return flow to Edit Mode** to clear the recorded messages and return the message flow to Edit mode. The blue line that highlights the path taken through the flow is no longer shown. You can then edit the message flow and redeploy the flow to the integration server, as described in step "3" on page 649. You can then resend the message, as described in step "4" on page 649.
- Leave the message flow in Record mode, and view the message assembly, as described in step "6" on page 652.

6. Optional: When the message flow is in Record mode, and the blue line that highlights the path taken through the flow is visible in the Flow Exerciser, you can view the recorded message assembly of the message.
   The message assembly is a logical representation of the message flow that is being handled at a particular point in the process. For more information, see Message Assembly editor.

   Open a read-only view of the message assembly by selecting a message icon that is on a connection between any two nodes in the path of the message flow.

   The view shows the logical message tree at that point in the flow. The logical message tree is referred to as the *message assembly*. The message assembly consists of four trees:

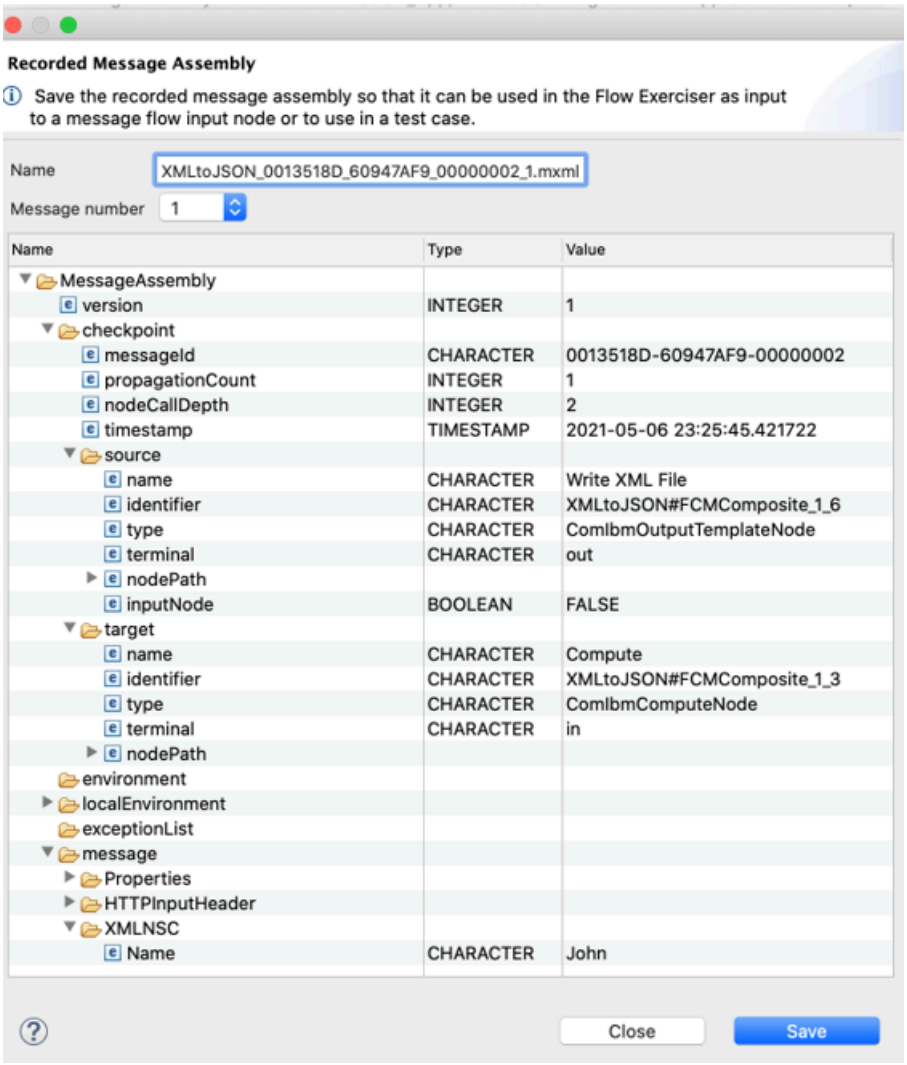
   - *environment*
   - *localEnvironment*
   - *exceptionList*
   - *message*

   The message tree contains message headers and the message body. The message body part of the message assembly is automatically expanded when the view is shown.

   A checkpoint folder is also shown in the message assembly. The checkpoint shows details of where in the flow the message was recorded. It shows the source node and the target node details.

   If you send multiple messages to the flow, you can select which message you want to view by selecting the appropriate entry in the **Message number** drop-down menu. When you change the

selection in the **Message number** menu, the name of the message is automatically updated in the **Name** field .



If you want to save the message assembly, follow the instructions in step “7” on page 654.

7. Optional: When you view the message assembly in the read-only view, you can save it by completing the following steps:
   a) Optional: You can change the name of the message assembly by overwriting the default name that appears in the Name field of the **Recorded Message Assembly** window. The name of the message assembly must have the extension `.mxml`.
   b) Click **Save**.

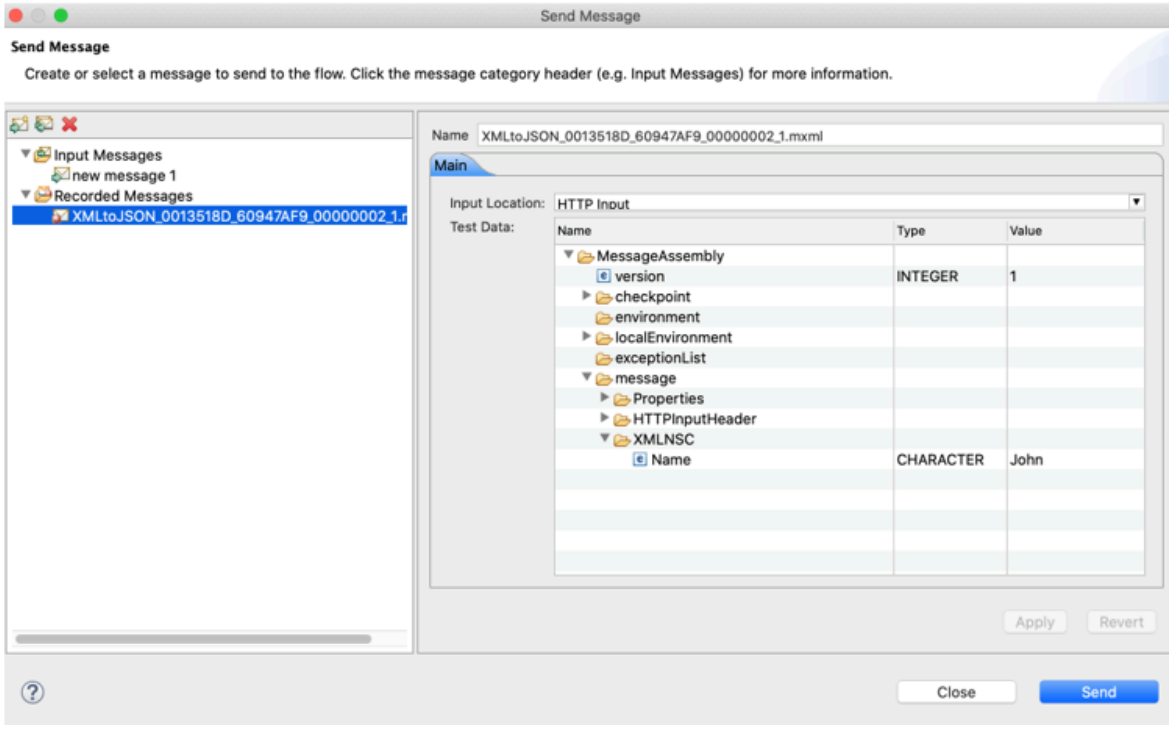
   - The message assembly is saved under Other Resources in the application that contains the message flow that is being recorded.
   - You can now view a different message number in the same window and save that message too.
   - When you have finished viewing and saving the message assembly, select **Close** to close the window. You can now see the saved message assembly under the application in the Application Development view.
8. Optional: Click **Save All** if you want to save the message assemblies from all the connections in the highlighted path in the Flow Exerciser.

   All the message assemblies for every invocation of the flow now appear in the Application Development View under the application that contains the message flow that was recorded.

   These message assemblies are also visible under Recorded Messages the next time that you select **Send Message**.

   These message assemblies can also be used as resources for integration tests for your message flow nodes.

9. Optional: Edit a message assembly by completing the following steps:
   a) Double-click the saved message assembly under the Application Development view in the IBM App Connect Enterprise Toolkit.
   b) Select **Open with** > **Message Assembly Editor** from the menus.
      The message assembly opens in the Message Assembly Editor.
   c) Edit the values under the Name, Type, and Value columns.
   d) Save your changes.
   e) Edit the message flow to expect the updated values. For example, if your flow has a Compute node, update the ESQL. For more information, see Editors.
10. If you save a recorded message assembly, you can send it as a message to a message flow, by completing the following steps:
   a) Click **Send Message**.
      - The saved, recorded message assembly is shown under Recorded Messages.
      - A read-only view of the contents of the recorded message assembly is shown under the Main tab.
      - If you need to change the message assembly, select it from the Application Development view to open it, then edit it in the Message Assembly Editor.
      - The input node is not saved with the message assembly, and you can select which input node to send it to. All input nodes that are in the message flow are listed in the **Input Location** field.
   b) Press **Send**.



The message is sent and the path of the message is highlighted in blue in the flow editor, as shown in step “5” on page 650.

Messages that you can use with the Flow Exerciser to check that a message flow processes messages as expected

You can create input messages and save recorded messages. You can then use either of these types of message to check that a message flow is processing messages as expected.

Input messages

Input messages are messages that are processed by the input node in a message flow.

Input messages can be generated and sent from a third-party tool or client, or created by using the Flow Exerciser. If you create input messages by using the Flow Exerciser, you can create messages for message flows that contain the following input nodes:

- MQInput node
- HTTPInput node
- SOAPInput node

If the message flow is part of a REST API, you cannot use input messages created by the Flow Exerciser; however, you can use an external tool or client to form and send the input messages to the flow.

If the input node in the message flow expects an XML message from an associated message model, the message structure is provided and can be edited to produce an appropriate sample input message. Alternatively, you can manually create a new input message, or import an existing message from your file system.

You can duplicate, edit, and delete the messages to create a set of input messages that validate the operation of your message flow, and you can export the content of an input message to a file. To use input messages, you must have a method of invoking the flow.

For more information, see Creating input messages.

Recorded messages

Recorded messages are messages that are captured when a message flow is in recording mode. These messages contain the logical message tree assembly that is the result of an input node processing an input message. You can save a recorded message and then use the recorded message when you do not have a method of invoking the flow, or an external system to receive the message.

Note: To create the recorded message, you must have a method of invoking the flow.

You can save and reuse recorded messages that are sent to the following input nodes:

- MQInput node
- HTTPInput node
- SOAPInput node
- FileInput node
- MQTTSubscribe node

If the message flow is part of a REST API, you cannot use recorded messages; however, you can use an external tool or client to form and send input messages to the flow.

You save recorded messages by clicking the highlighted connection from the input node to the next node in the message flow, and clicking the **Save** icon. You can rename a recorded message but you cannot edit the content of a recorded message, or create a recorded message from scratch.

When you send a recorded message to the message flow, the message is sent to the output terminal of the input node of the message flow. A recorded message is not processed by the input node, and so you do not need a method of invoking the flow.

HTTPReply and SOAPReply nodes can detect that the message that is being processed by the flow is a recorded message. If one of these nodes receives a recorded message, the node suppresses the reply.

(Attempting to send a reply would generate an error because there is no external system to receive the reply.)

For more information, see Using recorded messages.

If you create a set of input messages and recorded messages, these messages can be included with the message flow if you export the message flow (or application that contains the message flow) as a project interchange file. However, you cannot copy the messages to another message flow.

Creating input messages by using the Flow Exerciser to check that your message flow processes messages as expected

You can create a new input message, or duplicate or edit a previously saved input message by using the Flow Exerciser. You can then send the message to the flow.

Before you begin

You must have a message flow that is in recording mode and that contains MQInput, HTTPInput, or SOAPInput nodes.

You cannot use the Flow Exerciser to send messages to an MQInput node in a flow in the following situations:

- The MQInput node is configured with a policy.
- The MQInput node has the `MQ connection` property set to `Client channel definition table (CCDT) file`.
- The message flow is deployed to a remote integration node, and the message flow receives messages on an MQInput node that is configured to use a local queue manager.

Instead, you can use an external tool or client to send messages to the message flow.

If the message flow is part of a REST API, you cannot use recorded messages or input messages created by the Flow Exerciser; however, you can use an external tool or client to form and send input messages to the flow.

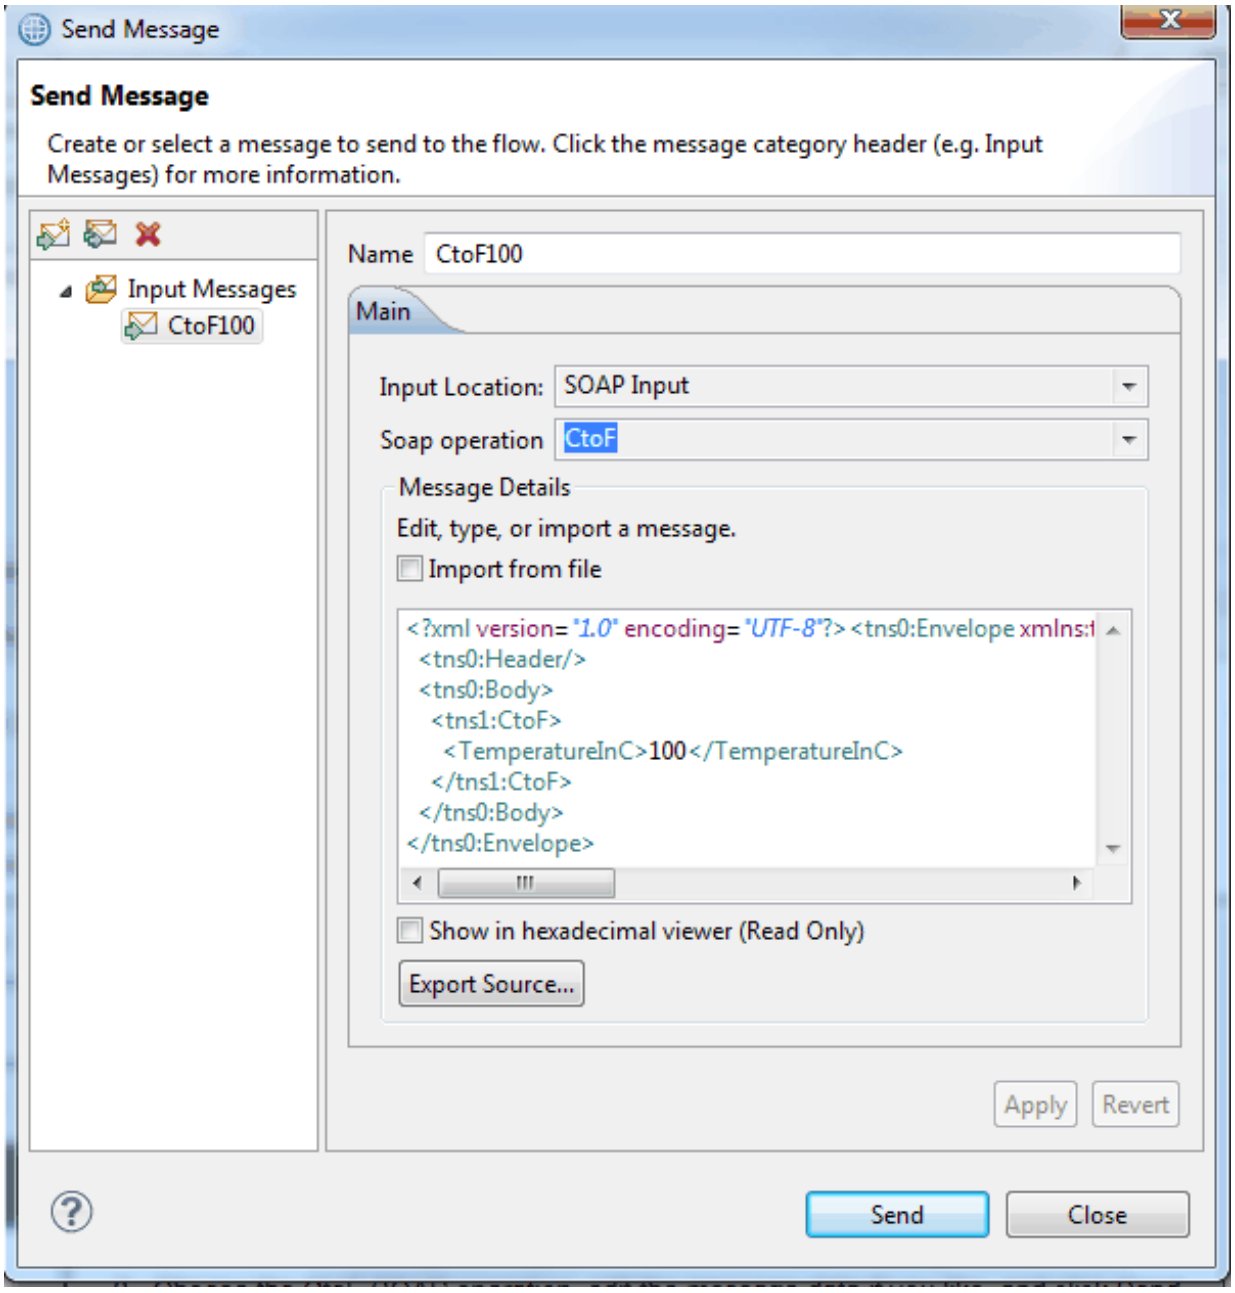
Procedure

1. Click the **Send message to the flow** icon () in the Flow Exerciser toolbar.

   The **Send Message** dialog opens.

2. Click the **New message** icon ( )

   A default message is displayed. If the input node in the message flow expects an XML message from an associated message model, the message structure is provided. If the input node does not have an associated message model, the message content is blank.



3. Enter a name for your message or accept the default value.
4. Optional: If you are using an integration service that contains more than one operation, click the **Soap operation** field and select the operation name.
5. Finalize the message by completing one of the following steps:
   - If the message structure is provided, you can replace the default values with appropriate values of your own, or you can leave the message as it is.
   - You can manually create the message structure and values from scratch.
   - You can click **Import** and import an XML message from a file.
6. Optional: Click **Apply** to save any changes.

7. Click **Send** to send the message to the message flow.

   The message is sent to the flow, and the connections through which the message passed are highlighted.

What to do next

In the Flow Exerciser, you can create additional input messages by duplicating and editing existing input messages, and you can export the structure and content of an input message to a file.

Using recorded messages with the Flow Exerciser to check that your message flow processes messages as expected

From the **Send Message** dialog, you can select a previously saved recorded message and send it to the message flow.

Before you begin

You must have the following components:

- A message flow that is in recording mode
- One or more recorded messages

About this task

Recorded messages are created by sending input messages to a message flow by using the Flow Exerciser. A recorded message contains the logical message tree assembly that is the result of an input node processing an input message. You cannot modify the recorded message or create one from scratch. For more information, see Messages that you can use.

Procedure

1. Click the **Send message to the flow** icon () in the Flow Exerciser toolbar.

   The **Send Message** dialog opens. The recorded messages that you previously saved are listed under **Recorded Messages** in the navigator.
2. Select a recorded message to see the content.

   You can change the name of the recorded message if you want, by typing a new name and clicking **Apply**. However, you cannot duplicate the message or edit the content of the message.
3. By default, the recorded message is sent to the input node where it was saved. If there are other input nodes of the same type in the message flow, you can select one of these other input nodes instead.

   Note: If you select an input node other than the input node where the message was saved, you might get an error in your flow when you send the message. For example, the selected input node might send messages in a different format.
4. Click **Send**.

   The message is sent to the flow, and the connections through which the message passed are highlighted.

Testing your message flow by using the flow debugger

Use the tasks described in this section of the documentation to manage and work with the flow debugger.

Before you begin

If you are new to debugging, see: “Flow debugger overview” on page 660.

Deploy your message flow to an integration server in an integration node and make sure that the integration node is running. See: “Deployment rules and guidelines” on page 2465.

About this task

To debug a message flow, perform the following tasks. You might want to vary the tasks that you perform and repeat certain tasks, depending on your particular debugging requirements. If your message flow contains WebSphere Adapters nodes, also see "Debugging message flows that contain WebSphere Adapters nodes" on page 683.

Procedure

1. Start the flow debugger.

   Set the required preferences, then start debugging by attaching the flow debugger to an integration server. You can then send test messages along the flow. See: "Starting the Flow debugger" on page 665.

   Note: It is not possible to use the Flow debugger with the Flow Exerciser. When you use the Flow debugger, you must use a third-party tool or the Test Client to send a message to the flow; see #unique_955. If your integration server is in recording mode, you must stop recording mode before you can launch the Flow debugger.
2. Work with breakpoints.

   Add and manipulate breakpoints in your message flow. See: "Working with breakpoints in the flow debugger" on page 669.
3. Follow the progress of a test message.

   Use breakpoints to pause the progress of a test message so that you can observe its behavior. See: "Stepping through message flow instances in the debugger" on page 672.
4. View message data.

   View (and change) data in messages, ESQL code, or Java code as debugging progresses. See: "Debugging data" on page 677.
5. Manage message flows.

   During a debugging session, there are various administrative tasks you might need to do. When you have finished debugging, detach the debugger from the integration server. See: "Managing flows and flow instances during debugging" on page 680.

Flow debugger overview

Use the Flow debugger in the IBM App Connect Enterprise Toolkit to track messages through your message flows.

Use the Debug perspective in the IBM App Connect Enterprise Toolkit to use the Flow debugger. For an introduction to the Debug perspective and the views it presents, see #unique_971.

You can set breakpoints in a message flow, then step through the flow. While you are stepping through, you can examine and change the message variables and the variables used by ESQL code and Java code. You can debug a wide variety of error conditions in flows, for example:

- Nodes that are wired incorrectly (for example, outputs that are connected to the wrong inputs)
- Incorrect conditional branching in transition conditions
- Unintended infinite loops in flow

From a single IBM App Connect Enterprise Toolkit, you can attach the Flow debugger to one or more integration servers, and debug multiple flows in different integration servers (and therefore multiple messages) at the same time. However, an integration server can be debugged by only one user at a time. Therefore, if you attach your Flow debugger to an integration server, another user cannot attach a Flow debugger to that same integration server until you have ended your debugging session.

When you debug message flows, use an integration node that is not being used in a production environment. Debugging might degrade the performance of all message flows in the same integration server and message flows in other integration servers that share the same integration node because they might be affected by resource contention.

Debugging code in message flow nodes

You can use the Flow debugger to examine the behavior of code in message flow nodes.

After you have deployed a message flow, you can set a breakpoint just before one of the nodes listed in this section so that, when the flow pauses at the breakpoint, you can step through the code line by line. This allows you to examine the logic, and check the actions taken and their results. You can set additional breakpoints and you can also examine and change variables.

The following nodes can contain ESQL code modules:

- Compute node
- Filter node
- Database node

The following nodes can contain Java code modules:

- User-defined nodes
- JavaCompute node

Restrictions

The following restrictions apply when you debug a message flow:

- You cannot use the Flow debugger with the Flow Exerciser. When you use the Flow debugger, you must use a third-party tool or the Test Client to send a message to the flow; see #unique_955.
- You must use the same version of the integration node and the IBM App Connect Enterprise Toolkit; for example, you cannot use the IBM App Connect Enterprise Toolkit Version 12.0 to debug a message flow that you have deployed to an integration node at an earlier version.
- You should not debug message flows over the Internet, because there might be security issues.
- You can debug a message flow that contains a Mapping node, but you cannot step into the graphical data mapping to view or set breakpoints on the transforms.

The following topics provide reference information to help you use the Flow debugger effectively:

- “Flow debugger shortcuts” on page 661
- “Flow debugger icons and symbols” on page 662

You can also use the “Java Debugger” on page 664 provided by the Java Development tools to debug Java code within the IBM App Connect Enterprise Toolkit.

Flow debugger shortcuts

You can use function keys and shortcut keys to complete actions in the flow debugger views and windows.

Shortcut keys are shown as a pair that you press together, followed by a subsequent key, for example `Shift-F10, C` means hold the Shift key down and press F10, then release both and press key C.

The following tables describe the main shortcuts that are available in the debug session:

- “Debug view” on page 662
- “Breakpoints view” on page 662
- “Flow Breakpoint Properties dialog” on page 662
- “Variables view” on page 662

To see a complete list of all the shortcuts that are available, press `Shift-F10` and release; the contextual menu is displayed.

Debug view

Key combination	Function
Shift-F10, C	Run to completion
Shift-F10, E	Disconnect
F5 or Shift-F10, I	Step into
F8 or Shift-F10, M	Resume
Shift-F10, N	Terminate All
F6 or Shift-F10, O	Step over
Shift-F10, T	Terminate
F7 or Shift-F10, U	Step return
Shift-F10, V	Terminate and Remove

Breakpoints view

Key combination	Function
Shift-F10, A	Select All
Shift-F10, B	Add breakpoint
Shift-F10, D	Disable the selected breakpoints
Shift-F10, E	Enable the selected breakpoints
Shift-F10, L	Remove all breakpoints
Shift-F10, O	Remove the selected breakpoints

Flow Breakpoint Properties dialog

Key combination	Function
E	Enable the breakpoint
Alt-R, <space>	Restrict the breakpoint to the selected flow instances

Variables view

Key combination	Function
Shift-F10, A	Select All
Shift-F10, C	Change the value of the selected flow variable
Shift-F10, V	Copy variables

Flow debugger icons and symbols
The Debug perspective uses various debugger icons and symbols.

This topic describes the icons and symbols used in the Debug perspective and its views:

Debug perspective

These icons and symbols are used in the Debug perspective *outside* any individual view.

Icon or Symbol	Description
	Debug perspective (symbol)
	Attach to Flow runtime environment (icon)

Debug view

Icon or Symbol	Description
	Debug view (symbol)
	Flow engine (symbol)
	Flow (symbol)
	Flow instance paused (symbol)
	Flow instance running (symbol)
	Flow instance terminated (symbol)
	Stack frame (symbol)
	Detach from the selected flow engine (icon)
	Resume flow execution (icon)
	Run the flow to completion (icon)
	Step into subflow (icon)
	Step over node (icon)
	Step out of subflow (icon)
	Step into source code (icon)

Message Flow editor

These icons and symbols in the message flow editor are specific to the flow debugger.

Icon or Symbol	Description
	Enabled breakpoint (symbol)
	Disabled breakpoint (symbol)

Icon or Symbol	Description
	Paused at breakpoint (symbol)
	Source code available (symbol)
	Error or exception (symbol)

Breakpoints view

Icon or Symbol	Description
	Breakpoints view (symbol)
	Enabled breakpoint (symbol)
	Disabled breakpoint (symbol)
	Remove selected breakpoints (icon)
	Remove all breakpoints (icon)

Variables view

These icons and symbols in the Variables view are specific to ESQL.

Icon or Symbol	Description
	Variable view (symbol)
	Tree reference variable (symbol)
	Message (symbol)
	ESQL reference variable (symbol)
	ESQL constant (symbol)
	ESQL scalar variable (symbol)
	ESQL schema variable (symbol)
	ESQL module variable (symbol)

Java Debugger

The Java Development Tools include a debugger that enables you to detect and diagnose errors in your programs running on local or remote systems. You can control the execution of your program by setting breakpoints, suspending launched programs, stepping through your code, and examining the contents of variables.

For further information about the Java debugger, refer to the Java Development User Guide - Debugger. (This link works only if you are accessing this documentation from the IBM App Connect Enterprise Toolkit.)

Starting the Flow debugger

To start the Flow debugger, you must attach it to an integration server. When the Flow debugger is started, you can introduce test messages to your message flow.

About this task

Note: It is not possible to use the Flow debugger with the Flow Exerciser. If your integration server is in recording mode, you must stop recording mode before you can launch the Flow debugger.

Complete the following tasks to start the debugger:

Procedure

1. "Attaching the flow debugger to an integration server for debugging" on page 665
2. Optional: "Debug: putting a test message on an input queue" on page 666
3. Optional: "Debug: getting a test message from an output queue" on page 668

Attaching the flow debugger to an integration server for debugging

Before you can debug your message flow, you must attach the flow debugger to the integration server where your flow is deployed, then start a debugging session.

Before you begin

- If authorization permissions are required, see: "Authorizing users for administration" on page 2516
- Create a message flow. See: Chapter 6, "Developing integration solutions," on page 481
- Deploy your message flow to an integration server. See: "Deployment rules and guidelines" on page 2465
- Start the integration node. See: "Starting and stopping an integration node" on page 247

About this task

From the IBM App Connect Enterprise Toolkit, you can attach the flow debugger to multiple integration servers that are running on the same or on different host computers, and debug their flows (and therefore multiple messages) simultaneously.

An integration server can be debugged by only one user at a time. If you attach your debugger to an integration server, another user cannot attach a debugger to that same integration server until you have ended your debugging session.

Procedure

To attach the debugger to an integration server:

1. Set the JVM debug port by modifying the `server.conf.yaml` configuration file for your integration server.
   a) Open the `server.conf.yaml` configuration file by using a YAML editor.

      If you do not have access to a YAML editor, you can edit the file by using a plain text editor; however, you must ensure that you do not include any tab characters, because they are not valid characters in YAML files and would cause your integration server configuration to fail. If you are using a plain text editor, ensure that you use a YAML validation tool to validate the content of your file.

   b) In the Resource Managers section of the `.yaml` file, specify a value for the **`jvmDebugPort`** property, which sets the JVM debug port to be used for debugging flows in the Toolkit.

2. Restart the integration server for the changes to take effect.
3. In the IBM App Connect Enterprise Toolkit, click the down-arrow to the right of the Debug button in the action bar, and then click the **Debug configurations** menu item.
4. In the **Debug configurations** dialog, right-click **IBM App Connect Enterprise debug**, and then click **New**.
5. Enter a name for the new debug configuration in the **Name** field; if you do not specify a name, it will be called `New_configuration [IBM App Connect Enterprise Debug]` by default. In the **Connect** tab, set the host name and the Java debug port to match the details of your integration server, as specified in the **`jvmDebugPort`** property in the `server.conf.yaml` file. Click **Debug**.
6. Open the message flow that you want to debug in the Message Flow editor by double-clicking its name in the Application Development view.
7. Add a breakpoint to a connection that leads out of the input node to ensure that the message flow does not run to completion before you can begin to debug it.

   The breakpoint appears as  . For information about adding a breakpoint, see "Working with breakpoints in the flow debugger" on page 669.
8. Switch to the Debug perspective.
9. Optional: If the message flow that you are going to debug references additional resources in other projects, such as ESQL in libraries or independent projects, or Java in Java projects, add those resources by completing the following steps:
   a) In the **Debug** view, right-click the debug configuration that you created in step 5 and then click **Edit Source Lookup** from the pop-up menu. If you did not specify a name when you created the debug configuration, it will have the default name `New_configuration [IBM App Connect Enterprise Debug]`.

      You can use **Edit Source Lookup Path** to tell the debugger where to look for your source files for message flows and related resources such as ESQL and Java during debugging.
   b) Click **Add**, and select the type of source to add to the lookup path.

      The lookup path can be an Eclipse project name, an external folder, or a compressed (`.zip`) file. You can specify multiple locations, but the debugger always looks first in the message flow project that you specify in the **Edit Source Lookup Path** dialog.
   c) Select the resources to include in the lookup path, and click **OK**.
   d) Click **Add** to include more resources in the lookup path, click **Up**, or **Down** to modify the order of the resources.
   e) Click **OK** to exit the **Edit Source Lookup Path** dialog, and save your changes.
10. When the next message comes into your flow and arrives at a breakpoint that you added after the input node, the flow pauses, the breakpoint icon is highlighted:  , and you can start debugging.
11. In the **Debug view**, double-click the message flow that you want to debug. The message flow opens in the Message Flow editor. You can now add more breakpoints, start stepping over the flow, and so on.

What to do next

Send a message through your message flow.

Debug: putting a test message on an input queue
You can put a message on an input queue to test a message flow that you are debugging.

Before you begin

Complete the steps described in "Attaching the flow debugger to an integration server for debugging" on page 665.

About this task

If your message flow includes MQInput and MQOutput nodes, you can test the flow by putting a message on the input queue of your first MQInput node.

You can use the command line interfaces or IBM MQ Explorer to put a message to a queue.

Note: It is not possible to use the Flow debugger with the Flow Exerciser.

You can also use the Test Client as a repeatable alternative. To use the Test Client, complete the steps described in the following sections.

Note: The Test Client is not enabled by default. To use the Test Client, you must enable this facility in the Test Client preferences; see preferences.

- "Using enqueue in the Test Client" on page 667
- "Adding data to your message" on page 667
- "Optional: Using a file of sample data" on page 668

If the message is processed by the message flow and is put on an output queue, you can retrieve it from that queue. See: "Debug: getting a test message from an output queue" on page 668.

Using enqueue in the Test Client

About this task

To configure an enqueue event in the Test Client so that you can use it to send a test message:

Procedure

1. Switch to the Integration Development perspective.
2. Open your message flow in the Message Flow editor.
3. Right-click the input node of the message flow and click **Test**.

   The message flow is deployed and the Test Client editor opens and displays the **Events** window.
4. On the toolbar of the Test Client editor, under **Message Flow Test Events**, click the **Enqueue** icon  .
5. Under **Detailed Properties**, enter the names of the queue manager and the queue for the input node for this flow.

   Queue manager names are case-sensitive; make sure that you enter the name correctly.

   If you are putting a message onto an input queue that is on a remote computer, ensure that the queue manager of the associated integration node has a server-connection channel called SYSTEM.BKR.CONFIG.
6. If you are putting a message onto a remote queue, enter values to identify the host and port of the computer that is hosting the queue.
7. Optional: If you want to save the Test Client file, complete the following steps:

   a) Click **File** > **Save** and select the project where you want to save the file.

   b) Enter a name for the file and click **Finish**.

   The Test Client file is saved in the **Flow Tests** folder in the project.

Adding data to your message

About this task

If you want to add just a small amount of test data in your test message, type the data into the **Source** section of the **Message** pane:

Procedure

1. Open your Test Client file.
2. Type your test data directly into the **Source** section of the Message pane.
3. Put the test message by clicking **Send Message**.

Optional: Using a file of sample data

About this task

If you want your test message to contain a larger quantity of sample data (for example some structured XML), you can import a file containing that data into the Test Client:

Procedure

1. In the **Events** tab of your Test Client file, click **Import Source**.
2. Select the file you want to use as the content for the test message, and click **Open**.
   The contents of the selected file is added to the **Source** pane.
3. Click **File** > **Save** when you have finished.
4. Put the test message by clicking the **Send Message** button.

Debug: getting a test message from an output queue
You can get a message from an output queue to test a message flow that you are debugging.

Before you begin

Completed the following tasks:

- Chapter 6, “Developing integration solutions,” on page 481
- Chapter 7, “Deploying integration solutions,” on page 2463
- “Attaching the flow debugger to an integration server for debugging” on page 665
- “Debug: putting a test message on an input queue” on page 666

About this task

If your message flow includes MQInput and MQOutput nodes, you can test the flow by putting a message on the input queue of your first MQInput node and retrieving it from an MQOutput node.

You can use the command line interfaces or IBM MQ Explorer to get a message from an output queue.

You can also use the Test Client as a repeatable alternative.

Note: The Test Client is not enabled by default. To use the Test Client, you must enable this facility in the Test Client preferences; see preferences.

To use the Test Client, complete the following steps:

Procedure

1. Switch to the Integration Development perspective.
2. Open your message flow in the Message Flow editor.
3. Right-click the input node of the message flow and click **Test**.
   The message flow is deployed and the Test Client editor opens and displays the **Events** window.
4. On the toolbar at the upper right of the Test Client editor, under **Message Flow Test Events**, click the **Dequeue** icon  .
5. Under **Detailed Properties**, enter the name of the queue manager and output node queue.

6. Click **Get Message** to read a message from the queue.
7. Optional: If you want to save the Test Client file, complete the following steps:
   a) Click **File** > **Save** and select the project where you want to save the file.
   b) Enter a name for the file and click **Finish**.

   The Test Client file is saved in the **Flow Tests** folder in the project.

Results

When a message is available on an output queue, you can see it in the Test Client editor.

Working with breakpoints in the flow debugger

When you have started a debugging session by attaching the debugger to an integration server, you can set breakpoints to control where the message flow will pause.

About this task

Use the following tasks to manage breakpoints:

- "Adding breakpoints in the flow debugger" on page 669
- "Restricting breakpoints in the flow debugger to specific flow instances" on page 670
- "Enabling and disabling breakpoints in the flow debugger" on page 671
- "Removing breakpoints in the flow debugger" on page 671

What to do next

After you have set one or more breakpoints in the message flow, continue your debugging session by stepping through the message flow, pausing at each active breakpoint. See: "Stepping through message flow instances in the debugger" on page 672.

You can also examine message data, code, and mappings at appropriate points. See: "Debugging data" on page 677.

Adding breakpoints in the flow debugger

Add breakpoints to connections in your message flow to control where flow processing will pause.

Before you begin

Attach the flow debugger to the integration server where your flow is deployed. See: "Attaching the flow debugger to an integration server for debugging" on page 665.

About this task

You can add breakpoints to the connections of a message flow that is open in the Message Flow editor. Each breakpoint that you add to a flow is also automatically added to all other instances of the flow and you do not need to restart any of the instances.

Every breakpoint is automatically enabled when you add it to a connection and the connection is flagged with the enabled breakpoint symbol  .

Manually set a breakpoint after the collector node or any other multithreaded node. When you use the Debug perspective on the node, you see that the thread has been ended.

To add breakpoints to the connections of a message flow:

Procedure

1. Switch to the Debug perspective.

2. Add breakpoints to the appropriate connections.

   Use any of the following methods:

Option	Method
Add breakpoints individually to selected connections.	a. In the Message Flow editor, right-click the connection where you want to set the breakpoint. b. Click **Add Breakpoint**.
Add breakpoints simultaneously to all connections *entering* a selected node.	a. In the Message Flow editor, right-click the node before which you want to set breakpoints. b. Click **Add Breakpoints Before Node**.
Add breakpoints simultaneously to all connections *leaving* a selected node.	a. In the Message Flow editor, right-click the node after which you want to set breakpoints. b. Click **Add Breakpoints After Node**.

What to do next

After you have set one or more breakpoints in the message flow, step through the flow, pausing at each active breakpoint. See: "Stepping through message flow instances in the debugger" on page 672.

You can also examine message data, code, and mappings at appropriate points. See: "Debugging data" on page 677.

Restricting breakpoints in the flow debugger to specific flow instances

Breakpoints can be applied to particular flow instances, instead of all instances, which is the default behavior.

Before you begin

Add one or more breakpoints to your message flow. See: "Adding breakpoints in the flow debugger" on page 669.

About this task

When you add a breakpoint to a message flow in the Message Flow editor, the breakpoint automatically applies to all instances of the flow. However, you can restrict a breakpoint to one or more instances of a flow. This enables you to work more easily with just those instances that you are currently interested in, rather than with all instances.

To restrict a breakpoint to one or more flow instances:

Procedure

1. Switch to the Debug perspective.
2. In the Breakpoints view, right-click the breakpoint that you want to restrict, then click **Properties** to open the **Flow Breakpoints Properties** window.
3. In the **Restrict to Selected Flow Instance(s)** list box, select those instances to which you want to restrict the breakpoint.
   - You must have at least one instance active; if not, the **Restrict to Selected Flow Instance(s)** list box is empty.
   - If any instance is currently paused at the breakpoint, all check boxes in the **Restrict to Selected Flow Instance(s)** list box are disabled and you cannot select them.

4. Click **OK**.

What to do next

Now you can add additional breakpoints (if needed), step through the flow instance, and work with data:

- "Adding breakpoints in the flow debugger" on page 669
- "Stepping through message flow instances in the debugger" on page 672
- "Debugging data" on page 677

Enabling and disabling breakpoints in the flow debugger
You can disable breakpoints that are currently enabled, and vice versa.

Before you begin

Add one or more breakpoints to your message flow. See: "Adding breakpoints in the flow debugger" on page 669.

About this task

Message flow processing pauses only at breakpoints that are enabled. By controlling which breakpoints are enabled and which are disabled, you can, for example, allow processing to continue to the part of a flow that you are interested in without having to continually add and remove breakpoints.

The following symbols identify breakpoints:

 Enabled breakpoint

 Disabled breakpoint

If you disable all the breakpoints in a message flow, you cannot perform any other debugging tasks until you add a new breakpoint, or enable an existing breakpoint.

To change the state of breakpoints:

Procedure

1. Switch to the Debug perspective.
2. In the Breakpoints view, select one or more breakpoints that you want to enable or disable.
3. Right-click the selected breakpoints and click **Enable** or **Disable**.
4. Optional: to change the state of a single breakpoint, right-click the breakpoint and click **Properties**. Select or clear the **Enabled** check box as required, then click **OK**.

Results

The state of breakpoints is changed in all instances of the message flow where they are set.

What to do next

If you have finished debugging, continue with: "Debug: ending a session" on page 683.

Removing breakpoints in the flow debugger
Remove breakpoints that are no longer required from connections in your message flow.

Before you begin

Add one or more breakpoints to your message flow. See: "Adding breakpoints in the flow debugger" on page 669.

About this task

The following symbols identify breakpoints:

- Enabled breakpoint
- Disabled breakpoint

If you remove a breakpoint from a message flow, it is automatically removed from all instances of the message flow where it is set.

If you remove all the breakpoints that you have added to your message flow, you cannot perform any other debugging tasks until you add a new breakpoint.

To remove breakpoints:

Procedure

1. Switch to the Debug perspective.
2. Remove the breakpoints.

   Use one of the following methods, depending on how many breakpoints you want to remove:

Option	Method
Remove individual breakpoints.	a. In the Message Flow editor, right-click the breakpoint that you want to remove, then click **Remove Breakpoint**.
Remove several breakpoints simultaneously.	a. Click the **Flow Breakpoints** tab to show the Breakpoints view. b. Select one or more breakpoints that you want to remove. c. Click the **Remove Selected Breakpoints** icon on the toolbar, or right-click the selected breakpoints, then click Remove.
Remove all breakpoints simultaneously.	a. Click the **Breakpoints** tab to show the Breakpoints view. b. Click the **Remove All Breakpoints** icon on the toolbar, or right-click any breakpoint, then click Remove All.

What to do next

If you have finished debugging, continue with: “Debug: ending a session” on page 683.

Stepping through message flow instances in the debugger

After you have added one or more breakpoints to a message flow in the debugger, you can step through the flow, pausing as required.

Before you begin

Add one or more breakpoints to your message flow. See: “Adding breakpoints in the flow debugger” on page 669.

About this task

The message flow debugger pauses flow processing at the first breakpoint it encounters. You can then continue with one or more of the following tasks, as appropriate:

- "Debugging: resuming message flow processing" on page 673
- "Debugging: running to completion" on page 674
- "Debugging: stepping over nodes" on page 674
- "Debugging: stepping into subflows" on page 675
- "Debugging: stepping out of subflows" on page 675
- "Debugging: stepping through source code" on page 676

What to do next

As you step through the message flow you can look at the processing data. When you have finished, end your debugging session:

- "Debugging data" on page 677
- "Debug: ending a session" on page 683

Debugging: resuming message flow processing
Each time message flow processing pauses at an active breakpoint, you can investigate the state of the flow, then resume processing.

Before you begin

Add one or more breakpoints to your message flow; see "Adding breakpoints in the flow debugger" on page 669.

About this task

When message flow processing is paused at a breakpoint, you can resume processing:

Procedure

1. Switch to the Debug perspective.
2. In the Debug view, click **Resume Flow Execution**  on the toolbar.

   Alternatively, right-click the flow stack frame, then click **Resume**  .

Results

Message flow processing continues until the next breakpoint that is set in the logical processing of the current message. If no further enabled breakpoint exists at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

What to do next

If message flow debugging is complete, you can remove the breakpoints, or end the debugging session:

- "Removing breakpoints in the flow debugger" on page 671
- "Debug: ending a session" on page 683

Debugging: running to completion
When message flow processing pauses at an active breakpoint, you can let it continue to the end of the flow, ignoring other breakpoints.

Before you begin

Add one or more breakpoints to your message flow; see "Adding breakpoints in the flow debugger" on page 669.

About this task

When message flow processing is paused at a breakpoint, you can restart processing so that the message flow runs to completion.

If you want the flow to continue processing, but you want to pause at the next enabled breakpoint instead of running to completion, see "Debugging: resuming message flow processing" on page 673.

Procedure

1. Switch to the Debug perspective.
2. In the Debug view, click **Run to completion** on the toolbar.

   Alternatively, right-click the flow stack frame, then click **Run to completion**.

Results

The flow instance ignores all breakpoints and processing continues to the end. The flow instance is removed automatically from the Debug view.

What to do next

If debugging is complete, you can remove the breakpoints, or end the debugging session:

- "Removing breakpoints in the flow debugger" on page 671
- "Debug: ending a session" on page 683

Debugging: stepping over nodes
When message flow processing pauses at an active breakpoint, you can step over the node and continue processing until the next active breakpoint, ignoring breakpoints that are set in code in the node.

Before you begin

Add one or more breakpoints to your message flow. See: "Adding breakpoints in the flow debugger" on page 669.

About this task

To step over the next node and continue message flow processing:

Procedure

1. Switch to the Debug perspective.
2. In the Debug view, click **Step Over Node** on the toolbar.

   Alternatively, right-click the flow stack frame, then click **Step Over Node**.

Results

Message flow processing continues until the next breakpoint that is set in the logical processing of the current message. If no further enabled breakpoint exists at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

What to do next

If debugging is complete, you can remove the breakpoints, or end the debugging session:

- “Removing breakpoints in the flow debugger” on page 671
- “Debug: ending a session” on page 683

Debugging: stepping into subflows

When message flow processing pauses at a breakpoint, you can step into the subflow that follows.

Before you begin

Add one or more breakpoints to your message flow; see “Adding breakpoints in the flow debugger” on page 669.

About this task

To step into a subflow, complete the following steps.

Procedure

1. Switch to the Debug perspective.
2. In the Debug view, click **Step Into Subflow** on the toolbar.

   Alternatively, right-click the flow stack frame, then click **Step Into Subflow**.

Results

The subflow opens in the Message Flow editor and displaces the parent message flow. Message flow processing continues until the next breakpoint that is set in the logical processing of the current message. If no further enabled breakpoint exists at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

What to do next

If debugging is complete, you can remove the breakpoints, or end the debugging session:

- “Removing breakpoints in the flow debugger” on page 671
- “Debug: ending a session” on page 683

Debugging: stepping out of subflows

When message flow processing is paused at a breakpoint in a subflow, you can step out of the subflow.

Before you begin

Complete the following tasks:

- “Adding breakpoints in the flow debugger” on page 669
- “Debugging: stepping into subflows” on page 675

About this task

To step out of a subflow, complete the following steps.

Procedure

1. Switch to the Debug perspective.
2. In the Debug view, click **Step Out of Subflow** on the toolbar.

   Alternatively, right-click the flow stack frame, then click **Step Out of Subflow**.

Results

The debugger continues processing until it reaches the connection from the output terminal of the subflow, where it pauses. The parent flow opens in the Message Flow editor, displacing the subflow.

What to do next

If debugging is complete, you can remove the breakpoints, or end the debugging session:

- "Removing breakpoints in the flow debugger" on page 671
- "Debug: ending a session" on page 683

Debugging: stepping through source code

When message flow processing is paused at a breakpoint on entry to a node that contains ESQL code or Java code, you can step through the code.

Before you begin

Add one or more breakpoints to your message flow; see "Adding breakpoints in the flow debugger" on page 669.

About this task

The nodes that can contain ESQL code or Java code are listed in "Flow debugger overview" on page 660.

To step through your source code, complete the following steps.

Procedure

1. Switch to the Debug perspective.
2. In the Debug view, click **Step into Source Code** on the toolbar.

   Alternatively, right-click the flow stack frame, then click **Step Into**.
3. When message flow processing is paused at a breakpoint in the ESQL or Java code, you can step through the source code line by line. In the Debug view, click **Step Over** on the toolbar.

   Alternatively, right-click the flow stack frame, then click **Step Over**.

   Repeat this step as often as necessary.

   A single line of source code runs and the flow pauses at the next line of code. What you can do depends on what type of code is contained within the node. For more information, see on of the following topics:

   - "Debugging ESQL" on page 678
   - "Debugging Java" on page 679

   If the debugger is paused before the last line of code when you step over, the last line of code runs and message flow processing continues until the next breakpoint in the logical processing of the current message. If no further enabled breakpoint exists at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

4. If you finish looking at the code before the last breakpoint, you can continue processing the message flow. In the Debug view, click **Step Return** on the toolbar.

   Alternatively, right-click the flow stack frame, then click **Step Return**.

   The source code runs to completion from the current breakpoint and message flow processing continues until the next breakpoint that is set in the logical processing of the current message. If no further enabled breakpoint exists at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

What to do next

If message flow debugging is complete, you can remove the breakpoints or end the debugging session:

- “Removing breakpoints in the flow debugger” on page 671
- “Debug: ending a session” on page 683

Debugging data

You can view (and change) data in messages, ESQL code, or Java code as debugging progresses.

About this task

When you have added one or more breakpoints to a deployed message flow, the debugger stops the message flow processing at each breakpoint. Depending on the context of the breakpoint, you can do one of the following tasks:

- “Debugging messages” on page 677
- “Debugging ESQL” on page 678
- “Debugging Java” on page 679

Results

When you have finished debugging a message flow, you can remove the breakpoints, or end the debugging session:

- “Removing breakpoints in the flow debugger” on page 671
- “Debug: ending a session” on page 683

Debugging messages

When message flow processing has paused at a breakpoint in your message flow, you can examine and modify the message content.

Before you begin

Add one or more breakpoints to your message flow. See: “Adding breakpoints in the flow debugger” on page 669.

About this task

To examine and modify message data:

Procedure

1. Switch to the Debug perspective.
2. View the messages in the Variables view.

   The Breakpoints view and the Variables view share the same pane. Click the tab at the bottom to select the view that you want.

3. To alter a message, right-click it and select an option from the menu.

   You cannot alter the content of exceptions within a message.

Results

Message flow processing continues until the next breakpoint that is set in the logical processing of the current message. If there is no further enabled breakpoint at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

What to do next

If you have finished debugging this message flow, you can remove the breakpoints, or end the debugging session:

- "Removing breakpoints in the flow debugger" on page 671
- "Debug: ending a session" on page 683

Debugging ESQL

When message flow processing has paused at a breakpoint that you have set in source code within a node that contains ESQL code, you can examine and modify the ESQL variables in the Flow Debugger.

Before you begin

Complete the following tasks:

- "Adding breakpoints in the flow debugger" on page 669
- "Debugging: stepping through source code" on page 676

About this task

You can browse ESQL variables in the Variables view in the Debug Perspective, and change their associated data values. You can also set breakpoints on lines in the ESQL code. See the following sections for further details:

- "Using breakpoints on ESQL code lines" on page 678
- "Working with ESQL variables" on page 678

Using breakpoints on ESQL code lines

Procedure

1. Switch to the Debug perspective.
2. Open the ESQL editor.
3. Right-click a line where you want to set a breakpoint.

   You cannot set a breakpoint on a comment line or a blank line.
4. Select from the menu to create, delete, or restrict the breakpoint, in a similar way to normal debugger breakpoints, as described in "Working with breakpoints in the flow debugger" on page 669.

Working with ESQL variables

Procedure

1. Switch to the Debug perspective.
2. Open the Variables view.

   Variables are shown in a tree, using the symbol  .

3. To work with a variable, right-click it and select an option from the pop-up menu.

   You cannot update message trees, or REFERENCE variables.

   For example, if you have declared the following ESQL variables, you can change their values in the debugger:

```
DECLARE myInt INT 0;
DECLARE myFloat FLOAT 0.0e-1;
DECLARE myDecimal DECIMAL 0.1;
DECLARE myInterval INTERVAL DAY TO MONTH;
```

Results

Message flow processing continues until the next breakpoint that is set in the logical processing of the current message. If there is no further enabled breakpoint at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

What to do next

If you have finished debugging this message flow, you can remove the breakpoints, or end the debugging session:

- "Removing breakpoints in the flow debugger" on page 671
- "Debug: ending a session" on page 683

Debugging Java

When message flow processing has paused at a breakpoint that you have set in source code within a node that contains Java code, you can examine and modify the Java variables in the Flow Debugger.

Procedure

1. To open the Command Console, click **Start** > **All Programs** > **IBM App Connect Enterprise 12.0.n** > **IBM App Connect Enterprise Console 12.0.n**.
2. Start the integration node by running the **mqsistart** command in the Command Console.
3. Check that the Java debug port is set by running the **mqsireportproperties** command (all on one line) in the Command Console:

   ```
   mqsireportproperties integrationNodeName -e integrationServerName -o ComIbmJVMManager -r
   ```

   For example:

   ```
   mqsireportproperties TEST -e default -o ComIbmJVMManager -r
   ```

4. Set the Java debug port by running the **mqsichangeproperties** command (all on one line) in the Command Console:

   ```
   mqsichangeproperties integrationNodeName -e integrationServerName
   -o ComIbmJVMManager -n jvmDebugPort -v port_number
   ```

   For example:

   ```
   mqsichangeproperties TEST -e default
   -o ComIbmJVMManager -n jvmDebugPort -v 3920
   ```

5. Stop and restart the integration node by running the **mqsistop** and **mqsistart** commands.
6. Open the message flow that you want to debug in the Message Flow editor by double-clicking its name in the Application Development view.
7. Add a breakpoint where the Java method is called, by following the instructions in "Adding breakpoints in the flow debugger" on page 669.
8. To step directly into the Java code during the debugging process, add a breakpoint in the Java code.

9. Deploy the BAR file that includes the JAR file that contains the Java code, by following the instructions in "Deploying integration solutions to a production environment" on page 2480.
10. Click **Run** > **Debug** to open the **Debug** wizard.
11. Right-click **Debug** in the list of elements on the left and click **New**.
12. Set the **Java Debug Port** with the same value that you specified for the **-v** parameter on the **mqsichangeproperties** command, and click **Apply** to save your changes.
13. Click the **Source** tab, specify the source file location, and click **Apply** to save your changes.
14. Click **Debug** to start the debug process.

Working with Java variables

About this task

When message flow processing has paused at a breakpoint in the source code within a node that contains Java code (a user-defined node or a JavaCompute node), you can browse Java variables in the Variables view on the Debug perspective, and change their associated data values.

Procedure

1. Switch to the Debug perspective.
2. Click the **Variables** tab to open the Variables view if it is not already open.

   Variables are shown in a tree, using the symbol  .
3. To work with a variable, right-click it and select an option from the menu.

Results

Message flow processing continues until the next breakpoint that is set in the logical processing of the current message. If there is no further enabled breakpoint at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

What to do next

When you have completed debugging the message flow, you can remove the breakpoints or end the debugging session:

- "Removing breakpoints in the flow debugger" on page 671
- "Debug: ending a session" on page 683

Managing flows and flow instances during debugging

During a debugging session, there are various administrative tasks that you might need to do, which include detaching the debugger from the integration server when you have finished.

About this task

When you have started a session for message flow debugging, you might want to complete one or more of the following associated tasks:

- "Debug: querying an integration server to find deployed flows" on page 681
- "Debug: stopping a message flow instance" on page 681
- "Debug: redeploying a message flow" on page 682
- "Debug: ending a session" on page 683

Debug: querying an integration server to find deployed flows
You can find the message flow that you want to work with in the Flow Debugger by refreshing the list of available flows.

About this task

During an active debugging session, you can query an integration server to find out what flows are currently deployed to it. The displayed list of message flows that are available in that integration server is updated. The updated list might include message flows that were not previously deployed, or that were not accessible because the flow was already being accessed by another developer.

To query an integration server for deployed flows:

Procedure

1. Switch to the Debug perspective.
2. In the Debug view, select the integration server that you want to query, then take one of the following actions:
   - Click **Refresh Selected Flow Engine to Get More Flow Types**  on the toolbar.
   - Right-click the integration server, then click **Refresh**  .

Results

The Debug view is refreshed with the names of the flows that are currently deployed to the integration server and are available.

What to do next

You can continue your debugging session and debug one of the listed message flows, or end your debugging session:

- “Working with breakpoints in the flow debugger” on page 669
- “Debug: ending a session” on page 683

Debug: stopping a message flow instance
While debugging, a message flow cannot be redeployed until it has been stopped.

About this task

While you are debugging, you might need to stop a message flow instance. For example, you might want to correct an error in your flow or source code. To do this, you must stop the flow and then redeploy it. See “Debug: redeploying a message flow” on page 682.

To stop message flow processing, run it to completion:

Procedure

1. Switch to the Debug perspective.
2. In the Debug view:
   - either, click **Run to completion**  on the toolbar.
   - or, right-click the flow stack frame, then click **Run to completion**  .

Results

The flow instance ignores all breakpoints and processing continues to the end. The flow instance is automatically removed from the Debug view.

What to do next

After stopping a flow instance, you can start to debug another message flow, or end your debugging session:

- "Attaching the flow debugger to an integration server for debugging" on page 665
- "Debug: ending a session" on page 683

Debug: redeploying a message flow

If you want to change your message flow while you are debugging it, you must redeploy it to the integration server, then reattach the flow debugger.

Before you begin

Stop the message flow before you redeploy it. See: "Debug: stopping a message flow instance" on page 681

About this task

During your debugging session, you might find a problem in a message flow that you want to correct or see a behavior that you want to change. You can alter the flow to resolve the situation and redeploy the flow to the integration node:

Procedure

1. Switch to the Debug perspective.
2. Detach the debugger from the integration server by clicking **Detach from the Selected Flow Engines**  on the toolbar.
3. Switch to the Integration Development perspective.
4. Edit the flow in the Message Flow editor and save your changes.
5. Double-click the BAR file that contains your flow. Remove the flow, then add your edited version and save your changes.

   See "Adding resources to a BAR file" on page 2470.
6. Deploy your BAR file.

   Drag your BAR file from the Application Development view to the integration server in the Integration Explorer view. Check the Administration log to make sure that the deployment was successful.

   See: "Deploying integration solutions to a production environment" on page 2480.
7. Switch to the Debug perspective.
8. Reattach the debugger to the integration server.

   Click the down-arrow on the **Debug** icon  on the toolbar, and select **Debug** to invoke the **Debug (Create, manage, and run configurations)** wizard, and attach the flow engine again, following the instructions in "Attaching the flow debugger to an integration server for debugging" on page 665.

Results

The modified message flow is now deployed to the integration node, and the debugging session is ready for you to debug the new flow logic.

What to do next

Continue to use these tasks to debug your message flow:

- "Working with breakpoints in the flow debugger" on page 669
- "Stepping through message flow instances in the debugger" on page 672

Debug: ending a session
Finish debugging by detaching the flow debugger from the integration server to which your message flows are deployed.

About this task

When you have finished debugging a flow, detach the flow debugger from the integration server. Other developers are then able to attach the debugger to the integration server. Detaching the flow debugger also restores the performance of your workbench environment, which might have been reduced by having the debugger attached.

To detach the flow debugger from an integration server:

Procedure

1. Switch to the Debug perspective.
2. In the Debug view, select the name of the integration server from which you want to detach the flow debugger, then take one of the following steps:
   - On the toolbar, click **Detach from the Selected Flow Engines**  .
   - Right-click the integration server, then click  **Detach**).

Results

All existing flow instances are automatically run to completion and the flow debugger is detached from the integration server. Your debugging session is now finished. You can start a new debugging session at any time.

Debugging message flows that contain WebSphere Adapters nodes

You can use various methods to monitor message flows that include WebSphere Adapters nodes.

About this task

Before you use any of the methods listed in this section, ensure that the appropriate JAR files and shared libraries are available to the WebSphere Adapters nodes. For more information, see "Preparing the environment for WebSphere Adapters nodes" on page 209.

Also, check for the latest information about WebSphere Adapters; see WebSphere Adapters technotes.

- **User and service trace:** You can use user and service trace to trace a message flow that contains WebSphere Adapters nodes. For more information, see "Using trace" on page 3026.
- **Flow debugger:** Use the flow debugger in the normal way to debug a message flow that contains WebSphere Adapters nodes. For more information, see "Testing your message flow by using the flow debugger" on page 659.
- **Adapter event table:** The WebSphere Adapters nodes use an event table to communicate the outcome of operations asynchronously to a calling application. For more information, see "Creating a custom event project in PeopleTools" on page 1127.

Handling exceptions that are raised by a WebSphere Adapters request node

The WebSphere Adapters request nodes raise exceptions that indicate the following Enterprise Information System (EIS) failures.

Message number	Exception type	Explanation
BIP3511	RecordNotFound	The requested record could not be found in the EIS.
BIP3512	DuplicateRecord	An attempt was made to create a record that already exists in the EIS.
BIP3513	MultipleMatchingRecords	A retrieve request matched more than one record. To retrieve multiple records, perform a `retrieveall` operation.
BIP3515	MatchesExceededLimit	A `retrieveall` exception returned more entries than the maximum allowed number.
BIP3516	MissingData	The message tree that was sent to the adapter request node does not have all the required fields set.

If an exception occurs that does not fit into the categories in the table, the node raises a general BIP3450 message that describes the problem.

You can use these exceptions to perform special processing when you do not want the exceptions to be treated as errors. For example:

- If a `create` operation fails because the record already exists, you could modify the request to an `update`.
- If a `retrieve` operation fails because the request matches more than one record, you could try a `retrieveall` operation instead.
- If a `retrieve` operation fails because the record could not be found, an empty record could be returned.

To handle these exceptions, you can connect a message routing node, Compute node, or JavaCompute node to the Failure terminal of the WebSphere Adapters request node, and route the exception to other processing nodes based on the exception message number.

XSD Schema Validation problem

When you configure an SAP adapter in the IBM App Connect Enterprise Toolkit, you might see the following warning, referring to an unresolvable IBM XML schema:

```
CTDX1101W : XSD: The location '' has not been resolved
example1.xsd /EAI_ESB_LIB line 2
example2.xsd /EAI_ESB_LIB line 2
XSD Schema Validation Problem
```

This warning is caused by the following namespace reference in an `<xsd:import>` element:

```
<xsd:import namespace="http://www.ibm.com/xmlns/prod/websphere/j2ca/sap/metadata"/>
```

No types or elements from this namespace are referenced in the logical structure of the XSD. An XML schema that references this namespace is in the referenced connector project, and is pointed to from the XML catalog. The XML catalog entry is populated when the SAP connector project is brought into the workspace.

This warning is benign and can be safely ignored, because it does not affect the structural content of your schema definition.

Tuning the SAP adapter for scalability and performance

You can monitor the performance of a message flow that contains SAP nodes by using user trace, and accounting and statistics data, then use that information to tune your flow by configuring an appropriate number of listeners and additional instances for the message flow.

Testing your message flow by adding Trace nodes

By adding a Trace node to a message flow, you can write debugging messages to a file, to user trace, or to the system log, and review those messages after the message flow has processed some data.

About this task

You must add a Trace node when the message flow is designed. "Viewing the logical message tree in trace output" on page 685 explains how to view the structure of the logical message tree at any point in the message flow, and contains an example of the message content. You can turn the Trace node off when a message flow is promoted to production to improve performance, but you can turn the node on when required. Performance can be affected when Trace nodes are active. The extent to which performance is affected depends on the destination that you choose for the debugging messages; for example, writing to user trace is typically faster than writing to a file or to the system log.

The debug messages can include writing part or all of the logical message tree, but they can also include hard-coded strings to identify a particular point in the message flow (such as PRINTF in a C program). If you write the entire message tree in a Trace node, the behavior of the message flow might be changed. Typically, only the parts of the message that are referenced are parsed, rather than the entire message.

Procedure

- Add a Trace node to your message flow, then set the following properties on the node (as described in detail in node):
  - Set the destination of the trace record that is written by the node to `User Trace`, `Local Error Log`, or `File`.
  - If you choose `File`, set the file path of the file to which to write records.
  - Use the `Pattern` property to create an ESQL pattern that specifies the data to be included in the trace record.
  - Specify the message catalog from which the error text for the error number of the exception is extracted.
  - Specify the error number of the message that is written.
  -
- After you have added a Trace node to your message flow, you can turn it on or off, as described in "Switching Trace nodes on and off" on page 3038.
- To view the structure of the logical message tree at any point in the message flow, include a Trace node and write some or all of the message (including headers and all four message trees) to the trace output destination. The following topics describes how to view that output: "Viewing the logical message tree in trace output" on page 685

Viewing the logical message tree in trace output

To view the structure of the logical message tree at any point in the message flow, include a Trace node and write some or all the message (including headers and all four message trees) to the trace output destination.

About this task

You might find trace output useful to check or record the content of a message before and after a node has changed it, or on its receipt by the input node. For example, if you include a Compute node that builds a destination list in the local environment tree, you might want a record of the structure that it has created as part of an audit trail, or you might want to check that the Compute node is working as you expect it to.

UNIX On UNIX, syslog entries are restricted in length and messages that are sent to the syslog are truncated by the newline character. To record a large amount of data in a log on UNIX, set the `Destination` property on the Trace node to `File` or `User Trace` instead of `Local Error Log`.

Procedure

1. Switch to the Integration Development perspective.
2. Open the message flow for which you want to view messages.

   Open an existing message flow, or create a message flow.
3. Include a Trace node wherever you want to view part or all the message tree structure.

   You can include as many Trace nodes as you choose; however, each node that you introduce can affect the performance of message flow processing.
4. Set the Trace node properties to trace the message, or parts of the message, that you want to view.

   Specify the parts of the message by using ESQL field references. Several examples are included later in this topic.
5. If you have added a Trace node to investigate a particular behavior of your message flow, and have now resolved your concerns or checked that the message flow is working correctly, remove the Trace node or nodes, and redeploy the message flow.

Example

Assume that you have configured a message flow that receives an XML message on an IBM MQ queue in an MQInput node. The input message includes an MQRFH2 header. The message has the following content:

```
<Trade type='buy'
 Company='IBM'
 Price='200.20'
 Date='2000-01-01'
 Quantity='1000'/>
```

You can include and configure a Trace node to produce output that shows one or more of the trees created from this message: the message body, environment, local environment, and exception trees. If you choose to record the content of the message body, the Properties tree and the contents of all headers (in this example, at least an MQMD and an MQRFH2) are included. You specify what you want to be recorded when you set the Trace node property `Pattern`. You can use most of the correlation names to define this pattern (you cannot use those names that are specific to the Compute node).

Message body

If you want the Trace node to write the message body tree including Properties and all headers, set `Pattern` to ${Root}. If you want only the message data, set `Pattern` to ${Body}.

The trace output generated for the message tree of the preceding message with `Pattern` set to ${Root} would look like the following example:

```
Root
      Properties
         CreationTime=GMTTIMESTAMP '1999-11-24 13:10:00'          (a GMT timestamp field)

  ... and other fields ...

      MQMD
         PutDate=DATE '19991124'                                  (a date field)

         PutTime=GMTTIME '131000'                                 (a GMTTIME field)

  ... and other fields ...

      MQRFH
          mcd
          msd='xml'                                              (a character string field)

         .. and other fields ...

      XML
         Trade
          type='buy'                                             (a character string field)

         Company='IBM'                                           (a character string field)

         Price='200'                                             (a character string field)

         Date='2000-01-01'                                       (a character string field)

         Quantity='1000'                                         (a character string field)
```

Environment

To trace any data in the environment tree, set `Pattern` to ${Environment}. This setting produces output like the following example:

```
 (0x1000000)Environment = (
      (0x1000000)Variables = (
        (0x1000000)MyVariable1 = (
          (0x2000000) = '3'
        )
        (0x1000000)MyVariable2 = (
          (0x2000000) = 'Hello'
        )
      )
  )
```

To trace particular variables in the variables folder of the environment tree, you can use a more specific pattern, for example ${Environment.Variables.MyVariable1}. This setting returns the value only (for example, it returns just the value 3).

LocalEnvironment

To trace data in the local environment tree, set `Pattern` to ${LocalEnvironment}. The output you get is like the following example, which shows that a destination list has been created in the local environment tree:

```
(0x1000000)Destination = (
    (0x1000000)MQ                = (
      (0x1000000)DestinationData = (
        (0x3000000)queuename = 'MQOUT'
      )
    )
     (0x1000000)MQDestinationList = (
      (0x1000000)DestinationData = (
        (0x3000000)queuename = 'OLDMQOUT'
      )
    )
    (0x1000000)RouterList        = (
      (0x1000000)DestinationData = (
        (0x3000000)labelname = 'continue'
      )
      (0x1000000)DestinationData = (
        (0x3000000)labelname = 'custdetails'
      )
      (0x1000000)DestinationData = (
        (0x3000000)labelname = 'trade'
      )
    )
  )
```

Another example, shown here, includes a WrittenDestination folder. This example represents a trace that has been written by a Trace node that is included after an MQOutput node, where the Out terminal of the MQOutput node is connected to a sequence of nodes including the Trace node. When an Out terminal is connected, the local environment is augmented with information about the action that the output node has performed.

```
(0x1000000)Destination        = (
    (0x1000000)MQ                = (
      (0x1000000)DestinationData = (
        (0x3000000)queuename = 'MQOUT'
      )
    )
  (0x1000000)WrittenDestination = (
    (0x1000000)MQ = (
      (0x1000000)DestinationData = (
        (0x3000000)queueName        = 'MQOUT'
        (0x3000000)queueManagerName = 'MQSI_SAMPLE_QM'
        (0x3000000)replyIdentfier   = X'414d51204d5153495f53414d504c455f1f442f3b12600100'
        (0x3000000)msgId            = X'414d51204d5153495f53414d504c455f1f442f3b12600100'
        (0x3000000)correlId         = X'0000000000000000000000000000000000000000000000000000'
        (0x03000000):GroupId          = X'414d512042524f4b45523220202020203f59934620001803'
        (0x03000000:NameValue):bindingType             = 'CLIENT' (CHARACTER)
        (0x03000000:NameValue):destinationQueueManager = 'QM1_REG1' (CHARACTER)
        (0x03000000:NameValue):queueManagerHostname    = 'MYQUEUEMANAGERHOSTNAME' (CHARACTER)
        (0x03000000:NameValue):listenerPortNumber      = 9000 (INTEGER)
        (0x03000000:NameValue):channelName             = 'MYCHANNELNAME' (CHARACTER)
      )
    )
  )
)
```

ExceptionList
To trace data in the exception list, set `Pattern` to ${ExceptionList}.

You can also view message structure in the message flow, and other information, when you use the flow debugger.

Enabling the exception log

The exception log enables the diagnosis of exceptions that occur at any time during processing on an integration server.

About this task

The exception log resource manager enables data relating to exceptions that occur at any time during processing on an integration server to be recorded, in an exception log, so that the message flow developer or administrator can diagnose such exceptions. The exception log is particularly useful when you are trying to diagnose exceptions that are not reported to the error log because the exception has

been handled in a message flow. The exception log is controlled by three properties that are available in the `server.conf.yaml` configuration file. The values of these properties can be viewed by using the **mqsireportproperties** command.

Even if the exception is not present in the error log meaning that it has been handled by flow logic, the exception is added to the exception log.

The exception log is written to one of the following locations depending on whether the integration server is independent or is managed by an integration node:

- `WorkDirectory/config/common/log/integration_server.`*`IntegrationServerName`*`.exceptionLog.txt` when the integration server is independent.
- `MQSI-REGISTRY/common/log/`*`IntegrationNodeName`*`.`*`IntegrationServerName`*`.exceptionLog.txt` when the integration server is managed by an integration node.

The exception log is a rolling collection of 4 files; when a file is full, data is added to the next file. When the last file has been filled, data starts to be added to the first file, overwriting the previous data there. This cycle of writing continues, ensuring that the newest data is retained. Restarting the integration server causes the previous log to be moved and a numeric suffix added to it.

The exception log includes:

- A summary or short description of the exception.
- A list of the exception's inserts.
- Message numbers of any nested exceptions.
- Optionally, details recorded by the Flow Thread Reporter. If the exception occurs in a message flow, the Flow Thread Reporter provides data to enable you to identify the location in the message flow at which the exception occurred.

Exceptions are listed in the order of their creation.

Procedure

Enable the exception log by amending properties in the `ExceptionLog` subsection of the `ResourceManagers` section of the `server.conf.yaml` configuration file.

The parameters are:

enabled
Controls whether the exception log is enabled.

Valid values are `true` and `false`.

The default value is `false`.

-n includeFlowThreadReporter
Controls whether, if an exception occurs on a message flow thread, additional information from the Flow Thread Reporter is added to the exception log. The additional information includes the flow thread history and stack. This information is quite verbose but is useful if you want to identify the precise location in a flow that an exception occurred, or what the passage through the flow was.

Valid values are `true` and `false`.

The default value is `false`.

showNestedExceptionDetails
Controls whether the exception log includes the details of any nested exceptions.

Valid values are `true` and `false`.

By default, the exception log does not include the details of any nested exceptions because they will already have been printed earlier in the log. Setting this option to `true` results in nested exceptions being re-printed, which is useful if your exception log has multiple concurrent exceptions. However, it might not be obvious which previous entry relates to the current exception.

To enable the exception log and set it to include details of any nested exceptions and additional information from the Flow Thread Reporter, specify the parameters in the `server.conf.yaml` file as follows:

```
ExceptionLog:
    enabled: true                    # Enables logging of exceptions to <workdir>/config/
common/log/integration_server.<name>.exceptionLog.txt
    includeFlowThreadReporter: true   # Toggles whether exception in the exception log include a
 flow stack and history from the flow thread reporter
    showNestedExceptionDetails: true  # Toggles whether nested exceptions are shown by default
 in the exception log
```

Message flow behavior

Message flow behavior is initially defined by IBM App Connect Enterprise, but there are some aspects of behavior that you can modify.

When a message is received and processed by a message flow, App Connect Enterprise handles both successful and failed processing. The default actions, which are independent of the protocol that you are using to exchange messages with your message flows, are described in "Default message flow behavior" on page 690.

If the default behavior does not meet your processing requirements, you can change some aspects of the behavior by tuning or reconfiguring your message flows.

- Learn about the default behavior supported by App Connect Enterprise.
- Review the options that are available to you if you want to change the behavior.

Default message flow behavior

IBM App Connect Enterprise controls the behavior of your message flows, and defines the default actions that are taken if you do not modify the message flow behavior.

The following default actions are provided for all messages that are processed by your message flows:

The execution and threading model
When you deploy a message flow to an integration server, App Connect Enterprise allocates a certain number of threads to that message flow. For further information about how this processing works, see "Execution and threading models in a message flow" on page 691.

Error handling
When you configure your message flows to process messages, you can include error processing of your own. App Connect Enterprise runs default processing if an error occurs for which you have not provided additional processing; this processing is independent of the protocol that you are using for communication. It is described in "Default error handling" on page 691.

Transactional support
App Connect Enterprise handles all messages individually, and does not relate an action taken by the message flow to other actions, processes, or messages. A message flow that is not configured to implement transactional support succeeds or fails regardless of the outcome of interactions with, or updates to, other resources such as IBM MQ queues and databases. Learn more about transactional support in "Message flow transactions" on page 691.

Data conversion
Different hardware platforms and operating systems operate in different code pages. Operating system code pages are also affected by the locale in which you operate. App Connect Enterprise does not allow for these differences unless you change some aspects of its configuration. If you are exchanging messages between unlike systems, you might have to update App Connect Enterprise or IBM MQ configuration, or design and supply your own conversion procedures.

For information about how you can change the configuration of App Connect Enterprise, its IBM MQ queue manager, and your message flows to influence these behaviors, see "Changing message flow behavior" on page 696.

Execution and threading models in a message flow

The execution model is the system that is used to start message flows, which process messages through a series of message flow nodes.

When an integration server is initialized, the appropriate loadable implementation library (LIL) files and Plug-in Archive (PAR) files are made available to the runtime environment. The integration server runtime process starts, and creates a dedicated configuration thread.

The message flow execution environment is conceptually like procedural programming. Nodes that you insert into a message flow are like subroutines that are called by using a function call interface. However, rather than a call-return interface, in which parameters are passed in the form of input message data, the execution model is referred to as a propagation-and-return model.

In the message flow execution environment, the message flow is thread-safe. You can run message flows concurrently on many operating system threads, without having to consider serialization issues.

Each input message that passes through a message flow for processing (by one or more message flow nodes) executes on a single thread; it is processed only by the thread that received it. If you want to increase the throughput of a message flow, you can increase the number of threads that are assigned to that message flow. The memory requirements of an integration server are not unduly affected by running message flows on more operating system threads.

With a larger number of threads, the message flow can handle peak message loads. At other times, the additional threads remain idle.

You can increase or decrease the number of threads that are servicing a flow, by using the `Additional instances` property on the input node of the message flow.

Each instance of a message flow processing node is shared, and used by all the threads that service the message flow in which the node is defined.

Default error handling

IBM App Connect Enterprise provides basic error handling for all your message flows.

When an exception is detected within a message flow node, the message and the exception information are propagated to the Failure terminal on the node. If the node does not have a Failure terminal, or is not connected, App Connect Enterprise throws an exception and returns control to the closest upstream node that can process it. The default behavior is that the message is returned to the input node.

The actions taken by the input node are protocol-dependent; if your message flow starts with an MQInput, its error handling is different from the error handling provided by a FileInput node. For more information, review the terminals and properties in the reference topic for the input node type.

The actions also depend on whether you have configured the message flow to be transactional. Some message flow nodes support transactions; others are non-transactional. If the flow is transactional, the message is returned to its source; for example, it is restored on the IBM MQ queue. For an overview of IBM MQ connection behavior, see "IBM MQ topologies" on page 739.

If basic error processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling. For example, you can add in a sequence of nodes to deal with one or more errors that you might expect to occur in your flow. You can also configure your flow to handle unexpected errors (exceptions). For more details about the actions that you can take, see "Handling errors in message flows" on page 1883.

Message flow transactions

A transaction describes a set of updates that are made by an application program, which must be managed together. The updates might be made to one or more systems. The updates made by the program are controlled by the environment in which the program executes, and either all are completed, or none. This property of a transaction is known as *consistency*: transactions might have other properties of *atomicity*, *isolation*, and *durability*.

IBM App Connect Enterprise supports transactions, and every piece of data processed by a message flow has an associated transaction. A message flow transaction is started when input data is received at an

input node in the flow; it is committed when the flow has finished with that message, or rolled back if an error occurs.

If the flow contains more than one input node, one transaction is started for each input node when it receives input data. A transaction is started for every type of input node, including user-defined input nodes.

The message flow nodes that you include in your message flow provide specific processing of a message, according to the defined function of each node. The processing that they do includes internal work, some of which you can influence by configuring the node properties. Some message flow nodes perform additional tasks that might affect systems that are external to the message flow, integration server, or integration node.

If an external system, such as a database, supports the concept of commit and rollback, and it can take part in an App Connect Enterprise transaction, you can configure the message flow node so that the work it does is included in the flow transaction. Depending on the message flow node, you can also specify if the work done in an external system that supports transactions is committed immediately, or when the message flow transaction completes.

Many of the resources with which your message flows can interact are controlled by resource managers that can participate in coordinated transactions; for example, databases, IBM MQ messages and queues, CICS, and JMS messages. Other resource managers do not provide transactional support; for example, the HTTP protocol and file systems.

Commit or rollback

If the resource can participate in a transaction, you can configure it so that the work it does is committed or rolled back only when the message flow completes, or when the node completes. Databases and IBM MQ queues are examples of resources that you can use in this way. If the resource does not have transactional behavior, all the work that it does is committed immediately. For example, files and HTTP connections do not support transactions.

Updates that are made by a message flow are committed when the flow processes the input message successfully. The updates are rolled back if the following conditions are met:

- A node in the flow throws an exception that is not caught by a node other than the input node (for example, the node itself, or a TryCatch node)
- The Catch terminal of the input node is not connected
- The Catch terminal of the input node is connected, but an unhandled exception occurs in the message flow nodes that are connected to the Catch terminal.

On distributed systems, message flow transactions are managed by App Connect Enterprise, by default. These transactions are known as *local transactions* or *locally coordinated transactions*. When control returns to the input node when the flow finishes processing, the input node either commits or rolls back the operations that have been taken, excluding the individual nodes that have been configured to perform their own commits and rollbacks, or that have no support for this option.

If more than one resource is accessed by the message flow, an error might occur that prevents all the resources committing all the work that has been done. App Connect Enterprise raises an exception and handles exception processing in a way that is determined by the transport that is involved. For example, messages that were read from IBM MQ queues are restored to those queues, and fault messages are sent to applications that submitted a message across HTTP (because HTTP has no concept of rollback). As a result of these actions, the status of the resources might become inconsistent.

If it is important that your data and operations remain consistent, and that all operations are committed, or rolled back if one or more operations fail, you can coordinate the activity of the message flow.

Coordinating transactions

Coordination is provided by an external transaction manager, which uses XA protocols to interact with resource managers. The transaction manager is called by the input node when the message flow has

concluded (successfully or with errors). The transaction manager, rather than the input node and the integration node, interacts with the relevant resource managers to initiate the correct actions for each resource. Transactions that are controlled by a transaction manager in this way are known as *globally coordinated transactions*.

On distributed systems, an IBM MQ queue manager associated with the integration node performs the transaction manager role, which means that App Connect Enterprise requires access to IBM MQ when processing messages. The queue manager must be local, and configured to be the transaction manager. All other queue managers that interact with MQ nodes in that message flow are treated as locally-coordinated resources. For more information about using IBM MQ with App Connect Enterprise, see “Enhanced flexibility in interactions with IBM MQ ” on page 26.

The role of the transaction manager

The result of the actions taken by message flows is the same for both local and globally coordinated transactions if the message flow is successful in all its actions. The advantage of a globally coordinated transaction is the ability to ensure that either all actions are committed, or none.

The external transaction manager, which operates a two-phase commit strategy, supports cases where one or more external resource managers are temporarily unavailable during commit processing. This potentially small window for failure might be costly for your business environment; the external transaction manager helps to eliminate the occurrence of a failure window. Therefore, the decision to include an external transaction manager, which involves a performance overhead, is an administrative decision, not one to be taken at message flow design time.

An external transaction manager does not prevent message loss; even if you use transaction coordination, you must configure and code your message flows to handle potential errors as much as you can.

To configure a message flow to be globally coordinated, you must also set up your environment so that your resource managers are defined to the supported transaction manager. On distributed systems, transactions can be coordinated by IBM MQ.

This configuration might require you to change settings in the transaction manager as well as the participating resource managers.

Database access modes and locks

You must use separate ODBC connections if you want to include message flow nodes with Automatic transaction status and nodes with Commit transaction status in the same message flow, where the nodes operate on the same external database. Set up one connection for the nodes that are not to commit until the completion of the message flow, and a second connection for the nodes that are to commit immediately.

- If nodes with Commit transaction status are followed by a node with Automatic transaction status, the nodes with Commit transaction status commit independently of the flow transaction, and the nodes with Automatic transaction status commit at the end of the flow.
- However, if nodes with Automatic transaction status are followed by a node with Commit transaction status, and you do not use separate ODBC connections, error message BIP4001 is issued, because otherwise the node with Commit transaction status commits the work of the Automatic nodes prematurely.

Linux Windows UNIX On distributed systems, individual relational databases might not support this mode of operation.

If you define more than one ODBC connection to the same data source, you might get database locking problems. In particular, if a message flow node with Automatic transaction status carries out an operation, such as an INSERT or an UPDATE, that causes a database object (such as a table) to be locked, and a subsequent node tries to access that database object by using a different ODBC connection, an infinite lock (deadlock) occurs.

The second message flow node waits for the lock acquired by the first to be released, but the first node does not commit its operations and release its lock until the message flow completes. The flow cannot complete because the second node is waiting for the database lock held by the first node to be released.

Such a situation cannot be detected by a DBMS automatic deadlock-avoidance routine because the two operations are interfering with each other indirectly by using the integration node.

You can use either of two options to avoid this type of locking problem:

- Design your message flow so that uncommitted (automatic) operations do not lock database objects that subsequent operations access across a different ODBC connection.
- Configure the lock timeout parameter of your database so that an attempt to acquire a lock fails after a specified length of time. If a database operation fails because of a lock timeout, an exception is thrown that the integration node handles in the usual way.

For information concerning which database objects are locked by particular operations, and how to configure the lock timeout parameter of your database, consult your database product documentation.

The transactional model

The transactional model describes the way in which you can use transactions in message flows to accomplish certain tasks and results.

A message flow consists of the following constituent parts:

- An input source
- The message flow or logic, which is defined by a sequence of nodes
- Zero or more external resources that are accessed during the flow
- Zero or more output targets

The following steps represent a typical sequence of events in the message flow transaction:

1. A message is taken from the input source; for example, a queue.
2. Data is read from or written to one or more external resources; for example, a database.
3. A message is sent to an output target; for example, a queue.
4. The system quiesces and waits for the next input message.

During this sequence of events, the state of the data in the system changes, regardless of the number of external resources that the message flow accesses, and whether it generates an output message.

Consider the following diagram:

```
-----x---------x---x-------x-------------x----x-----
     1         2   3       4             5    6
```

The line represents the data in the system as time passes. At time 1, a message arrives and is taken from the input source. At times 2, 3, 4, and 5, data is used to update external resources; for example, a database table or an output queue. Changes in the state of the data are indicated in the diagram by the *x* symbol. At time 6, the output messages are sent and the system is inactive. Between these events, the state of the data does not change; this state is indicated in the diagram by the = symbol.

If a failure occurs on the system (for example, a loss of power to the computer on which the integration node is running), the changes to the state of external resources that were made before the failure have been implemented, but no more changes take place after the failure. This situation is unacceptable in certain circumstances; for example, if a system failure occurs when making a payment from a current account to a mortgage account, the payment might be taken from the current account, but it is not added to the mortgage account.

Transactions

To avoid the problem that is described previously, the integration node and the external resource managers with which it works, have a *transactional model*. The integration node starts a transaction when data is received by an input node in the message flow, and completes when the processing on that data

is finished. For more details about message flow transactions, see “Message flow transactions” on page 691.

As processing proceeds in a transaction, additional data is recorded that allows the original state to be restored in the event of a failure. The following diagram illustrates the state of this extra data:

```
-----x=========x===x=======x=============x====x-----
     1         2   3       4             5    6
```

The line in the diagram represents the extra data in the system as time passes. At time 1, input data arrives from the input source; for example, a queue. Before time 1, no extra data exists in the system; this state is indicated in the diagram by the - symbol. After time 1, the state represents the fact that data has been received from the input source, so that it can be restored, if necessary. At times 2, 3, 4, and 5, data is used to update external resources such as databases or files. Again, the state of the extra data changes so that the changes to those external resources can be undone, if necessary. At time 6, the output messages are sent, the system is inactive, and extra data in the system no longer exists.

Between these events, the state of the extra data does not change; this state is indicated by the = symbol. If a failure occurs between time 1 and time 6, the extra data is used to restore the original state of the data held by the external resources. Therefore, effectively, no output data has been written to the output target, none of the external resources have been updated, and the input data has not been received from the input source. If no failure occurs, the changes become permanent at time 6 (an undo operation that follows a subsequent failure will not undo the changes).

This mode of operation is known as *coordinated transaction mode*. The successful completion of a transaction is known as its *commit*. Unsuccessful completion is known as *rollback*.

Uncoordinated auxiliary transactions

The key feature of the coordinated transaction mode of operation is that, regardless of where or when the failure appears, either all of the changes to external resources that are associated with one input message are made, or none of the changes are made. However, this behavior is not always suitable, as the following examples illustrate:

- You want to create an audit log of all attempts at processing. The log entries must be committed, even when updates to other resources are rolled back.
- You want to send an acknowledgment or non-acknowledgment message back to the originator of the messages that you are processing, according to whether the message processing succeeds or fails. These messages must be sent even when the updates to other resources are rolled back.

If your message flows have requirements like these, you can configure message flows to change one or more resources in a separate, or auxiliary, transaction. Not all resource managers support this type of transaction.

For some resources, an auxiliary transaction is automatically started; for example, each database connection starts a transaction that is specific to that database, and all updates made in that transaction can be committed or rolled back.

The behavior of an auxiliary transaction is shown in the following diagram:

```
MAIN -----x=========x===x=======x=============x====x-----
          1         2   4       5             8    9

1st AUX --------------x======x========x------
                      3      6        7
```

The *MAIN* line represents the main transaction, which includes the extra data that is recorded to restore the original state if necessary. The *1st AUX* line represents an auxiliary transaction. At time 3, an external resource is updated, and another update is made at time 6. At time 7, the message flow determines that all the changes that must be made under the auxiliary transaction are complete, and it commits the changes.

If the message flow fails before time 7, the state of the system would be unchanged because both transactions would be rolled back. If failure occurs after time 7 but before time 9, the auxiliary transaction

would already have been committed. However, the main transaction would be rolled back. If a failure has not occurred by time 9, both transactions are committed.

Database auxiliary transactions

You can use more than one auxiliary transaction, and make a number of updates to database tables that can be committed or rolled back. You can then make additional changes to the same database tables, or to different tables, then commit or rollback these changes.

Each database that you use has its own auxiliary transaction; therefore, if the message flow updates tables that belong to different database instances (different data source names), an auxiliary transaction exists for each database. You can optionally commit or roll back these auxiliary transactions individually. Updates that have not been committed or rolled back when the message flow completes (at time 9 in the example shown previously) are committed or rolled back automatically by the integration node, according to whether the processing succeeded or failed.

Use the ESQL COMMIT and ROLLBACK statements to commit and roll back auxiliary database transactions. Obtain operations outside the main transaction by specifying the UNCOORDINATED keyword on the individual database statements (for example, the INSERT and UPDATE statements).

Queue auxiliary transactions

Not all queuing systems have the database capability that is described in the previous section. With IBM MQ, each individual uncoordinated read or write operation to a queue has an implied commit action. Therefore, you cannot put two messages, then decide to commit both or roll back both. The COMMIT and ROLLBACK statements therefore operate only on databases.

Nodes

The previous sections refer to message flows, but not to nodes. The way in which a message flow is divided into nodes has no effect on transactions. For operations on databases, an unlimited number of nodes can make updates to the main transaction, and to an unlimited number of auxiliary transactions, without restriction.

Changing message flow behavior

You can change the behavior that is taken by your message flows to process messages in different ways and at different times.

About this task

If one or more of the default behaviors that are described in “Default message flow behavior” on page 690 is not sufficient or appropriate for your message processing, you can change some characteristics of that behavior at different times during the design, development, and production cycles:

- “Behavior you can change when you design your message flows” on page 696
- “Behavior you can change when you deploy your message flows” on page 697
- “Behavior you can change at any time” on page 697
- “Behavior you can change during message flow processing” on page 698

Behavior you can change when you design your message flows

About this task

You can influence the behavior of your message flows when you set message flow node properties, and when you connect together the nodes that you select to run in that flow.

Transactional support

You can configure your message flows to handle your messages, and other data, in transactions. These options are described in “Configuring transactionality for message flows” on page 698.

Error handling
App Connect Enterprise provides an initial level of error processing for all message flows. If you require further support in your message flows, you can add your own processing. You can learn more about these options in “Handling errors in message flows” on page 1883.

The message flow nodes that support some protocols provide extra default error handling; this support is described, where relevant, in the sections in “Connecting client applications” on page 737.

Data conversion
If you are exchanging messages between unlike systems, you can update App Connect Enterprise or IBM MQ configuration, or design and supply your own conversion procedures. Options are described in “Configuring message flows for data conversion” on page 727.

User-defined properties
You can create user-defined properties for your message flows to associate values with those message flows. You can then configure the nodes in your message flows to access those properties and their values by coding ESQL or Java programs. Read more about user-defined properties, and see how to create them in the Message Flow editor.

Promoted properties
You can promote some message flow node properties to the level of the message flow in which the node is included. The advantages of this technique are described in “Promoted properties” on page 568; see “Defining a promoted property” on page 729 for details of how to use these properties.

Behavior you can change when you deploy your message flows

About this task

After you have decided on the message flow content, you can change some aspects of its operation before or after deployment.

Configurable properties and BAR overrides
Some of the properties on message flow nodes are configurable; that is, you can change their values when you deploy the message flow. By using this option, you can change some characteristics of a deployed message flow without changing the message flow definitions. For example, you can update queue manager and data source information in the BAR file when you deploy it.

You can change these values by using the IBM App Connect Enterprise Toolkit or the **`mqsiapplybaroverride`** command.

The execution and threading model
You can increase the number of threads that your message flows use to reduce the time in which your messages are handled. You can also deploy multiple copies of a message flow to one or more integration nodes. For more information, see “Optimizing message flow throughput” on page 2763.

Behavior you can change at any time

About this task

The following technique can be implemented at any time in the solution lifecycle to enable developers, administrators, and operators to dynamically control certain aspects of message flow behavior.

Policies
A policy enables you to define a common approach to controlling certain aspects of message flow behavior, including flow rate, and particular node properties such as connection credentials. You can update a policy at any time in the solution lifecycle. For more information about policies, see “Overriding properties at run time with policies” on page 324.

Behavior you can change during message flow processing

About this task

If you want to change the behavior of your message flows in a more dynamic way, you can use the techniques that are described here. However, you must design your message flows so that they can take advantage of these additional services.

Policies

By using a policy, you can create and configure properties that relate to external services called by the integration node from your message flows.

Learn more about this option in "Overriding properties at run time with policies" on page 324.

Local environment overrides

You can configure some nodes to include your own processing; by coding ESQL, Java, or maps, you can modify the contents of the local environment tree within a message. Some fields in the local environment are used by nodes to determine how the message is processed, therefore by changing the tree contents, you can influence the behavior of subsequent nodes in the message flow. For more information about this option, see "Transforming and enriching messages" on page 1249.

Configuring transactionality for message flows

Process messages in either local or global transactions, by setting message flow node properties that determine how the resources that they represent participate within the transaction.

Before you begin

- Ensure that you understand how IBM App Connect Enterprise handles transactions, and the difference between local and globally coordinated transactions; see "Message flow transactions" on page 691.
- Create a message flow by following the instructions in "Creating a message flow" on page 574.

About this task

If you have configured an integration node that specifies a local MQ queue manager, you can set up globally coordinated transactions for the message flows that are managed by the integration node. The specified queue manager then performs the transaction manager role.

How individual message flow nodes, and the message flow itself, participate in transactions depends on the way you design and develop the message flow, and the level of additional configuration you perform.

1. You must configure the message flow node properties in your message flow to set the required level of participation in transactions.
2. If you want the updates that are made by the message flow to be globally coordinated by an external transaction manager (IBM MQ), you must configure the message flow properties.

   To use global transactions, IBM App Connect Enterprise must have access to IBM MQ. For more information about using IBM MQ with IBM App Connect Enterprise, see "Enhanced flexibility in interactions with IBM MQ " on page 26.

You can configure the message flow nodes in your message flow to determine how the work taken by each node participates in the message flow transaction. Most nodes for which transactionality is relevant have one or more properties that you can configure to dictate behavior. Therefore, you can decide for each individual message flow node whether it participates in the message flow transaction, or operates independently. Typically, these properties include an option of **Automatic**, so that subsequent nodes in the flow assume the characteristics set by the input node.

Message flow nodes that support transports that cannot participate in transactions might have other properties to determine what the integration node does when a message flow failure occurs. For example, the FileInput node has a set of **Retry** properties that you can set to determine failure behavior.

A few message flow nodes that interact with external resources do not provide properties; typically, these nodes are included in the message flow transactions. However, some exceptions exist. Review the

properties for each message flow node that you include in your flow to ensure that you understand what action is taken. For more information about each type of message flow node, see Built-in nodes.

If you configure a message flow node not to participate in the message flow transaction, the actions that it takes are committed, or rolled back, when the node exits. No further action is taken when the message flow itself completes.

To configure message flow behavior for transactions by setting node properties:

Procedure

1. Open the message flow that you want to configure.
2. Set the `Transaction mode` property for the input nodes in this message flow.

   The value that you set determines the behavior of the input node, and sets the default behavior for the rest of the message flow. Typically, you can choose the value **Yes** or **No**:

   - **Yes** means that the input node completes its own operation under sync point. The default behavior in the message flow is for actions to be taken under sync point.
   - **No** means that the input node completes its own operation out of sync point. The default behavior in the message flow is for actions to be taken out of sync point.

   Some nodes have extra or alternative values. For example, you can set the property on the MQInput node to **Automatic**, which means that the node gets the message under sync point if the message is persistent, and out of sync point if it is non-persistent.

   For details of the specific options for and actions that are taken by each node, see the relevant node reference topic. Review the node description, its properties, and the tabs on which the properties are set, because the resulting behavior is not identical across all input node types. Alternatively, you can read how to configure the following specific node types:

   - "Configuring JMS and SOAP nodes for local transactions" on page 700
   - "Configuring MQ nodes for transactions" on page 701
3. If your message flow includes nodes that interact with external resources, including output, request, and reply nodes, you can set a transaction property on most of these nodes.

   Set the property only if you want to change the behavior of the individual node from the default behavior for the message flow, which you set on the input node. The value that you set on this node has no effect on subsequent nodes in the message flow. If the node does not have a transactional property, its behavior is governed by the default behavior for the message flow, which you set in the input node.

   If your message flow is updating a database from multiple nodes in a single message flow, read "Message flow transactions" on page 691 to understand the possible interactions.

   a) Set the `Transaction` property for each node, if supported.

   b) Set the properties that define how errors are handled, if supported.
      For example, for nodes like the Compute node that can access databases, set the **Treat warnings as errors** and **Throw exception on database error** properties to define how that node handles database warnings and errors. Whether you select these properties, and how you connect the failure terminals of the nodes, also affect how database updates are committed or rolled back.

After you have configured your message flow, you must add it to a BAR file before you can deploy it. When you add it to a BAR file, the message flow is compiled, and more properties are available for configuration.

On distributed systems, use the `Coordinated Transaction` property to configure for globally coordinated transactions. By default, this property is cleared (not selected), which means the message flow is using local transactions, and the integration node commits or rolls back the message flow transaction. If you select this property, the transaction is globally coordinated; the input node calls the external transaction manager IBM MQ for commit and rollback processing. For more information, see

the “Coordinating transactions” on page 692 section in the topic “Message flow transactions” on page 691.

To configure message flow properties:

4. Add the message flow to a BAR file.
5. Select the **Manage and Configure** tab below the BAR file editor view, and select the message flow.

   The configurable properties for the message flow in the BAR file are displayed in the **Properties** view.

   Select `coordinatedTransaction` to configure the message flow as globally coordinated; when you set this property, the external transaction manager (IBM MQ) coordinates the transaction with all the resource managers that you have defined to the queue manager.

What to do next

When message flow design and development is complete, you can deploy the BAR file to the integration server on which you want the message flow to run.

If you are configuring your message flows for globally coordinated transactions, additional configuration is required. You, or your system administrator, must ensure that your App Connect Enterprise environment, the transaction manager, and the participating resource managers are all correctly configured to support coordinated transactions, before you run the message flow. For more information on what might be required, see “Configuring global coordination of transactions (two-phase commit)” on page 702.

If the App Connect Enterprise environment, the transaction manager, and the external resource managers are not correctly configured for global coordination, the message flow will run, but transactions will not be globally coordinated.

Configuring JMS and SOAP nodes for local transactions

When you include a node that uses JMS transport in a message flow, such as the JMSInput or SOAPInput node, the options that you select for the properties define behavior for the coordinated transaction.

Before you begin

Review “Configuring transactionality for message flows” on page 698 to understand what configuration is required for transactionality.

Procedure

- The option that you select for the `Transaction Mode` property defines whether the message is written under sync point:
  - If you set this property to `Yes` with the `Coordinated transaction` flow property selected, the message is received under external sync point coordination; that is, within an IBM MQ unit of work. Any messages that are sent later, by an output node in the same instance of the message flow, are put under sync point, unless the output node overrides this setting explicitly.
  - If you set this property to `Yes` with the `Coordinated transaction` flow property not selected, the message is received under the local sync point control of the node. Any messages that are sent later, by an output node in the flow, are not put under local sync point, unless an individual output node specifies that the message must be put under local sync point.
  - If you set this property to `No`, the message is not received under sync point. Any messages that are sent later, by an output node in the flow, are not put under sync point, unless an individual output node specifies that the message must be put under sync point.

What to do next

To receive messages under external sync point, you must take additional configuration steps, which need be applied only the first time that a specific node using JMS transport is deployed to the integration server for a particular JMS provider.

- On distributed systems, an IBM MQ queue manager provides the coordinated transaction support, which means that IBM App Connect Enterprise must have access to IBM MQ when it is processing the messages in the message flow. For more information about using IBM MQ with IBM App Connect Enterprise, see "Installing IBM MQ" on page 96.
- Before you deploy a message flow in which the `Transaction mode` property is set to `Global` or `Yes`, and is intended to use global (XA) coordinated transactions, modify the queue manager `.ini` file to include extra definitions for each JMS provider resource manager that participates in globally coordinated transactions. For more information, see "Configuring JMS and SOAP nodes to support globally coordinated transactions" on page 721.

  For more information on transactionality, see Transactional support in the IBM MQ product documentation online.

Configuring MQ nodes for transactions
When you define an MQInput, MQGet, MQOutput, or MQReply node, the options that you select for the properties define behavior for the transaction.

Before you begin

Review "Configuring transactionality for message flows" on page 698 to understand what configuration is required for transactionality.

About this task

You can use IBM MQ resources in either local or globally coordinated transactions:

- For local transactions, you can have multiple queue managers participating in a message flow. Connections to queue managers can be local, client, or both.
- For globally coordinated transactions, you must specify a local queue manager on the integration node. This queue manager is the global transaction manager, and no other IBM MQ resources can be used in the message flow. For more information about configuring for globally coordinated transactions, see "Configuring global coordination of transactions (two-phase commit)" on page 702.

  If the connection is lost to the queue manager that was specified on the integration node in a globally-coordinated transaction, the integration node enters a standby state until the queue manager becomes available again. If the integration node was configured by using an MQ Service, the integration node is stopped.

If a connection to a queue manager is lost, and that connection is enlisted in a transaction, automatic reconnection is delayed until the inflight transaction is complete. Other queue managers that are required, but are not part of the transaction, reconnect automatically without delay. A completed transaction can include the following cases:

- The unavailable MQ resource was not required and was not used, because exception handling was defined in the message flow, so the inflight transaction was successful and committed.
- The unavailable MQ resource was required, and the message flow cannot succeed without it, so the inflight transaction was rolled back.

Review how to set the properties for MQ nodes to determine how they participate in transactions.

Configuring transactions for MQInput and MQGet nodes

Procedure

- The option that you select for the `Transaction Mode` property defines whether the message is read under sync point:
  - `Yes` (the default): if a transaction is not already inflight, the node starts a transaction.
  - `No`: the node does not start a transaction.
  - `Automatic`: if a transaction is not already inflight, and the message is specified in IBM MQ as persistent, the node starts a new transaction.

  All nodes that are subsequent in the message flow use the `Transaction mode` property that is set on the MQInput or MQGet node as their default transaction mode.
- If you set the `Browse Only` property for an MQInput or MQGet node, the value that is set for the `Transaction mode` property is ignored. However, when the `Transaction mode` property of the output node is set to **Automatic**, any messages that are propagated later to that output node in the same instance of the message flow use the `Transaction mode` value set on the input node.

  The `Browse Only` property for an MQGet node is on the **Request** tab.

Configuring transactions for MQOutput and MQReply nodes

Procedure

- The option that you select for the `Transaction Mode` property defines whether the message is written under sync point:
  - If you set the property to `Automatic`, the node participates in a transaction. If there is no inflight transaction, processed messages are committed immediately.
  - If you set the property to `Yes`, the node participates in the transaction currently inflight. If there is no transaction, a new transaction is started for this node, and all other nodes that are connected to its output terminal.
  - If you set the property to `No`, an inflight message is immediately committed.

What to do next

To use MQ nodes in global transactions, follow the steps in "Configuring global coordination of transactions (two-phase commit)" on page 702.

To understand when you might want to use a globally coordinated transaction for your message flow, see the "Coordinating transactions" on page 692 section in the topic "Message flow transactions" on page 691.

Configuring global coordination of transactions (two-phase commit)

Globally coordinate message flow transactions with a transaction manager to ensure the data integrity of transactions.

Before you begin

Read "Message flow transactions" on page 691 to understand how IBM App Connect Enterprise handles transactions. Depending on the external resource managers that are accessed during the processing of deployed message flows, you must complete the appropriate resource-dependent set of tasks to ensure that all resources are configured correctly. For example, you might have to create and configure databases, following the tasks in "Working with databases" on page 1130.

The IBM MQ queue manager that is associated with the integration node performs the transaction manager role, which means that App Connect Enterprise requires access to IBM MQ when processing messages. For more information, see "Enhanced flexibility in interactions with IBM MQ " on page 26.

You, or your message flow developer, must also ensure that the message flows deployed to the integration node are set up to support coordination. The tasks for configuring the message flows correctly are described in “Configuring transactionality for message flows” on page 698.

About this task

If you have configured an integration node that specifies a local MQ queue manager, you can set up globally coordinated transactions for the message flows that are managed by the integration node. The specified queue manager then performs the transaction manager role.

The following external resources are able to participate in a globally-coordinated message flow transaction:

- IBM MQ queues and messages
- CICS
- Databases
- JMS providers

On distributed platforms, the default behavior of the integration node is to manage all message flow transactions by using local transactions (a one-phase commit approach). In many contexts this approach is sufficient, but if your business requires assured data integrity and consistency (for example, for audit reasons, or for financial transactions), you can configure the integration node with a local IBM MQ queue manager to manage the message flow transactions as globally coordinated (a two-phase commit approach), by using the XA protocol standard. To globally coordinate transactions, there must be a queue manager specified on the integration node, and that queue manager performs the transaction manager role. The queue manager that is specified on the integration node is used as a globally coordinated resource. Other queue managers cannot participate in the message flow transaction.

If the connection is lost to an IBM MQ resource when the message flow is running, automatic reconnection is delayed until the inflight transaction is complete; see “Configuring MQ nodes for transactions” on page 701.

You configure the IBM MQ queue manager to act as the transaction manager by updating its `qm.ini` file, to add definitions of the additional resource managers with which you want IBM MQ to coordinate updates. Resource managers must register with the transaction manager, and there are two methods of registration:

- Static registration: The transaction manager involves all the resource managers in a transaction that are using static registration, even if a resource manager does not have a role to play in that transaction. Therefore all resource managers that use static registration must be available for the beginning of each globally coordinated transaction, even if they are not actively participating in that transaction, otherwise the transaction fails.
- Dynamic registration: Resource managers using dynamic registration must register with the transaction manager on a per transaction basis to get involved in a transaction (that is, if they are being updated as part of the globally coordinated transaction). A resource manager that uses dynamic registration does not need to be available for the beginning of each globally coordinated transaction.

Follow the instructions for the resource managers that are relevant in your environment and note whether they use static or dynamic registration:

- CICS
- ODBC connections to databases
- JDBC connections to databases
- JMS providers

Procedure

- You must specify a local queue manager on the integration node, and configured that queue manager for global transactions. You must use this queue manager only for your MQ nodes in your message flow.
- Set the node `Transaction mode` property to either `Automatic` or `Yes` for each node that is required in the global transaction.

  Review which `Transaction mode` option to set for each type of node in its node reference topic
- Configure the BAR file to enable global transactions:
  a) Below the BAR file editor view, select the **Manage and Configure** tab.
  b) In the **Properties** view, select `coordinatedTransaction`.

Results

When you have completed these steps, your message flows are processed by using global coordination, which is managed by the queue manager.

You must complete all of the steps, because if your resources are not correctly configured for global coordination the message flow will run, but transactions will not be globally coordinated.

Configuring databases for global coordination of transactions

If your message flow interacts with a database, and you want to globally coordinate the updates made to the database with other actions within the message flow, configure your databases for globally coordinated transactions.

About this task

If you have configured an integration node that specifies a local MQ queue manager, you can set up globally coordinated transactions for the message flows that are managed by the integration node. The specified queue manager then performs the transaction manager role.

If you restart a database while the integration node is still running, you must also restart the integration node. The integration node cannot detect that the database has stopped, and IBM MQ therefore retains its old connections to the database. When the database starts again, the integration node tries, and fails, to use these connections.

To configure databases for coordinated message flows, follow the instructions relevant to your database manager:

- DB2
- Oracle
- Sybase

Configuring DB2 for global coordination of transactions

Before you begin

You must complete these steps for databases that you connect to with an ODBC or a JDBC connection.

You must have database administrator (DBA) privileges to perform the following tasks.

About this task

To configure DB2 database instances for global coordination of transactions:

Procedure

1. Windows

   Windows systems only: for each 32-bit DB2 instance that is involved in the global coordination, run the following commands to set the Transaction Process Monitor name (TP_MON_NAME) to MQ:

   ```
   db2 update dbm cfg using TP_MON_NAME MQ
   db2stop
   db2start
   ```

2. If you are connecting an integration node on a distributed platform to a DB2 instance on z/OS, you must configure DB2 Connect to enable support for global coordination.

   Ensure that you have already configured a DB2 alias to represent the database by using DB2 Connect.

   Perform the following tasks on the system that hosts the integration node:

   a) Turn on the Connection Concentrator by configuring the DB2 database manager configuration parameters so that the value of the **MAX_CONNECTIONS** parameter is greater than the value of the **MAX_COORDAGENTS** parameter:

   ```
   db2 update dbm cfg using MAX_CONNECTIONS max_connections_value
   ```

   where *max_connections_value* is greater than the existing value of the **MAX_COORDAGENTS** parameter.

   b) Define the SPM name as the name of the system that hosts the integration node:

   ```
   db2 update dbm cfg using SPM_NAME host_name
   ```

   where *host_name* is the TCP/IP name of the system that hosts the integration node.

   c) Stop, then restart DB2 on the system that hosts the integration node to apply the changes:

   ```
   db2stop
   db2start
   ```

   DB2 Connect is now configured to enable global coordination of message flows that are deployed to the integration node (on a distributed platform) and that access DB2 on z/OS.

Results

The DB2 database instances are now configured for global coordination.

What to do next

See “Configuring ODBC connections for globally coordinated transactions” on page 708.

Configuring Oracle for global coordination of transactions

Before you begin

You must complete these steps for databases that you connect to with an ODBC connection only.

You must have database administrator (DBA) privileges to perform the following tasks.

About this task

To configure Oracle databases for global coordination of transactions:

Procedure

1. Ensure that the JAVA_XA package is present on the Oracle database by using, for example, the following Oracle SQLPLUS command:

   ```
   describe JAVA_XA;
   ```

   For more information, see the Oracle product documentation.
2. Ensure that the user ID that the integration node uses to access the database has the necessary Oracle privileges to access the DBA_PENDING_TRANSACTIONS view.

   You can grant the required access by using, for example, the following Oracle SQLPLUS command:

   ```
   grant select on DBA_PENDING_TRANSACTIONS to userid;
   ```

   If more than one user ID is involved (for example, if IBM App Connect Enterprise and IBM MQ run under different user IDs), you also need the privilege FORCE ANY TRANSACTION.

Results

The Oracle databases are now configured for global coordination.

What to do next

See “Configuring ODBC connections for globally coordinated transactions” on page 708.

Configuring Sybase for global coordination of transactions

Before you begin

You must complete these steps for databases that you connect to with an ODBC connection only.

You must have database administrator (DBA) privileges to perform the following tasks.

Procedure

- To configure Sybase databases for global coordination of transactions, ensure that the user ID that the integration node uses to access the database has been granted the Sybase role of `dtm_tm_role`.

Results

The Sybase databases are now configured for global coordination.

What to do next

See “Configuring ODBC connections for globally coordinated transactions” on page 708.

Configuring the CICSRequest node for global transactions on distributed systems

Configure the CICSRequest node for local and globally coordinated transactions for CICS on Linux, UNIX, and Windows.

Before you begin

Review CICSRequest node to understand what `Transaction mode` properties you can set on a CICSRequest node for transactions.

Linux UNIX Ensure that the user that is running the IBM MQ queue manager, typically mqm, is a member of the mqbrkrs group.

About this task

If you have configured an integration node that specifies a local MQ queue manager, you can set up globally coordinated transactions for the message flows that are managed by the integration node. The specified queue manager then performs the transaction manager role.

The queue manager provides the coordinated transaction support, which means that IBM App Connect Enterprise must have access to IBM MQ when it is processing the messages in the message flow. For more information about using IBM MQ with IBM App Connect Enterprise, see "Installing IBM MQ" on page 96.

To configure the CICSRequest node for globally coordinated transactions:

Procedure

1. Create a CICS Connection policy for the CICSRequest node (see "Creating policies with the IBM App Connect Enterprise Toolkit" on page 327).
   a) On the `Integration server used for XA recovery` property, specify the integration server for XA recovery, and which will own the connection. You cannot use any other integration server with the policy. When this property is set, the CICSRequest node is treated as a global resource, otherwise it participates as a non-global resource.
   b) On the `CICS server` property, you can choose either a direct connection or a connection through CICS Transaction Gateway.
   c) On the `Security identity (DSN)` property, set up a valid security ID to authenticate the connection to CICS (see "Security identities for the integration server connecting to external systems" on page 2582).

   Note: You should not use multiple CICS Connection policies that connect to the same CICS system in the same transaction or you might have problems with the overall transaction results.

   For more information, see CICS Connection policy (CICSConnection).
2. In the IBM App Connect Enterprise Toolkit, switch to the Integration Development perspective.
3. In the BAR file properties, set the `Coordinated Transaction` message flow property value to **yes**.
4. In the Message Flow editor, set the **Transaction mode** property to `Yes` or `Automatic` for each CICSRequest node that is required in the globally coordinated transaction.
5. Copy the switch file. The IIBXASwitch switch file is supplied by IBM App Connect Enterprise, and uses dynamic XA registration (see "Configuring databases for global coordination of transactions" on page 704):
   - On Windows:
     - If you are using 64-bit IBM MQ, copy the 64-bit switch file `IIBXASwitch.dll` from the IBM App Connect Enterprise installation directory (*`IIB_installation_directory`*`\bin\IIBXASwitch.dll`) to the `\exits64` subdirectory in the IBM MQ installation directory (*`MQ_installation_directory`*`\exits64\IIBXASwitch.dll`).
     - If you are using 32-bit IBM MQ, copy the 32-bit switch file (`IIBXASwitch32.dll`) from the IBM App Connect Enterprise installation directory (*`IIB_installation_directory`*`\bin\IIBXASwitch32.dll`) to the `\exits` subdirectory in the IBM MQ installation directory, and rename it to `IIBXASwitch.dll` (*`MQ_installation_directory`*`\exits\IIBXASwitch.dll`).
   - On Linux and UNIX systems, create a symbolic link to the switch file that is supplied in your *`install_dir`*`/server/lib` directory.

     install_dir is the directory to which you installed IBM App Connect Enterprise. The default location for this directory is *`install_dir`*`/ace-12.0.`*`n`*`.0/server` on Linux, or `/opt/IBM/`

`mqsi/12.0.n.0/server` on UNIX systems. The default directory includes the version, release, modification, and fix of the product, in the format v.r.m.f (version.release.modification.fix).

Set up links in the `/var/mqm/exits64` directory. The file name is `libIIBXASwitch.so`. For example:

```
ln -s install_dir/server/lib/libIIBXASwitch.so /var/mqm/exits64/libIIBXASwitch.so
```

6. Add a stanza to the queue manager `qm.ini` file for CICS, in the following format:

   On Linux and UNIX:

   ```
   XAResourceManager:
       Name=name
       SwitchFile=libIIBXASwitch.so
       XAOpenString=integrationNodeName,CICS,CICS_configurable_service
       XACloseString=
       ThreadOfControl=THREAD
   ```

   On Windows:

   ```
   XAResourceManager:
       Name=name
       SwitchFile=IIBXASwitch.dll
       XAOpenString=integrationNodeName,CICS,CICS_policy
       XACloseString=
       ThreadOfControl=THREAD
   ```

   where *name* is any name, *integrationNodeName* is the name of the integration node, and *CICS_policy* is the name of the CICS policy.

What to do next

- Check your configuration:
  - In the message flow, ensure that the `Coordinated Transaction` property is enabled for the BAR file by using the IBM App Connect Enterprise Archive editor.
  - Ensure that each node that is part of the globally-coordinated (XA) transaction has its `Transaction Mode` property set to a valid global transaction value (`Yes` or `Automatic`).
  - Ensure that the service ID that is used for the integration node and the queue manager is the same user ID.
  - Ensure that CICS two-phase commit is working by using the activity log. Define an Activity log policy by naming a file and setting the **RM** property to `CICS`.
  - Look for issues in the error log for the queue manager.
- Optional: secure the message flow connection; see "Creating a security profile" on page 2584.

Configuring ODBC connections for globally coordinated transactions
Configure the definition of your ODBC databases to the transaction manager (the queue manager).

Before you begin

You must create and configure the databases by following the instructions in "Working with databases" on page 1130.

You, or your message flow developer, must also ensure that the message flows deployed to the integration node are set up to support coordination. The tasks that are involved in configuring the message flows correctly are described in "Configuring transactionality for message flows" on page 698.

On distributed systems, an IBM MQ queue manager associated with the integration node performs the transaction manager role, which means that IBM App Connect Enterprise requires access to IBM MQ when processing messages. For more information about using IBM MQ with App Connect Enterprise, see "Installing IBM MQ" on page 96.

Procedure

1. Ensure that your databases are configured for global coordination.

   For the databases that your message flows connect to, complete the tasks that are described in “Configuring databases for global coordination of transactions” on page 704.
2. Configure the App Connect Enterprise environment so that the integration node queue manager coordinates transactions with database resource managers.

   The steps to configure the environment depend on the database manager that you are using.

   - “Configuring global coordination with DB2” on page 709
   - “Configuring global coordination with Oracle” on page 712
   - “Configuring global coordination with Sybase” on page 716

Results

When you have completed these steps, your message flows are processed by using global coordination, which is managed by the queue manager.

You must complete all the steps correctly; if you do not, global coordination will not work.

Configuring global coordination with DB2
Configure your IBM App Connect Enterprise environment to globally coordinate message flow transactions with updates in DB2 databases under the control of your integration node queue manager.

Before you begin

Ensure that the databases are configured for global coordination of transactions, see “Configuring databases for global coordination of transactions” on page 704.

On distributed systems, an IBM MQ queue manager associated with the integration node performs the transaction manager role, which means that IBM App Connect Enterprise requires access to IBM MQ when processing messages. For more information about using IBM MQ with IBM App Connect Enterprise, see “Installing IBM MQ” on page 96.

Procedure

Follow the instructions appropriate to your platform:

- Linux “Linux and UNIX” on page 709
- Windows “Windows” on page 711

Linux and UNIX

Procedure

1. Run the **mqsimanagexalinks** command to create the links that are required by IBM MQ to include databases in XA transactions.

   For more information, see command.
2. Configure the integration node queue manager with XA resource manager information for each database that is involved in the transaction that the queue manager will globally coordinate.
   a) Open the queue manager's `qm.ini` file in a text editor.

      The `qm.ini` file is located at `/var/mqm/qmgrs/`*queue_manager_name*`/qm.ini`, where *queue_manager_name* is the name of the integration node that is associated with the queue manager.

   b) At the end of the `qm.ini` file, paste the following stanza:

```
XAResourceManager:
```

```
Name=DB2
SwitchFile=db2swit
XAOpenString=db=MyDataSource,uid=MyUserId,pwd=MyPassword,toc=t
XACloseString=
ThreadOfControl=THREAD
```

c) On the **XAOpenString** line, replace the following values with values that are appropriate for your configuration:

- *MyDataSource* is the name of the data source to which you want to connect.
- *MyUserId* must be the user name that the integration node uses to connect to the database.

  You can define the user name that the integration node uses in a number of ways; make sure that you specify the correct name in this file. The integration node determines the user name by checking the following conditions in the order listed:

  i) A specific user name and password for this data source name (DSN), that you have defined by running the **mqsisetdbparms** command.

  ii) A default user name and password for all DSNs, that you have defined by running the **mqsisetdbparms** command.

  iii) The integration node service user name, which you define with the **-i** parameter on the **mqsicreatebroker** command
- *MyPassword* is the password that is associated with the user name.

d) Accept the default values for all the other lines in the stanza.
For example:

```
XAResourceManager:
Name=DB2
SwitchFile=db2swit
XAOpenString=db=MYDB,uid=wbrkuid,pwd=wbrkpw,toc=t
XACloseString=
ThreadOfControl=THREAD
```

3. The DB2 switch file is supplied by IBM App Connect Enterprise, and uses dynamic XA registration (see “Configuring databases for global coordination of transactions” on page 704).
4. Linux UNIX

   Stop then restart the queue manager to apply the changes, because `qm.ini` is read only while the queue manager is running. Before you restart the queue manager, ensure that the `ODBCINI` and `ODBCSYSINI` environment variables have been exported, and that the user ID that the queue manager processes will run under has read access to the `odbc.ini` and `odbcinst.ini` files.

   To stop and restart the queue manager, enter the following commands, where *queue_manager_name* is the name of the queue manager:

   ```
   endmqm queue_manager_name
   strmqm queue_manager_name
   ```

   When the queue manager restarts, check the queue manager log for all warnings that are associated with the restart. The log files are located in `/var/mqm/qmgrs/`*queue_manager_name*`/errors`, where *queue_manager_name* is the name of the queue manager that you restarted.

   When the queue manager restarts successfully, the changes that you made to `qm.ini` are applied.

Results

DB2 is now configured for global coordination with the integration node queue manager coordinating transactions.

What to do next

You can deploy globally coordinated message flows to the integration node.

Procedure

1. Windows

   Configure the integration node queue manager with XA resource manager information for each database that is involved in the transaction that the queue manager will globally coordinate.

   a) From the **Start** menu, open IBM MQ Explorer.

   b) Open the queue manager Properties dialog box, then open **XA resource managers**.

   c) Click the **Add** button to create a resource manager.

      i) In the **Name** field, enter a name to refer to a resource manager.

      ii) In the **SwitchFile** field, enter `db2swit`

      iii) Copy the provided DB2 switch files from the integration node install location to the queue managers exits and `exits64` directories (by default under `C:\Program Files (x86)\IBM\WebSphere MQ`).

      Copy the file:

      ```
      install_dir\server\sample\xatm\db2swit32.dll
      ```

      into the queue managers `exits` directory, and rename it to `db2swit.dll`.

      Copy the file

      ```
      install_dir\server\sample\xatm\db2swit.dll
      ```

      into the queue managers `exits64` directory.

      iv) In the **XAOpenString** field, paste the following string:

      ```
      db=MyDataSource,uid=MyUserId,pwd=MyPassword,toc=t
      ```

      v) In the **XAOpenString** field, replace the values with values that are appropriate for your configuration:

      a) *MyDataSource* is the name of the data source to which you want to connect.

      b) *MyUserId* must be the user name that the integration node uses to connect to the database.

      You can define the user name that the integration node uses in a number of ways; make sure that you specify the correct name in this file. The integration node determines the user name by checking the following conditions in the order listed:

      i. A specific user name and password for this data source name (DSN), that you have defined by running the **mqsisetdbparms** command.

      ii. A default user name and password for all DSNs, that you have defined by running the **mqsisetdbparms** command.

      iii. The integration node service user name, which you define with the **-i** parameter on the **mqsicreatebroker** command

      c) *MyPassword* is the password that is associated with the user name.

      For example:

      ```
      db=MYDB,uid=wbrkuid,pwd=wbrkpw,toc=t
      ```

      vi) Accept the default values for all the other fields on the page.

2. Windows

   Stop then restart the queue manager to apply the changes.

   To stop and restart the queue manager, enter the following commands, where *queue_manager_name* is the name of the queue manager:

   ```
   endmqm queue_manager_name
   strmqm -si queue_manager_name
   ```

   When the queue manager restarts, check the queue manager log for all warnings that are associated with the restart. The log files are located in *install_dir*`\WebSphere MQ\Qmgrs\QMGR\errors`, where *install_dir* is the location in which the integration node is installed and QMGR is the name of your IBM MQ Queue manager.

   When the queue manager restarts successfully, the changes that you made are applied.

Results

DB2 is now configured for global coordination with the integration node queue manager coordinating transactions.

What to do next

you can deploy globally coordinated message flows to the integration node.

Configuring global coordination with Oracle
Configure your IBM App Connect Enterprise environment to globally coordinate message flow transactions with updates in Oracle databases under the control of an IBM MQ queue manager.

Before you begin

- Ensure that you have configured the databases for global coordination of transactions.

On distributed systems, an IBM MQ queue manager associated with the integration node performs the transaction manager role, which means that IBM App Connect Enterprise requires access to IBM MQ when processing messages. For more information about using IBM MQ with IBM App Connect Enterprise, see “Installing IBM MQ” on page 96.

About this task

Configure your IBM App Connect Enterprise environment for global coordination by using a 64-bit queue manager as the transaction manager with the DataDirect drivers:

Procedure

1. Linux Windows

   Run the **mqsimanagexalinks** command.

2. Windows

   Add the directory specified as the queue manager’s *ExitsDefaultPath* to the system PATH.

3. Configure the integration node queue manager with XA resource manager information for each database that is involved in the transaction that the queue manager will globally coordinate.

   On Linux and UNIX:

   a) Open the queue managers' `qm.ini` file in a text editor.

   The `qm.ini` file is located at `/var/mqm/qmgrs/`*queue_manager_name*`/qm.ini`. Where *queue_manager_name* is the name of the integration node that is associated with the queue manager.

   b) Add the following stanza to the end of the `qm.ini` file:

```
XAResourceManager:
Name=OracleXA
SwitchFile=UKoradtc95.so
XAOpenString=ORACLE_XA
   +HostName=MyHostName
   +PortNumber=MyPortNumber
   +ServiceName=MyServiceName
   +ACC=P/MyUserId/MyPassword
   +sestm=100+threads=TRUE
   +DataSource=MyDataSourceName
   +K=2
XACloseString=
ThreadOfControl=THREAD
```

   c) On the **XAOpenString** line, replace the following values with values that are appropriate for your configuration:

   - *MyHostName* is the name of the TCP/IP host that hosts the Oracle database listener. When you are using Oracle Real Application Clusters with multiple listeners for the given Service Name, if the Oracle listener identified by the values for *MyHostName* and *MyPortNumber* in the **XAOpenString** is unavailable, the alternative Oracle listeners that you might have defined in the **AlternateServers** list in your odbc.ini file are also tried.
   - *MyPortNumber* is the TCP/IP port on which the Oracle database listener is listening.
   - *MyUserId* must be the user name that the integration node uses to connect to the database.

     You can define the user name that the integration node uses in a number of ways; make sure that you specify the correct name in this file. The integration node determines the user name by checking the following conditions in the order listed:

     i) A specific user name and password for this data source name (DSN), that you have defined by running the **mqsisetdbparms** command.

     ii) A default user name and password for all DSNs, that you have defined by running the **mqsisetdbparms** command.

     iii) The integration node service user name, which you define with the **-i** parameter on the **mqsicreatebroker** command

   - *MyPassword* is the password that is associated with the user name.
   - *MyDataSourceName* is the ODBC data source name for the database, as defined in your odbc.ini file.
   - *MyServiceName* is the value set for the Service Name in the stanza for *MyDataSourceName* in your odbc.ini file.

   d) Accept the default values for all the other lines in the stanza.
   For example:

   - On AIX:

```
XAResourceManager:
Name=OracleXA
SwitchFile=UKoradtc95.so
XAOpenString=ORACLE_XA
   +HostName=diaz.hursley.ibm.com
   +PortNumber=1521
   +ServiceName=accounts_service
```

```
   +ACC=P/wbrkuid/wbrkpw
   +sestm=100+threads=TRUE
   +DataSource=MYDB+K=2
XACloseString=
ThreadOfControl=THREAD
```

e) If you are using Global coordination to Oracle:

- Set the ODBCINI environment variable to be visible in the environment from which you start your queue manager. The ODBCINI variable must reference the same file as the one being used by your integration node.
- An optional additional property, `CTO=`*`Value`*, is available for the **XAOpenString**. `CTO` is the value set for a Connection TimeOut, indicating the number of seconds that the Oracle XA switch file will wait for a response from the Oracle database to an XA request. For example, the timeout can be used to prevent long delays in the integration node failing over to an alternative Oracle Real Application Clusters node, when the active Oracle instance fails abruptly leaving socket connections hanging. The *Value* should be set to a value larger than the Oracle session timeout `sestm` value set in the **XAOpenString**. If this property is used, you must set the corresponding connection option. `ConnectionTimeout=`*`Value`* for the data source in the `odbc.ini` file. If this property is not used, or is set to zero, there will be no timeout (this is the default behavior).

On Windows:

a) From the **Start** menu, open IBM MQ Explorer.

b) Open the queue manager Properties dialog box, then open **XA resource managers**.

c) In the **SwitchFile** field, enter the name of the switch file, `ukora95.dll`.

d) In the **XAOpenString** field, paste the following string:

```
ORACLE_XA+
   +HostName=MyHostName
   +PortNumber=MyPortNumber
   +ServiceName=MyServiceName
   +ACC=P/MyUserId/MyPassword
   +sestm=100+threads=TRUE
   +DataSource=MyDataSourceName
   +K=2
```

e) In the **XAOpenString** field, replace the values with values that are appropriate for your configuration:

- *MyHostName* is the name of the TCP/IP host that hosts the Oracle database listener. When you are using Oracle Real Application Clusters with multiple listeners for the given Service Name, if the Oracle listener identified by the values for *MyHostName* and *MyPortNumber* in the

XAOpenString is unavailable, the alternative Oracle listeners that you might have defined in the **AlternateServers** list in your odbc.ini file are also tried.

- *MyPortNumber* is the TCP/IP port on which the Oracle database listener is listening.
- *MyUserId* must be the user name that the integration node uses to connect to the database.

  You can define the user name that the integration node uses in a number of ways; make sure that you specify the correct name in this file. The integration node determines the user name by checking the following conditions in the order listed:

  i) A specific user name and password for this data source name (DSN), that you have defined by running the **mqsisetdbparms** command.

  ii) A default user name and password for all DSNs, that you have defined by running the **mqsisetdbparms** command.

  iii) The integration node service user name, which you define with the **-i** parameter on the **mqsicreatebroker** command
- *MyPassword* is the password that is associated with the user name.
- *MyDataSourceName* is the ODBC data source name for the database, as defined in your odbc.ini file.
- *MyServiceName* is the value set for the Service Name in the ODBC definition for the data source *MyDataSourceName*.

For example:

```
ORACLE_XA+
   +HostName=diaz.hursley.ibm.com
   +PortNumber=1521
   +ServiceName=accounts_service
   +ACC=P/wbrkuid/wbrkpw
   +sestm=100+threads=TRUE
   +DataSource=MYDB+K=2
```

f) Accept the default values for all the other fields on the page.

4. The Oracle switch file is supplied by IBM App Connect Enterprise, and uses static XA registration by default. On AIX and Linux on x86-64 only, if you want to enable Oracle data sources to perform dynamic XA registration, set the following environment variable: DDTEK_XA_DYNAMIC_REGISTRATION=1 (See "Configuring databases for global coordination of transactions" on page 704).
5. Linux UNIX

   Stop then restart the queue manager to apply the changes, because qm.ini is read only while the queue manager is running. Before you restart the queue manager, ensure that the ODBCINI and ODBCSYSINI environment variables have been exported, and that the user ID that the queue manager processes will run under has read access to the odbc.ini and odbcinst.ini files.

   To stop and restart the queue manager, enter the following commands, where *queue_manager_name* is the name of the queue manager:

   ```
   endmqm queue_manager_name
   strmqm queue_manager_name
   ```

   When the queue manager restarts, check the queue manager log for all warnings that are associated with the restart. The log files are located in /var/mqm/qmgrs/*queue_manager_name*/errors, where *queue_manager_name* is the name of the queue manager that you restarted.

   When the queue manager restarts successfully, the changes that you made to qm.ini are applied.

6. Windows

   Stop then restart the queue manager to apply the changes.

   To stop and restart the queue manager, enter the following commands, where *queue_manager_name* is the name of the queue manager:

   ```
   endmqm queue_manager_name
   strmqm -si queue_manager_name
   ```

   When the queue manager restarts, check the queue manager log for all warnings that are associated with the restart. The log files are located in `/var/mqm/qmgrs/`*queue_manager_name*`/errors`, where *queue_manager_name* is the name of the queue manager that you restarted.

   When the queue manager restarts successfully, the changes that you made are applied.

Results

Oracle is now configured for global coordination with the integration node queue manager coordinating transactions.

What to do next

You can deploy globally coordinated message flows to the integration node.

Configuring global coordination with Sybase

Configure you IBM App Connect Enterprise environment to globally coordinate message flow transactions with updates in Sybase databases under the control of a queue manager.

Before you begin

- Ensure that the databases are configured for global coordination of transactions.

On distributed systems, an IBM MQ queue manager that is associated with the integration node performs the transaction manager role, which means that IBM App Connect Enterprise requires access to IBM MQ when processing messages. For more information about using IBM MQ with IBM App Connect Enterprise, see “Installing IBM MQ” on page 96.

About this task

To configure your IBM App Connect Enterprise environment for global coordination by using an IBM MQ queue manager as the transaction manager with the DataDirect drivers:

Procedure

1. Run the **mqsimanagexalinks** command.
2. Configure the integration node queue manager with XA resource manager information for each database that is involved in the transaction that the queue manager will globally coordinate.

   Linux **On Linux and UNIX:**

   a) Open the queue manager's `qm.ini` file in a text editor.

   The `qm.ini` file is at `/var/mqm/qmgrs/`*queue_manager_name*`/qm.ini`, where *queue_manager_name* is the name of the integration node that is associated with the queue manager.

   b) At the end of the `qm.ini` file, paste the following stanza:

   ```
   XAResourceManager:
       Name=SYBASEXA
       SwitchFile=UKasedtc95.so
       XAOpenString=-NSYBASEDB -AMyServerName,MyPortNumber -Uuid -Ppwd -K2
       XACloseString=
   ```

```
    ThreadOfControl=THREAD
```

c) On the **XAOpenString** line, replace the following values with values that are appropriate for your configuration:

- *MyServerName* is the name of the TCP/IP host that hosts the Sybase ASE server.
- *MyPortNumber* is the TCP/IP port on which the Sybase ASE server is listening.
- *uid* must be the user name that the integration node uses to connect to the database.

  You can define the user name that the integration node uses in a number of ways; make sure that you specify the correct name in this file. The integration node determines the user name by checking the following conditions in the order listed:

  i) A specific user name and password for this data source name (DSN), that you have defined by running the **mqsisetdbparms** command.

  ii) A default user name and password for all DSNs, that you have defined by running the **mqsisetdbparms** command.

  iii) The integration node service user name, which you define with the **-i** parameter on the **mqsicreatebroker** command

- *pwd* is the password that is associated with the user name.

d) Accept the default values for all the other lines in the stanza.
For example:

- On AIX:

```
XAResourceManager:
    Name=SYBASEXA
    SwitchFile=UKasedtc95.so
    XAOpenString=-NSYBASEDB -Adiaz,4100 -Uwbrkuid -Pwbrkpw -K2
    XACloseString=
```

```
ThreadOfControl=THREAD
```

On Windows:

a) From the **Start** menu, open IBM MQ Explorer.

b) Open the Properties dialog box, then open **XA resource managers**.

c) In the **SwitchFile** field, enter the name of the switch file, `ukase95.dll`.

d) In the **XAOpenString** field, paste the following string:

```
-NSYBASEDB -AMyServerName,MyPortNumber -WWinsock -Uuid -Ppwd -K2
```

e) In the **XAOpenString** field, replace the values with values that are appropriate for your configuration:

- *install_dir* is the location in which IBM App Connect Enterprise is installed.
- *MyServerName* is the name of the TCP/IP host that hosts the Sybase ASE server.
- *MyPortNumber* is the TCP/IP port on which the Sybase ASE server is listening.
- *uid* must be the user name that the integration node uses to connect to the database.

  You can define the user name that the integration node uses in a number of ways; make sure that you specify the correct name in this file. The integration node determines the user name by checking the following conditions in the order listed:

  i) A specific user name and password for this data source name (DSN), that you have defined by running the **mqsisetdbparms** command.

  ii) A default user name and password for all DSNs, that you have defined by running the **mqsisetdbparms** command.

  iii) The integration node service user name, which you define with the **-i** parameter on the **mqsicreatebroker** command

- *pwd* is the password that is associated with the user name.

For example:

```
-NSYBASEDB -Adiaz,4100 -WWinsock -Uwbrkuid -Pwbrkpw -K2
```

f) Accept the default values for all the other fields on the page.

3. The Sybase switch file is supplied by IBM App Connect Enterprise, and uses static XA registration (see “Configuring databases for global coordination of transactions” on page 704).
4. Linux UNIX

Stop then restart the queue manager to apply the changes, because `qm.ini` is read only while the queue manager is running. Before you restart the queue manager, ensure that the `ODBCINI` and `ODBCSYSINI` environment variables have been exported, and that the user ID that the queue manager processes will run under has read access to the `odbc.ini` and `odbcinst.ini` files.

To stop and restart the queue manager, enter the following commands, where *queue_manager_name* is the name of the queue manager:

```
endmqm queue_manager_name
strmqm queue_manager_name
```

When the queue manager restarts, check the queue manager log for all warnings that are associated with the restart. The log files are located in `/var/mqm/qmgrs/`*queue_manager_name*`/errors`, where *queue_manager_name* is the name of the queue manager that you restarted.

When the queue manager restarts successfully, the changes that you made to `qm.ini` are applied.

5. Windows

   Stop then restart the queue manager to apply the changes.

   To stop and restart the queue manager, enter the following commands, where *queue_manager_name* is the name of the queue manager:

   ```
   endmqm queue_manager_name
   strmqm -si queue_manager_name
   ```

   When the queue manager restarts, check the queue manager log for all warnings that are associated with the restart. The log files are located in *install_dir*\WebSphere MQ\Qmgrs\QMGR\errors, where *install_dir* is the location in which the integration node is installed and QMGR is the name of your IBM MQ Queue manager.

   When the queue manager restarts successfully, the changes that you made are applied.

Results

Sybase is now configured for global coordination with your queue manager coordinating the transactions.

What to do next

You can deploy globally coordinated message flows to the integration node.

Configuring a JDBC type 4 connection for globally coordinated transactions
If you want the database that you access through a JDBC type 4 connection to participate in globally coordinated transactions, set up the appropriate environment.

Before you begin

Set up your JDBC provider definition.

About this task

On distributed systems, an IBM MQ queue manager associated with the integration node performs the transaction manager role, which means that IBM App Connect Enterprise requires access to IBM MQ when processing messages. For more information about using IBM MQ with IBM App Connect Enterprise, see “Installing IBM MQ” on page 96.

Updates that you make to a database across a JDBC type 4 connection can be coordinated with other actions taken within the message flow, if you set up the resources to support coordination.

Complete the following steps:

Procedure

1. Check that the definition of your JDBC Providers policy is appropriate for coordinated transactions.

   For example, to set up the required JDBC classes:

   - For DB2, set **JDBC type 4 data source class name** to `com.ibm.db2.jcc.DB2XADataSource` and **JDBC driver class name** to `com.ibm.db2.jcc.DB2Driver`.
   - For Oracle, set **JDBC type 4 data source class name** to `oracle.jdbc.xa.client.OracleXADataSource` and **JDBC driver class name** to `oracle.jdbc.OracleDriver`.

   Consult your database administrator or the documentation provided by your database supplier, to confirm that all the JDBC Providers policy properties are set appropriately. For example, a database supplier might require secure access if it is participating in coordinated transactions.

2. Define the switch file and the database properties:
   a) The JDBC switch file is supplied by IBM App Connect Enterprise, and uses static XA registration (see “Configuring databases for global coordination of transactions” on page 704).
   b) Linux

      On Linux and UNIX systems, open the `qm.ini` file for the integration node queue manager with a text editor. Add the following stanza for each database:

      ```
      XAResourceManager:
             Name=Database_Name
             SwitchFile=JDBCSwitch
             XAOpenString=JDBC_DataSource
             ThreadOfControl=THREAD
      ```

      Database_Name is the database name (DSN) of the database defined to the JDBC Providers policy.

      `JDBCSwitch` is a fixed generic name that represents the switch file for XA coordination. Use this value, or another single fixed value, in each stanza; the specific switch file that the queue manager uses is defined by the symbolic links you create in the next step.

      JDBC_DataSource is the identifier of the JDBC Providers policy.

      Define a stanza for each database (DSN) that you connect to from this integration server. You must create separate definitions even if the DSNs resolve to the same physical database. Therefore, you must have a stanza for each JDBC Providers policy that you have defined, because each service can define the properties for a single database.
   c) Windows

      On Windows, open IBM MQ Explorer and select the queue manager, for example BROKERQM.

      Open the **XA resource manager** page, and modify the attributes to create the definition of the database. The attributes are the same as those shown for Linux and UNIX; **Name**, **SwitchFile**, **XAOpenString**, and **ThreadofControl**. Leave the additional attribute, **XACloseString**, blank.

      Enter *JDBCSwitch* in **SwitchFile**.
3. Set up queue manager access to the switch file:
   a) Linux

      On Linux and UNIX systems, create a symbolic link to the switch files that are supplied in your *install_dir*`/server/lib` directory.

      install_dir is the directory to which you installed IBM App Connect Enterprise. The default location for this directory is *install_dir*`/ace-12.0.`*n*`.0/server` on Linux, or `/opt/IBM/mqsi/12.0.`*n*`.0/server` on UNIX systems. The default directory includes the version, release, modification, and fix of the product, in the format v.r.m.f (version.release.modification.fix).

      Set up links in the `/var/mqm/exits64` directory. The file name for all platforms is `libJDBCSwitch.so`.

      Specify the same name of the switch file, `JDBCSwitch` or your own value, in the `/exits64` directory. For example, on AIX:

      ```
      ln -s install_dir/server/lib/libJDBCSwitch.so /var/mqm/exits64/JDBCSwitch
      ```
   b) Windows

      On Windows, copy the `JDBCSwitch32.dll` file from the *install_dir*`\server\bin` directory to the `\exits` subdirectory in the IBM MQ installation directory, and rename the file to `JDBCSwitch.dll`. Then, copy the `JDBCSwitch.dll` file from the *install_dir*`\server\bin` directory to the `\exits64` subdirectory in the IBM MQ installation directory.

4. Configure the message flow that includes one or more nodes that access databases that are to participate in a globally coordinated transaction.
   a) Open an IBM App Connect Enterprise Toolkit session.
   b) Switch to the Integration Development perspective.
   c) Add the message flow that includes the node or nodes that connect to the database that is to participate in a globally coordinated transaction to a new or existing BAR file.
   d) Build the BAR file.
   e) Click the **Configure** tab, select the message flow that you have added, and select the **Coordinated Transaction** check box.

What to do next

If your integration node is running on Windows, authorize the queue manager to access resources that are associated with the JDBC Providers policy (see "Authorizing access to JDBC type 4 JDBCProvider resources on Windows" on page 204).

If you have been following the instructions in "Working with databases" on page 1130, the next task is "Configuring ODBC connections for globally coordinated transactions" on page 708 (optional).

Configuring JMS and SOAP nodes to support globally coordinated transactions

To include message flow nodes that use JMS transport, such as the JMS and SOAP nodes, in globally coordinated transactions, you must complete additional configuration.

Before you begin

Review "Configuring JMS and SOAP nodes for local transactions" on page 700 to understand what properties you must set on a SOAP or JMS node to use globally coordinated transactions.

Note: Global (XA) transaction coordination for nodes that use JMS transport is supported only if the message flow that contains the nodes is deployed to an integration node that has a dedicated queue manager; the integration node cannot share a queue manager with other integration nodes.

About this task

If you require global transaction coordination, choose a JMS provider that conforms to the Java Message Service Specification version 1.1 or 2.0, and that supports the JMS XAResource API through the JMS session.

If you specify your own JMS provider by using the JMS Providers policy, set the `XA is supported` property of the policy to true to indicate that the selected JMS provider supports XA coordinated transactions. If you set this property to true, and the selected JMS provider does not support XA transactions, an exception is raised. If you set this property to false, but the `Transaction mode` property on the node is set to `Yes` and the `Coordinated Transaction` message flow property is selected, an exception is raised.

If the message designer specified a non-XA-compliant provider, only the non-transactional mode is supported. In this case, you must set the `Transaction mode` property to `None` for all JMS and SOAP nodes that use JMS transport.

On distributed systems, an IBM MQ queue manager provides the coordinated transaction support, which means that IBM App Connect Enterprise must have access to IBM MQ when it is processing the messages in the flow. For more information about using IBM MQ with IBM App Connect Enterprise, see "Installing IBM MQ" on page 96.

Procedure

To configure the message flow nodes, complete the following steps:

1. In the IBM App Connect Enterprise Toolkit, switch to the Integration Development perspective.
2. In the BAR file properties, set the `Coordinated Transaction` message flow property value to **yes**.

3. In the Message Flow editor, set the **Transaction mode** property to Yes for each node that uses JMS transport that is required in the XA coordinated transaction.
4. Create a Queue Connection Factory, and use either the default name, *recoverXAQCF*, or supply your own name.

   For more information about creating JNDI administered objects, see "JNDI administered objects" on page 866.
5. There are two modes for enlisting an XAResource with the transaction coordinator:

   a. Static enlistment, which means that the XAResource is called to perform a start transaction when any message flow in the same Integration Bus starts a global coordinated transaction.

   b. Dynamic enlistment where the JMS node registers an interest in joining a global transaction when it has work to perform.

   Before deployment on distributed systems, you must set up a stanza for each JMS provider that you want to use. For Windows, the JMS provider switch file is called `DynJMSSwitch.dll`. For all other operating systems, the JMS provider switch file is called `libDynJMSSwitch.so`.

   Follow the steps in the appropriate topic for the operating system, or systems, that your enterprise uses:

   - Linux Linux and UNIX systems
   - Windows Windows systems

     On Windows only, you must also modify the queue manager authorization, as described in "Windows systems: modifying the queue manager authorization" on page 882.

What to do next

The JMS provider might supply additional JAR files that are required for transactional support; for more information, see the documentation that is supplied with the JMS provider. For example, on distributed systems, the IBM MQ JMS provider supplies an extra JAR file, `com.ibm.mqetclient.jar`.

You must add any additional JAR files to the `shared_classes` directory:

- Linux On Linux and UNIX: `var/mqsi/shared-classes`.
- Windows On Windows: `C:\ProgramData\IBM\MQSI\shared-classes`.

For more information, see the section about making the JMS provider client available to the JMS nodes in node.

Configuring the queue manager to coordinate JMS resources on Linux and UNIX

Configure the global (XA) resource managers for the queue manager by defining a stanza in the integration node's queue manager `qm.ini` file for each new JMS provider.

About this task

The JMS provider can be specified by a JMS or SOAP node that is included in a message flow that is running on the integration node.

Before you deploy a message flow in which the `Transaction mode` property is set to `Global` or `Yes`, and is intended to use XA coordinated transactions, modify the queue manager `.ini` file to include extra definitions for each JMS provider resource manager that participates in globally coordinated transactions.

To configure the queue manager for Linux and UNIX:

Procedure

1. Add a stanza to the queue manager `.ini` file for each JMS provider, in the following format:

```
XAResourceManager:
    Name=<Name>
```

```
SwitchFile=/install_dir/server/lib/libDynJMSSwitch.so
XAOpenString=<Initial Context Factory>,
          <location of JNDI bindings>'
          <LDAP Principal>,
          <LDAP Credentials>,
          <Recovery Connection Factory Name>,
          <JMS Principal>,
          <JMS Credentials>
          ThreadOfControl=THREAD
```

The parameters for the stanza are as follows:

<Name>
Required. The name of the defined JMS provider resource manager.

<SwitchFile>
Required. The file system path to the Switch library that is supplied in the `bin` directory of the integration node. There are two options:

a. The library called JMSSwitch, which manages XAResources that statically enlist with the transaction coordinator.

b. The library called DynJMSSwitch, which manages dynamically enlisted XAresources.

install_dir
The location of the IBM App Connect Enterprise installation. This value is required where the LDAP parameters are omitted, but a user-defined Queue Connection Factory is specified for recovery.

<Initial Context Factory>
Required. The Initial Context Factory identifier for the JMS provider. This value is set in the JMSInput node property `Initial context factory`.

<Location of JNDI bindings>
Required. Use either the filepath to the bindings file, or the LDAP directory location of the JNDI administered objects that can be used to create an initial context factory for the JMS connection. If you supply a file path to the bindings file, do not include the file name. For more information about creating the JNDI administered objections, see node or node.

The values for the *Initial Context factory* and *Location of JNDI bindings* in the stanza must match the values that you specified in the JMS or SOAP nodes in the message flows.

<LDAP Principal>
Optional. Specify the principal (user ID) that might be required when an LDAP database is used to hold the JNDI administered objects. `LDAP Principal` must match the value that is set for the integration node by using the **`mqsicreatebroker`** command. `LDAP Principal` is not currently supported, it is reserved for future use.

<LDAP Credentials>
Optional. Specify the Credentials (password) that might be required if a password protected LDAP database is used to hold the JNDI administered objects. `LDAP Credentials` must match the value that is set for the integration node by using the **`mqsicreatebroker`** command. `LDAP Credentials` is not currently supported, it is reserved for future use.

<Recovery Connection Factory Name>
Optional. Specify the name of a Queue Connection Factory object in the JNDI administered objects for recovery purposes. If a value is not specified, you must add a default value for `recover`XAQCF to the bindings file. In either case, the Recovery Connection Factory must be defined as an XA

Queue Connection Factory for the JMS provider that is associated with the `Initial context factory`.

<JMS Principal>
Optional. Provide the user ID required to connect to a JMS provider, by using a secure JMS Connection Factory. `JMS Principal` is not currently supported, it is reserved for future use.

<JMS Credentials>
Optional. Provide the password that is required to connect to the same JMS provider in conjunction with the JMS principal. `JMS Credentials` is not currently supported, it is reserved for future use.

The JMS Principal and JMS Credentials must be configured together.

The optional parameters are comma-separated and are positional. Therefore, any parameters that are missing must be represented by a comma, as seen in the following example stanza.

The example stanza describes IBM MQ Java as the JMS provider for global transactions:

```
XAResourceManager:
    Name=XAJMS_PROVIDER1
    SwitchFile=/install_dir/server/lib/libDynJMSSwitch.so
    XAOpenString= com.sun.jndi.fscontext.RefFSContextFactory,
              /Bindings/JMSProvider1_Bindings_Directory,
              ,
              ,
              ,
              myJMSuser1,
              passwd
              ThreadOfControl=THREAD
```

where:

- `XAJMS_PROVIDER1` is the user-defined name for the resource manager
- `/install_dir/server/lib/libDynJMSSwitch.so` is the installation path
- `com.sun.jndi.fscontext.RefFSContextFactory` is the *<Initial Context Factory>*
- `/Bindings/JMSProvider1_Bindings_Directory` is the location of the bindings file
- `myJMSuser1` is the *<JMS Principal>*
- `passwd` is the password used in *<JMS Credentials>*

In this example, the optional fields `<LDAP Principal>`, `<LDAP Credentials>`, and `<Recovery Connection Factory Name>` are not required, therefore the positional comma delimiters only are configured in the `XAOpenString` stanza.

2. Update the Java PATH environment variable for the queue manager of the integration node to point to the `bin` directory in which the switch file is located.
For example:

```
install_dir/server/bin
```

Switch files are installed in the *install_dir*`/server/lib` directory. To simplify the contents of the `qm.ini` file, create a symbolic link to the switch file for the queue manager to retrieve from the `/var/mqm/exits64` directory. For example:

```
ln -s install_dir/server/lib/libDynJMSSwitch.so /var/mqm/exits64/libDynJMSSwitch
```

What to do next

Check your configuration:

- In the message flow, ensure that the coordinated property is enabled by using the IBM App Connect Enterprise Archive editor.
- Ensure that each message flow node that is part of the XA transaction is set to the global transaction mode.

- Ensure that the service ID that is used for the integration node and the queue manager is the same user ID.
- Ensure that the JNDI connection factory objects that the JMS nodes use for a global transaction are configured to be of the type MQXAConnectionFactory, MQXAQueueConnectionFactory, or MQXATopicConnectionFactory.
  - If you create the bindings by using JMSAdmin, use the command **DEF XAQCF** or **DEF XATCF**, instead of **DEF QCF** or **DEF TCF**, when you define your connection factory.

For more information, see Transactional support in the IBM MQ product documentation online.

Configuring the queue manager to coordinate JMS resources on Windows
Use IBM MQ Explorer to configure the global (XA) resource managers for the queue manager.

About this task

Before you deploy a message flow in which the `Transaction mode` property is set to `Global` or `Yes`, and is intended to use XA coordinated transactions, modify the queue manager `.ini` file to include extra definitions for each JMS provider resource manager that participates in globally coordinated transactions.

To configure the queue manager for Windows:

Procedure

1. Open IBM MQ Explorer.
2. Select the queue manager for your integration node and click **Properties**.
3. Select **XA resource managers** in the left pane and click **Add**.
4. Complete the fields to define a new resource manager:
   a) **Name**: Enter the name of the resource manager; for example, `IIBWMQJMS`.
   b) **SwitchFile**: Enter **DynJMSSwitch**.
   c) On **XAOpenString**, enter the following values, which are comma delimited and positional. Represent missing optional parameters by a comma if you include other parameters later in the string.

      Initial Context Factory
      The Initial Context Factory identifier for the JMS provider; this value is required.

      Location of JNDI bindings
      Either the file path to the bindings file, or the LDAP directory location of the JNDI administered objects that can be used to create an initial context factory for the JMS connection. If you supply the file path to the bindings file, do not include the file name. See the JMSInput or

JMSOutput node for further details about creating the JNDI administered objects; this value is required.

The values for the *Initial Context factory* and *Location of JNDI binding*s in the stanza must match the values that you specified in the JMS or SOAP nodes in the message flows.

LDAP Principal
Optional: The principal (user ID) that might be required when an LDAP database is used to hold the JNDI administered objects. `LDAP Principal` is not currently supported, it is reserved for future use.

LDAP Credentials
Optional: The credentials (password) that might be required if a password protected LDAP database is used to hold the JNDI administered objects.

All LDAP parameters must match the values that you specified on the **mqsicreatebroker** command. `LDAP Credentials` is not currently supported, it is reserved for future use.

Recovery Connection Factory Name
Optional: The name of a Queue Connection Factory object in the JNDI administered objects for recovery purposes, when the non-default name is required.

The Recovery Factory Name must match a Queue Connection Factory name that is created in the JNDI administered objects. If you do not specify a name, a default factory that is called `recover`XAQCF is used. In either case, this value must refer to a JNDI administered object that has already been created.

JMS Principal
The user ID that is required to connect to a JMS provider, using a secure JMS Connection Factory. `JMS Principal` is not currently supported, it is reserved for future use.

JMS Credentials
The password that is required to connect to the same JMS provider with the JMS principal. `JMS Credentials` is not currently supported, it is reserved for future use.

The JMS Principal and JMS Credentials must be configured together.

a) **XACloseString**: Leave this field blank.

b) **ThreadOfControl**: Set the value to `Thread`.

5. Click **OK** to complete the XA resource manager definition.
6. Click **OK** to close the queue manager properties dialog.
7. Click **File** > **Exit** to close IBM MQ Explorer.
8. Copy the `DynJMSSwitch.dll` file to the `\exits64` folder in the IBM MQ installation directory.
9. Copy the `DynJMSSwitch32.dll` file to the `\exits` directory in the IBM MQ installation directory and then rename the file to `DynJMSSwitch.dll`.
10. Set the `XAOpenString` property to a string value as follows: *`Initial Context,location JNDI,Optional_parms`*.
11. Set the `ThreadOfControl` property to `Thread`.

What to do next

- Check your configuration:
  - In the message flow, ensure that the coordinated property is enabled by using the IBM App Connect Enterprise Archive editor.
  - Ensure that each node that must be part of the XA transaction is set to the global transaction mode.
  - Ensure that the service ID that is used for the integration node and the queue manager is the same user ID.
  - Ensure that the JNDI connection factory objects that the JMS nodes use for a global transaction are configured to be of the type MQXAConnectionFactory, MQXAQueueConnectionFactory, or MQXATopicConnectionFactory.
    - If you create the bindings by using JMSAdmin, use the command **DEF XAQCF** or **DEF XATCF**, instead of **DEF QCF** or **DEF TCF**, when you define your connection factory.
- Authorize the integration node and queue manager to access shared resources that are associated with the JMS provider; see "Windows systems: modifying the queue manager authorization" on page 882.

For more information, see Transactional support in the IBM MQ product documentation online.

Troubleshooting

IBM App Connect Enterprise examines the IBM MQ registry to determine if the queue manager is XA enabled. If IBM App Connect Enterprise is unable to locate the location of the queue managers working directory, an error is issued at startup. You can specify this location by setting the following environment variable in the `mqsiprofile` script: `MQ_DATA_PATH` For example:

```
MQ_DATA_PATH="C:\Program Files (x86)\IBM\IBM MQ"
```

Configuring message flows for data conversion

If you exchange messages between applications that run on systems that are incompatible in some way, you can configure your system to provide data conversion as the message passes through the integration node.

About this task

Data conversion might be necessary if either of the following two values are different on the sending and receiving systems:

1. CCSID. The Coded Character Set Identifier refers to a set of coded characters and their code point assignments. IBM App Connect Enterprise can process and construct application messages in any code page for which IBM MQ provides conversion to and from Unicode, on all operating systems. For more information about code page support, see the *Application Programming Reference* section of the IBM MQ product documentation online.

   This behavior might be affected by the use of other products in conjunction with IBM App Connect Enterprise. Check the documentation for other products, including any databases that you use, for further code page support information.
2. Encoding. This setting defines the way in which a machine encodes numbers; that is, binary integers, packed-decimal integers, and floating point numbers. Numbers that are represented as characters are handled in the same way as all other string data.

If the native CCSID and encoding on the sending and receiving systems are the same, you do not need to call data conversion processes.

IBM App Connect Enterprise and IBM MQ provide data conversion facilities to support message exchange between unlike systems. Your choice of which facilities to use depends on the characteristics of the messages that are processed by your message flows:

- Messages that contain text only
- Message that include numerics

- Messages that are self-defining

Messages that contain text only

Read this section if your messages are IBM MQ messages that contain all text (character data or string).

If IBM MQ supports the systems on which both sending and receiving applications are running for data conversion, use IBM MQ facilities which provide the most efficient data conversion option.

The default behavior of IBM MQ is to put messages to queues specifying the local system CCSID and encoding. Applications issuing MQGET can request that the queue manager provides conversion to their local CCSID and encoding as part of get processing.

To use this option:

1. Design messages to be text-only. If you are using COBOL, move numeric fields to USAGE DISPLAY to put them into string form.
2. Set the Format field in the MQMD to MQFMT_STRING (value MQSTR).
3. Call MQGET with MQGMO_CONVERT in the receiving application. If you prefer, you can convert when the message is received by the integration node, by setting the Convert property of the MQInput node to yes (by selecting the check box).

If you require more sophisticated data conversion than IBM MQ provides in this way (for example, to an unsupported code page), use IBM MQ data conversion exits. For more information about these, see the *Application Programming Reference* section of the IBM MQ product documentation online.

Messages that include numerics

Read this section if your messages include numeric data, or are text only but are not IBM MQ messages.

If these messages can be predefined (that is, their content and structure is known and predictable), use the facilities provided by IBM App Connect Enterprise and the MRM.

All application messages are handled by the integration node in Unicode, to which they are converted on input, and from which they are converted on output. You can configure message flows to influence the way in which output messages are constructed.

To use this option:

1. Define the output message in the MRM domain. You can create this definition in one of the following ways:
   - Import an external message definition (for example a C header or COBOL copybook).
   - Create the message model in the message definition editor.
2. Configure a message flow to receive and process this message:
   a. If you include an MQInput node, do not request conversion by this node.
   b. Include a Compute node in the message flow to create the output message with the required content:
      - If the output message is an IBM MQ message, code ESQL in the Compute node to set the CCSID and encoding for the target system in the MQMD.

        For example, to set values for a target z/OS system running with CCSID of 37 and encoding of 785:

        ```
        SET OutputRoot.MQMD.CodedCharSetId = 37;
        SET OutputRoot.MQMD.Encoding = 785;
        ```

      - If the output message is not an IBM MQ message, code ESQL in the Compute node to set the CCSID and encoding for the target system in the Properties folder.

Messages that are self-defining

Read this section if your messages are self-defining.

Self-defining messages are supported in the XML and JMS domains. These messages are all text and can be handled by IBM MQ, if they originate from, or are destined for, IBM MQ applications. If not, use IBM App Connect Enterprise facilities by setting the CCSID and Encoding fields in the Properties folder in the message when it passes through a Compute node.

Defining a promoted property

When you create a message flow, you can promote properties from individual nodes in that message flow to the message flow level. Properties promoted in this way override the property values that you have set for the individual nodes.

Before you begin

Read the concept topic about promoted properties.

About this task

You can perform the following tasks related to promoting properties:

- "Promoting a property" on page 729
- "Renaming a promoted property" on page 732
- "Removing a promoted property" on page 733
- "Converging multiple properties" on page 735

Some of the properties that you can promote to the message flow are also configurable; you can modify them when you deploy the BAR file in which you have stored the message flow to each integration node. If you set values for configurable properties when you deploy a BAR file, the values that you set override values set in the individual nodes, and those that you have promoted.

Promoting a property

You can promote a message flow node property to the message flow level to simplify the maintenance of the message flow and its nodes, and to provide common values for multiple message flow nodes in the flow by converging promoted properties.

Before you begin

- Create a message flow, as described by "Creating a message flow" on page 574
- Read the concept topic about promoted properties

About this task

The majority of message flow node properties are available for promotion, but you cannot promote the following properties:

- Properties that name mapping modules
- A property group (but you can promote an individual property)
- A property that you cannot edit (for example, the `Fix` property of the MQInput node)
- The description properties (`Short Description` and `Long Description`)
- Complex properties (for example, the `Query elements` property of the DatabaseRoute node, or the `Opaque elements` property of the MQInput and several other nodes)

Procedure

To promote message flow node properties to the message flow level, complete the following steps:

1. Switch to the Integration Development perspective.
2. Open the message flow for which you want to promote properties.
3. Right-click the appropriate node and click **Promote Property**.

   The Promote Property dialog box is displayed.

   The Available node properties pane lists all available properties for all the nodes in the message flow. The properties for the node that you clicked are expanded. You can expand the properties for all the nodes in the open message flow, regardless of the node that you clicked initially.

   The Promoted properties pane displays the name of the open message flow and all the properties that are currently promoted to the message flow. If you have not yet promoted any properties, only the message flow name is displayed as the root of the promoted property tree, as shown in the previous example. If you have already promoted properties from this node, the properties appear in the Promoted properties pane, but not in the Available node properties pane.

4. Select the property or properties that you want to promote to the message flow.

   You can select multiple properties by holding down **Ctrl** and selecting the properties.

5. Click **Promote**.

   The **Target Selection** dialog box opens and displays valid targets for the promotion.

6. Select the destination group or property for the properties that you want to promote. You can group together related properties from the same or different nodes in the message flow by dropping the selected properties onto a group or property that already exists, or you can create a new target for the promotion by clicking **New Group** or **New Property**.

   You can rename groups and properties by selecting them and clicking **Rename**.

7. Click **OK** to confirm your selections and close the **Target Selection** dialog box.

   If you create a new group or property by using the **Target Selection** dialog box, the changes persist even if you select **Cancel** in the dialog box. When the dialog box closes, groups or properties that you have created by using the **Target Selection** dialog box appear in the **Promote Property** dialog box.

You can remove any of these properties from the **Promote Property** dialog box by selecting them and clicking **Remove**.

8. Click **OK** to commit your changes and close the **Promoted Property** dialog box.

   If you click **Apply**, the changes are committed but the dialog box remains open.

Results

The message flow node properties are promoted to the message flow. When you have promoted a property, you can no longer make any changes to that property at the node level; you can update its value only at the message flow level. To view the message flow's properties, click the message flow (not the individual nodes) in the Message Flow editor to display the properties in the Properties view. The properties that you have promoted are organized in the groups that you created. If you now set a value for one of these properties, that value appears as the default value for the property whenever the message flow is included in other message flows.

When you select an embedded message flow in another message flow (a subflow) and view its properties, you see the promoted property values. If you look inside the embedded flow (by selecting **Open Subflow**), you see the original values for the properties. The value of a promoted property does not replace the original property, but it takes precedence when you deploy the message flow.

Promoting properties by dragging

About this task

You can also promote properties from the **Promote Property** dialog box by dragging the selected property or properties from the Available node properties pane of the **Promote Property** dialog box to the Promoted properties pane, as described in the following steps.

Procedure

1. Select the property that you want to promote. You can select multiple properties by holding down **Ctrl**, and selecting the properties.
2. You can promote the selected properties using the following methods:
   - Drop the selected property or properties in an empty space.

     A new group is created automatically for the message flow, and the property is placed in it, with the original name of the property and the name of the message flow node from which it came displayed beneath the property entry.

     The name of the first group that is created is `Group1` by default. If a group called `Group1` already exists, the group is given the name `Group2`, and so on. You can rename the group by double-clicking it and entering new text, or by selecting the group in the Promoted properties pane and clicking **Rename**.

     When you create a new promoted property, the name that you enter is the name by which the property is known within the system, and must meet certain Java and XML naming restrictions. These restrictions are enforced by the dialog box, and a message is displayed if you enter a name that includes a non-valid character. For example, you cannot include a space or quotation marks (").

     If you are developing a message flow in a user-defined project that will be delivered as an Eclipse plug-in, you can add translations for the promoted properties that you have added. Translated names can contain characters, such as space, that are restricted for system names. The option to

provide translated strings for promoted properties is not available if you are working with a message flow in an integration project.

- Drop the selected property or properties onto a group that already exists, to group together related properties from the same or different nodes in the message flow.

  For example, you might want to group all promoted properties that relate to database interactions. You can change the groups to which promoted properties belong at any time by selecting a property in the Promoted properties pane and dragging it onto a different group.

- Drop the selected property or properties onto a property that already exists, to converge related properties from the same or different nodes in the message flow.

  For example, you might want to create a single promoted property that overrides the property on each node that defines a data source.

  For more information on converging properties, see "Converging multiple properties" on page 735.

Promoting mandatory properties

About this task

If you promote a property that is mandatory (that is, an asterisk appears beside the name in the Properties view), the mandatory characteristic of the property is preserved. When a mandatory property is promoted, its value does not need to be set at the node level. If the flow that contains the mandatory promoted property is included as a subflow in another flow, the property must be populated for the subflow node.

Promoting properties through a hierarchy of message flows

About this task

You can repeat the process of promoting message flow node properties through several levels of message flow. You can promote properties from any level in the hierarchy to the next level above, and so on through the hierarchy to the top level. The value of a property is propagated from the highest point in the hierarchy at which it is set down to the original message flow node when the message flow is deployed to an integration node. The value of that property on the original message flow node is overridden.

Renaming a promoted property
If you have promoted a property from the node to the message flow level, it is initially assigned the same name that it has at the node level. You can rename the property to have a more meaningful name in the context of the message flow.

Before you begin

- Promote a property
- Read the concept topic about promoted properties

About this task

Procedure

To rename a promoted property:

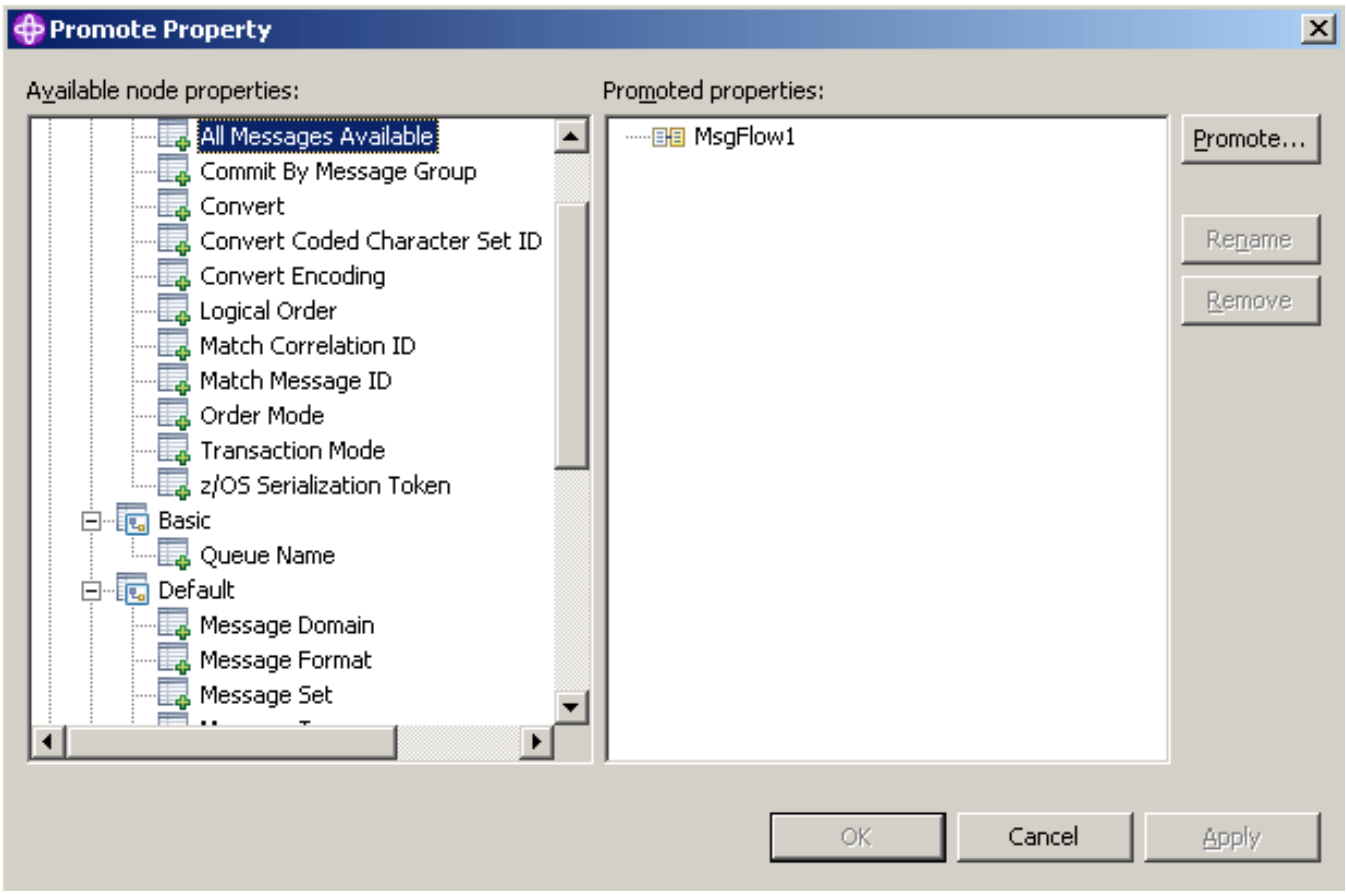
1. Switch to the Integration Development perspective.
2. Open the message flow for which you want to promote properties by double-clicking the message flow in the Application Development view.

   You can also open the message flow by right-clicking it in the Application Development view and clicking **Open**

   The message flow contents are displayed in the editor view.

3. In the editor view, right-click the symbol of the message flow node for which you want to promote properties.
4. Select **Promote Property**.

   The **Promote Property** dialog box is displayed.



5. Promoted properties are shown in the Promoted properties pane on the right of the **Promote Property** dialog box. Double-click the promoted property in the list of properties that are currently promoted to the message flow level, or select the property that you want to rename and click **Rename**.

   The name is highlighted, and you can edit it. Modify the existing text or enter new text to give the property a new name, and press Enter.
6. Click **Apply** to commit this change without closing the **Promote Property** dialog box. Click **OK** to complete your updates and close the dialog box.

Removing a promoted property
If you have promoted a property from the node to the message flow level, you can remove (delete) it if you no longer want to specify its value at the message flow level. The property reverts to the value that you specified at the node level. If you remove a promoted property that is a mandatory property, ensure that you have set a value at the node level. If you have not, you cannot successfully deploy a BAR file that includes this message flow.

Before you begin

- Promote a property
- Read the concept topic about promoted properties

About this task

Procedure

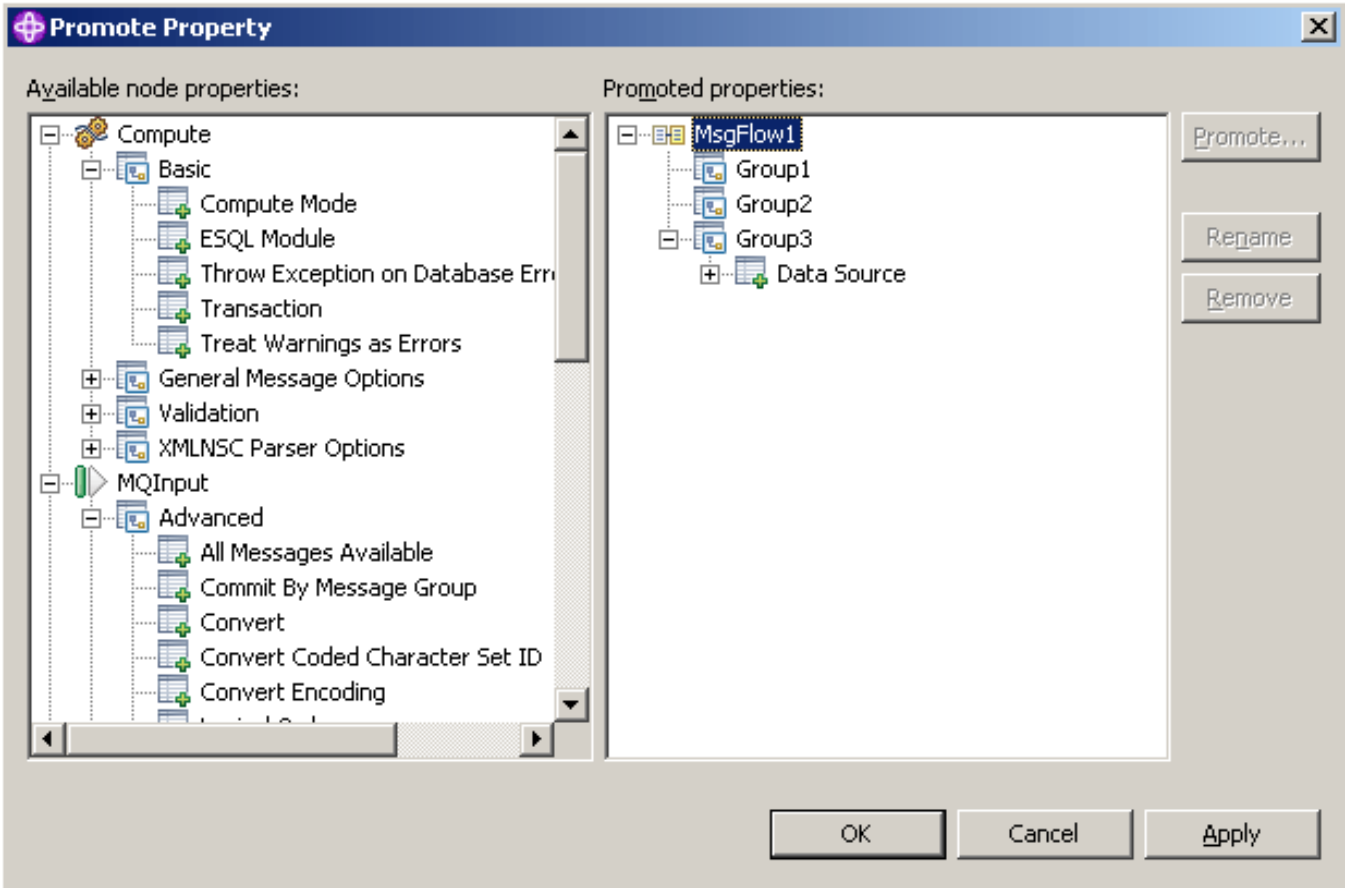
If you have promoted one or more message flow node properties, and want to delete them, complete the following steps:

1. Switch to the Integration Development perspective.
2. Open the message flow for which you want to promote properties by double-clicking the message flow in the Application Development view.

   You can also open the message flow by right-clicking it in the Application Development view and clicking **Open**

   The message flow contents are displayed in the editor view.
3. In the Editor view, right-click the symbol of the message flow node whose properties you want to promote.
4. Select **Promote Property**.

   The Promote Property dialog is displayed.



5. Select the promoted property that you want to remove from the list of properties in the Promoted properties pane, and click **Remove**.

   The property is removed from the Promoted properties pane and is restored to the list in the Available node properties pane, in the appropriate place in the tree of properties for the node from which you promoted it. You can promote this property again.
6. To delete all the promoted properties in a single group, select the group in the Promoted properties pane and click **Remove**.

   The group and all the properties it contains are deleted from this list: the individual properties that you promoted are restored to the nodes from which you promoted them.
7. Click **Apply** to commit this change without closing the **Promote Property** dialog box. Click **OK** to complete your updates and close the dialog box.

Results

If you have included this message flow in a higher-level message flow, and have set a value for a promoted property that you have now deleted, the embedding flow is not automatically updated to reflect the deletion. However, when you deploy that embedding message flow in the integration node domain, the deleted property is ignored.

Converging multiple properties
You can promote properties from several nodes in a message flow to define a single promoted property, which applies to all those nodes.

Before you begin

- Create a message flow, as described in "Creating a message flow" on page 574
- Read the concept topic about promoted properties

About this task

One example for the use of promoting properties is for database access. If a message flow contains two Database nodes that each refer to the same physical database, you can define the physical database just once on the message flow by promoting the `Data Source` property of each Database node to the message flow, and setting the property at the message flow (promoted) level.

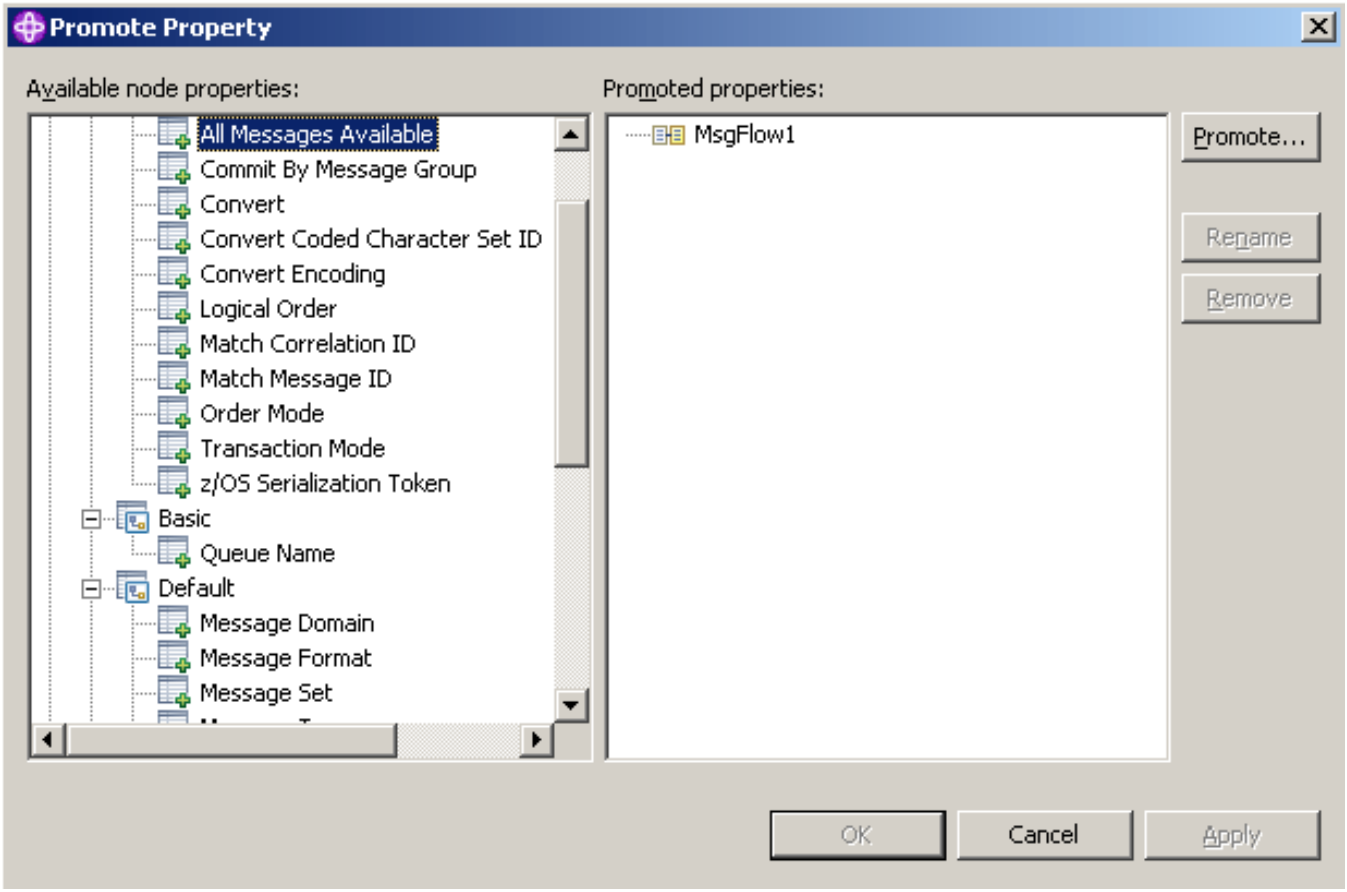
To converge multiple node properties to a single promoted property:

Procedure

1. Switch to the Integration Development perspective.
2. Open the message flow in the Message Flow editor.

3. Right-click the node for which you want to promote the properties, then click **Promote Property**.

   The Promote Property dialog box is displayed.



4. Select the property that you want to converge.

   The list in the Available node properties pane initially shows the expanded list of all available properties for the selected node. If you have already promoted properties from this node, they do not appear in this pane, but they appear in the Promoted properties pane.

   The Available node properties pane also includes the other nodes in the open message flow. You can expand the properties that are listed under each node and work with all these properties at the same time. You do not have to close the dialog box and select another node from the Message Flow editor to continue promoting properties.

   You can select multiple properties to promote by selecting a property, holding down **Ctrl**, and selecting one or more other properties.

   If you have you selected multiple properties to converge, all the properties that you have selected must be available for promotion. If one or more of the selected properties is not available for promotion, the entire selection becomes unavailable for promotion, and the **Promote** button is disabled.

5. Click **Promote** to promote the property or properties

   The **Target Selection** dialog box opens:

   The **Target Selection** dialog box displays only the valid targets for the promotion of the previously selected property or properties and allows you to create a new target for the promotion, such as to a new group or to a new property.

6. To converge properties from the same or different nodes in the message flow, expand the tree and click a property that already exists.

   You can rename the properties by selecting them and clicking **Rename**, or by double-clicking the group or property.

7. Click **OK** to confirm your selections.

   Note: If you create a new group or property by using the **Target Selection** dialog box, the changes persist even if you click **Cancel**. When the dialog box closes, groups or properties that you have created by using the **Target Selection** dialog box appear in the **Promote Property** dialog box.
8. Expand the property trees for all the nodes for which you want to promote properties.
9. Drag the first instance of the property that you want to converge from the Available node properties pane, and drop it onto the appropriate group in the Promoted properties pane.
   - If the group already contains one or more promoted properties, the new property is added at the end of the group. You can rename the new property by double-clicking the property, or by selecting the property and clicking **Rename**.
   - If you want the promoted property to appear in a new group, drag the property into an empty space below the existing groups to create a new group. Alternatively:
     a. Select the property that you want to promote, and click **Promote**. The **Target Selection** dialog box opens.
     b. Click **New Group**, and enter the name of the new group.
     c. Click **OK** to confirm your changes.
   - If you drag the property onto an existing promoted property of a different type, a no-entry icon is displayed and you cannot drop the property. You must create this property as a new promoted property, or drop it onto a compatible existing promoted property. Properties must be associated with the same property editor to be compatible. For example, if you are using built-in nodes, you can converge only properties of the same type (string with string, Boolean with Boolean).

   If you are using user-defined nodes, you must check the compatibility of the property editors for the properties that you want to converge. If you have written compiler classes for a node, you must also ensure that converged properties have the same compiler class.
10. Drag all remaining instances of the property from each of the nodes in the Available node properties pane onto the existing promoted property. The new property is added under the existing promoted property, and is not created as a new promoted property.
11. Click **Apply** to commit this change without closing the **Promote Property** dialog box. Click **OK** to complete your updates and close the dialog box.

    You can also converge properties from the **Promote Property** dialog box by dragging the selected property or properties from the Available node properties pane to the Promoted properties pane:
    a. Select the property that you want to promote. You can select multiple properties to promote by selecting a property, holding down **Ctrl**, and selecting one or more other properties.
    b. Drop the selected property or properties onto a property in the Promoted properties pane to converge related properties from the same or different nodes in the message flow.

       For example, you might want to create a single promoted property that overrides the property on each node that defines a data source.

Results

You have promoted properties from several nodes to define a single promoted property, which is used for all those nodes.

Connecting client applications

Connect your client applications to the integration node by using one or more of the supported protocols from other resources and software servers in your network.

Processing IBM MQ messages

IBM App Connect Enterprise provides a number of nodes for handling messages that are received from or sent to IBM MQ applications.

About this task

If you intend to use IBM App Connect Enterprise to process MQ messages, you must install IBM MQ in addition to installing IBM App Connect Enterprise. On distributed systems, if you want to connect to a remote queue manager to process MQ messages, you must install either an MQ Client or MQ Server on the same machine as IBM App Connect Enterprise, in addition to installing MQ server on the machine that is running your queue manager. IBM MQ is available as a separate installation package, and your IBM App Connect Enterprise license entitles you to install and use IBM MQ with IBM App Connect Enterprise. For more information, see “Enhanced flexibility in interactions with IBM MQ ” on page 26 and “Installing IBM MQ” on page 96.

The following nodes are provided for working with IBM MQ messages:

node
: Use an MQInput node if the messages arrive on an IBM MQ queue, and the node is to be at the start of a message flow.

node
: Use an MQOutput node if the target application expects to receive messages on an IBM MQ queue, or on the IBM MQ reply-to queue that is specified in the input message MD.

node
: Use an MQGet node to retrieve a message from an IBM MQ queue, if you want to get the message later in the message flow.

node
: Use an MQReply node if the target application expects to receive messages on the IBM MQ reply-to queue that is specified in the input message MD.

node
: Use the MQHeader nodes to manipulate IBM MQ transport headers and their properties without writing compute nodes. Use the MQHeader node to add, modify, or delete Message Descriptor (MD) and Dead Letter Header (DLH) headers.

node
Use the JMSMQTransform node to transform a message with a JMS message tree into a message that has a tree structure that is compatible with the format of messages that are produced by the IBM MQ JMS provider.

The JMSMQTransform node can be used to send messages to existing message flows and to interoperate with IBM MQ JMS and IBM MQ Publish/Subscribe.

node
Use the MQJMSTransform node to receive messages that have an IBM MQ JMS provider message tree format, and transform them into a format that is compatible with messages that are to be sent to JMS destinations.

You can use the MQJMSTransform node to send messages to existing message flows and to interoperate with IBM MQ JMS and IBM MQ Publish/Subscribe.

The following topics contain information that you need to understand before you can use the IBM MQ support in IBM App Connect Enterprise:

- "Enhanced flexibility in interactions with IBM MQ " on page 26
- "IBM MQ topologies" on page 739
- "Configuring connections to IBM MQ" on page 743

For step-by-step information about how to use MQ nodes to perform a set of typical tasks, see "Working with IBM MQ" on page 753.

See the following topics for more information about configuring your message flows, and about related resources for handling messages that are received from or sent to IBM MQ applications:

- "Enabling IBM MQ applications" on page 777
- "Application programming interfaces" on page 779
- "Using IBM MQ cluster queues for input and output" on page 780
- "Using queues on an IBM MQ uniform cluster" on page 781
- "Configuring flows to handle IBM MQ message groups" on page 783
- "Ensuring that messages are not lost" on page 786
- connections

IBM MQ topologies

You can use IBM MQ to create flexible connection topologies from the different connectivity options.

If you already have an IBM MQ solution, you do not need to change your existing IBM MQ topology to work with IBM App Connect Enterprise; the products integrate automatically.

Your IBM MQ applications exchange messages and other data by communicating with message flows that are running in the integration server. You can connect your applications to the integration server by using one of the supported communication methods. If your applications are written to use IBM MQ, the requirement for the channels or client connections are determined by the types of nodes that you include in your message flows. These resources are application-specific, and you must create these resources yourself.

You might need some or all of the following resources:

- A queue manager that is associated with the integration node or server. For some capabilities, you might also need to define queues for the queue manager; see "IBM App Connect Enterprise features requiring supplementary products" on page 9.
- Defined TCP/IP listener connections on the queue manager that is associated with the integration node or server.

For more information about creating resources, see Intercommunication in the IBM MQ product documentation online.

Local and client connections

A local connection is a connection to a local queue manager that uses server bindings. A client connection connects to remote queue managers. You can use local connections, client connections, or a combination of local and client connections to your queue managers.

When you configure a connection from an MQ node to an IBM MQ queue manager, you can optionally configure the connection to use a security identity for authentication, SSL for confidentiality, or both. The security identity, which passes user name and password security credentials to the queue manager, can be used on connections to local or remote queue managers. For connections to remote queue managers, you can choose whether to use the SSL protocol to provide confidentiality on the client connection. IBM App Connect Enterprise supports a subset of the SSL functionality that is supported by IBM MQ. For more information, see "Connecting to a secured IBM MQ queue manager" on page 747.

For globally coordinated transactions, you must designate a local queue manager as the transaction manager by associating it with the integration node. Other queue managers can only participate as locally-coordinated in that message flow. For more information, see "Configuring MQ nodes for transactions" on page 701.

There are some extra considerations if you use a remote queue manager: for example, you might want to set up security for connecting over the network. For more information, see "Administration security overview" on page 2497.

Connection management

If a connection is lost between an integration server and queue manager, the integration server automatically attempts to reconnect to the queue manager. All resources and transports that do not require access to that connection continue to run. In a non-transactional message flow, MQInput, MQOutput, MQGet, and MQReply nodes automatically attempt to reconnect once. If the node still cannot connect, then normal exception processing occurs.

If a connection to a queue manager is lost, and that connection is enlisted in a transaction, automatic reconnection is delayed until the inflight transaction is complete. Other queue managers that are required, but are not part of the transaction, reconnect automatically without delay. A completed transaction can include the following cases:

- The unavailable MQ resource was not required and was not used, because exception handling was defined in the message flow, so the inflight transaction was successful and committed.
- The unavailable MQ resource was required, and the message flow cannot succeed without it, so the inflight transaction was rolled back.

To learn more about using IBM MQ in transactions, see "Configuring MQ nodes for transactions" on page 701.

Remote default connection management

If an integration server is configured to use a remote default queue manager connection, the server shuts down if the connection is lost. This is the same behavior as for a local default queue manager, and ensures that state information stored on queues is kept intact. Separately-configured client links, where a specific input node is connected to a different remote queue manager, follow the reconnect pattern described above, but all other MQ-related nodes that are using the remote default queue manager (including event-driven processing nodes) trigger a server shutdown if the connection is lost. For information about using a remote default queue manager connection, see "Using a remote default queue manager" on page 750 and "Configuring an integration server to use a remote default queue manager" on page 751.

MQEndpoint policy

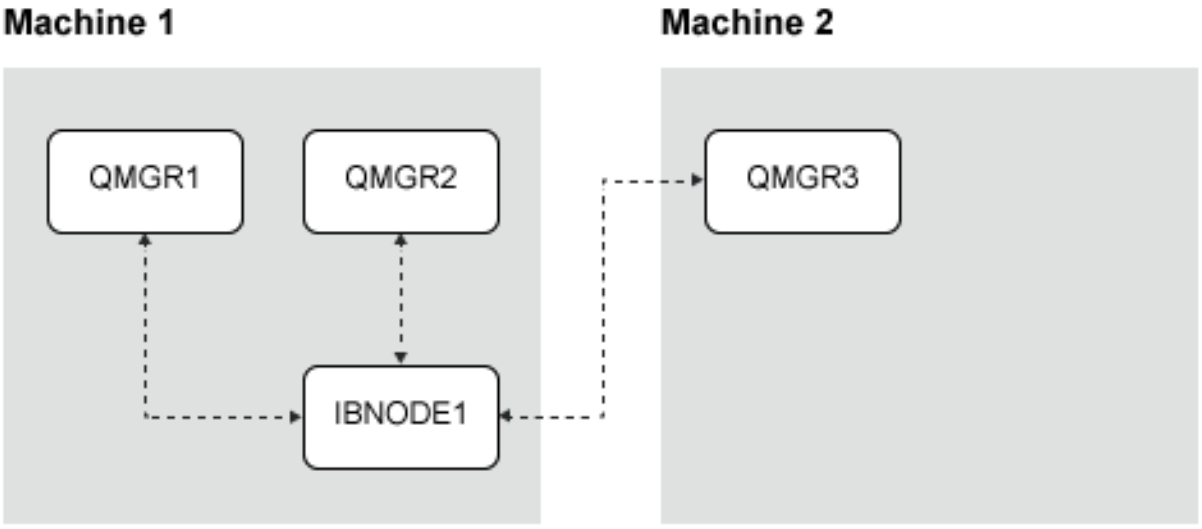
Connection details for MQ nodes can be managed by MQEndpoint policies (see policy).

IBM MQ topologies

You can have almost any topology configuration to connect between IBM App Connect Enterprise and IBM MQ by using combinations of multiple local and client connections. The following diagrams provide examples of these basic topologies.

Scenario 1

This scenario uses multiple queue managers to a single integration node.



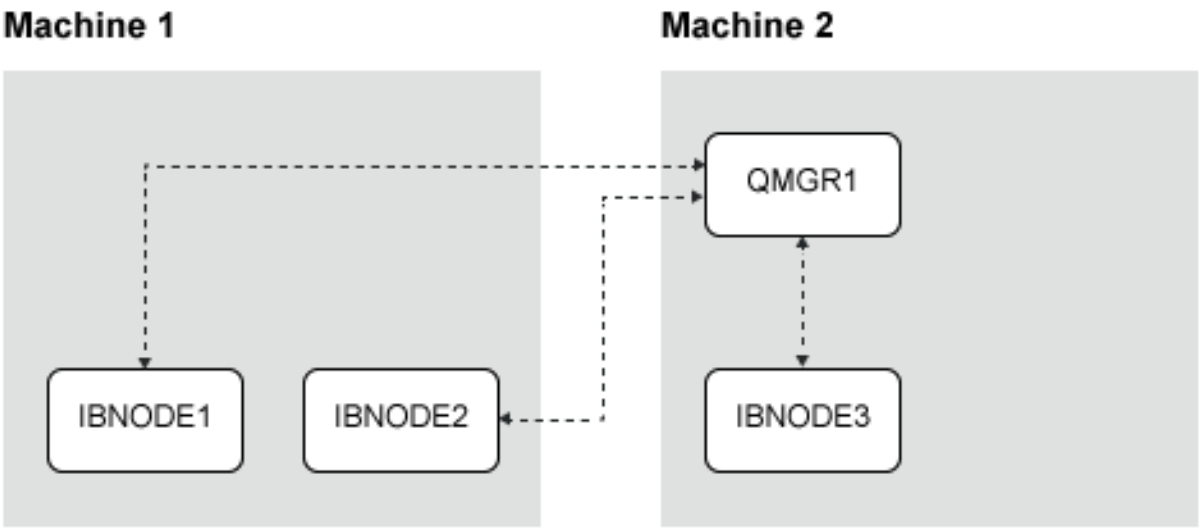
In this diagram, multiple queue managers are connected to a single integration node, IBNODE1. For example, the message flow might contain an MQInput and MQOutput node, which both share QMGR1 to process the messages. QMGR3 is available to IBNODE1 by a TCP/IP client connection.

Table 13. Strengths and weaknesses of scenario 1:

Strengths	**Weaknesses**
• The integration node can connect to a queue manager, both local and remote, without changing an existing IBM MQ topology	• Failover: there is a single point of failure (IBNODE1). To mitigate this risk, you can add more integration nodes

Scenario 2

This scenario uses multiple integration nodes to a single queue manager.



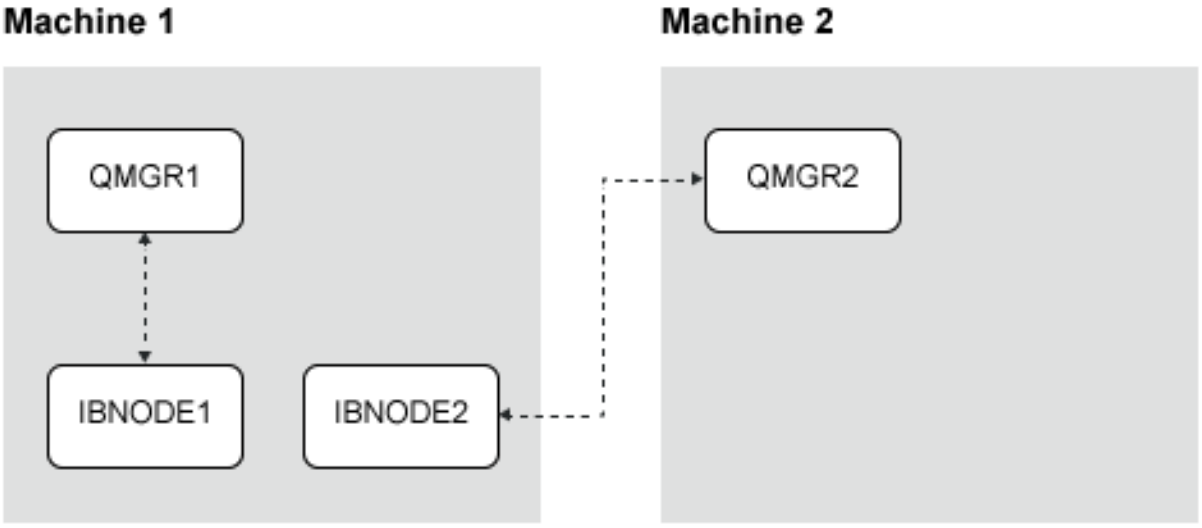
In this diagram, integration node IBNODE1 and IBNODE2 have client connections to the QMGR1 queue manager. The integration nodes are configured as a failover as part of a high availability IBM MQ solution, handling the messaging processing and saved states for QMGR1. To learn more about high availability configurations, see "Configuring integration nodes for high availability" on page 120.

Table 14. Strengths and weaknesses of scenario 2:

Strengths	Weaknesses
• The integration node can connect to a queue manager, both local and remote, without changing an existing IBM MQ topology • High availability IBM MQ-based solution	• Failover: there is a single point of failure (QMGR1). To mitigate this risk, you can add more queue managers

Scenario 3

This scenario uses a single integration node to a single queue manager.



In this diagram, the relationship between integration node and queue managers is 1:1. A 1:1 locally connected configuration was the only option that was available before the release of IBM Integration Bus 10.0.

Table 15. Strengths and weaknesses of scenario 3:	
Strengths	**Weaknesses**
• High level of control of connection behavior between IBM App Connect Enterprise and IBM MQ	• Inflexible topology, requiring more manual effort to control connection behavior and maintain solution

For more information about queue manager architecture, see Designing an IBM MQ architecture in the IBM MQ product documentation online

Configuring connections to IBM MQ

You can configure a local or client connection to IBM MQ to enable your IBM App Connect Enterprise message flows to access messages on IBM MQ queues.

If you intend to use an integration node (or an integration server that is managed by an integration node) to process IBM MQ messages, you must install IBM MQ in addition to installing IBM App Connect Enterprise. If you want to connect to a remote queue manager to process IBM MQ messages, you must install either an MQ Client or an MQ Server on the same machine as IBM App Connect Enterprise, in addition to installing an MQ Server on the machine that is running your queue manager. IBM MQ is available as a separate installation package, and your IBM App Connect Enterprise license entitles you to install and use IBM MQ with IBM App Connect Enterprise. For more information, see “Enhanced flexibility in interactions with IBM MQ ” on page 26 and “Installing IBM MQ” on page 96.

Alternatively, if you are using an independent integration server, you can configure a remote default queue manager to process the IBM MQ messages, by specifying the name of an MQEndpoint policy in the `server.conf.yaml` configuration file for the integration server. For more information, see “Configuring an integration server to use a remote default queue manager” on page 751.

You can configure MQ Connection properties on the following nodes to specify a local or client connection with IBM MQ:

- node
- node
- node
- node

You can also specify the properties through an policy.

You can connect to a secured IBM MQ queue manager (local or remote), by passing a user name and password to the queue manager when the connection is made. You can also choose whether to use the SSL protocol when a client connection is made to a remote queue manager. For information about securing connections to IBM MQ, see “Connecting to a secured IBM MQ queue manager” on page 747.

You can choose to configure either a local or client connection between your integration node and your queue manager, depending on the configuration of your existing architecture. If your queue manager is running on the same machine as your integration node, you can specify a local connection, either by choosing a specific queue manager to be used for the MQ node or by using the queue manager that is specified on the integration node. Alternatively, if IBM MQ is installed on separate machines from IBM App Connect Enterprise, you can define a client connection, either by configuring the connection details on the MQ node or policy, or by specifying a client channel definition table (CCDT) to control the client connection information. For more information, see “Configuring a client connection to IBM MQ” on page 745.

You can specify either a local or client connection by using one of the following methods:

- Set explicit connection properties for a specific MQ node on the MQ Connection tab.
- Specify an MQEndpoint policy to control connection properties for one or more MQ nodes on the Policy tab.

An MQEndpoint policy dynamically controls the connection properties that are applied at run time. You can use a single MQEndpoint policy for multiple MQ nodes, so that when you update the connection properties in the MQEndpoint policy, the updated properties are automatically applied to all MQ nodes that have the policy attached.

You can also configure an independent integration server to use a remote default queue manager for interactions with IBM MQ, by specifying the name of an MQEndpoint policy in the **remoteDefaultQueueManager** property in the integration server's `server.conf.yaml` file. This property enables the connection details that are set in the MQEndpoint policy to be used by default when connections to IBM MQ are required by flows that are deployed to the integration server. For more information, see "Using a remote default queue manager" on page 750 and "Configuring an integration server to use a remote default queue manager" on page 751.

All MQ nodes that do not have either MQ Connection properties set, or an MQEndpoint policy specified, use the connection details of the queue manager that is associated with the integration node or server at run time. If no queue manager was specified for the integration node, the message flow cannot deploy.

If you want to set explicit connection properties, select a value for the `Connection` property on the MQ Connection tab:

- Select `Local queue manager` to specify a local connection to a named queue manager, which is specified in the `Destination queue manager name` property.
- Select `MQ client connection properties` to choose a client connection to a queue manager, and specify the connection details of the queue manager in the following properties:
  - `Queue manager host name`
  - `Listener port number`
  - `Channel name`
  - `Destination queue manager name`
- Select `Connect with CCDT` to use the client connection details that are specified in a client channel definition table (CCDT).

The following topics describe how to configure local and client connections to IBM MQ:

- "Configuring a local connection to IBM MQ" on page 744
- "Configuring a client connection to IBM MQ" on page 745
- "Connecting to a secured IBM MQ queue manager" on page 747
- "Configuring an integration server to use a remote default queue manager" on page 751

By default, a thread that is processing IBM MQ messages becomes idle when it has not received any messages on its input queue for 1 minute, at which point the connection times out. However, you can change the length of time after which a connection for an idle message flow is released, by setting the **sharedConnectorIdleTimeout** property of the **mqsichangeproperties** command. For more information, see connections.

Configuring a local connection to IBM MQ
You can configure a local connection to IBM MQ by specifying the Connection properties on the MQInput, MQOutput, MQGet, or MQReply node.

Before you begin

Complete the following tasks:

- Read the topic "Configuring connections to IBM MQ" on page 743.
- Ensure that the required queue manager has been created, and that the user ID that is running the integration node has the necessary permissions to access the queue manager.
- Decide how you want to connect to the queue manager. You can either configure the connection properties on the MQ Connection tab of the MQ node, or you can use an MQEndpoint policy on the Policy tab. The steps in this topic explain how to configure connections by using the properties on the MQ

Connection tab. The properties that you can set in a policy are listed in the MQ node topics, such as the node; for more information about using an MQEndpoint policy, see policy.

About this task

IBM MQ is available as a separate installation package, and your IBM App Connect Enterprise license entitles you to install and use IBM MQ with IBM App Connect Enterprise. For more information, see “Enhanced flexibility in interactions with IBM MQ ” on page 26 and “Installing IBM MQ” on page 96.

If your IBM MQ queue manager is running on the same machine as IBM App Connect Enterprise, you can specify a local connection to enable your IBM App Connect Enterprise message flows to access messages on IBM MQ queues.

Procedure

1. On the MQ Connection tab, select the `Local queue manager` property to specify a local connection to a named local queue manager.

   If you do not set any MQ Connection properties, the queue manager that is specified on the integration node is used by default. If the MQ Connection properties are not set and no queue manager is specified on the integration node, the flow fails to deploy.
2. Specify the name of the required queue manager in the `Destination queue manager name` property.
3. Configure the connection to use a security identity for authentication. For more information, see “Connecting to a secured IBM MQ queue manager” on page 747.

What to do next

For MQInput nodes, the connection is made when the flow is deployed. For MQOutput, MQGet, and MQReply nodes, the connection is made when the first message is sent or received.

If you later decide that you want to control connection properties by using an MQEndpoint policy, property values that are set on the MQ Connection tab are ignored when a policy is attached to the message flow node. If you want to revert to using the connection details of the queue manager that was specified on the integration node, remove the settings for the **Policy URL** and MQ Connection tab properties.

Configuring a client connection to IBM MQ

On distributed systems, you can configure a client connection to IBM MQ by defining a connection channel and listener on IBM MQ and setting the MQ Connection properties of the MQ node on IBM App Connect Enterprise.

Before you begin

Complete the following tasks:

- Read the topic “Configuring connections to IBM MQ” on page 743.
- Ensure that the required queue manager has been created on the IBM MQ server.
- Ensure that the user ID that is running the integration node has the necessary permissions to access the queue manager.
- Decide how you want to connect to the queue manager. You can either configure the connection properties on the MQ Connection tab of the MQ node (such as the node), or you can specify an MQEndpoint policy on the Policy tab. The properties set in the MQEndpoint policy override the connection properties on the node at run time. The steps in this topic explain how to configure connections by using the properties on the MQ Connection tab. For information about the properties that you can set in a policy, see policy.

  For independent integration servers, you can configure a remote default queue manager for interactions with IBM MQ, by specifying the name of an MQEndpoint policy in the **`remoteDefaultQueueManager`** property in the integration server's `server.conf.yaml` file. This property enables the connection details that are specified in the MQEndpoint policy to be used by default when MQ connections are

required by flows that are deployed to the integration server. For more information, see “Using a remote default queue manager” on page 750 and “Configuring an integration server to use a remote default queue manager” on page 751.

About this task

IBM MQ is available as a separate installation package, and your IBM App Connect Enterprise license entitles you to install and use IBM MQ with IBM App Connect Enterprise. For more information, see “Enhanced flexibility in interactions with IBM MQ ” on page 26 and “Installing IBM MQ” on page 96.

If IBM MQ is running on a separate machine from IBM App Connect Enterprise, you can configure a client connection so that your integration node or server can access messages on the remote queue managers.

You can define a client connection on the MQ node either by specifying the connection details of the queue manager explicitly, through the `MQ client connection properties`, or by selecting the `Connect with CCDT` property to use a client channel definition table (CCDT) that contains the details of the connection. The MQ Connection properties are available on the following MQ nodes:

- MQInput
- MQOutput
- MQGet
- MQReply

Procedure

You configure a client connection by configuring the connection channel and listener on IBM MQ, and setting the MQ Connection properties on IBM App Connect Enterprise.

On the machine that is running your IBM MQ queue manager:

1. Define a server-connection channel for the queue manager, and ensure that the number of shared conversations is set to a minimum of 10.

   The number of conversations that can share a TCP/IP connection is specified by the **SHARECNV** property on the IBM MQ channel, and the default for this property is 10. If too few shared conversations are defined on the channel, errors can occur when the MQ node attempts to connect to the queue. For information about how to define a channel, see the IBM MQ product documentation online.
2. Define a TCP/IP listener.

   For information about how to define a listener, see the IBM MQ product documentation online.

Define the client connections on the machine that is running your integration server:

3. Decide how you want to define the connections to the queue manager.

   You can either configure them on the **MQ Connection** tab of the MQ node, or you can control them by using an MQEndpoint policy, specified on the **Policy** tab. The remaining steps in this topic explain how to configure connections by using the properties on the **MQ Connection** tab. For information about the MQ connection properties that you can set in a policy, see policy.
4. On the **MQ Connection** tab, choose one of the following options for the `Connection` property:

   - Select `MQ client connection properties` to make a client connection to the queue manager by explicitly specifying the connection details of the target queue manager. Specify the following connection properties for the target queue manager:

     – `Queue manager host name`

     – `Listener port number`

     – `Channel name`

     – `Destination queue manager name`

5. Configure the connection to use a security identity for authentication, SSL for confidentiality, or both, by completing the steps described in "Connecting to a secured IBM MQ queue manager" on page 747.

What to do next

All IBM MQ connections remain open until one of the following events occurs:

- An error occurs while the queue manager is being accessed, and a new connection is required as a result.
- The message flow is stopped.
- The message flow is idle for a time that exceeds the timeout threshold set for the connection. By default, this threshold is set to 1 minute; however, you can change the threshold by setting the **sharedConnectorIdleTimeout** property of the **mqsichangeproperties** command. For more information, see connections.

If you later decide that you want to control connection properties by using an MQEndpoint policy, property values that are set on the MQ Connection tab are ignored when a policy is attached to the message flow node.

Connecting to a secured IBM MQ queue manager
You can configure a connection to a secured local or remote IBM MQ queue manager, by setting properties on an MQ node or in an MQEndpoint policy.

Before you begin

- Read the topic "Configuring connections to IBM MQ" on page 743.
- Ensure that the required queue manager has been created on the IBM MQ server.
- Ensure that the user ID that is running the integration node has the necessary permissions to access the queue manager.

About this task

When you configure an MQ connection from an MQ node to an IBM MQ queue manager, you can optionally configure the connection to use a security identity for authentication, SSL for confidentiality, or both. The security identity, which passes user name and password security credentials to the queue manager, can be used on connections to local or remote queue managers. For connections to remote queue managers, you can choose whether to use the SSL protocol to provide confidentiality on the client connection. IBM App Connect Enterprise supports a subset of the SSL functionality that is supported by IBM MQ.

You can use the `Security identity` property on the MQ node or policy to pass a user name and password to the queue manager, by specifying a security identity that contains those credentials. The identity is defined using the **mqsisetdbparms** command.

You can specify that the SSL protocol is to be used when a client connection is made to a remote queue manager, by selecting the `Use SSL` property on the MQ node or policy. You can use SSL for client connections that are configured using either the `MQ client connection properties` or a client channel definition table (CCDT). If you specify SSL on the client connection, you must also specify the location of the SSL key repository. The SSL key repository is created by using the IBM MQ GSKit, and it holds the required private and public certificates appropriate to the chosen certificate policy for the queue manager. The SSL key repository password stash file *key repository file name*`.sth`, which is created using IBM MQ GSKit, must be located in same folder as the key repository.

You can use the **SSL certificate label** property in the MQEndpoint policy to specify the label of the certificate to be used when establishing the SSL client connection to the queue manager. If no value is supplied, the certificate with the MQ default label of `ibmwebspheremq`*user_id* is used, where *user_id* is the user identifier of the integration server. When multiple MQ SSL certificates are used by the same integration server, the MQ SVRCONN channel must be configured with a SHARECNV value of either `0` or `1`, to ensure that the correct certificate is used for the channel.

You can define the security properties for a local or client connection on an MQ node by using the MQ Connection properties on the following nodes:

- MQInput
- MQOutput
- MQGet
- MQReply

You can also set the security properties for an MQ connection by using an MQEndpoint policy, and these values override the values of properties set on the node, at run time. For more information, see policy.

Procedure

Follow these steps to complete the configuration of the integration server:

1. If your IBM MQ queue managers require a user name and password, you can use the **mqsisetdbparms** command to provide them for the secured connection. You can specify these credentials for all MQ connections (`mq::MQ`), for all connections to a specified queue manager (`mq::QMGR::`*`QMName`*), or for a connection with a specified security identity (`mq::`*`securityIdentityName`*). If you intend to use a security identity to provide user name and password information for a connection to a secured queue manager, you can use the **mqsisetdbparms** command to define that identity. The name of this identity can then be referred to by the **Security identity** property in the MQ nodes or MQEndpoint policy, as a method of retrieving credentials for a secured connection. When you set the security identity by using this command, ensure that it is prefixed by `mq::`.
   For example:
   - Create a security identity to be used for retrieving user name and password credentials when making a connection:

     ```
     mqsisetdbparms -w workDir -n mq::securityIdentityName -u username -p password
     ```
