Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. The length is given in bytes. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`* or *`Length Reference`* property. The default is `Bytes`.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • `1 Bytes`. The default value. • `2 Bytes` • `4 Bytes` • `8 Bytes` • `16 Bytes`
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.

Property	Type	Meaning
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

CWF properties for attribute reference and local attribute dateTime types:

CWF properties for attribute reference and local attribute dateTime types.

The Custom Wire Format properties described here apply to:

- Objects: Attribute Reference, Local Attribute
- DateTime schema types: date, dateTime, gDay, gMonth, gMonthDay, gYear, gYearMonth, time

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Fixed Length String`. The element's length is determined by other length properties as follows. • `Length Encoded String 1`. The first byte of the element contains the length of the string following the length byte in length units. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The element's first 2 bytes contain the length of the string following the two length bytes in length units. The maximum length of a `Length Encoded String 2` element is 65535 length units. The two length bytes are in the format of the WebSphere MQ queue manager Encoding. • `Null Terminated String`. The string ends with the hexadecimal NULL character, `X'00'`. • `Packed Decimal`. The dateTime is coded as a Packed Decimal number. It is valid only if the *`DateTime Format`* property represents numeric-only data. • `Binary`. The dateTime is encoded as a binary sequence of bytes. If you select this option, the range of symbols that you can specify for the Format String property is less than the range of symbols you can specify if you select a string option (see "DateTime formats" on page 6310 for details). • `Time Seconds`. This value supports C time_t and Java Date and Time objects. It is valid only if the *`DateTime Format`* property represents numeric-only data. • `Time Milliseconds`. This value supports C time_t and Java Date and Time objects. It is valid only if the *`DateTime Format`* property represents numeric-only data. The default value is `fixed length string`.
DateTime Format	String	Specify a template for date and time. The default dateTime format is dependent on the logical type of the object. For information about the defaults for the dateTime format according to the logical type, see "DateTime defaults by logical type" on page 6320. See "DateTime formats" on page 6310 for details of date and time formats.
Length	Button and Integer	If you have selected a *`Physical Type`* of `Fixed Length String`, `Packed Decimal`, or `Binary`, and have selected the length to be defined by *`Length`*, enter the number of length units for the element. The minimum value that you can specify is 1 for all three physical types. The maximum value that you can specify is `256` for `Fixed Length String`, `10` for `Packed Decimal`, and `2147483647` for `Binary`. The default value is 0 (zero).
Length Reference	Button and Enumerated type	If you have selected the length to be defined by *`Length Reference`*, select the name of the integer object that specifies the length of this object. Make your selection from the displayed list of integer objects that are defined as siblings of the current object, and occur before it in the structure of the message. For information about reordering elements, see "Reordering objects" on page 2900.

Property	Type	Meaning
Inclusive Length Reference	Check box	This property is applicable only if *Length Reference* is set. If the check box is selected, the value of the sibling integer object that is identified by *Length Reference* is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by *Length Reference* is the length of the current object only. If the check box is selected, the *Length Units* property of the sibling integer object must be the same as that of the current object.
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • Bytes. The length is given in bytes. • Characters. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • Character Units. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to Characters. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the Length property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • End of Bitstream. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *Length Count* or *Length Reference* property. The default is Bytes.
Justification	Enumerated type	If you have set the *Physical Type* property to Fixed Length String, select Left Justify (the default value) or Right Justify from the list. If you have selected another value for *Physical Type*, this property is inactive.

Property	Type	Meaning
Padding Character	String	If you have set the *Physical Type* property to `Fixed Length String`, and the *Justification* property is either `Left Justify` or `Right Justify`, this property is applicable. When writing an output message, use the padding character to fill out the remaining character positions when the string length is less than the length implied by the *Length* or *Length Reference* property. Whether the string is padded from the left or the right is governed by the *Justification* property. When parsing an input message, the padding character is trimmed from the end of the string. Whether the string is trimmed from the left or the right is governed by the *Justification* property. Specify this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the displayed list. • Enter a character between quotation marks; for example, `"c"` or `'c'`, where c is any alphanumeric character. • Enter a Unicode value in the form `U+xxxx` where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, it is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Numeric representation

Property	Type	Meaning
Signed	Check box	Specify whether the value is signed. This property is applicable only if the *Physical type* property is `Packed Decimal`. By default, this check box is cleared, which indicates that the value is not signed.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • `1 Bytes`. The default value. • `2 Bytes` • `4 Bytes` • `8 Bytes` • `16 Bytes`
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

CWF properties for attribute reference and local attribute decimal types:

CWF properties for attribute reference and local attribute decimal types.

The Custom Wire Format properties described here apply to:

- Objects: Attribute Reference, Local Attribute
- Decimal schema types: decimal, integer, negativeInteger, nonNegativeInteger, nonPositiveInteger, positiveInteger, unsignedLong

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Integer`. This equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. Equates to the COMP-3 data type in COBOL. • `External Decimal`. Equates to the data type PIC 9 USAGE DISPLAY in COBOL. The representation of numeric elements can be affected by the Encoding and CodedCharSetId attributes that are set for the WebSphere MQ queue manager: • Elements that have *`Physical Type`* set to `Integer` and `Packed Decimal` are represented in the appropriate WebSphere MQ Encoding value. • Elements that have *`Physical Type`* set to `External Decimal` are represented in the WebSphere MQ CodedCharSetId value.
Length	Integer	Enter the number of bytes to specify the element length: • If you set the *`Physical Type`* to `Integer`, select `1`, `2`, or `4` (the default) from the displayed list. • If you set the *`Physical Type`* to `Packed Decimal`, enter a value between 1 and 10. • If you set the *`Physical Type`* to `Extended Decimal`, enter a value between 1 and 256. (Numbers greater than the maximum COBOL PICTURE clause of 18 are assumed to be 18.)

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`*. The default is `Bytes`.
Justification	Enumerated type	If you have set the *`Physical Type`* property to `External Decimal`, select `Left Justify` or `Right Justify` (the default value) from the list. If you have selected another value for *`Physical Type`*, this property is inactive.

Property	Type	Meaning
Padding Character	String	The padding character is used to fill out the remaining character positions when the string length is less than the specified string size. If you have set the *Physical Type* property to Extended Decimal, and the *Justification* property is either Left Justify or Right Justify, specify this character in one of the following ways: • Select NUL, '0', or SPACE from the displayed list. • Enter a character between quotation marks; for example, "c" or 'c', where c is any alphanumeric character. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form 0xYY, where YY is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, this is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Numeric representation

Property	Type	Meaning
Signed	Check box	Select (the default) or clear this property. This property is used with *Sign Orientation*.

Property	Type	Meaning
Sign EBCDIC Custom Overpunched	Check box	If the *Physical Type* is set to External Decimal and the *Signed EBCDIC Custom* property is set, this indicates that the Sign EBCDIC Custom Overpunched representation is to be used within an ASCII environment. If this check box is not selected (the default), the Sign ASCII representation is used. The setting of the *Sign EBCDIC Custom Overpunched* check box is appropriate only if the *Sign Orientation* property is set to Leading or Trailing (indicating that the element/attribute has an embedded sign representation). The check box is not available if the element/attribute is unsigned (for example, if the *Signed* check box is not set).
Sign Orientation	Enumerated type	If you have set *Physical Type* to External Decimal and you have selected *Signed*, choose from the following options that represent the COBOL options for displaying numeric data: • Leading Overpunched. This option sets a bit in the first byte if the number is negative. No setting is made if the number is positive. For example, the ASCII hexadecimal representation of the number 22 is x'3232'. Using this option, the number +22 would be x'3232' and the number -22 would be x'7232'. The default value. • Leading Separate. This option sets the first byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. • Trailing Overpunched. This option sets a bit in the last byte if the number is negative. No setting is made if the number is positive. Using this option, the number +22 would be x'3232' and the number -22 would be x'3272'. • Trailing Separate. This option sets the last byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. If you have set *Physical Type* to any other value, the value Not Applicable is set for you.
Virtual Decimal Point	Integer	Specify the number of places to the left (for a positive value) or right (for a negative value) that a decimal point is to be moved from its assumed position. For example, a decimal element containing 1234 with a Virtual Decimal value of 3 is 1.234, equivalent to 'V' or 'P' in a COBOL picture clause. There is no C equivalent

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • 1 Bytes. The default value. • 2 Bytes • 4 Bytes • 8 Bytes • 16 Bytes
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.

Property	Type	Meaning
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

More information about the MRM domain.

CWF properties for attribute reference and local attribute float types:

CWF properties for attribute reference and local attribute float types.

The Custom Wire Format properties described here apply to:

- Objects: Attribute Reference, Local Attribute
- Float schema types: double, float

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Integer`. This equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Float`. This equates to the data type FLOAT or DOUBLE in C or the COMP-1 or COMP-2 data type in COBOL and is the default value. • `Packed Decimal`. Equates to the COMP-3 data type in COBOL. • `External Decimal`. Equates to the data type PIC 9 USAGE DISPLAY in COBOL. The representation of numeric elements can be affected by the Encoding and CodedCharSetId attributes that are set for the WebSphere MQ queue manager: • Elements that have *`Physical Type`* set to `Integer`, `Packed Decimal`, and `Float` are represented in the appropriate WebSphere MQ Encoding value. • Elements that have *`Physical Type`* set to `External Decimal` are represented in the WebSphere MQ CodedCharSetId value.
Length	Integer	Enter the number of bytes to specify the element length: • If you set the *`Physical Type`* to `Float`, select a value from the displayed list. The default value is `8`. • If you set the *`Physical Type`* to `Integer`, select `1`, `2`, or `4` (the default) from the displayed list. • If you set the *`Physical Type`* to `Packed Decimal`, enter a value between 1 and 10. • If you set the *`Physical Type`* to `Extended Decimal`, enter a value between 1 and 256. (Numbers greater than the maximum COBOL PICTURE clause of 18 are assumed to be 18.)

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`*. The default is `Bytes`.
Justification	Enumerated type	If you have set the *`Physical Type`* property to `External Decimal`, select `Left Justify` or `Right Justify` (the default value) from the list. If you have selected another value for *`Physical Type`*, this property is inactive.

Property	Type	Meaning
Padding Character	String	The padding character is used to fill out the remaining character positions when the string length is less than the specified string size. If you have set the *Physical Type* property to Extended Decimal, and the *Justification* property is either Left Justify or Right Justify, specify this character in one of the following ways: • Select NUL, '0', or SPACE from the displayed list. • Enter a character between quotation marks; for example, "c" or 'c', where c is any alphanumeric character. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form 0xYY, where YY is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, this is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Numeric representation

Property	Type	Meaning
Signed	Check box	Select or clear (unsigned, the default) this property. If you have set *Physical Type* to Float, this is selected. This property is used with *Sign Orientation*.

Property	Type	Meaning
Sign EBCDIC Custom Overpunched	Check box	If the *Physical Type* is set to External Decimal and the *Signed EBCDIC Custom* property is set, this indicates that the Sign EBCDIC Custom Overpunched representation is to be used within an ASCII environment. If this check box is not selected (the default), the Sign ASCII representation is used. The setting of the *Sign EBCDIC Custom Overpunched* check box is appropriate only if the *Sign Orientation* property is set to Leading or Trailing (indicating that the element/attribute has an embedded sign representation). The check box is not available if the element/attribute is unsigned (for example, if the *Signed* check box is not set).
Sign Orientation	Enumerated type	If you have set *Physical Type* to External Decimal and you have selected *Signed*, choose from the following options that represent the COBOL options for displaying numeric data: • Leading Overpunched. This option sets a bit in the first byte if the number is negative. No setting is made if the number is positive. For example, the ASCII hexadecimal representation of the number 22 is x'3232'. Using this option, the number +22 would be x'3232' and the number -22 would be x'7232'. The default value. • Leading Separate. This option sets the first byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. • Trailing Overpunched. This option sets a bit in the last byte if the number is negative. No setting is made if the number is positive. Using this option, the number +22 would be x'3232' and the number -22 would be x'3272'. • Trailing Separate. This option sets the last byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. If you have set *Physical Type* to any other value, the value Not Applicable is set for you.
Virtual Decimal Point	Integer	Specify the number of places to the left (for a positive value) or right (for a negative value) that a decimal point is to be moved from its assumed position. For example, a float element containing 1234 with a Virtual Decimal value of 3 is 1.234. This property is not applicable if you have set *Physical Type* to Float.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • 1 Bytes. The default value. • 2 Bytes • 4 Bytes • 8 Bytes • 16 Bytes
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.

Property	Type	Meaning
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Integer`. This equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. Equates to the COMP-3 data type in COBOL. • `External Decimal`. Equates to the data type PIC 9 USAGE DISPLAY in COBOL. The representation of numeric elements can be affected by the Encoding and CodedCharSetId attributes that are set for the WebSphere MQ queue manager: • Elements that have *`Physical Type`* set to `Integer` and `Packed Decimal` are represented in the appropriate WebSphere MQ Encoding value. • Elements that have *`Physical Type`* set to `External Decimal` are represented in the WebSphere MQ CodedCharSetId value.
Length	Integer	Enter the number of bytes to specify the element length: • If you set the *`Physical Type`* to `Integer`, select `1`, `2`, or `4` (the default) from the displayed list. • If you have set *`Physical Type`* to `Packed Decimal`, enter a value between 1 and 6. • If you have set *`Physical Type`* to `Extended Decimal`, enter a value between 1 and 11.

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`*. The default is `Bytes`.
Justification	Enumerated type	If you have set the *`Physical Type`* property to `External Decimal`, select `Left Justify` or `Right Justify` (the default value) from the list. If you have selected another value for *`Physical Type`*, this property is inactive.

Property	Type	Meaning
Padding Character	String	The padding character is used to fill out the remaining character positions when the string length is less than the specified string size. If you have set the *Physical Type* property to Extended Decimal, and the *Justification* property is either Left Justify or Right Justify, specify this character in one of the following ways: • Select NUL, '0', or SPACE from the displayed list. • Enter a character between quotation marks; for example, "c" or 'c', where c is any alphanumeric character. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form 0xYY, where YY is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, this is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Numeric representation

Property	Type	Meaning
Signed	Check box	Select (the default) or clear this property. This property is used with *Sign Orientation*.

Property	Type	Meaning
Sign EBCDIC Custom Overpunched	Check box	If the *Physical Type* is set to External Decimal and the *Signed EBCDIC Custom* property is set, this indicates that the Sign EBCDIC Custom Overpunched representation is to be used within an ASCII environment. If this check box is not selected (the default), the Sign ASCII representation is used. The setting of the *Sign EBCDIC Custom Overpunched* check box is appropriate only if the *Sign Orientation* property is set to Leading or Trailing (indicating that the element/attribute has an embedded sign representation). The check box is not available if the element/attribute is unsigned (for example, if the *Signed* check box is not set).
Sign Orientation	Enumerated type	If you have set *Physical Type* to External Decimal and you have selected *Signed*, choose from the following options that represent the COBOL options for displaying numeric data: • Leading Overpunched. This option sets a bit in the first byte if the number is negative. No setting is made if the number is positive. For example, the ASCII hexadecimal representation of the number 22 is x'3232'. Using this option, the number +22 would be x'3232' and the number -22 would be x'7232'. The default value. • Leading Separate. This option sets the first byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. • Trailing Overpunched. This option sets a bit in the last byte if the number is negative. No setting is made if the number is positive. Using this option, the number +22 would be x'3232' and the number -22 would be x'3272'. • Trailing Separate. This option sets the last byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. If you have set *Physical Type* to any other value, the value Not Applicable is set for you.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • 1 Bytes. The default value. • 2 Bytes • 4 Bytes • 8 Bytes • 16 Bytes
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.

Property	Type	Meaning
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

CWF properties for attribute reference and local attribute string types:

CWF properties for attribute reference and local attribute string types.

The Custom Wire Format properties described here apply to:

- Objects: Attribute Reference, Local Attribute
- String schema types: anyURI, ENTITIES, ENTITY, ID, IDREF, IDREFS, language, Name, NCName, NMTOKEN, NMTOKENS, normalizedString, NOTATION, QName, string, token

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Fixed Length String`. The element's length is determined by other length properties as follows. • `Length Encoded String 1`. The first byte of the element contains the length of the string following the length byte in length units. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The element's first 2 bytes contain the length of the string following the two length bytes in length units. The maximum length of a `Length Encoded String 2` element is 65535 length units. The two length bytes are in the format of the WebSphere MQ queue manager Encoding. • `Null Terminated String`. The string ends with the hexadecimal NULL character, `X'00'`. The default is `Fixed Length String`.
Length	Button and Integer	If you have selected a *`Physical Type`* of `Fixed Length String` or `Binary`, and have selected the length to be defined by *`Length`*, enter the number of length units for the element. The minimum value that you can specify is `0` (zero), the maximum value that you can specify is `2147483647` The default value is `0` (zero).
Length Reference	Button and Enumerated type	If you have selected the length to be defined by *`Length Reference`*, select the name of the integer object that specifies the length of this object. Make your selection from the displayed list of integer objects that are defined as siblings of the current object, and occur before it in the structure of the message. For information about reordering elements, see “Reordering objects” on page 2900.
Inclusive Length Reference	Check box	This property is applicable only if *`Length Reference`* is set. If the check box is selected, the value of the sibling integer object that is identified by *`Length Reference`* is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by *`Length Reference`* is the length of the current object only. If the check box is selected, the *`Length Units`* property of the sibling integer object must be the same as that of the current object.

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. The length is given in bytes. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`* or *`Length Reference`* property. The default is `Bytes`.
Justification	Enumerated type	If you have set the *`Physical Type`* property to `Fixed Length String`, select `Left Justify` (the default value) or `Right Justify` from the list. If you have selected another value for *`Physical Type`*, this property is inactive.

Property	Type	Meaning
Padding Character	String	If you have set the *Physical Type* property to `Fixed Length String`, and the *Justification* property is either `Left Justify` or `Right Justify`, this property is applicable. When writing an output message, use the padding character to fill out the remaining character positions when the string length is less than the length implied by the *Length* or *Length Reference* property. Whether the string is padded from the left or the right is governed by the *Justification* property. When parsing an input message, the padding character is trimmed from the end of the string. Whether the string is trimmed from the left or the right is governed by the *Justification* property. Specify this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the displayed list. • Enter a character between quotation marks; for example, `"c"` or `'c'`, where c is any alphanumeric character. • Enter a Unicode value in the form `U+xxxx` where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, it is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • `1 Bytes`. The default value. • `2 Bytes` • `4 Bytes` • `8 Bytes` • `16 Bytes`
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Local attribute XML properties:

The properties, and their permissible values, vary according to the object type.

The properties that are displayed on the object page, and the values that those properties can take, can vary according to the type of the object. For example, the properties for type *string* are different from those of type *Boolean*. Select the link for the object type from the following table.

Type of object	**Properties**
Binary types	• base64Binary • hexBinary
Boolean types	• Boolean
DateTime types	• date • dateTime • gDay • gMonth • gMonthDay • gYear • gYearMonth • time
Decimal types	• decimal • integer • negativeInteger • nonNegativeInteger • nonPositiveInteger • positiveInteger • unsignedLong
Float types	• double • float

Type of object	Properties
Integer types	• byte • int • long • short • unsignedByte • unsignedInt • unsignedShort
Interval types	• duration
String types	• anyURI • ENTITIES • ENTITY • ID • IDREF • IDREFS • language • Name • NCName • NMTOKEN • NMTOKENS • normalizedString • NOTATION • QName • string • token

Note: The physical format properties for simple type *duration* are the same as the physical properties of the string logical types.

XML properties for attribute reference, element reference, local attribute, local element binary types:

XML wire format properties for attribute reference, element reference, local attribute, and local element binary types.

The XML Wire Format properties described here apply to:

- Objects: Attribute Reference, Element Reference, Local Attribute, Local Element
- Binary schema types: base64Binary, hexBinary

Field identification

A number of the following properties only become active depending on the value that *Render* property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their *`XML Name`*property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLAttribute`. If you select this value, the object (or type) is rendered as an attribute of the parent XML object. The identity of the child is determined by the attribute name. The value is the attribute value. This is only valid for simple elements. If you select this value for more than one object , you must set their *`XML Name`* property to different values. This is the default value for attribute objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in *`ID Attribute Name`* and a value as specified in *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. • `XMLElementAttrVal`. If you specify this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the value of a specified attribute. The name of the attribute is specified in *`Value Attribute Name`*. • `XMLElementAttrIDVal`. This option combines the two options, `XMLElementAttrID` and `XMLElementAttrVal`. The object is rendered as a child of the parent complex type. The identity of the child is determined by the value of *`ID Attribute Name`*. The value is the value of *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrID` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.

Property	Type	Meaning
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.
Value Attribute Name	String	Specify the name of the attribute used for the value of the child. This must be a valid XML Attribute Name. This is only used if required by the setting of *Render*. The default value is `val`.
Namespace	String	Enter the namespace associated with the *Value Attribute*.

Physical representation

Property	Type	Meaning
Encoding	String	Select one of the following values from the drop-down list: : • `CDatahex` (the default). Hexadecimal values in this field are specified with the CDATA qualifier, for example <e1><![CDATA[62]]></e1> • `hex`. Hexadecimal values in this field are specified as digits only, for example <e1>62</e1>. • `base64`. Values in this field are specified as digits only, coded in base 64.

XML properties for attribute reference, element reference, local attribute, local element float types:

XML wire format properties for attribute reference, element reference, local attribute, and local element float types.

The XML Wire Format properties described here apply to:

- Objects: Attribute Reference, Element Reference, Local Attribute, Local Element
- Float schema types: double, float

Field identification

A number of the following properties only become active depending on the value that *Render* property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their *`XML Name`*property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLAttribute`. If you select this value, the object (or type) is rendered as an attribute of the parent XML object. The identity of the child is determined by the attribute name. The value is the attribute value. This is only valid for simple elements. If you select this value for more than one object , you must set their *`XML Name`* property to different values. This is the default value for attribute objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in *`ID Attribute Name`* and a value as specified in *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. • `XMLElementAttrVal`. If you specify this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the value of a specified attribute. The name of the attribute is specified in *`Value Attribute Name`*. • `XMLElementAttrIDVal`. This option combines the two options, `XMLElementAttrID` and `XMLElementAttrVal`. The object is rendered as a child of the parent complex type. The identity of the child is determined by the value of *`ID Attribute Name`*. The value is the value of *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrID` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.

Property	Type	Meaning
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.
Value Attribute Name	String	Specify the name of the attribute used for the value of the child. This must be a valid XML Attribute Name. This is only used if required by the setting of *Render*. The default value is `val`.
Namespace	String	Enter the namespace associated with the *Value Attribute*.

XML properties for attribute reference, element reference, local attribute, local element string types:

XML wire format properties for attribute reference, element reference, local attribute, and local element string types.

The XML Wire Format properties described here apply to:

- Objects: Attribute Reference, Element Reference, Local Attribute, Local Element
- String schema types: anyURI, ENTITIES, ENTITY, ID, IDREF, IDREFS, language, Name, NCName, NMTOKEN, NMTOKENS, normalizedString, NOTATION, QName, string, token

Field identification

A number of the following properties only become active depending on the value that *Render* property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their *`XML Name`*property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLAttribute`. If you select this value, the object (or type) is rendered as an attribute of the parent XML object. The identity of the child is determined by the attribute name. The value is the attribute value. This is only valid for simple elements. If you select this value for more than one object , you must set their *`XML Name`* property to different values. This is the default value for attribute objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in *`ID Attribute Name`* and a value as specified in *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. • `XMLElementAttrVal`. If you specify this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the value of a specified attribute. The name of the attribute is specified in *`Value Attribute Name`*. • `XMLElementAttrIDVal`. This option combines the two options, `XMLElementAttrID` and `XMLElementAttrVal`. The object is rendered as a child of the parent complex type. The identity of the child is determined by the value of *`ID Attribute Name`*. The value is the value of *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrID` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.

Property	Type	Meaning
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.
Value Attribute Name	String	Specify the name of the attribute used for the value of the child. This must be a valid XML Attribute Name. This is only used if required by the setting of *Render*. The default value is `val`.
Namespace	String	Enter the namespace associated with the *Value Attribute*.

Local attribute TDS properties:

The properties, and their permissible values, vary according to the object type.

The properties that are displayed on the object page, and the values that those properties can take, can vary according to the type of the object. For example, the properties for type *string* are different from those of type *Boolean*. Select the link for the object type from the following table.

Binary types	Boolean types	DateTime types	Decimal types
• base64Binary • hexBinary	• Boolean	• date • dateTime • gDay • gMonth • gMonthDay • gYear • gYearMonth • time	• decimal • integer • negativeInteger • nonNegativeInteger • nonPositiveInteger • positiveInteger • unsignedLong

Float types	Integer types	Interval types	String types
• double • float	• byte • int • long • short • unsignedByte • unsignedInt • unsignedShort	• duration	• anyURI • ENTITIES • ENTITY • ID • IDREF • IDREFS • language • Name • NCName • NMTOKEN • NMTOKENS • normalizedString • NOTATION • QName • string • token

Note: The physical format properties for simple type *duration* are the same as the physical properties of the string logical types.

TDS properties for local attribute binary types:

The TDS format properties for local attribute binary types.

The TDS Format properties described here apply to:

- Objects: Local Attribute
- Binary schema types: base64Binary, hexBinary

Field Identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.

Physical representation

Property	Type	Meaning
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. The default is dependent on the setting of the message set property `Derive default length from logical type`. If `Derive default length from logical type` is selected, the default value is derived from any length or maxLength value constraint (schema facet) on the object's simple type.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see "Reordering objects" on page 2900.

Property	Type	Meaning
Inclusive Length Reference	Check box	This property is applicable only if `Length Reference` is set. If the check box is selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object only. If the check box is selected, the `Length Units` property of the sibling integer object must be the same as that of the current object.

TDS properties for local attribute Boolean types:

The TDS format properties for local attribute Boolean types.

The TDS Format properties described here apply to:

- Objects: Local Attribute
- Boolean schema types: Boolean

Field Identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Binary`. The data is in bit string format. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.

Property	Type	Meaning
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see “Regular expression syntax” on page 6304.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Length Encoded String 1`. The first byte of the data contains the length (in length units) of the data string that follows the length byte. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The first two bytes of the data contain the length (in length units) of the data string that follows the two length bytes. The maximum length of a `Length Encoded String 2` element is 65535 length units. • `Null Terminated String`. The data string ends with the hexadecimal NULL character, `X'00'`. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `Binary`. The data is in bit string format. • `Time Seconds`. This value supports C time_t, and Java Date and Time objects. It is valid only if the `DateTime Format` property represents numeric-only data. • `Time Milliseconds`. This value supports C time_t, and Java Date and Time objects. It is valid only if the `DateTime Format` property represents numeric-only data. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. If this property is not set and the message set property `Derive default length from logical type` is selected, and the `Physical type` is 'Character', the default value is derived from any length or maxLength value constraint (schema facet) on the simple type.

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the object. Select one of the following options (some physical types do not offer both options): • `Bytes`. The length is given in bytes. • `Characters`. The length is given in characters. The number of bytes that are processed in the bit stream depends on the code page of the message. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the contents of the bit stream. The parser reads one character at a time and determines whether the character comprises one or more bytes. The default is dependent on the physical type of the object.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
DateTime Format	String	Specify a template for date and time. The default DateTime format is dependent on the logical type of the object. For information about the defaults for the dateTime format according to the logical type, see “DateTime defaults by logical type” on page 6320. See “DateTime formats” on page 6310 for details of date and time formats.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Property	Type	Meaning
Inclusive Length Reference	Check box	This property is applicable only if `Length Reference` is set. If the check box is selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object only. If the check box is selected, the `Length Units` property of the sibling integer object must be the same as that of the current object.

Numeric representation

Property	Type	Meaning
Signed	Check box	Specify whether the value is signed. This property is applicable only if the `Physical type` property is `Packed Decimal`. By default, this check box is cleared, which indicates that the value is not signed.

TDS properties for local attribute decimal types:

The TDS format properties for local attribute decimal types.

The TDS Format properties described here apply to:

- Objects: Local Attribute
- Decimal schema types: decimal, integer, negativeInteger, nonNegativeInteger, nonPositiveInteger, positiveInteger, unsignedLong

Field Identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `TLOG Specific` - this option can be selected only if the `Message Standard` property of the message set is `TLOG`. This option indicates that the format of the data is specific to the TLOG messaging standard. • `Integer`. Equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `External Decimal`. The data is a decimal number that equates to the data type PIC 9 USAGE DISPLAY in COBOL. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. If this property is not set and the message set property `Derive default length from logical type` is selected, and the `Physical type` is 'Character', the default value is derived from any length or maxLength value constraint (schema facet) on the simple type.
Length Units	Enumerated type	Select the unit of length for the object. Select one of the following options (some physical types do not offer both options): • `Bytes`. The length is given in bytes. • `Characters`. The length is given in characters. The number of bytes that are processed in the bit stream depends on the code page of the message. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the contents of the bit stream. The parser reads one character at a time and determines whether the character comprises one or more bytes. The default is dependent on the physical type of the object.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Property	Type	Meaning
Inclusive Length Reference	Check box	This property is applicable only if `Length Reference` is set. If the check box is selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object only. If the check box is selected, the `Length Units` property of the sibling integer object must be the same as that of the current object.

Numeric representation

Property	Type	Meaning
Sign Orientation	Enumerated type	The values that you can choose for this property are: • `Leading Separate` • `Trailing Separate` • `Leading Overpunched` • `Trailing Overpunched` This property is enabled only if you have set `Physical Type` to `Text` or `External Decimal`, and you have selected `Signed`. If `Physical Type` is `Text`, the only valid values of `Sign Orientation` are `Leading Separate` and `Trailing Separate`. If `Physical Type` is `External Decimal` and `Sign EBCDIC Customer Overpunched` is selected, the only valid values of `Sign Orientation` are `Leading Overpunched` and `Trailing Overpunched`.
Positive Sign	String	Specify the value that represents the positive symbol. Do not specify a numeric value. If no value is set, "+" is assumed. The positive sign is not written when creating an output message; it is used only to recognize the positive sign when parsing a message bit stream. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.
Negative Sign	String	Specify the value that represents the negative symbol. Do not specify a numeric value. If no value is set, "-" is assumed. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.
Virtual Decimal Point	Button and Integer	Specify a non-zero integer that represents the position of an implied decimal point within a number, or specify 0, the default, to use the formatting of Float or Decimal numbers as specified by the `Precision` property. If you specify a positive integer, the position of the decimal point is moved left from the right side of the number. For example, if you specify 3, the decimal value `1234` represents 1.234 If you specify a negative integer, the position of the decimal point is moved right from the right side of the number. For example, if you specify `-3`, the decimal value `1234` represents 1,234,000.

Property	Type	Meaning
Precision	Button and Integer	This property is applicable only if `Physical Type` is `Text`. It is used if the value of the `Virtual Decimal Point` property is 0, which indicates that the decimal point is present in the data. It deals with truncation, and specifies how many digits are to follow the decimal point. Either specify a number of digits: • If you set `Precision` to 0, data is truncated so that the fractional part is lost. For example, the value `123.45` is truncated to `123`. • If you set `Precision` to a number less than the number of fractional digits, data is truncated. For example, the value `123.4567` is truncated to `123.45` if you set `Precision` to 2. • If you set `Precision` to a number greater than the number of fractional digits, the value is padded with extra zeros. For example, the value `12.345` is padded to `12.34500` if you set `Precision` to 5. Or select one option from the list: • `All Significant Digits - decimal separator only required if fractional digits` (the default): all significant digits are written to the output bit stream, and no decimal separator is written if no fractional digits are present. • `Explicit Decimal Separator - decimal separator always required`: all significant digits are written to the output bit stream and the decimal separator is always included, even when no fractional digits are present. The decimal separator must be present in the input bit stream, even when no fractional digits are present.

Field Identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Float`. Equates to the data type FLOAT or DOUBLE in C, or the COMP-1 or COMP-2 numeric data type in COBOL. • `Integer`. Equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `External Decimal`. The data is a decimal number that equates to the data type PIC 9 USAGE DISPLAY in COBOL. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. If this property is not set and the message set property `Derive default length from logical type` is selected, and the `Physical type` is 'Character', the default value is derived from any length or maxLength value constraint (schema facet) on the simple type.
Length Units	Enumerated type	Select the unit of length for the object. Select one of the following options (some physical types do not offer both options): • `Bytes`. The length is given in bytes. • `Characters`. The length is given in characters. The number of bytes that are processed in the bit stream depends on the code page of the message. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the contents of the bit stream. The parser reads one character at a time and determines whether the character comprises one or more bytes. The default is dependent on the physical type of the object.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Property	Type	Meaning
Inclusive Length Reference	Check box	This property is applicable only if `Length Reference` is set. If the check box is selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object only. If the check box is selected, the `Length Units` property of the sibling integer object must be the same as that of the current object.

Numeric representation

Property	Type	Meaning
Sign Orientation	Enumerated type	The values that you can choose for this property are: • `Leading Separate` • `Trailing Separate` • `Leading Overpunched` • `Trailing Overpunched` This property is enabled only if you have set `Physical Type` to `Text` or `External Decimal`, and you have selected `Signed`. If `Physical Type` is `Text`, the only valid values of `Sign Orientation` are `Leading Separate` and `Trailing Separate`. If `Physical Type` is `External Decimal` and `Sign EBCDIC Customer Overpunched` is selected, the only valid values of `Sign Orientation` are `Leading Overpunched` and `Trailing Overpunched`.
Positive Sign	String	Specify the value that represents the positive symbol. Do not specify a numeric value. If no value is set, "+" is assumed. The positive sign is not written when creating an output message; it is used only to recognize the positive sign when parsing a message bit stream. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.
Negative Sign	String	Specify the value that represents the negative symbol. Do not specify a numeric value. If no value is set, "-" is assumed. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.
Virtual Decimal Point	Button and Integer	Specify a non-zero integer that represents the position of an implied decimal point within a number, or specify 0, the default, to use the formatting of Float or Decimal numbers as specified by the `Precision` property. If you specify a positive integer, the position of the decimal point is moved left from the right side of the number. For example, if you specify `3`, the decimal value `1234` represents 1.234 If you specify a negative integer, the position of the decimal point is moved right from the right side of the number. For example, if you specify `-3`, the decimal value `1234` represents 1,234,000.

Property	Type	Meaning
Precision	Button and Integer	This property is applicable only if `Physical Type` is `Text`. It is used if the value of the `Virtual Decimal Point` property is 0, which indicates that the decimal point is present in the data. It deals with truncation, and specifies how many digits are to follow the decimal point. Either specify a number of digits: • If you set `Precision` to 0, data is truncated so that the fractional part is lost. For example, the value `123.45` is truncated to `123`. • If you set `Precision` to a number less than the number of fractional digits, data is truncated. For example, the value `123.4567` is truncated to `123.45` if you set `Precision` to 2. • If you set `Precision` to a number greater than the number of fractional digits, the value is padded with extra zeros. For example, the value `12.345` is padded to `12.34500` if you set `Precision` to 5. Or select one option from the list: • `All Significant Digits - decimal separator only required if fractional digits` (the default): all significant digits are written to the output bit stream, and no decimal separator is written if no fractional digits are present. • `Explicit Decimal Separator - decimal separator always required`: all significant digits are written to the output bit stream and the decimal separator is always included, even when no fractional digits are present. The decimal separator must be present in the input bit stream, even when no fractional digits are present. • `Exponential Notation - Example "1.23456e002"`: data is written out to the bit stream as a signed value having the format `[sign1]a.bbbe[sign2]ccc` where: – `[sign1]` is the value of `Negative Sign` if the value is negative – `a` is a single decimal digit – `bbb` is one or more decimal digits – `[sign2]` is the value of `Negative Sign` if the exponent is negative – `ccc` is exactly three decimal digits (the exponent) `[sign1]` and `[sign2]` are absent if the value and exponent are positive. For example, the value -123.456 is represented as `-1.23456e002` and the value 0.00012 is represented as `1.2e-004` in the output bit stream, assuming that the value of `Negative Sign` is "-", and the value of `Sign Orientation` is `Leading`. The value -0.00012 is represented as `1.2*e*004` if `Negative Sign` is "*" and `Sign Orientation` is `Trailing`.

TDS properties for local attribute integer types:

The TDS format properties for local attribute integer types.

The TDS Format properties described here apply to:

- Objects: Local Attribute
- Integer schema types: byte, int, long, short, unsignedByte, unsignedInt, unsignedShort

Field Identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Integer`. Equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `External Decimal`. The data is a decimal number that equates to the data type PIC 9 USAGE DISPLAY in COBOL. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. If this property is not set and the message set property `Derive default length from logical type` is selected, and the `Physical type` is 'Character', the default value is derived from any length or maxLength value constraint (schema facet) on the simple type.
Length Units	Enumerated type	Select the unit of length for the object. Select one of the following options (some physical types do not offer both options): • `Bytes`. The length is given in bytes. • `Characters`. The length is given in characters. The number of bytes that are processed in the bit stream depends on the code page of the message. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the contents of the bit stream. The parser reads one character at a time and determines whether the character comprises one or more bytes. The default is dependent on the physical type of the object.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Property	Type	Meaning
Inclusive Length Reference	Check box	This property is applicable only if `Length Reference` is set. If the check box is selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object only. If the check box is selected, the `Length Units` property of the sibling integer object must be the same as that of the current object.

Numeric representation

Property	Type	Meaning
Sign Orientation	Enumerated type	The values that you can choose for this property are: • `Leading Separate` • `Trailing Separate` • `Leading Overpunched` • `Trailing Overpunched` This property is enabled only if you have set `Physical Type` to `Text` or `External Decimal`, and you have selected `Signed`. If `Physical Type` is `Text`, the only valid values of `Sign Orientation` are `Leading Separate` and `Trailing Separate`. If `Physical Type` is `External Decimal` and `Sign EBCDIC Customer Overpunched` is selected, the only valid values of `Sign Orientation` are `Leading Overpunched` and `Trailing Overpunched`.
Positive Sign	String	Specify the value that represents the positive symbol. Do not specify a numeric value. If no value is set, "+" is assumed. The positive sign is not written when creating an output message; it is used only to recognize the positive sign when parsing a message bit stream. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.
Negative Sign	String	Specify the value that represents the negative symbol. Do not specify a numeric value. If no value is set, "-" is assumed. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.

TDS properties for local attribute string types:

The TDS format properties for local attribute string types.

The TDS Format properties described here apply to:

- Objects: Local Attribute
- String schema types: anyURI, ENTITIES, ENTITY, ID, IDREF, IDREFS, language, Name, NCName, NMTOKEN, NMTOKENS, normalizedString, NOTATION, QName, string, token

Field Identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.

Property	Type	Meaning
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.
Interpret Element Value	Enumerated type	Specify whether values stored within this object are interpreted as having significance for the parser and, if so, the type of interpretation that occurs. This interpretation is standard-specific and is therefore hard coded. The possible values for this property are: • `None` (the default value) • `EDIFACT Service String` • `X12 Service String` • `Message Key` • `EDIFACT Syntax Level ID` • `HL7 Service String` • `HL7 Field Separator` **Note:** The `Message Key` enumeration has been deprecated.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Length Encoded String 1`. The first byte of the data contains the length (in length units) of the data string that follows the length byte. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The first two bytes of the data contain the length (in length units) of the data string that follows the two length bytes. The maximum length of a `Length Encoded String 2` element is 65535 length units. • `Null Terminated String`. The data string ends with the hexadecimal NULL character, `X'00'`. • `TLOG Specific` - this option can be selected only if the `Message Standard` property of the message set is `TLOG`. This option indicates that the format of the data is specific to the TLOG messaging standard. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. If this property is not set and the message set property `Derive default length from logical type` is selected, and the `Physical type` is 'Character', the default value is derived from any length or maxLength value constraint (schema facet) on the simple type.

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the object. Select one of the following options (some physical types do not offer both options): • `Bytes`. The length is given in bytes. • `Characters`. The length is given in characters. The number of bytes that are processed in the bit stream depends on the code page of the message. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the contents of the bit stream. The parser reads one character at a time and determines whether the character comprises one or more bytes. The default is dependent on the physical type of the object.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Property	Type	Meaning
Inclusive Length Reference	Check box	This property is applicable only if `Length Reference` is set. If the check box is selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object only. If the check box is selected, the `Length Units` property of the sibling integer object must be the same as that of the current object.

Local element logical properties:

The logical properties of a local element include properties that specify the number of occurrences and value of the local element.

Property	Type	Meaning
Name	String	Specify a name for the object when you create it. Names can consist of alphanumeric characters, including the letters *A* through *Z*, *a* through *z*, and the digits *0* through *9*. They might also include the following punctuation characters; • - the hyphen • _ the underscore • . the period Names can start only with a letter or the underscore character, and not with a number, hyphen, or period. Names that begin with `xml`, or any variant of these characters (for example `XmL`), are reserved by the XML standards specification. Further details of naming conventions and allowable characters can be found in the Extensible Markup Language (XML) specification that can be found on the World Wide Web Consortium (W3C) Web site.

Property	Type	Meaning
Type	Enumerated type	The Type property constrains the type of data that can be present in the object. Select from the following options: • `int` • `string` • `Boolean` • `hexBinary` • `dateTime` • `date` • `time` • `decimal` • `float` • `(More...)` • `(New Simple Type)` • `(New Complex Type)` If you select (More...), the Type Selection wizard starts. In this wizard, you can select any of the available types. If you select (New Simple Type), the New Simple Type wizard starts. In this wizard, you can create an Anonymous simple type that is based on an existing type. This type can be created locally or globally. If you select (New Complex Type), the New Complex Type wizard starts. In this wizard, you can create an Anonymous complex type, which can be derived from an existing base type. This type can be created locally or globally. For further information about these types, and examples of their use, see the XML Schema Part 0: Primer. This document is available on the World Wide Web Consortium (W3C) Web site.
Namespace	Enumerated type	Namespaces are a simple method for qualifying element and attribute names by associating them with namespaces identified by URI references. If <no target namespace> is displayed, a namespace has not been set for this object. If the property is inactive, the message set has not been configured to support namespaces. Where the property is active, namespaces that are available for selection are displayed in the drop-down list.

Occurrences

Property	Type	Meaning
Min Occurs	Integer	Specify the minimum number of times that the object can repeat. The default value is 1. If the value is set to 0, the object is optional. With the exception of `Max Occurs` being set to -1, if a value is set for `Min Occurs`, it must be less than or equal to the value in `Max Occurs`.

Property	Type	Meaning
Max Occurs	Integer	Specify the maximum number of times that the object can repeat. The default value is 1. If this property is not set, the object cannot occur more than once. If this property is set to 0, it is interpreted as if the object does not exist in the message. It can also be set to -1, to indicate that the limit is unbounded and there is no maximum to the number of occurrences.

Value

Property	Type	Meaning
Default	Button and String	This property provides the default value for an element or attribute. **XMLNSC domain** When parsing with validation enabled, default values are applied to missing attributes and empty elements as required by the XML Schema 1.0 specification. When writing, elements or attributes that are missing from the message tree are not automatically added to the output XML bit stream, even if they have default values. If missing elements or attributes are required, the message tree can be serialized and then re-parsed with validation enabled. **MRM (CWF and TDS physical formats)** When writing a fixed-length portion of a message (CWF or fixed-length TDS), if an attribute or element is missing from the message tree, the default value is inserted into the bit stream so that the message structure is preserved. **MRM (XML physical format)** No support for default values **Other domains** No support for default values.
Fixed	Button and String	This property provides the fixed value for an element or attribute. **XMLNSC domain** When parsing with validation enabled, if an attribute or element is present, the value is validated against the fixed value. If the values are not equal, a validation error is signalled. Also, when parsing with validation enabled, fixed values are applied to missing attributes and empty elements as required by the XML Schema 1.0 specification. When writing, elements or attributes that are missing from the message tree are not automatically added to the output XML bit stream, even if a fixed value has been specified. If missing elements or attributes are required, the message tree can be serialized and then re-parsed with validation enabled. **MRM (CWF and TDS physical formats)** When writing a fixed-length portion of a message (CWF or fixed-length TDS), if an attribute or element is missing from the message tree, the fixed value is inserted into the bit stream so that the message structure is preserved. **MRM (XML physical format)** No support for fixed values **Other domains** No support for fixed values.

Property	Type	Meaning
Nillable	Check box	Select this option if you want the element to be able to be defined as null. A null value is distinct from being empty, when the element contains no data.
Interpret Value As	Enumerated type	Specify if values stored within this object must be interpreted as having significance for the parser and, if so, the type of interpretation that must occur. Select one of the following options: • None This value is the default value, and indicates that the element or attribute does not have a key value associated with it. • MessageSetIdentity. Specifies that the value of the element or attribute corresponds to the identifier, name, or alias (in that priority order) that is associated with the message set where all subsequent embedded messages that are descendents of the enclosing message are defined. This value remains in force unless a new element or attribute MessageSetIdentity field is encountered which resets the MessageSetIdentity value. • MessageIdentity. Specifies that the value of the element or attribute corresponds to the name or alias (in that priority order) that is associated with a message, and acts as an identifier for subsequent embedded messages which are the immediate children of the enclosing message. This identity applies until a new element or attribute MessageIdentity field is encountered at the same level in the tree. The embedded message can be defined in either the current message set, or in a message set identified by using a MessageSetIdentity. **Note:** This property is applicable only when the type of the object is derived from xsd:string.

Substitution settings

Substitution Groups provide a means by which one element may be substituted for another in a message. The element which can be substituted is called the 'head' element, and the substitution group is the list of elements that may be used in its place. An element can be in at most one substitution group.

Property	Type	Meaning
Final	Enumerated type	Limit the set of elements that can belong to its substitution group. • Empty • restriction. Prohibit element substitution by elements whose types are restrictions of the type of the head element. • extension. Prohibit element substitution by elements whose types are extensions of the type of the head element. • #all. Prohibit substitution by all methods.
Block	Enumerated type	Limit the set of elements that can be substituted for this element in a message. • Empty • restriction. Prohibit element substitution by elements whose types are restrictions of the type of the head element • extension. Prohibit element substitution by elements whose types are extensions of the type of the head element • substitution. Prohibit element substitution by members of the element's substitution group. • #all. Prohibit substitution by all methods.
Substitution Group	Enumerated type	Specify the name of a 'head' element. Setting this property indicates that this element is a member of the substitution group for the head element.

Property	Type	Meaning
Abstract	Check box	Select this option if you do not want the element to appear in the message, but require one of the members of its substitution group to appear in its place.

"Message model object properties by object" on page 5536
The following objects have properties that can be viewed or set.

Local element CWF properties:

The properties, and their permissible values, vary according to the object type.

The properties that are displayed on the object page, and the values that those properties can take, can vary according to the type of the object. For example, the properties for type *string* are different from those of type *Boolean*. Select the link for the object type from the following table.

Type of object	Properties
Binary types	• base64Binary • hexBinary
Boolean types	• Boolean
DateTime types	• date • dateTime • gDay • gMonth • gMonthDay • gYear • gYearMonth • time
Decimal types	• decimal • integer • negativeInteger • nonNegativeInteger • nonPositiveInteger • positiveInteger • unsignedLong
Float types	• double • float

Type of object	Properties
Integer types	• byte • int • long • short • unsignedByte • unsignedInt • unsignedShort
Interval types	• duration
String types	• anyURI • ENTITIES • ENTITY • ID • IDREF • IDREFS • language • Name • NCName • NMTOKEN • NMTOKENS • normalizedString • NOTATION • QName • string • token

Note: The physical format properties for simple type *duration* are the same as the physical properties of the string logical types.

Related concepts:

"Physical formats in the MRM domain" on page 1211
Each message definition file within a message set describes both the *logical structure* of your messages, and the *physical formats* that describe the precise appearance of your message bit stream during transmission.

"MRM Custom Wire Format" on page 1214
Custom Wire Format (CWF) is the physical representation of a message that is composed of a number of fixed-format data structures or elements, which are not separated by delimiters.

"MRM Custom wire format: Relationship to the logical model" on page 1219
Some restrictions exist in relation to the logical model for messages that are defined by using the CWF.

Related tasks:

"Working with physical formats" on page 2847
If you are using the MRM domain to parse and write your messages, when you are developing your message model you might want to add one or more physical format layers to a message set, then configure the properties of these physical formats.

CWF wire format properties for element reference and local element binary types.

The Custom Wire Format properties described here apply to:

- Objects: Element Reference, Local Element
- Binary schema types: base64Binary, hexBinary

Physical representation

Property	Type	Meaning
Length	Button and Integer	If you have selected the length to be defined by *Length*, enter the number of length units for the element. The minimum value that you can specify is 1. The maximum value that you can specify is 2147483647. The default value is empty (not set).
Length Reference	Button and Enumerated type	If you have selected the length to be defined by *Length Reference*, select the name of the integer object that specifies the length of this object. Make your selection from the displayed list of integer objects that are defined as siblings of the current object, and occur before it in the structure of the message. For information about reordering elements, see "Reordering objects" on page 2900.
Inclusive Length Reference	Check box	This property is applicable only if *Length Reference* is set. If the check box is selected, the value of the sibling integer object that is identified by *Length Reference* is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by *Length Reference* is the length of the current object only. If the check box is selected, the *Length Units* property of the sibling integer object must be the same as that of the current object.

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. The length is given in bytes. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`* or *`Length Reference`* property. The default is `Bytes`.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • `1 Bytes`. The default value. • `2 Bytes` • `4 Bytes` • `8 Bytes` • `16 Bytes`
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.

Property	Type	Meaning
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *`Repeat Reference`* is specified, it overrides any setting for the *`Max Occurs`* logical property when parsing and writing the message, but not for validation of the message.

The Custom Wire Format properties described here apply to:

- Objects: Element Reference, Local Element
- Boolean schema types: Boolean

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • `1 Bytes`. The default value. • `2 Bytes` • `4 Bytes` • `8 Bytes` • `16 Bytes`
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *Repeat Reference* is specified, it overrides any setting for the *Max Occurs* logical property when parsing and writing the message, but not for validation of the message.

CWF properties for element reference and local element dateTime types:

The CWF wire format properties for element reference and local element dateTime types.

The Custom Wire Format properties described here apply to:

- Objects: Element Reference, Local Element
- DateTime schema types: date, dateTime, gDay, gMonth, gMonthDay, gYear, gYearMonth, time

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Fixed Length String`. The element's length is determined by other length properties as follows. • `Length Encoded String 1`. The first byte of the element contains the length of the string following the length byte in length units. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The element's first 2 bytes contain the length of the string following the two length bytes in length units. The maximum length of a `Length Encoded String 2` element is 65535 length units. The two length bytes are in the format of the WebSphere MQ queue manager Encoding. • `Null Terminated String`. The string ends with the hexadecimal NULL character, `X'00'`. • `Packed Decimal`. The dateTime is coded as a Packed Decimal number. It is valid only if the *`DateTime Format`* property represents numeric-only data. • `Binary`. The dateTime is encoded as a binary sequence of bytes. If you select this option, the range of symbols that you can specify for the Format String property is less than the range of symbols you can specify if you select a string option (see "DateTime formats" on page 6310 for details). • `Time Seconds`. This value supports C time_t and Java Date and Time objects. It is valid only if the *`DateTime Format`* property represents numeric-only data. • `Time Milliseconds`. This value supports C time_t and Java Date and Time objects. It is valid only if the *`DateTime Format`* property represents numeric-only data. The default value is `fixed length string`.
Length	Button and Integer	If you have selected a *`Physical Type`* of `Fixed Length String`, `Packed Decimal`, or `Binary`, and have selected the length to be defined by *`Length`*, enter the number of length units for the element. The minimum value that you can specify is 1 for all three physical types. The maximum value that you can specify is `256` for `Fixed Length String`, `10` for `Packed Decimal`, and `2147483647` for `Binary`. The default value is 0 (zero).
Length Reference	Button and Enumerated type	If you have selected the length to be defined by *`Length Reference`*, select the name of the integer object that specifies the length of this object. Make your selection from the displayed list of integer objects that are defined as siblings of the current object, and occur before it in the structure of the message. For information about reordering elements, see "Reordering objects" on page 2900.

Property	Type	Meaning
Inclusive Length Reference	Check box	This property is applicable only if *Length Reference* is set. If the check box is selected, the value of the sibling integer object that is identified by *Length Reference* is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by *Length Reference* is the length of the current object only. If the check box is selected, the *Length Units* property of the sibling integer object must be the same as that of the current object.
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • Bytes. The length is given in bytes. • Characters. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • Character Units. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to Characters. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the Length property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • End of Bitstream. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *Length Count* or *Length Reference* property. The default is Bytes.
Justification	Enumerated type	If you have set the *Physical Type* property to Fixed Length String, select Left Justify (the default value) or Right Justify from the list. If you have selected another value for *Physical Type*, this property is inactive.

Property	Type	Meaning
Padding Character	String	If you have set the *Physical Type* property to `Fixed Length String`, and the *Justification* property is either `Left Justify` or `Right Justify`, this property is applicable. When writing an output message, use the padding character to fill out the remaining character positions when the string length is less than the length implied by the *Length* or *Length Reference* property. Whether the string is padded from the left or the right is governed by the *Justification* property. When parsing an input message, the padding character is trimmed from the end of the string. Whether the string is trimmed from the left or the right is governed by the *Justification* property. Specify this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the displayed list. • Enter a character between quotation marks; for example, `"c"` or `'c'`, where c is any alphanumeric character. • Enter a Unicode value in the form `U+xxxx` where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, it is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.
DateTime Format	String	Specify a template for date and time. The default dateTime format is dependent on the logical type of the object. For information about the defaults for the dateTime format according to the logical type, see “DateTime defaults by logical type” on page 6320. See “DateTime formats” on page 6310 for details of date and time formats.

Numeric representation

Property	Type	Meaning
Signed	Check box	Specify whether the value is signed. This property is applicable only if the *Physical type* property is Packed Decimal. By default, this check box is cleared, which indicates that the value is not signed.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the displayed list. The option that you select determines the value that you must set for the property *Encoding Null Value*: • NULLPadFill. This option is valid only if *Physical Type* is Fixed Length String. The field is filled with the value specified by the *Padding Character*. The default value. • NULLLogicalValue. The *Encoding Null Value* property is first converted to an actual value, and rendered in the way specified for the field. • NULLLiteralValue. This specifies that *Encoding Null Value* contains a value that is directly substituted as if it is a string. Use this option when the value you have set for *Encoding Null Value* to specify a null date is not a dateTime value, or does not conform to the standard dateTime format yyyy-MM-dd 'T'HH:mm:ss. • NULLLiteralFill. The field is filled with the value specified by the *Encoding Null Value*. *Encoding Null Value* must resolve to a single character.
Encoding Null Value	String	If you set the *Encoding Null* property to NULLPadFill, this property is disabled. If you set the *Encoding Null* property to NULLLogicalValue, you must set this property to an ISO8601 dateTime format. These formats are described in "DateTime as string data" on page 6311. For example, specify a value conforming to yyyy-MM-dd'T'HH:mm:ss such as 1970-12-01. If you set the *Encoding Null* property to NULLLiteralValue, you can enter any value that is the same length as the field. If you set the *Encoding Null* property to NULLLiteralFill, the value must resolve to a single character. Set the character in one of the following ways: • Select SPACE, NUL, 0x00 or 0xFF from the displayed list • Enter a character between quotation marks, for example 'c' or "c", where c is any alphanumeric character. • Enter a hexadecimal character code in the form 0xYY where YY is a hexadecimal value. • Enter a decimal character code in the form YY where YY is a decimal value. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal format.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • `1 Bytes`. The default value. • `2 Bytes` • `4 Bytes` • `8 Bytes` • `16 Bytes`
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *`Repeat Reference`* is specified, it overrides any setting for the *`Max Occurs`* logical property when parsing and writing the message, but not for validation of the message.

CWF properties for element reference and local element decimal types:

The CWF wire format properties for element reference and local element decimal types.

The Custom Wire Format properties described here apply to:

- Objects: Element Reference, Local Element
- Decimal schema types: decimal, integer, negativeInteger, nonNegativeInteger, nonPositiveInteger, positiveInteger, unsignedLong

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Integer`. This equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. Equates to the COMP-3 data type in COBOL. • `External Decimal`. Equates to the data type PIC 9 USAGE DISPLAY in COBOL. The representation of numeric elements can be affected by the Encoding and CodedCharSetId attributes that are set for the WebSphere MQ queue manager: • Elements that have *`Physical Type`* set to `Integer` and `Packed Decimal` are represented in the appropriate WebSphere MQ Encoding value. • Elements that have *`Physical Type`* set to `External Decimal` are represented in the WebSphere MQ CodedCharSetId value.

Property	Type	Meaning
Length	Integer	Enter the number of bytes to specify the element length: • If you set the *Physical Type* to Integer, select 1, 2, or 4 (the default) from the displayed list. • If you set the *Physical Type* to Packed Decimal, enter a value between 1 and 10. • If you set the *Physical Type* to Extended Decimal, enter a value between 1 and 256. (Numbers greater than the maximum COBOL PICTURE clause of 18 are assumed to be 18.)
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • Bytes. • Characters. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • Character Units. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to Characters. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the Length property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • End of Bitstream. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *Length Count*. The default is Bytes.
Justification	Enumerated type	If you have set the *Physical Type* property to External Decimal, select Left Justify or Right Justify (the default value) from the list. If you have selected another value for *Physical Type*, this property is inactive.

Property	Type	Meaning
Padding Character	String	The padding character is used to fill out the remaining character positions when the string length is less than the specified string size. If you have set the *Physical Type* property to Extended Decimal, and the *Justification* property is either Left Justify or Right Justify, specify this character in one of the following ways: • Select NUL, '0', or SPACE from the displayed list. • Enter a character between quotation marks; for example, "c" or 'c', where c is any alphanumeric character. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form 0xYY, where YY is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, this is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Numeric representation

Property	Type	Meaning
Signed	Check box	Select (the default) or clear this property. This property is used with *Sign Orientation*.

Property	Type	Meaning
Sign EBCDIC Custom Overpunched	Check box	If the *Physical Type* is set to External Decimal and the *Signed EBCDIC Custom* property is set, this indicates that the Sign EBCDIC Custom Overpunched representation is to be used within an ASCII environment. If this check box is not selected (the default), the Sign ASCII representation is used. The setting of the *Sign EBCDIC Custom Overpunched* check box is appropriate only if the *Sign Orientation* property is set to Leading or Trailing (indicating that the element/attribute has an embedded sign representation). The check box is not available if the element/attribute is unsigned (for example, if the *Signed* check box is not set).
Sign Orientation	Enumerated type	If you have set *Physical Type* to External Decimal and you have selected *Signed*, choose from the following options that represent the COBOL options for displaying numeric data: • Leading Overpunched. This option sets a bit in the first byte if the number is negative. No setting is made if the number is positive. For example, the ASCII hexadecimal representation of the number 22 is x'3232'. Using this option, the number +22 would be x'3232' and the number -22 would be x'7232'. The default value. • Leading Separate. This option sets the first byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. • Trailing Overpunched. This option sets a bit in the last byte if the number is negative. No setting is made if the number is positive. Using this option, the number +22 would be x'3232' and the number -22 would be x'3272'. • Trailing Separate. This option sets the last byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. If you have set *Physical Type* to any other value, the value Not Applicable is set for you.
Virtual Decimal Point	Integer	Specify the number of places to the left (for a positive value) or right (for a negative value) that a decimal point is to be moved from its assumed position. For example, a decimal element containing 1234 with a Virtual Decimal value of 3 is 1.234, equivalent to 'V' or 'P' in a COBOL picture clause. There is no C equivalent

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the displayed list: • NULLPadFill. This option is valid only if *Physical Type* is External Decimal. The field is filled with the value specified by the *Padding Character*. *Encoding Null Value* must be set to an empty string. • NULLLogicalValue. The *Encoding Null Value* is transformed to match the required format for the field. The default value. • NULLLiteralValue. The *Encoding Null Value* is directly substituted as if it is a string. You can specify a nonnumeric value for *Encoding Null Value*. • NULLLiteralFill. The field is filled with the value specified by the *Encoding Null Value*. *Encoding Null Value* must resolve to a single character.

Property	Type	Meaning
Encoding Null Value	String	The use of this property depends on the *Encoding Null* property, except for NULLLiteralFill. The default value is zero. If you set the *Encoding Null* property to NULLLiteralFill, the value must resolve to a single character. Set the character in one of the following ways: • Select SPACE, NUL, 0x00 or 0xFF from the displayed list • Enter a character between quotation marks, for example 'c' or "c", where c is any alphanumeric character. • Enter a hexadecimal character in the form 0xYY where YY is a hexadecimal value. • Enter a decimal character code in the form YY where YY is a decimal value. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal format.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • 1 Bytes. The default value. • 2 Bytes • 4 Bytes • 8 Bytes • 16 Bytes
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *Repeat Reference* is specified, it overrides any setting for the *Max Occurs* logical property when parsing and writing the message, but not for validation of the message.

The CWF wire format properties for element reference and local element float types.

The Custom Wire Format properties described here apply to:

- Objects: Element Reference, Local Element
- Float schema types: double, float

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Integer`. This equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Float`. This equates to the data type FLOAT or DOUBLE in C or the COMP-1 or COMP-2 data type in COBOL and is the default value. • `Packed Decimal`. Equates to the COMP-3 data type in COBOL. • `External Decimal`. Equates to the data type PIC 9 USAGE DISPLAY in COBOL. The representation of numeric elements can be affected by the Encoding and CodedCharSetId attributes that are set for the WebSphere MQ queue manager: • Elements that have *`Physical Type`* set to `Integer`, `Packed Decimal`, and `Float` are represented in the appropriate WebSphere MQ Encoding value. • Elements that have *`Physical Type`* set to `External Decimal` are represented in the WebSphere MQ CodedCharSetId value.
Length	Integer	Enter the number of bytes to specify the element length: • If you set the *`Physical Type`* to `Float`, select a value from the displayed list. The default value is 8. • If you set the *`Physical Type`* to `Integer`, select `1`, `2`, or `4` (the default) from the displayed list. • If you set the *`Physical Type`* to `Packed Decimal`, enter a value between 1 and 10. • If you set the *`Physical Type`* to `Extended Decimal`, enter a value between 1 and 256. (Numbers greater than the maximum COBOL PICTURE clause of 18 are assumed to be 18.)

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`*. The default is `Bytes`.
Justification	Enumerated type	If you have set the *`Physical Type`* property to `External Decimal`, select `Left Justify` or `Right Justify` (the default value) from the list. If you have selected another value for *`Physical Type`*, this property is inactive.

Property	Type	Meaning
Padding Character	String	The padding character is used to fill out the remaining character positions when the string length is less than the specified string size. If you have set the *Physical Type* property to Extended Decimal, and the *Justification* property is either Left Justify or Right Justify, specify this character in one of the following ways: • Select NUL, '0', or SPACE from the displayed list. • Enter a character between quotation marks; for example, "c" or 'c', where c is any alphanumeric character. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form 0xYY, where YY is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, this is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Numeric representation

Property	Type	Meaning
Signed	Check box	Select or clear (unsigned, the default) this property. If you have set *Physical Type* to Float, this is selected. This property is used with *Sign Orientation*.

Property	Type	Meaning
Sign EBCDIC Custom Overpunched	Check box	If the *Physical Type* is set to External Decimal and the *Signed EBCDIC Custom* property is set, this indicates that the Sign EBCDIC Custom Overpunched representation is to be used within an ASCII environment. If this check box is not selected (the default), the Sign ASCII representation is used. The setting of the *Sign EBCDIC Custom Overpunched* check box is appropriate only if the *Sign Orientation* property is set to Leading or Trailing (indicating that the element/attribute has an embedded sign representation). The check box is not available if the element/attribute is unsigned (for example, if the *Signed* check box is not set).
Sign Orientation	Enumerated type	If you have set *Physical Type* to External Decimal and you have selected *Signed*, choose from the following options that represent the COBOL options for displaying numeric data: • Leading Overpunched. This option sets a bit in the first byte if the number is negative. No setting is made if the number is positive. For example, the ASCII hexadecimal representation of the number 22 is x'3232'. Using this option, the number +22 would be x'3232' and the number -22 would be x'7232'. The default value. • Leading Separate. This option sets the first byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. • Trailing Overpunched. This option sets a bit in the last byte if the number is negative. No setting is made if the number is positive. Using this option, the number +22 would be x'3232' and the number -22 would be x'3272'. • Trailing Separate. This option sets the last byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. If you have set *Physical Type* to any other value, the value Not Applicable is set for you.
Virtual Decimal Point	Integer	Specify the number of places to the left (for a positive value) or right (for a negative value) that a decimal point is to be moved from its assumed position. For example, a float element containing 1234 with a Virtual Decimal value of 3 is 1.234. This property is not applicable if you have set *Physical Type* to Float.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the displayed list: • NULLPadFill. This option is valid only if *Physical Type* is External Decimal. The field is filled with the value specified by the *Padding Character*. *Encoding Null Value* must be set to an empty string. • NULLLogicalValue. The *Encoding Null Value* is transformed to match the required format for the field. The default value. • NULLLiteralValue. The *Encoding Null Value* is directly substituted as if it is a string. You can specify a nonnumeric value for *Encoding Null Value*. • NULLLiteralFill. The field is filled with the value specified by the *Encoding Null Value*. *Encoding Null Value* must resolve to a single character.

Property	Type	Meaning
Encoding Null Value	String	The use of this property depends on the *Encoding Null* property, except for NULLLiteralFill. The default value is zero. If you set the *Encoding Null* property to NULLLiteralFill, the value must resolve to a single character. Set the character in one of the following ways: • Select SPACE, NUL, 0x00 or 0xFF from the displayed list • Enter a character between quotation marks, for example 'c' or "c", where c is any alphanumeric character. • Enter a hexadecimal character in the form 0xYY where YY is a hexadecimal value. • Enter a decimal character code in the form YY where YY is a decimal value. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal format.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • 1 Bytes. The default value. • 2 Bytes • 4 Bytes • 8 Bytes • 16 Bytes
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *Repeat Reference* is specified, it overrides any setting for the *Max Occurs* logical property when parsing and writing the message, but not for validation of the message.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Integer`. This equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. Equates to the COMP-3 data type in COBOL. • `External Decimal`. Equates to the data type PIC 9 USAGE DISPLAY in COBOL. The representation of numeric elements can be affected by the Encoding and CodedCharSetId attributes that are set for the WebSphere MQ queue manager: • Elements that have *`Physical Type`* set to `Integer` and `Packed Decimal` are represented in the appropriate WebSphere MQ Encoding value. • Elements that have *`Physical Type`* set to `External Decimal` are represented in the WebSphere MQ CodedCharSetId value.
Length	Integer	Enter the number of bytes to specify the element length: • If you set the *`Physical Type`* to `Integer`, select `1`, `2`, or `4` (the default) from the displayed list. • If you have set *`Physical Type`* to `Packed Decimal`, enter a value between 1 and 6. • If you have set *`Physical Type`* to `Extended Decimal`, enter a value between 1 and 11.
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`*. The default is `Bytes`.

Property	Type	Meaning
Justification	Enumerated type	If you have set the *Physical Type* property to `External Decimal`, select `Left Justify` or `Right Justify` (the default value) from the list. If you have selected another value for *Physical Type*, this property is inactive.
Padding Character	String	The padding character is used to fill out the remaining character positions when the string length is less than the specified string size. If you have set the *Physical Type* property to `Extended Decimal`, and the *Justification* property is either `Left Justify` or `Right Justify`, specify this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the displayed list. • Enter a character between quotation marks; for example, `"c"` or `'c'`, where c is any alphanumeric character. • Enter a Unicode value in the form `U+xxxx` where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, this is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Numeric representation

Property	Type	Meaning
Signed	Check box	Select (the default) or clear this property. This property is used with *Sign Orientation*.

Property	Type	Meaning
Sign EBCDIC Custom Overpunched	Check box	If the *Physical Type* is set to External Decimal and the *Signed EBCDIC Custom* property is set, this indicates that the Sign EBCDIC Custom Overpunched representation is to be used within an ASCII environment. If this check box is not selected (the default), the Sign ASCII representation is used. The setting of the *Sign EBCDIC Custom Overpunched* check box is appropriate only if the *Sign Orientation* property is set to Leading or Trailing (indicating that the element/attribute has an embedded sign representation). The check box is not available if the element/attribute is unsigned (for example, if the *Signed* check box is not set).
Sign Orientation	Enumerated type	If you have set *Physical Type* to External Decimal and you have selected *Signed*, choose from the following options that represent the COBOL options for displaying numeric data: • Leading Overpunched. This option sets a bit in the first byte if the number is negative. No setting is made if the number is positive. For example, the ASCII hexadecimal representation of the number 22 is x'3232'. Using this option, the number +22 would be x'3232' and the number -22 would be x'7232'. The default value. • Leading Separate. This option sets the first byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. • Trailing Overpunched. This option sets a bit in the last byte if the number is negative. No setting is made if the number is positive. Using this option, the number +22 would be x'3232' and the number -22 would be x'3272'. • Trailing Separate. This option sets the last byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. If you have set *Physical Type* to any other value, the value Not Applicable is set for you.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the displayed list: • NULLPadFill. This option is valid only if *Physical Type* is External Decimal. The field is filled with the value specified by the *Padding Character*. *Encoding Null Value* must be set to an empty string. • NULLLogicalValue. The *Encoding Null Value* is transformed to match the required format for the field. The default value. • NULLLiteralValue. The *Encoding Null Value* is directly substituted as if it is a string. You can specify a nonnumeric value for *Encoding Null Value*. • NULLLiteralFill. The field is filled with the value specified by the *Encoding Null Value*. *Encoding Null Value* must resolve to a single character.

Property	Type	Meaning
Encoding Null Value	String	The use of this property depends on the *Encoding Null* property, except for NULLLiteralFill. The default value is zero. If you set the *Encoding Null* property to NULLLiteralFill, the value must resolve to a single character. Set the character in one of the following ways: • Select SPACE, NUL, 0x00 or 0xFF from the displayed list • Enter a character between quotation marks, for example 'c' or "c", where c is any alphanumeric character. • Enter a hexadecimal character in the form 0xYY where YY is a hexadecimal value. • Enter a decimal character code in the form YY where YY is a decimal value. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal format.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • 1 Bytes. The default value. • 2 Bytes • 4 Bytes • 8 Bytes • 16 Bytes
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *Repeat Reference* is specified, it overrides any setting for the *Max Occurs* logical property when parsing and writing the message, but not for validation of the message.

CWF properties for element reference and local element string types:

The CWF wire format properties for element reference and local element string types.

The Custom Wire Format properties described here apply to:

- Objects: Attribute Reference, Local Attribute
- String schema types: anyURI, ENTITIES, ENTITY, ID, IDREF, IDREFS, language, Name, NCName, NMTOKEN, NMTOKENS, normalizedString, NOTATION, QName, string, token

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Fixed Length String`. The element's length is determined by other length properties as follows. • `Length Encoded String 1`. The first byte of the element contains the length of the string following the length byte in length units. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The element's first 2 bytes contain the length of the string following the two length bytes in length units. The maximum length of a `Length Encoded String 2` element is 65535 length units. The two length bytes are in the format of the WebSphere MQ queue manager Encoding. • `Null Terminated String`. The string ends with the hexadecimal NULL character, `X'00'`. The default is `Fixed Length String`.
Length	Button and Integer	If you have selected a *`Physical Type`* of `Fixed Length String` or `Binary`, and have selected the length to be defined by *`Length`*, enter the number of length units for the element. The minimum value that you can specify is `0` (zero), the maximum value that you can specify is `2147483647` The default value is `0` (zero).
Length Reference	Button and Enumerated type	If you have selected the length to be defined by *`Length Reference`*, select the name of the integer object that specifies the length of this object. Make your selection from the displayed list of integer objects that are defined as siblings of the current object, and occur before it in the structure of the message. For information about reordering elements, see “Reordering objects” on page 2900.
Inclusive Length Reference	Check box	This property is applicable only if *`Length Reference`* is set. If the check box is selected, the value of the sibling integer object that is identified by *`Length Reference`* is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by *`Length Reference`* is the length of the current object only. If the check box is selected, the *`Length Units`* property of the sibling integer object must be the same as that of the current object.

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. The length is given in bytes. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`* or *`Length Reference`* property. The default is `Bytes`.
Justification	Enumerated type	If you have set the *`Physical Type`* property to `Fixed Length String`, select `Left Justify` (the default value) or `Right Justify` from the list. If you have selected another value for *`Physical Type`*, this property is inactive.

Property	Type	Meaning
Padding Character	String	If you have set the *Physical Type* property to `Fixed Length String`, and the *Justification* property is either `Left Justify` or `Right Justify`, this property is applicable. When writing an output message, use the padding character to fill out the remaining character positions when the string length is less than the length implied by the *Length* or *Length Reference* property. Whether the string is padded from the left or the right is governed by the *Justification* property. When parsing an input message, the padding character is trimmed from the end of the string. Whether the string is trimmed from the left or the right is governed by the *Justification* property. Specify this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the displayed list. • Enter a character between quotation marks; for example, `"c"` or `'c'`, where c is any alphanumeric character. • Enter a Unicode value in the form `U+xxxx` where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, it is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the displayed list: • NULLPadFill. This is valid only if *Physical Type* is Fixed Length String. The field is filled with the value specified by the *Padding Character*. *Encoding Null Value* must be set to an empty string. • NULLLogicalValue. The *Encoding Null Value* is transformed to match the required format for the field. The default value. • NULLLiteralValue. The *Encoding Null Value* is directly substituted as if it is a string. • NULLLiteralFill. The field is filled with the value specified by the *Encoding Null Value*. *Encoding Null Value* must resolve to a single character.
Encoding Null Value	STRING	The use of this property depends on the *Encoding Null* property. If specified, its length must be equal to the length of the string element, except for NULLLiteralFill. The default value is empty (not set). If you set the *Encoding Null* property to NULLLiteralFill, the value must resolve to a single character. Set the character in one of the following ways: • Select SPACE, NUL, 0x00 or 0xFF from the displayed list • Enter a character between quotation marks, for example 'c' or "c", where c is any alphanumeric character. • Enter a hexadecimal character code in the form 0xYY where YY is a hexadecimal value. • Enter a decimal character code in the form YY where YY is a decimal value. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal format.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • 1 Bytes. The default value. • 2 Bytes • 4 Bytes • 8 Bytes • 16 Bytes
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *Repeat Reference* is specified, it overrides any setting for the *Max Occurs* logical property when parsing and writing the message, but not for validation of the message.

Local element XML properties:

The properties, and their permissible values, vary according to the object type.

The properties that are displayed on the object page, and the values that those properties can take, can vary according to the type of the object. For example, the properties for type *string* are different from those of type *Boolean*. Select the link for the object type from the following table.

Type of object	**Properties**
Binary types	• base64Binary • hexBinary
Boolean types	• Boolean
DateTime types	• date • dateTime • gDay • gMonth • gMonthDay • gYear • gYearMonth • time
Decimal types	• decimal • integer • negativeInteger • nonNegativeInteger • nonPositiveInteger • positiveInteger • unsignedLong
Float types	• double • float
Integer types	• byte • int • long • short • unsignedByte • unsignedInt • unsignedShort
Interval types	• duration

Type of object	Properties
String types	• anyURI • ENTITIES • ENTITY • ID • IDREF • IDREFS • language • Name • NCName • NMTOKEN • NMTOKENS • normalizedString • NOTATION • QName • string • token

Note: The physical format properties for simple type *duration* are the same as the physical properties of the string logical types.

The XML Wire Format properties described here apply to:

- Objects: Attribute Reference, Element Reference, Local Attribute, Local Element
- Binary schema types: base64Binary, hexBinary

Field identification

A number of the following properties only become active depending on the value that *Render* property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their *XML Name*property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLAttribute`. If you select this value, the object (or type) is rendered as an attribute of the parent XML object. The identity of the child is determined by the attribute name. The value is the attribute value. This is only valid for simple elements. If you select this value for more than one object , you must set their *XML Name* property to different values. This is the default value for attribute objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in *ID Attribute Name* and a value as specified in *ID Attribute Value*. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set *XML Name*, *ID Attribute Name*, *ID Attribute Value* to the same values: – You must also set *Value Attribute Name* to the same value for the two objects. – Both objects must refer to the same element. • `XMLElementAttrVal`. If you specify this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the value of a specified attribute. The name of the attribute is specified in *Value Attribute Name*. • `XMLElementAttrIDVal`. This option combines the two options, `XMLElementAttrID` and `XMLElementAttrVal`. The object is rendered as a child of the parent complex type. The identity of the child is determined by the value of *ID Attribute Name*. The value is the value of *ID Attribute Value*. If you select this value for one object, and set this same value or the value `XMLElementAttrID` for a second object, and set *XML Name*, *ID Attribute Name*, *ID Attribute Value* to the same values: – You must also set *Value Attribute Name* to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.

Property	Type	Meaning
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.
Value Attribute Name	String	Specify the name of the attribute used for the value of the child. This must be a valid XML Attribute Name. This is only used if required by the setting of *Render*. The default value is `val`.
Namespace	String	Enter the namespace associated with the *Value Attribute*.

Physical representation

Property	Type	Meaning
Encoding	String	Select one of the following values from the drop-down list: : • `CDatahex` (the default). Hexadecimal values in this field are specified with the CDATA qualifier, for example <e1><![CDATA[62]]></e1> • `hex`. Hexadecimal values in this field are specified as digits only, for example <e1>62</e1>. • `base64`. Values in this field are specified as digits only, coded in base 64.

The XML Wire Format properties described here apply to:

- Objects: Attribute Reference, Element Reference, Local Attribute, Local Element
- Boolean schema types: Boolean

Field identification

A number of the following properties only become active depending on the value that *Render* property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their *`XML Name`*property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLAttribute`. If you select this value, the object (or type) is rendered as an attribute of the parent XML object. The identity of the child is determined by the attribute name. The value is the attribute value. This is only valid for simple elements. If you select this value for more than one object , you must set their *`XML Name`* property to different values. This is the default value for attribute objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in *`ID Attribute Name`* and a value as specified in *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. • `XMLElementAttrVal`. If you specify this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the value of a specified attribute. The name of the attribute is specified in *`Value Attribute Name`*. • `XMLElementAttrIDVal`. This option combines the two options, `XMLElementAttrID` and `XMLElementAttrVal`. The object is rendered as a child of the parent complex type. The identity of the child is determined by the value of *`ID Attribute Name`*. The value is the value of *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrID` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.

Property	Type	Meaning
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.
Value Attribute Name	String	Specify the name of the attribute used for the value of the child. This must be a valid XML Attribute Name. This is only used if required by the setting of *Render*. The default value is `val`.
Namespace	String	Enter the namespace associated with the *Value Attribute*.

XML properties for attribute reference, element reference, local attribute, local element dateTime types:

XML wire format properties for attribute reference, element reference, local attribute, and local element dateTime types.

The XML Wire Format properties described here apply to:

- Objects: Attribute Reference, Element Reference, Local Attribute, Local Element
- DateTime schema types: date, dateTime, gDay, gMonth, gMonthDay, gYear, gYearMonth, time

Field identification

A number of the following properties only become active depending on the value that *Render* property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their *XML Name*property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLAttribute`. If you select this value, the object (or type) is rendered as an attribute of the parent XML object. The identity of the child is determined by the attribute name. The value is the attribute value. This is only valid for simple elements. If you select this value for more than one object , you must set their *XML Name* property to different values. This is the default value for attribute objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in *ID Attribute Name* and a value as specified in *ID Attribute Value*. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set *XML Name*, *ID Attribute Name*, *ID Attribute Value* to the same values: – You must also set *Value Attribute Name* to the same value for the two objects. – Both objects must refer to the same element. • `XMLElementAttrVal`. If you specify this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the value of a specified attribute. The name of the attribute is specified in *Value Attribute Name*. • `XMLElementAttrIDVal`. This option combines the two options, `XMLElementAttrID` and `XMLElementAttrVal`. The object is rendered as a child of the parent complex type. The identity of the child is determined by the value of *ID Attribute Name*. The value is the value of *ID Attribute Value*. If you select this value for one object, and set this same value or the value `XMLElementAttrID` for a second object, and set *XML Name*, *ID Attribute Name*, *ID Attribute Value* to the same values: – You must also set *Value Attribute Name* to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.

Property	Type	Meaning
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.
Value Attribute Name	String	Specify the name of the attribute used for the value of the child. This must be a valid XML Attribute Name. This is only used if required by the setting of *Render*. The default value is `val`.
Namespace	String	Enter the namespace associated with the *Value Attribute*.

Physical representation

Property	Type	Meaning
DateTime Format	String	Specify a format string that specifies the rendering of the value for dateTime elements. The default dateTime format is dependent on the logical type of the object. For information about the defaults for the dateTime format according to the logical type see “DateTime defaults by logical type” on page 6320. See “DateTime formats” on page 6310 for details of dateTime formats.

Field identification

A number of the following properties only become active depending on the value that *Render* property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their *`XML Name`*property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLAttribute`. If you select this value, the object (or type) is rendered as an attribute of the parent XML object. The identity of the child is determined by the attribute name. The value is the attribute value. This is only valid for simple elements. If you select this value for more than one object , you must set their *`XML Name`* property to different values. This is the default value for attribute objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in *`ID Attribute Name`* and a value as specified in *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. • `XMLElementAttrVal`. If you specify this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the value of a specified attribute. The name of the attribute is specified in *`Value Attribute Name`*. • `XMLElementAttrIDVal`. This option combines the two options, `XMLElementAttrID` and `XMLElementAttrVal`. The object is rendered as a child of the parent complex type. The identity of the child is determined by the value of *`ID Attribute Name`*. The value is the value of *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrID` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.

Property	Type	Meaning
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.
Value Attribute Name	String	Specify the name of the attribute used for the value of the child. This must be a valid XML Attribute Name. This is only used if required by the setting of *Render*. The default value is `val`.
Namespace	String	Enter the namespace associated with the *Value Attribute*.

Field identification

A number of the following properties only become active depending on the value that *Render* property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their *XML Name*property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLAttribute`. If you select this value, the object (or type) is rendered as an attribute of the parent XML object. The identity of the child is determined by the attribute name. The value is the attribute value. This is only valid for simple elements. If you select this value for more than one object , you must set their *XML Name* property to different values. This is the default value for attribute objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in *ID Attribute Name* and a value as specified in *ID Attribute Value*. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set *XML Name*, *ID Attribute Name*, *ID Attribute Value* to the same values: – You must also set *Value Attribute Name* to the same value for the two objects. – Both objects must refer to the same element. • `XMLElementAttrVal`. If you specify this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the value of a specified attribute. The name of the attribute is specified in *Value Attribute Name*. • `XMLElementAttrIDVal`. This option combines the two options, `XMLElementAttrID` and `XMLElementAttrVal`. The object is rendered as a child of the parent complex type. The identity of the child is determined by the value of *ID Attribute Name*. The value is the value of *ID Attribute Value*. If you select this value for one object, and set this same value or the value `XMLElementAttrID` for a second object, and set *XML Name*, *ID Attribute Name*, *ID Attribute Value* to the same values: – You must also set *Value Attribute Name* to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.

Property	Type	Meaning
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.
Value Attribute Name	String	Specify the name of the attribute used for the value of the child. This must be a valid XML Attribute Name. This is only used if required by the setting of *Render*. The default value is `val`.
Namespace	String	Enter the namespace associated with the *Value Attribute*.

Local element TDS properties:

The properties, and their permissible values, vary according to the object type.

The properties that are displayed on the object page, and the values that those properties can take, can vary according to the type of the object. For example, the properties for type *string* are different from those of type *Boolean*. Select the link for the object type from the following table.

Type of object	**Properties**
Binary types	• base64Binary • hexBinary
Boolean types	• Boolean
Complex types	
DateTime types	• date • dateTime • gDay • gMonth • gMonthDay • gYear • gYearMonth • time
Decimal types	• decimal • integer • negativeInteger • nonNegativeInteger • nonPositiveInteger • positiveInteger • unsignedLong

Type of object	Properties
Float types	• double • float
Integer types	• byte • int • long • short • unsignedByte • unsignedInt • unsignedShort
Interval types	• duration
String types	• anyURI • ENTITIES • ENTITY • ID • IDREF • IDREFS • language • Name • NCName • NMTOKEN • NMTOKENS • normalizedString • NOTATION • QName • string • token

Note: The physical format properties for simple type *duration* are the same as the physical properties of the string logical types.

TDS properties for local element binary types:

The TDS format properties for local element binary types.

The TDS Format properties described here apply to:

- Objects: Local Element
- Binary schema types: base64Binary, hexBinary

Field Identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	For all `Messaging Standard` values, the `Physical Type` property is set to `Binary` and cannot be changed.

Property	Type	Meaning
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. The default is dependent on the setting of the message set property `Derive default length from logical type`. If `Derive default length from logical type` is selected, the default value is derived from any length or maxLength value constraint (schema facet) on the object's simple type.
Length Units	Enumerated type	Always set to `Bytes`.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.
Inclusive Length Reference	Check box	This property is applicable only if `Length Reference` is set. If the check box is selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object only. If the check box is selected, the `Length Units` property of the sibling integer object must be the same as that of the current object.

Occurrences

Property	Type	Meaning
Repeat reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, no integer objects exist before this one in the message structure. If a `Repeat Reference` is specified, it overrides any setting for the `Max Occurs` logical property when parsing and writing the message, but not for validating the message.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

TDS properties for local element Boolean types:

The TDS format properties for local element Boolean types.

The TDS Format properties described here apply to:

- Objects: Local Element
- Boolean schema types: Boolean

Field Identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see “Regular expression syntax” on page 6304.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Binary`. The data is in bit string format. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.

Occurrences

Property	Type	Meaning
Repeat reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, no integer objects exist before this one in the message structure. If a `Repeat Reference` is specified, it overrides any setting for the `Max Occurs` logical property when parsing and writing the message, but not for validating the message.

Property	Type	Meaning
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

TDS properties for local element of complex type:

The TDS Format properties that apply to local elements of complex type.

Field Identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.

Occurrences

Property	Type	Meaning
Repeat reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, no integer objects exist before this one in the message structure. If a `Repeat Reference` is specified, it overrides any setting for the `Max Occurs` logical property when parsing and writing the message, but not for validating the message.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

TDS properties for local element dateTime types:

The TDS format properties for local element dateTime types.

The TDS Format properties described here apply to:

- Objects: Local Element
- DateTime schema types: date, dateTime, gDay, gMonth, gMonthDay, gYear, gYearMonth, time

Field Identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Length Encoded String 1`. The first byte of the data contains the length (in length units) of the data string that follows the length byte. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The first two bytes of the data contain the length (in length units) of the data string that follows the two length bytes. The maximum length of a `Length Encoded String 2` element is 65535 length units. • `Null Terminated String`. The data string ends with the hexadecimal NULL character, `X'00'`. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `Binary`. The data is in bit string format. • `Time Seconds`. This value supports C time_t, and Java Date and Time objects. It is valid only if the `DateTime Format` property represents numeric-only data. • `Time Milliseconds`. This value supports C time_t, and Java Date and Time objects. It is valid only if the `DateTime Format` property represents numeric-only data. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.

Property	Type	Meaning
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if one of the following statements is true: • `Physical Type` is `Packed Decimal`. • `Physical Type` is `Text`, no `Length Reference` is specified, and the `Data Element Separation` of the parent complex type or group is `Fixed Length`, `Tagged Fixed Length`, or `Fixed Length AL3`. The default is dependent on the physical type of the object. If `Physical Type` is `Length Encoded String 1`, `Length Encoded String 2`, or `Null Terminated String`, this property is not applicable. If `Physical Type` is `Time Seconds`, the value of this property is 4, and cannot be changed. If `Physical Type` is `Time Milliseconds`, the value of this property is 8, and cannot be changed.
Length Units	Enumerated type	Select the unit of length for the object. Select one of the following options (some physical types do not offer both options): • `Bytes`. The length is given in bytes. • `Characters`. The length is given in characters. The number of bytes that are processed in the bit stream depends on the code page of the message. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the contents of the bit stream. The parser reads one character at a time and determines whether the character comprises one or more bytes. The default is dependent on the physical type of the object.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
DateTime Format	String	Specify a template for date and time. The default DateTime format is dependent on the logical type of the object. For information about the defaults for the dateTime format according to the logical type, see “DateTime defaults by logical type” on page 6320. See “DateTime formats” on page 6310 for details of date and time formats.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Property	Type	Meaning
Inclusive Length Reference	Check box	This property is applicable only if `Length Reference` is set. If the check box is selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object only. If the check box is selected, the `Length Units` property of the sibling integer object must be the same as that of the current object.

Numeric representation

Property	Type	Meaning
Signed	Check box	Specify whether the value is signed. This property is applicable only if the `Physical type` property is `Packed Decimal`. By default, this check box is cleared, which indicates that the value is not signed.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • `NULLPadFill`. This option is valid only for fixed-length objects and is the default value. • `NULLLogicalValue`. The `Encoding Null Value` property is first converted to an actual value, and rendered in the way specified for the field. • `NULLLiteralValue`. This option specifies that `Encoding Null Value` contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the `Encoding Null Value` property to test or compare the content of the field in the message. • `NULLLiteralFill`. This option specifies that the field is filled with the value specified by the `Encoding Null Value` property. `Encoding Null Value` must resolve to a single character. The option that you select determines the value that you must set for the property `Encoding Null Value`. For full information about using these options, see “TDS Null handling options” on page 6293.
Encoding Null Value	String	The use of this property depends on the `Encoding Null` property. The default value is zero. If you set the `Encoding Null` property for a dateTime object to `NULLLogicalValue`, the value that you set must be in an ISO8601 dateTime format. These formats are described in “DateTime as string data” on page 6311. For example, specify a value that conforms to the `yyyy-MM-dd'T'HH:mm:ss` format; for example, `1970-12-01`.

Occurrences

Property	Type	Meaning
Repeat reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, no integer objects exist before this one in the message structure. If a `Repeat Reference` is specified, it overrides any setting for the `Max Occurs` logical property when parsing and writing the message, but not for validating the message.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

TDS properties for local element decimal types:

The TDS format properties for local element decimal types.

The TDS Format properties described here apply to:

- Objects: Local Element
- Decimal schema types: decimal, integer, negativeInteger, nonNegativeInteger, nonPositiveInteger, positiveInteger, unsignedLong

Field Identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `TLOG Specific` - this option can be selected only if the `Message Standard` property of the message set is `TLOG`. This option indicates that the format of the data is specific to the TLOG messaging standard. • `Integer`. Equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `External Decimal`. The data is a decimal number that equates to the data type PIC 9 USAGE DISPLAY in COBOL. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. If this property is not set and the message set property `Derive default length from logical type` is selected, and the `Physical type` is 'Character', the default value is derived from any totalDigits value constraint (schema facet) or, if none, any `minInclusive`, `maxInclusive`, `minExclusive`, or `maxExclusive` value constraints (schema facets), on the simple type.
Length Units	Enumerated type	Select the unit of length for the object. Select one of the following options (some physical types do not offer both options): • `Bytes`. The length is given in bytes. • `Characters`. The length is given in characters. The number of bytes that are processed in the bit stream depends on the code page of the message. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the contents of the bit stream. The parser reads one character at a time and determines whether the character comprises one or more bytes. The default is dependent on the physical type of the object.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Property	Type	Meaning
Inclusive Length Reference	Check box	This property is applicable only if `Length Reference` is set. If the check box is selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object only. If the check box is selected, the `Length Units` property of the sibling integer object must be the same as that of the current object.

Numeric representation

Property	Type	Meaning
Signed	Check box	Specify whether the value is signed.
Sign EBCDIC Custom Overpunched	Check box	Specify whether EBCDIC custom sign format is used. This property is applicable only if the `Signed` property is selected and the `Physical Type` property is set to `External Decimal`.
Sign Orientation	Enumerated type	The values that you can choose for this property are: • `Leading Separate` • `Trailing Separate` • `Leading Overpunched` • `Trailing Overpunched` This property is enabled only if you have set `Physical Type` to `Text` or `External Decimal`, and you have selected `Signed`. If `Physical Type` is `Text`, the only valid values of `Sign Orientation` are `Leading Separate` and `Trailing Separate`. If `Physical Type` is `External Decimal` and `Sign EBCDIC Customer Overpunched` is selected, the only valid values of `Sign Orientation` are `Leading Overpunched` and `Trailing Overpunched`.
Positive Sign	String	Specify the value that represents the positive symbol. Do not specify a numeric value. If no value is set, "+" is assumed. The positive sign is not written when creating an output message; it is used only to recognize the positive sign when parsing a message bit stream. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.
Negative Sign	String	Specify the value that represents the negative symbol. Do not specify a numeric value. If no value is set, "-" is assumed. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.
Virtual Decimal Point	Button and Integer	Specify a non-zero integer that represents the position of an implied decimal point within a number, or specify 0, the default, to use the formatting of Float or Decimal numbers as specified by the `Precision` property. If you specify a positive integer, the position of the decimal point is moved left from the right side of the number. For example, if you specify `3`, the decimal value `1234` represents 1.234 If you specify a negative integer, the position of the decimal point is moved right from the right side of the number. For example, if you specify `-3`, the decimal value `1234` represents 1,234,000.

Property	Type	Meaning
Precision	Button and Integer	This property is applicable only if `Physical Type` is `Text`. It is used if the value of the `Virtual Decimal Point` property is 0, which indicates that the decimal point is present in the data. It deals with truncation, and specifies how many digits are to follow the decimal point. Either specify a number of digits: • If you set `Precision` to 0, data is truncated so that the fractional part is lost. For example, the value `123.45` is truncated to `123`. • If you set `Precision` to a number less than the number of fractional digits, data is truncated. For example, the value `123.4567` is truncated to `123.45` if you set `Precision` to 2. • If you set `Precision` to a number greater than the number of fractional digits, the value is padded with extra zeros. For example, the value `12.345` is padded to `12.34500` if you set `Precision` to 5. Or select one option from the list: • `All Significant Digits - decimal separator only required if fractional digits` (the default): all significant digits are written to the output bit stream, and no decimal separator is written if no fractional digits are present. • `Explicit Decimal Separator - decimal separator always required`: all significant digits are written to the output bit stream and the decimal separator is always included, even when no fractional digits are present. The decimal separator must be present in the input bit stream, even when no fractional digits are present.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • `NULLPadFill`. This option is valid only for fixed-length objects and is the default value. • `NULLLogicalValue`. The `Encoding Null Value` property is first converted to an actual value, and rendered in the way specified for the field. • `NULLLiteralValue`. This option specifies that `Encoding Null Value` contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the `Encoding Null Value` property to test or compare the content of the field in the message. • `NULLLiteralFill`. This option specifies that the field is filled with the value specified by the `Encoding Null Value` property. `Encoding Null Value` must resolve to a single character. The option that you select determines the value that you must set for the property `Encoding Null Value`. For full information about using these options, see “TDS Null handling options” on page 6293.
Encoding Null Value	String	The use of this property depends on the `Encoding Null` property. The default value is zero. If you set the `Encoding Null` property for a dateTime object to `NULLLogicalValue`, the value that you set must be in an ISO8601 dateTime format. These formats are described in “DateTime as string data” on page 6311. For example, specify a value that conforms to the `yyyy-MM-dd'T'HH:mm:ss` format; for example, `1970-12-01`.

Occurrences

Property	Type	Meaning
Repeat reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, no integer objects exist before this one in the message structure. If a `Repeat Reference` is specified, it overrides any setting for the `Max Occurs` logical property when parsing and writing the message, but not for validating the message.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

TDS properties for local element float types:

The TDS format properties for local element float types.

The TDS Format properties described here apply to:

- Objects: Local Element
- Float schema types: double, float

Field Identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Float`. Equates to the data type FLOAT or DOUBLE in C, or the COMP-1 or COMP-2 numeric data type in COBOL. • `Integer`. Equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `External Decimal`. The data is a decimal number that equates to the data type PIC 9 USAGE DISPLAY in COBOL. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified.
Length Units	Enumerated type	Select the unit of length for the object. Select one of the following options (some physical types do not offer both options): • `Bytes`. The length is given in bytes. • `Characters`. The length is given in characters. The number of bytes that are processed in the bit stream depends on the code page of the message. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the contents of the bit stream. The parser reads one character at a time and determines whether the character comprises one or more bytes. The default is dependent on the physical type of the object.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Property	Type	Meaning
Inclusive Length Reference	Check box	This property is applicable only if `Length Reference` is set. If the check box is selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object only. If the check box is selected, the `Length Units` property of the sibling integer object must be the same as that of the current object.

Numeric representation

Property	Type	Meaning
Signed	Check box	Specify whether the value is signed.
Sign EBCDIC Custom Overpunched	Check box	Specify whether EBCDIC custom sign format is used. This property is applicable only if the `Signed` property is selected and the `Physical Type` property is set to `External Decimal`.
Sign Orientation	Enumerated type	The values that you can choose for this property are: • `Leading Separate` • `Trailing Separate` • `Leading Overpunched` • `Trailing Overpunched` This property is enabled only if you have set `Physical Type` to `Text` or `External Decimal`, and you have selected `Signed`. If `Physical Type` is `Text`, the only valid values of `Sign Orientation` are `Leading Separate` and `Trailing Separate`. If `Physical Type` is `External Decimal` and `Sign EBCDIC Customer Overpunched` is selected, the only valid values of `Sign Orientation` are `Leading Overpunched` and `Trailing Overpunched`.
Positive Sign	String	Specify the value that represents the positive symbol. Do not specify a numeric value. If no value is set, "+" is assumed. The positive sign is not written when creating an output message; it is used only to recognize the positive sign when parsing a message bit stream. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.
Negative Sign	String	Specify the value that represents the negative symbol. Do not specify a numeric value. If no value is set, "-" is assumed. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.
Virtual Decimal Point	Button and Integer	Specify a non-zero integer that represents the position of an implied decimal point within a number, or specify 0, the default, to use the formatting of Float or Decimal numbers as specified by the `Precision` property. If you specify a positive integer, the position of the decimal point is moved left from the right side of the number. For example, if you specify `3`, the decimal value `1234` represents 1.234 If you specify a negative integer, the position of the decimal point is moved right from the right side of the number. For example, if you specify `-3`, the decimal value `1234` represents 1,234,000.

Property	Type	Meaning
Precision	Button and Integer	This property is applicable only if `Physical Type` is `Text`. It is used if the value of the `Virtual Decimal Point` property is 0, which indicates that the decimal point is present in the data. It deals with truncation, and specifies how many digits are to follow the decimal point. Either specify a number of digits: • If you set `Precision` to 0, data is truncated so that the fractional part is lost. For example, the value `123.45` is truncated to `123`. • If you set `Precision` to a number less than the number of fractional digits, data is truncated. For example, the value `123.4567` is truncated to `123.45` if you set `Precision` to 2. • If you set `Precision` to a number greater than the number of fractional digits, the value is padded with extra zeros. For example, the value `12.345` is padded to `12.34500` if you set `Precision` to 5. Or select one option from the list: • `All Significant Digits - decimal separator only required if fractional digits` (the default): all significant digits are written to the output bit stream, and no decimal separator is written if no fractional digits are present. • `Explicit Decimal Separator - decimal separator always required`: all significant digits are written to the output bit stream and the decimal separator is always included, even when no fractional digits are present. The decimal separator must be present in the input bit stream, even when no fractional digits are present. • `Exponential Notation - Example "1.23456e002"`: data is written out to the bit stream as a signed value having the format `[sign1]a.bbbe[sign2]ccc` where: – `[sign1]` is the value of `Negative Sign` if the value is negative – `a` is a single decimal digit – `bbb` is one or more decimal digits – `[sign2]` is the value of `Negative Sign` if the exponent is negative – `ccc` is exactly three decimal digits (the exponent) `[sign1]` and `[sign2]` are absent if the value and exponent are positive. For example, the value -123.456 is represented as `-1.23456e002` and the value 0.00012 is represented as `1.2e-004` in the output bit stream, assuming that the value of `Negative Sign` is "-", and the value of `Sign Orientation` is `Leading`. The value -0.00012 is represented as `1.2*e*004` if `Negative Sign` is "*" and `Sign Orientation` is `Trailing`.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • `NULLPadFill`. This option is valid only for fixed-length objects and is the default value. • `NULLLogicalValue`. The `Encoding Null Value` property is first converted to an actual value, and rendered in the way specified for the field. • `NULLLiteralValue`. This option specifies that `Encoding Null Value` contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the `Encoding Null Value` property to test or compare the content of the field in the message. • `NULLLiteralFill`. This option specifies that the field is filled with the value specified by the `Encoding Null Value` property. `Encoding Null Value` must resolve to a single character. The option that you select determines the value that you must set for the property `Encoding Null Value`. For full information about using these options, see "TDS Null handling options" on page 6293.
Encoding Null Value	String	The use of this property depends on the `Encoding Null` property. The default value is zero. If you set the `Encoding Null` property for a dateTime object to `NULLLogicalValue`, the value that you set must be in an ISO8601 dateTime format. These formats are described in "DateTime as string data" on page 6311. For example, specify a value that conforms to the `yyyy-MM-dd'T'HH:mm:ss` format; for example, `1970-12-01`.

Occurrences

Property	Type	Meaning
Repeat reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, no integer objects exist before this one in the message structure. If a `Repeat Reference` is specified, it overrides any setting for the `Max Occurs` logical property when parsing and writing the message, but not for validating the message.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

TDS properties for local element integer types:

The TDS format properties for local element integer types.

The TDS Format properties described here apply to:

- Objects: Local Element
- Integer schema types: byte, int, long, short, unsignedByte, unsignedInt, unsignedShort

Field Identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Integer`. Equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `External Decimal`. The data is a decimal number that equates to the data type PIC 9 USAGE DISPLAY in COBOL. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. If this property is not set and the message set property `Derive default length from logical type` is selected, and the `Physical type` is 'Character', the default value is derived from any totalDigits value constraint (schema facet) or, if none, any `minInclusive`, `maxInclusive`, `minExclusive`, or `maxExclusive` value constraints (schema facets), on the simple type.

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the object. Select one of the following options (some physical types do not offer both options): • `Bytes`. The length is given in bytes. • `Characters`. The length is given in characters. The number of bytes that are processed in the bit stream depends on the code page of the message. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the contents of the bit stream. The parser reads one character at a time and determines whether the character comprises one or more bytes. The default is dependent on the physical type of the object.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Property	Type	Meaning
Inclusive Length Reference	Check box	This property is applicable only if `Length Reference` is set. If the check box is selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object only. If the check box is selected, the `Length Units` property of the sibling integer object must be the same as that of the current object.

Numeric representation

Property	Type	Meaning
Signed	Check box	Specify whether the value is signed.
Sign EBCDIC Custom Overpunched	Check box	Specify whether EBCDIC custom sign format is used. This property is applicable only if the `Signed` property is selected and the `Physical Type` property is set to `External Decimal`.
Sign Orientation	Enumerated type	The values that you can choose for this property are: • `Leading Separate` • `Trailing Separate` • `Leading Overpunched` • `Trailing Overpunched` This property is enabled only if you have set `Physical Type` to `Text` or `External Decimal`, and you have selected `Signed`. If `Physical Type` is `Text`, the only valid values of `Sign Orientation` are `Leading Separate` and `Trailing Separate`. If `Physical Type` is `External Decimal` and `Sign EBCDIC Customer Overpunched` is selected, the only valid values of `Sign Orientation` are `Leading Overpunched` and `Trailing Overpunched`.
Positive Sign	String	Specify the value that represents the positive symbol. Do not specify a numeric value. If no value is set, "+" is assumed. The positive sign is not written when creating an output message; it is used only to recognize the positive sign when parsing a message bit stream. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.
Negative Sign	String	Specify the value that represents the negative symbol. Do not specify a numeric value. If no value is set, "-" is assumed. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • `NULLPadFill`. This option is valid only for fixed-length objects and is the default value. • `NULLLogicalValue`. The `Encoding Null Value` property is first converted to an actual value, and rendered in the way specified for the field. • `NULLLiteralValue`. This option specifies that `Encoding Null Value` contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the `Encoding Null Value` property to test or compare the content of the field in the message. • `NULLLiteralFill`. This option specifies that the field is filled with the value specified by the `Encoding Null Value` property. `Encoding Null Value` must resolve to a single character. The option that you select determines the value that you must set for the property `Encoding Null Value`. For full information about using these options, see "TDS Null handling options" on page 6293.
Encoding Null Value	String	The use of this property depends on the `Encoding Null` property. The default value is zero. If you set the `Encoding Null` property for a dateTime object to `NULLLogicalValue`, the value that you set must be in an ISO8601 dateTime format. These formats are described in "DateTime as string data" on page 6311. For example, specify a value that conforms to the `yyyy-MM-dd'T'HH:mm:ss` format; for example, `1970-12-01`.

Occurrences

Property	Type	Meaning
Repeat reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, no integer objects exist before this one in the message structure. If a `Repeat Reference` is specified, it overrides any setting for the `Max Occurs` logical property when parsing and writing the message, but not for validating the message.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

TDS properties for local element interval types:

The TDS format properties for local element string types.

The TDS Format properties described here apply to:

- Objects: Local Element
- Interval schema types: duration

Field Identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Length Encoded String 1`. The first byte of the data contains the length (in length units) of the data string that follows the length byte. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The data's first 2 bytes contains the length (in length units) of the data string that follows the two length bytes. The maximum length of a `Length Encoded String 2` element is 65535 length units. • `Null Terminated String`. The data string ends with the hexadecimal NULL character, `X'00'`. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. If this property is not set and the message set property `Derive default length from logical type` is selected, and the `Physical type` is 'Character', the default value is derived from any length or maxLength value constraint (schema facet) on the simple type.

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the object. Select one of the following options (some physical types do not offer both options): • `Bytes`. The length is given in bytes. • `Characters`. The length is given in characters. The number of bytes that are processed in the bit stream depends on the code page of the message. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the contents of the bit stream. The parser reads one character at a time and determines whether the character comprises one or more bytes. The default is dependent on the physical type of the object.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • `NULLPadFill`. This option is valid only for fixed-length objects and is the default value. • `NULLLogicalValue`. The `Encoding Null Value` property is first converted to an actual value, and rendered in the way specified for the field. • `NULLLiteralValue`. This option specifies that `Encoding Null Value` contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the `Encoding Null Value` property to test or compare the content of the field in the message. • `NULLLiteralFill`. This option specifies that the field is filled with the value specified by the `Encoding Null Value` property. `Encoding Null Value` must resolve to a single character. The option that you select determines the value that you must set for the property `Encoding Null Value`. For full information about using these options, see "TDS Null handling options" on page 6293.
Encoding Null Value	String	The use of this property depends on the `Encoding Null` property. The default value is zero. If you set the `Encoding Null` property for a dateTime object to `NULLLogicalValue`, the value that you set must be in an ISO8601 dateTime format. These formats are described in "DateTime as string data" on page 6311. For example, specify a value that conforms to the `yyyy-MM-dd'T'HH:mm:ss` format; for example, `1970-12-01`.

Occurrences

Property	Type	Meaning
Repeat reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, no integer objects exist before this one in the message structure. If a `Repeat Reference` is specified, it overrides any setting for the `Max Occurs` logical property when parsing and writing the message, but not for validating the message.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

TDS properties for local element string types:

The TDS format properties for local element string types.

The TDS Format properties described here apply to:

- Objects: Local Element
- String schema types: anyURI, ENTITIES, ENTITY, ID, IDREF, IDREFS, language, Name, NCName, NMTOKEN, NMTOKENS, normalizedString, NOTATION, QName, string, token

Field Identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.
Interpret Element Value	Enumerated type	Specify whether values stored within this object are interpreted as having significance for the parser and, if so, the type of interpretation that occurs. This interpretation is standard-specific and is therefore hard coded. The possible values for this property are: • `None` (the default value) • `EDIFACT Service String` • `X12 Service String` • `Message Key` • `EDIFACT Syntax Level ID` • `HL7 Service String` • `HL7 Field Separator` **Note:** The `Message Key` enumeration has been deprecated.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Length Encoded String 1`. The first byte of the data contains the length (in length units) of the data string that follows the length byte. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The first two bytes of the data contain the length (in length units) of the data string that follows the two length bytes. The maximum length of a `Length Encoded String 2` element is 65535 length units. • `Null Terminated String`. The data string ends with the hexadecimal NULL character, `X'00'`. • `TLOG Specific` - this option can be selected only if the `Message Standard` property of the message set is `TLOG`. This option indicates that the format of the data is specific to the TLOG messaging standard. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. If this property is not set and the message set property `Derive default length from logical type` is selected, and the `Physical type` is 'Character', the default value is derived from any length or maxLength value constraint (schema facet) on the simple type.
Length Units	Enumerated type	Select the unit of length for the object. Select one of the following options (some physical types do not offer both options): • `Bytes`. The length is given in bytes. • `Characters`. The length is given in characters. The number of bytes that are processed in the bit stream depends on the code page of the message. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the contents of the bit stream. The parser reads one character at a time and determines whether the character comprises one or more bytes. The default is dependent on the physical type of the object.

Property	Type	Meaning
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.

Property	Type	Meaning
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see "Reordering objects" on page 2900.
Inclusive Length Reference	Check box	This property is applicable only if `Length Reference` is set. If the check box is selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object plus the length of the sibling integer object. If the check box is not selected, the value of the sibling integer object that is identified by `Length Reference` is the length of the current object only. If the check box is selected, the `Length Units` property of the sibling integer object must be the same as that of the current object.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • `NULLPadFill`. This option is valid only for fixed-length objects and is the default value. • `NULLLogicalValue`. The `Encoding Null Value` property is first converted to an actual value, and rendered in the way specified for the field. • `NULLLiteralValue`. This option specifies that `Encoding Null Value` contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the `Encoding Null Value` property to test or compare the content of the field in the message. • `NULLLiteralFill`. This option specifies that the field is filled with the value specified by the `Encoding Null Value` property. `Encoding Null Value` must resolve to a single character. The option that you select determines the value that you must set for the property `Encoding Null Value`. For full information about using these options, see "TDS Null handling options" on page 6293.
Encoding Null Value	String	The use of this property depends on the `Encoding Null` property. The default value is zero. If you set the `Encoding Null` property for a dateTime object to `NULLLogicalValue`, the value that you set must be in an ISO8601 dateTime format. These formats are described in "DateTime as string data" on page 6311. For example, specify a value that conforms to the `yyyy-MM-dd'T'HH:mm:ss` format; for example, `1970-12-01`.

Occurrences

Property	Type	Meaning
Repeat reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, no integer objects exist before this one in the message structure. If a `Repeat Reference` is specified, it overrides any setting for the `Max Occurs` logical property when parsing and writing the message, but not for validating the message.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Local group logical properties:

The logical properties of a local group include properties that specify the number of occurrences of the local group.

Valid children in a local group that depend on both **`Composition`** and **`Content Validation`** are shown in "MRM content validation" on page 5422.

Property	Type	Meaning
Composition	Enumerated type	Define the order, and the number of occurrences, of the elements and groups in your messages. Composition does not affect the attributes in a complex type. Select from the following options: • Empty • sequence. If you select this option, you can define members that are elements or groups. These members, if present, must appear in the specified order in the message. They can repeat, and the same element or group can appear more than once. • choice. If you select this option, you can define members that are elements or groups. Exactly one of the defined members must be present in the message, and can repeat. Use this option if you want to model C unions and COBOL REDEFINES in a Custom Wire Format, or an XML DTD element that uses choice in an XML Wire Format, or a SWIFT field that has more than one option. • all. If you select this option, you can define members that are elements; groups are not allowed. The elements in an all group can appear in any order. Each element can appear once, or not at all. An all group can be used only at the top level of a complex type; it cannot be a member of another group within a type. • unorderedSet. This option is supported only by the MRM domain.If you select this option, you can define members that are elements. The elements can repeat, but the same element cannot appear twice in the list of members. The elements can appear in any order in the message. • orderedSet. This option is supported only by the MRM domain.If you select this option, you can define members that are elements. The elements can repeat, but the same element cannot appear twice in the list of members. The elements must appear in the specified order in the message. • message. This option is supported only by the MRM domain. If you select this option, you can define only messages as members. Each member can repeat, but the same message cannot appear twice in the list of members. Like choice, only one of the defined members can be present in a message. Unlike choice, when writing a message, if the complex type or group has more than one member, the bit stream is not padded to the length of the longest member. Use this option to model multipart messages, which are used in some industry standards; for example, SWIFT. For more information, see the section on multipart messages in “Multipart messages” on page 1191.

Property	Type	Meaning
Content Validation	Enumerated type	`Content Validation` is used only by the MRM domain. If validation is enabled in your message flow, `Content Validation` specifies the strictness of the MRM validation for members of a complex type or group. See "MRM content validation" on page 5422 for further details. Select from the following options: • Closed. The complex type can only contain the child elements that you have added to it. • Open Defined. The complex type can contain any valid element defined within the message set. • Open. The complex type can contain any valid element, not just those that you have added to this complex type. See "Combinations of Composition and Content Validation" on page 5612 for further details of these options.

Occurrences

Property	Type	Meaning
Min Occurs	Integer	Specify the minimum number of times that the object can repeat. The default value is 1. If the value is set to 0, the object is optional. With the exception of `Max Occurs` being set to -1, if a value is set for `Min Occurs`, it must be less than or equal to the value in `Max Occurs`.
Max Occurs	Integer	Specify the maximum number of times that the object can repeat. The default value is 1. If this property is not set, the object cannot occur more than once. If this property is set to 0, it is interpreted as if the object does not exist in the message. It can also be set to -1, to indicate that the limit is unbounded and there is no maximum to the number of occurrences.

The following objects have properties that can be viewed or set.

Local group CWF properties:

The CWF properties of a local group are described in the following tables.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • `1 Bytes`. The default value. • `2 Bytes` • `4 Bytes` • `8 Bytes` • `16 Bytes`
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *`Repeat Reference`* is specified, it overrides any setting for the *`Max Occurs`* logical property when parsing and writing the message, but not for validation of the message.

Related concepts:

"Physical formats in the MRM domain" on page 1211
Each message definition file within a message set describes both the *logical structure* of your messages, and the *physical formats* that describe the precise appearance of your message bit stream during transmission.

The following objects have properties that can be viewed or set.

Local group TDS properties:

TDS properties of a local group.

Field Identification

Property	Type	Meaning
Data Element Separation	Enumerated type	Select one of the following values to specify the method that is used to separate the data elements within the type. • `Tagged Delimited`. This value indicates that all elements within the complex type are identified by a tag, and, if a value is specified in the optional `Delimiter` property, are separated by that value. You must set the `Tag` property for all child elements of simple type, and you can set the `Delimiter` property to a non-empty value. See "Global element TDS properties" on page 5513. You must also set the `Tag Data Separator` or the `Length of Tag` property. • `Tagged Fixed Length`. This value indicates that each element is identified by a tag, and the data has a fixed length. There are no delimiters. You must set the `Tag` property for each of the child elements of this complex type, and each child element must have a `Length` or `Length Reference` property assigned to it. You must also set the `Tag Data Separator` or the `Length of Tag` property. • `Tagged Encoded Length`. This value indicates that all elements within the complex type are separated by a tag, and a length field follows each tag. There are no delimiters. The tag can be fixed length, as set by the `Length of Tag` property, or variable length delimited by the `Tag Data Separator` property. You must also set the `Length Of Encoded Length` property so that the parser knows the size of the length field, and set the `Extra Chars in Encoded Length` property. This property tells the parser what to subtract from the value in the `Length Of Encoded Length` property to get the actual length of the data that follows the length field. This method provides a more flexible way of handling ACORD AL3 standard messages than using the `Fixed Length AL3` value, by allowing different parts of the messages to be at different versions of the ACORD AL3 standard. • `All Elements Delimited`. This value indicates that all elements within the complex type are separated by a delimiter. You must set a value in the `Delimiter` property. • `Variable Length Elements Delimited`. This value indicates that some of the elements within the complex type might be of variable length. Variable length elements must be delimited by the value specified in the `Delimiter` property. • `Use Data Pattern`. This value indicates that the parser determines the elements by matching the data with the regular expression that is set in the `Data Pattern` property of the element or type member. See "Message definition file properties" on page 5409. • `Fixed Length`. This value indicates that all elements within the complex type are fixed length. The next data element is accessed by adding the value of the `Length` property to the offset. See "Global element TDS properties" on page 5513. If you set the `Data Element Separation` property of a complex type to `Fixed Length`, you must also set the `Data Element Separation` property of all complex children of this type to `Fixed Length`. Each child element must have a `Length` or `Length Reference` property assigned to it. • `Fixed Length AL3`. This value has a similar meaning to the separation type `Fixed Length`, but also indicates to the parser that a number of predefined rules regarding missing optional elements, encoded lengths, and versioning, must be applied. If you set the `Data Element Separation` property of a complex type to `Fixed Length AL3`, you must also set the `Data Element Separation` property of all complex children of this type to `Fixed Length AL3`. • `Undefined`. This value is set automatically if you set the `Type Composition` property of a complex type to `Message`, and you cannot change it to any other value. Do not set the `Type Composition` property to `Empty`, `Choice`, `Unordered Set`, `Ordered Set`, `Sequence`, or `Simple Unordered Set`. If you do, you cannot check in the type.

Property	Type	Meaning
Group Indicator	String	Specify the value of a special character, or string, that precedes the data that belongs to a group, or a complex type, within the bit stream.
Group Terminator	String	Specify the value of a special character, or string, that terminates the data that belongs to a group, or a complex type, within the bit stream.
Delimiter	String	Specify the value of a special character, or string, that specifies the delimiter that is used between data elements. This property applies only to the delimited `Data Element Separation` methods (`Tagged Delimited`, `All Elements Delimited`, and `Variable Length Elements Delimited`).
Suppress Absent Element Delimiters	Enumerated type	Use this property to select whether you want delimiters to be suppressed for elements that are missing within a message. Select from: • `End Of Type`. Use this option to suppress the delimiter when an element is missing. For example, if the model has been defined to have up to three elements and only two are present, the last delimiter can be omitted from the message. • `Never`. Use this option to ensure that even if optional elements are not present, all delimiters are written out. Use this option when the same delimiter is used to delimit parent and child objects. For example, if an optional child element is missing, message processing applications cannot tell where the child elements in a message end and the next parent element starts, if the delimiters are all the same.
Observe Element Length	Check box	This property is applicable when `Data Element Separation` is `All Elements Delimited` or `Tagged Delimited`. Select this check box if the `Length` property of child simple elements is significant when parsing and writing. • During parsing, an exception is thrown if the length of the extracted data exceeds the specified length. Otherwise, the data is trimmed according to the `Justification` and `Padding Character` properties of the child element. • During writing, an exception is thrown if the data to write exceeds the specified length. Otherwise, the data is padded according to the `Justification` and `Padding Character` properties of the child element. Clear this check box to ignore the `Length` property when parsing and writing. The default value depends on the setting of the `Messaging Standard` property (at the message set level) and the `Data Element Separation` property. • If `Data Element Separation` is `All Elements Delimited` and the `Messaging Standard` is `TLOG`, the check box is selected. • If `Data Element Separation` is `All Elements Delimited` and the `Messaging Standard` is other than `TLOG`, the check box is cleared. • If `Data Element Separation` is `Tagged Delimited`, the check box is cleared. For all other data element separation methods, the check box is disabled and does not influence the behavior of the TDS parser.
Tag Data Separator	Button and String	Specify the value of a special character or string that separates the Tag from the data. The `Tag Data Separator` and `Length of Tag` properties are mutually exclusive. If you set the property `Tag Data Separator`, it overrides `Length of Tag`. This property applies only to the tagged `Data Element Separation` methods (`Tagged Delimited`, `Tagged Fixed Length`, and `Tagged Encoded Length`).

Property	Type	Meaning
Length of Tag	Button and Integer	Specify the length of a tag value. When the message is parsed, this property allows tags to be extracted from the bit stream if the `Tag Data Separator` property is not set. The `Tag Data Separator` and `Length of Tag` properties are mutually exclusive. If you set the property `Tag Data Separator`, it overrides this value. This property applies only to the tagged `Data Element Separation` methods (`Tagged Delimited`, `Tagged Fixed Length`, and `Tagged Encoded Length`).
Length of Encoded Length	Integer	Specifies the number of characters (not bytes) after a tag that are used for the length field. Enter a value from 0 to 2147483647. You must set this property if you have set the `Data Element Separation` property to `Tagged Encoded Length`; it is not valid otherwise. The actual number of data characters that are parsed depends on the value of the `Extra Chars in Encoded Length` property.
Extra Chars in Encoded Length	Integer	(Only valid if the `Data Element Separation` method is set to `Tagged Encoded Length`.) Specifies the number of extra characters included in the value found in the length field. (For example, the value in the length might include the size of the length field itself as well as the size of the data field, or it might be the total size of the tag, length, and data fields.) Enter a value from 0 to 2147483647. The parser subtracts this number from the number found in the length field to get the number of data characters that follow the length field. You must set this property if you have set the `Data Element Separation` property to `Tagged Encoded Length`, and the actual number of data characters is less than the value found in the length field.

Field Identification

Property	Type	Meaning
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see “Regular expression syntax” on page 6304.

Occurrences

Property	Type	Meaning
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Property	Type	Meaning
Repeat reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, no integer objects exist before this one in the message structure. If a `Repeat Reference` is specified, it overrides any setting for the `Max Occurs` logical property when parsing and writing the message, but not for validating the message.

More information about the MRM domain.

Message logical properties:

This section describes the logical properties of a message.

Property	Type	Meaning
Name	String	Specify a name for the object when you create it. Names can consist of alphanumeric characters, including the letters *A* through *Z*, *a* through *z*, and the digits *0* through *9*. They might also include the following punctuation characters; • - the hyphen • _ the underscore • . the period Names can start only with a letter or the underscore character, and not with a number, hyphen, or period. Names that begin with `xml`, or any variant of these characters (for example `XmL`), are reserved by the XML standards specification. Further details of naming conventions and allowable characters can be found in the Extensible Markup Language (XML) specification that can be found on the World Wide Web Consortium (W3C) Web site.
Message Alias	String	Specify an alternative unique value that identifies the message. This property is only required if you are using the MRM domain and the Message Identity technique to identify embedded messages, and the bit stream does not contain the actual message name.

Use the documentation property of an object to add information that describes the function of the object.

"Message model object properties by object" on page 5536
The following objects have properties that can be viewed or set.

Message XML properties:

The following tables describe the XML properties of a message.

Namespace schema locations

This property is only active if namespaces have been enabled.

Property	Type	Meaning
Namespace URI	String	A unique string, usually in the form of a URL that identifies the schema. If namespaces have not been enabled, this property displays `<no target namespace>`. This property overrides the same property at the message set level.

Property	Type	Meaning
Schema location	String	Enter the location of the schema for the associated namespace name to be used to validate objects in the namespace.

XML declarations

Property	Type	Meaning
Output Namespace Declaration	Enumerated type	The `Output Namespace Declaration` property controls where the namespace declarations are placed in the output XML document. Select from: • `At start of document`. Declarations for all of the entries in the `Namespace schema locations` table above are produced as attributes of the message in the output XML document. The disadvantage of this option is that in some cases unnecessary declarations might be produced. • `As required`. Declarations are produced only when required by an element or attribute that is in that namespace. The disadvantage of this option is that the same namespace declaration might need to be produced more than once in the output XML document. The default option is `At start of document`. This property is active only if namespaces are enabled for this message set.

XML document type settings

Property	Type	Meaning
DOCTYPE System ID	String	Specify the System ID for DOCTYPE external DTD subset. It overrides the equivalent message set property setting for this particular message. If the message set property `Suppress DOCTYPE` is set to `Yes`, this parameter is ignored and cannot be changed (the field is disabled). The default value is the value that you specified for the `DOCTYPE System ID` property for the message set.
DOCTYPE Public ID	String	Specify the Public ID for DOCTYPE external DTD subset. It overrides the equivalent message set property setting for this particular message. If the message set property `Suppress DOCTYPE` is set to `Yes`, this parameter is ignored and cannot be changed (the field is disabled) . The default value is the value that you specified for the `DOCTYPE Public ID` property for the message set.
DOCTYPE Text	String	Enter optional additional text to include within the DOCTYPE. It overrides the message set property for this particular message. If the message set property `Suppress DOCTYPE` is set to `Yes`, this parameter is ignored and cannot be changed (the field is disabled). For more information, see “MRM XML: In-line DTDs and the DOCTYPE text property” on page 5407. The default value is the value that you specified for the `DOCTYPE Text` property for the message set.

Property	Type	Meaning
Root Tag Name	String	Specify the name of the root tag for a message bit stream XML document. It overrides the message set property set for this message. The default value is the value that you specified for the `Root Tag Name` property for the message set. **Note:** This property is deprecated. Do not change its value from its default setting.

Field identification

A number of the following properties will only become active depending on the value that `Render` property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (for output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their `XML Name` property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in `ID Attribute Name` and a value as specified in `ID Attribute Value`. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set `XML Name`, `ID Attribute Name`, `ID Attribute Value` to the same values: – You must also set `Value Attribute Name` to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).

Property	Type	Meaning
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.

The following objects have properties that can be viewed or set.

Message TDS properties:

Message TDS properties.

Property	Type	Meaning
Message Key	String	Specify an alternative unique value that identifies the message in the bit stream. This property is required if the message is embedded within another message. **Note:** From Version 6.0 onwards, the use of `Message Key` has been deprecated for identifying an embedded message. You now have the option of identifying an embedded message by Message Identity, using the `Message Alias` logical property.

Related concepts:

"Physical formats in the MRM domain" on page 1211
Each message definition file within a message set describes both the *logical structure* of your messages, and the *physical formats* that describe the precise appearance of your message bit stream during transmission.

"MRM TDS format" on page 1221
The Tagged/Delimited String format (TDS) is the physical representation of a message that has a number of data elements separated by tags and delimiters.

"Multipart messages" on page 1191
A *multipart message* contains one or more other messages within its structure. The contained message is sometimes referred to as an *embedded message*.

"Identifying an embedded message by using a Message Identity" on page 1193
You can identify an embedded message by using the Message Identity. This technique is used by the MRM domain, and replaces the use of the Message Key.

"MRM TDS format: Relationship to the logical model" on page 1243
TDS separation types and logical model properties have some restrictions, such as group composition and group content validation.

Related tasks:

"Working with physical formats" on page 2847

Simple type logical properties:

The logical properties of a simple type.

Property	Type	Meaning
Name	String	Specify a name for the object when you create it. Names can consist of alphanumeric characters, including the letters *A* through *Z*, *a* through *z*, and the digits *0* through *9*. They might also include the following punctuation characters; • - the hyphen • _ the underscore • . the period Names can start only with a letter or the underscore character, and not with a number, hyphen, or period. Names that begin with `xml`, or any variant of these characters (for example `XmL`), are reserved by the XML standards specification. Further details of naming conventions and allowable characters can be found in the Extensible Markup Language (XML) specification that can be found on the World Wide Web Consortium (W3C) Web site.
Base Type	Enumerated type	This property only applies to a simple type restriction. You can use this property to select a base type that is used as the starting point to define a new simple type that is derived by setting additional value constraints.
Item Type	Enumerated type	This property only applies to a simple type list. You can use this property to select the type that is used as the item type of the list.

Property	Type	Meaning
Variety	Enumerated type	This property displays the variety of the simple type you have selected, either atomic, list, or union.

A simple type can also have “Simple type logical value constraints” on page 5450.

“Message model object properties by object” on page 5536
The following objects have properties that can be viewed or set.

Simple type logical value constraints:

The properties, and their permissible values, vary according to the object type.

The properties that are displayed on the object page, and the values that those properties can take, can vary according to the type of the object. For example, the properties for type *string* are different from those of type *Boolean*. Select the link for the object type from the following table.

Type of object	Properties
Binary types	• base64Binary • hexBinary
Boolean types	• Boolean
DateTime types	• date • dateTime • gDay • gMonth • gMonthDay • gYear • gYearMonth • time
Decimal types	• decimal • integer • negativeInteger • nonNegativeInteger • nonPositiveInteger • positiveInteger • unsignedLong

Type of object	Properties
Float types	• double • float
Integer types	• byte • int • long • short • unsignedByte • unsignedInt • unsignedShort
Interval types	• duration
String types	• anyURI • ENTITIES • ENTITY • ID • IDREF • IDREFS • language • Name • NCName • NMTOKEN • NMTOKENS • normalizedString • NOTATION • QName • string • token

Logical properties for value constraints for simple type binary types:

The logical properties for simple type binary types.

The simple type value constraint properties described here apply to:

- Objects: Simple types

- Binary schema types: base64Binary, hexBinary

Length constraints

Property	Type	Meaning
Length	Integer	Specify the exact length of the simple type in bytes or characters. The value must be greater than 0, and less than 2147483648.
Min	Integer	Specify the minimum length of the simple type in bytes or characters. The value must be greater than 0, and less than 2147483648.
Max	Integer	Specify the maximum length of the simple type in bytes or characters. The value must be greater than 0, and less than 2147483648.

Property	Type	Meaning
White Space	Enumerated type	Set this property to control the processing of white space characters received for this type. Select one of the following values: • preserve. If you set the property to preserve, all white space characters including carriage return, line feed, and tab are preserved. • replace. If you set the property to replace, all carriage return, line feed, and tab characters are replaced with a space character. • collapse. If you set the property to collapse, all carriage return, line feed, and tab characters are replaced with a space character. All adjacent white space characters are then collapsed to a single space character, and leading or trailing spaces are stripped from the data.

Enumerations

Property	Type	Meaning
Enumerations	String	Set this property to constrain the values to the list that is specified in this property. For example, you might create a simple type called *RainbowColors*, and add Red, `Orange`, `Yellow`, `Green`, `Blue`, `Indigo`, and `Violet` to the enumerations list. You must ensure that you have all variations of the data that you are likely to receive in the message defined in the list. For example, Yellow, yellow, yel, and y might be variations of a single color. Select **Add** to add a default enumeration. Overtype the default with the data you require. To change an entry, select the entry, and click on the entry a second time (as distinct from double-click). You can now update the selected entry.

Patterns

Property	Type	Meaning
Patterns	String	`Patterns` are a regular expression, or a series of regular expressions, that are used to constrain the data within the simple type. For further information about patterns and their syntax see "Using regular expressions to parse data elements" on page 6301. Select **Add** to add a default pattern. Overtype the default with the data you require. To change an entry, select the entry, and click on the entry a second time (as distinct from double-click). You can now update the selected entry.

Logical properties for value constraints for simple type dateTime types:

The logical properties for simple type dateTime types.

The simple type value constraint properties described here apply to:

- Objects: Simple types
- DateTime schema types: date, dateTime, gDay, gMonth, gMonthDay, gYear, gYearMonth, time

Inclusive Constraints

Property	Type	Meaning
Min	Integer	Specify the minimum value for which the data in the message must be greater than, or equal to. When this value is set, it cannot be equal to, or greater than, the `Max` Inclusive Constraint property. You cannot specify both `Min` Inclusive Constraint and `Min` Exclusive Constraint properties together for the same simple type.
Max	Integer	Specify the maximum value for which the data in the message must be less than, or equal to. When this value is set, it cannot be equal to, or less than, the `Min` Inclusive Constraint property. You cannot specify both `Max` Inclusive Constraint and `Max` Exclusive Constraint properties together for the same simple type.

Exclusive Constraints

Property	Type	Meaning
Min	Integer	Specify the minimum value for which the data in the message must be greater than. When this value is set it cannot be equal to, or greater than, the `Max` Inclusive Constraint property. You cannot specify both `Min` Inclusive Constraint and `Min` Exclusive Constraint properties together for the same simple type.
Max	Integer	Specify the maximum value for which the data in the message must be less than. When this value is set, it cannot be equal to, or less than, the `Min` Inclusive Constraint property. You cannot specify both `Max` Inclusive Constraint and `Max` Exclusive Constraint properties together for the same simple type.

Property	Type	Meaning
White Space	Enumerated type	Set this property to control the processing of white space characters received for this type. Select one of the following values: • preserve. If you set the property to preserve, all white space characters including carriage return, line feed, and tab are preserved. • replace. If you set the property to collapse, all carriage return, line feed, and tab characters are replaced with a space character. All adjacent white space characters are then collapsed to a single space character, and leading or trailing spaces are stripped from the data.

Enumerations

Property	Type	Meaning
Enumerations	String	Set this property to constrain the values to the list that is specified in this property. For example, you might create a simple type called *RainbowColors*, and add Red, `Orange`, `Yellow`, `Green`, `Blue`, `Indigo`, and `Violet` to the enumerations list. You must ensure that you have all variations of the data that you are likely to receive in the message defined in the list. For example, Yellow, yellow, yel, and y might be variations of a single color. Select **Add** to add a default enumeration. Overtype the default with the data you require. To change an entry, select the entry, and click on the entry a second time (as distinct from double-click). You can now update the selected entry.

Patterns

Property	Type	Meaning
Patterns	String	`Patterns` are a regular expression, or a series of regular expressions, that are used to constrain the data within the simple type. For further information about patterns and their syntax see "Using regular expressions to parse data elements" on page 6301. Select **Add** to add a default pattern. Overtype the default with the data you require. To change an entry, select the entry, and click on the entry a second time (as distinct from double-click). You can now update the selected entry.

Logical properties for value constraints for simple type decimal types:

The logical properties for simple type decimal types.

The simple type value constraint properties described here apply to:

- Objects: Simple types
- Decimal schema types: decimal, integer, negativeInteger, nonNegativeInteger, nonPositiveInteger, positiveInteger, unsignedLong

Inclusive Constraints

Property	Type	Meaning
Min	Integer	Specify the minimum value for which the data in the message must be greater than, or equal to. When this value is set, it cannot be equal to, or greater than, the `Max` Inclusive Constraint property. You cannot specify both `Min` Inclusive Constraint and `Min` Exclusive Constraint properties together for the same simple type.
Max	Integer	Specify the maximum value for which the data in the message must be less than, or equal to. When this value is set, it cannot be equal to, or less than, the `Min` Inclusive Constraint property. You cannot specify both `Max` Inclusive Constraint and `Max` Exclusive Constraint properties together for the same simple type.

Exclusive Constraints

Property	Type	Meaning
Min	Integer	Specify the minimum value for which the data in the message must be greater than. When this value is set it cannot be equal to, or greater than, the `Max` Inclusive Constraint property. You cannot specify both `Min` Inclusive Constraint and `Min` Exclusive Constraint properties together for the same simple type.
Max	Integer	Specify the maximum value for which the data in the message must be less than. When this value is set, it cannot be equal to, or less than, the `Min` Inclusive Constraint property. You cannot specify both `Max` Inclusive Constraint and `Max` Exclusive Constraint properties together for the same simple type.

Property	Type	Meaning
Fraction Digits	Integer	Set this property to limit the number of digits in the fraction part of a numeric value to the number of digits specified in this property. The value must be greater than, or equal to, 0, and less than 2147483648. The value set for `Fraction Digits` cannot be greater than the value specified for `Total Digits`.

Property	Type	Meaning
Total Digits	Integer	Set this property to set the maximum number of digits in a numeric value to the number of digits specified in this property. The value must be greater than, or equal to, 0, and less than 2147483648. The value set for `Total Digits` cannot be less than the value specified for `Fraction Digits`.

Property	Type	Meaning
White Space	Enumerated type	Set this property to control the processing of white space characters received for this type. Select one of the following values: • preserve. If you set the property to preserve, all white space characters including carriage return, line feed, and tab are preserved. • replace. If you set the property to replace, all carriage return, line feed, and tab characters are replaced with a space character. • collapse. If you set the property to collapse, all carriage return, line feed, and tab characters are replaced with a space character. All adjacent white space characters are then collapsed to a single space character, and leading or trailing spaces are stripped from the data.

Enumerations

Property	Type	Meaning
Enumerations	String	Set this property to constrain the values to the list that is specified in this property. For example, you might create a simple type called *RainbowColors*, and add Red, `Orange`, `Yellow`, `Green`, `Blue`, `Indigo`, and `Violet` to the enumerations list. You must ensure that you have all variations of the data that you are likely to receive in the message defined in the list. For example, Yellow, yellow, yel, and y might be variations of a single color. Select **Add** to add a default enumeration. Overtype the default with the data you require. To change an entry, select the entry, and click on the entry a second time (as distinct from double-click). You can now update the selected entry.

Patterns

Property	Type	Meaning
Patterns	String	`Patterns` are a regular expression, or a series of regular expressions, that are used to constrain the data within the simple type. For further information about patterns and their syntax see "Using regular expressions to parse data elements" on page 6301. Select **Add** to add a default pattern. Overtype the default with the data you require. To change an entry, select the entry, and click on the entry a second time (as distinct from double-click). You can now update the selected entry.

Logical properties for value constraints for simple type integer types:

The logical properties for simple type integer types.

The simple type value constraint properties described here apply to:

- Objects: Simple types
- Integer schema types: byte, int, long, short, unsignedByte, unsignedInt, unsignedShort

Inclusive Constraints

Property	Type	Meaning
Min	Integer	Specify the minimum value for which the data in the message must be greater than, or equal to. When this value is set, it cannot be equal to, or greater than, the `Max` Inclusive Constraint property. You cannot specify both `Min` Inclusive Constraint and `Min` Exclusive Constraint properties together for the same simple type.
Max	Integer	Specify the maximum value for which the data in the message must be less than, or equal to. When this value is set, it cannot be equal to, or less than, the `Min` Inclusive Constraint property. You cannot specify both `Max` Inclusive Constraint and `Max` Exclusive Constraint properties together for the same simple type.

Exclusive Constraints

Property	Type	Meaning
Min	Integer	Specify the minimum value for which the data in the message must be greater than. When this value is set it cannot be equal to, or greater than, the `Max` Inclusive Constraint property. You cannot specify both `Min` Inclusive Constraint and `Min` Exclusive Constraint properties together for the same simple type.

Property	Type	Meaning
Max	Integer	Specify the maximum value for which the data in the message must be less than. When this value is set, it cannot be equal to, or less than, the `Min` Inclusive Constraint property. You cannot specify both `Max` Inclusive Constraint and `Max` Exclusive Constraint properties together for the same simple type.

Property	Type	Meaning
Fraction Digits	Integer	Set this property to limit the number of digits in the fraction part of a numeric value to the number of digits specified in this property. The value must be greater than, or equal to, 0, and less than 2147483648. The value set for `Fraction Digits` cannot be greater than the value specified for `Total Digits`.

Property	Type	Meaning
Total Digits	Integer	Set this property to set the maximum number of digits in a numeric value to the number of digits specified in this property. The value must be greater than, or equal to, 0, and less than 2147483648. The value set for `Total Digits` cannot be less than the value specified for `Fraction Digits`.

Property	Type	Meaning
White Space	Enumerated type	Set this property to control the processing of white space characters received for this type. Select one of the following values: • preserve. If you set the property to preserve, all white space characters including carriage return, line feed, and tab are preserved. • replace. If you set the property to replace, all carriage return, line feed, and tab characters are replaced with a space character. • collapse. If you set the property to collapse, all carriage return, line feed, and tab characters are replaced with a space character. All adjacent white space characters are then collapsed to a single space character, and leading or trailing spaces are stripped from the data.

Enumerations

Property	Type	Meaning
Enumerations	String	Set this property to constrain the values to the list that is specified in this property. For example, you might create a simple type called *RainbowColors*, and add Red, `Orange`, `Yellow`, `Green`, `Blue`, `Indigo`, and `Violet` to the enumerations list. You must ensure that you have all variations of the data that you are likely to receive in the message defined in the list. For example, Yellow, yellow, yel, and y might be variations of a single color. Select **Add** to add a default enumeration. Overtype the default with the data you require. To change an entry, select the entry, and click on the entry a second time (as distinct from double-click). You can now update the selected entry.

Patterns

Property	Type	Meaning
Patterns	String	`Patterns` are a regular expression, or a series of regular expressions, that are used to constrain the data within the simple type. For further information about patterns and their syntax see "Using regular expressions to parse data elements" on page 6301. Select **Add** to add a default pattern. Overtype the default with the data you require. To change an entry, select the entry, and click on the entry a second time (as distinct from double-click). You can now update the selected entry.

Logical properties for value constraints for simple type string types:

The logical properties for simple type string types.

The simple type value constraint properties described here apply to:

- Objects: Simple types
- Integer schema types: byte, int, long, short, unsignedByte, unsignedInt, unsignedShort

Length constraints

Property	Type	Meaning
Length	Integer	Specify the exact length of the simple type in bytes or characters. The value must be greater than 0, and less than 2147483648.
Min	Integer	Specify the minimum length of the simple type in bytes or characters. The value must be greater than 0, and less than 2147483648.

Property	Type	Meaning
Max	Integer	Specify the maximum length of the simple type in bytes or characters. The value must be greater than 0, and less than 2147483648.

Property	Type	Meaning
White Space	Enumerated type	Set this property to control the processing of white space characters received for this type. Select one of the following values: • preserve. If you set the property to preserve, all white space characters including carriage return, line feed, and tab are preserved. • replace. If you set the property to replace, all carriage return, line feed, and tab characters are replaced with a space character. • collapse. If you set the property to collapse, all carriage return, line feed, and tab characters are replaced with a space character. All adjacent white space characters are then collapsed to a single space character, and leading or trailing spaces are stripped from the data.

Enumerations

Property	Type	Meaning
Enumerations	String	Set this property to constrain the values to the list that is specified in this property. For example, you might create a simple type called *RainbowColors*, and add Red, `Orange`, `Yellow`, `Green`, `Blue`, `Indigo`, and `Violet` to the enumerations list. You must ensure that you have all variations of the data that you are likely to receive in the message defined in the list. For example, Yellow, yellow, yel, and y might be variations of a single color. Select **Add** to add a default enumeration. Overtype the default with the data you require. To change an entry, select the entry, and click on the entry a second time (as distinct from double-click). You can now update the selected entry.

Patterns

Property	Type	Meaning
Patterns	String	`Patterns` are a regular expression, or a series of regular expressions, that are used to constrain the data within the simple type. For further information about patterns and their syntax see "Using regular expressions to parse data elements" on page 6301. Select **Add** to add a default pattern. Overtype the default with the data you require. To change an entry, select the entry, and click on the entry a second time (as distinct from double-click). You can now update the selected entry.

More information about the MRM domain.

Wildcard attribute logical properties:

The logical properties of a wildcard attribute.

Property	Type	Meaning
Namespace	String	Namespaces are a simple method for qualifying element and attribute names by associating them with namespaces identified by URI references. This field is initially blank.

Property	Type	Meaning
Process Content	Enumerated type	If a message contains an attribute that corresponds to a wildcard in the message model, `Process Content` defines how the attribute is validated. Select one of the following options: • strict. The parser can match only against attributes declared in the specified namespace. • lax. The parser attempts to match against attributes declared in all accessible namespaces. If the specified namespace cannot be found, an error is not generated. • skip. If you select skip, the parser does not perform validation on the attribute.

More information about the MRM domain.

Wildcard element logical properties:

The logical properties of a wildcard element include properties that specify the number of occurrences of the wildcard element.

Property	Type	Meaning
Namespace	String	Namespaces are a simple method for qualifying element and attribute names by associating them with namespaces identified by URI references. This field is initially blank.

Property	Type	Meaning
Process Content	Enumerated type	If a message contains an element that corresponds to a wildcard in the message model, `Process Content` defines how the element is validated. Select one of the following options: • strict. The parser can match only against elements declared in the specified namespace. • lax. The parser attempts to match against elements declared in any accessible namespace. If the specified namespace cannot be found, an error is not generated. • skip. If you select skip the parser does not perform validation on the element.

Occurrences

Property	Type	Meaning
Min Occurs	Integer	Specify the minimum number of times that the object can repeat. The default value is 1. If the value is set to 0, the object is optional. With the exception of `Max Occurs` being set to -1, if a value is set for `Min Occurs`, it must be less than or equal to the value in `Max Occurs`. This property is ignored by brokers that are earlier than WebSphere Message Broker Version 6.0.

Property	Type	Meaning
Max Occurs	Integer	Specify the maximum number of times that the object can repeat. The default value is 1. If this property is not set, the object cannot occur more than once. If this property is set to 0, it is interpreted as if the object does not exist in the message. It can also be set to -1, to indicate that the limit is unbounded and there is no maximum to the number of occurrences. This property is ignored by brokers that are earlier than WebSphere Message Broker Version 6.0.

"Deprecated message model object properties by object" on page 6090
Properties for compound elements and embedded simple types.

Compound element logical properties:

The logical properties of a compound element include properties that specify the number of occurrences of the compound element.

Property	Type	Meaning
Name	String	Specify a name for the object when you create it. Names can consist of alphanumeric characters, including the letters *A* through *Z*, *a* through *z*, and the digits *0* through *9*. They might also include the following punctuation characters; • - the hyphen • _ the underscore • . the period Names can start only with a letter or the underscore character, and not with a number, hyphen, or period. Names that begin with `xml`, or any variant of these characters (for example `XmL`), are reserved by the XML standards specification. Further details of naming conventions and allowable characters can be found in the Extensible Markup Language (XML) specification that can be found on the World Wide Web Consortium (W3C) Web site.

Property	Type	Meaning
Namespace	Enumerated type	Namespaces are a simple method for qualifying element and attribute names by associating them with namespaces identified by URI references. If <no target namespace> is displayed, a namespace has not been set for this object. If the property is inactive, the message set has not been configured to support namespaces. Where the property is active, namespaces that are available for selection are displayed in the drop-down list.
Nillable	Check box	Select this option if you want the element to be able to be defined as null. A null value is distinct from being empty, when the element contains no data.
Abstract	Check box	Select this option if you do not want the element to appear in the message, but require one of the members of its substitution group to appear in its place.

Value

Property	Type	Meaning
Default	Button and String	This property provides the default value for an element or attribute. **XMLNSC domain** When parsing with validation enabled, default values are applied to missing attributes and empty elements as required by the XML Schema 1.0 specification. When writing, elements or attributes that are missing from the message tree are not automatically added to the output XML bit stream, even if they have default values. If missing elements or attributes are required, the message tree can be serialized and then re-parsed with validation enabled. **MRM (CWF and TDS physical formats)** When writing a fixed-length portion of a message (CWF or fixed-length TDS), if an attribute or element is missing from the message tree, the default value is inserted into the bit stream so that the message structure is preserved. **MRM (XML physical format)** No support for default values **Other domains** No support for default values.

Property	Type	Meaning
Fixed	Button and String	This property provides the fixed value for an element or attribute. **XMLNSC domain** When parsing with validation enabled, if an attribute or element is present, the value is validated against the fixed value. If the values are not equal, a validation error is signalled. Also, when parsing with validation enabled, fixed values are applied to missing attributes and empty elements as required by the XML Schema 1.0 specification. When writing, elements or attributes that are missing from the message tree are not automatically added to the output XML bit stream, even if a fixed value has been specified. If missing elements or attributes are required, the message tree can be serialized and then re-parsed with validation enabled. **MRM (CWF and TDS physical formats)** When writing a fixed-length portion of a message (CWF or fixed-length TDS), if an attribute or element is missing from the message tree, the fixed value is inserted into the bit stream so that the message structure is preserved. **MRM (XML physical format)** No support for fixed values **Other domains** No support for fixed values.
Interpret Value As	Enumerated type	Specify if values stored within this object must be interpreted as having significance for the parser and, if so, the type of interpretation that must occur. Select one of the following options: • None This value is the default value, and indicates that the element or attribute does not have a key value associated with it. • MessageSetIdentity. Specifies that the value of the element or attribute corresponds to the identifier, name, or alias (in that priority order) that is associated with the message set where all subsequent embedded messages that are descendents of the enclosing message are defined. This value remains in force unless a new element or attribute MessageSetIdentity field is encountered which resets the MessageSetIdentity value. • MessageIdentity. Specifies that the value of the element or attribute corresponds to the name or alias (in that priority order) that is associated with a message, and acts as an identifier for subsequent embedded messages which are the immediate children of the enclosing message. This identity applies until a new element or attribute MessageIdentity field is encountered at the same level in the tree. The embedded message can be defined in either the current message set, or in a message set identified by using a MessageSetIdentity. **Note:** This property is applicable only when the type of the object is derived from xsd:string.

Occurrences

Property	Type	Meaning
Min Occurs	Integer	Specify the minimum number of times that the object can repeat. The default value is 1. If the value is set to 0, the object is optional. With the exception of `Max Occurs` being set to -1, if a value is set for `Min Occurs`, it must be less than or equal to the value in `Max Occurs`.

Property	Type	Meaning
Max Occurs	Integer	Specify the maximum number of times that the object can repeat. The default value is 1. If this property is not set, the object cannot occur more than once. If this property is set to 0, it is interpreted as if the object does not exist in the message. It can also be set to -1, to indicate that the limit is unbounded and there is no maximum to the number of occurrences.

Compound element logical properties:

The logical properties of a compound element include properties that specify the number of occurrences of the compound element.

Property	Type	Meaning
Name	String	Specify a name for the object when you create it. Names can consist of alphanumeric characters, including the letters *A* through *Z*, *a* through *z*, and the digits *0* through *9*. They might also include the following punctuation characters; • - the hyphen • _ the underscore • . the period Names can start only with a letter or the underscore character, and not with a number, hyphen, or period. Names that begin with `xml`, or any variant of these characters (for example `XmL`), are reserved by the XML standards specification. Further details of naming conventions and allowable characters can be found in the Extensible Markup Language (XML) specification that can be found on the World Wide Web Consortium (W3C) Web site.
Namespace	Enumerated type	Namespaces are a simple method for qualifying element and attribute names by associating them with namespaces identified by URI references. If <no target namespace> is displayed, a namespace has not been set for this object. If the property is inactive, the message set has not been configured to support namespaces. Where the property is active, namespaces that are available for selection are displayed in the drop-down list.

Property	Type	Meaning
Nillable	Check box	Select this option if you want the element to be able to be defined as null. A null value is distinct from being empty, when the element contains no data.
Abstract	Check box	Select this option if you do not want the element to appear in the message, but require one of the members of its substitution group to appear in its place.

Value

Property	Type	Meaning
Default	Button and String	This property provides the default value for an element or attribute. **XMLNSC domain** When parsing with validation enabled, default values are applied to missing attributes and empty elements as required by the XML Schema 1.0 specification. When writing, elements or attributes that are missing from the message tree are not automatically added to the output XML bit stream, even if they have default values. If missing elements or attributes are required, the message tree can be serialized and then re-parsed with validation enabled. **MRM (CWF and TDS physical formats)** When writing a fixed-length portion of a message (CWF or fixed-length TDS), if an attribute or element is missing from the message tree, the default value is inserted into the bit stream so that the message structure is preserved. **MRM (XML physical format)** No support for default values **Other domains** No support for default values.
Fixed	Button and String	This property provides the fixed value for an element or attribute. **XMLNSC domain** When parsing with validation enabled, if an attribute or element is present, the value is validated against the fixed value. If the values are not equal, a validation error is signalled. Also, when parsing with validation enabled, fixed values are applied to missing attributes and empty elements as required by the XML Schema 1.0 specification. When writing, elements or attributes that are missing from the message tree are not automatically added to the output XML bit stream, even if a fixed value has been specified. If missing elements or attributes are required, the message tree can be serialized and then re-parsed with validation enabled. **MRM (CWF and TDS physical formats)** When writing a fixed-length portion of a message (CWF or fixed-length TDS), if an attribute or element is missing from the message tree, the fixed value is inserted into the bit stream so that the message structure is preserved. **MRM (XML physical format)** No support for fixed values **Other domains** No support for fixed values.

Property	Type	Meaning
Interpret Value As	Enumerated type	Specify if values stored within this object must be interpreted as having significance for the parser and, if so, the type of interpretation that must occur. Select one of the following options: • None This value is the default value, and indicates that the element or attribute does not have a key value associated with it. • MessageSetIdentity. Specifies that the value of the element or attribute corresponds to the identifier, name, or alias (in that priority order) that is associated with the message set where all subsequent embedded messages that are descendents of the enclosing message are defined. This value remains in force unless a new element or attribute MessageSetIdentity field is encountered which resets the MessageSetIdentity value. • MessageIdentity. Specifies that the value of the element or attribute corresponds to the name or alias (in that priority order) that is associated with a message, and acts as an identifier for subsequent embedded messages which are the immediate children of the enclosing message. This identity applies until a new element or attribute MessageIdentity field is encountered at the same level in the tree. The embedded message can be defined in either the current message set, or in a message set identified by using a MessageSetIdentity. **Note:** This property is applicable only when the type of the object is derived from xsd:string.

Occurrences

Property	Type	Meaning
Min Occurs	Integer	Specify the minimum number of times that the object can repeat. The default value is 1. If the value is set to 0, the object is optional. With the exception of `Max Occurs` being set to -1, if a value is set for `Min Occurs`, it must be less than or equal to the value in `Max Occurs`.
Max Occurs	Integer	Specify the maximum number of times that the object can repeat. The default value is 1. If this property is not set, the object cannot occur more than once. If this property is set to 0, it is interpreted as if the object does not exist in the message. It can also be set to -1, to indicate that the limit is unbounded and there is no maximum to the number of occurrences.

"Compound element properties" on page 6091
Logical, CWF, XML, TDS, and document properties for a compound element.

CWF properties for compound element binary types:

Physical representation, byte alignment, and occurrences.

The Custom Wire Format properties described here apply to:

- Objects: Compound elements

Physical representation

Property	Type	Meaning
Length	Button and Integer	If you have selected the length to be defined by *Length*, enter the number of length units for the element. The minimum value that you can specify is 1. The maximum value that you can specify is 2147483647. The default value is empty (not set).
Length Reference	Button and Enumerated type	If you have selected the length to be defined by *Length Reference*, select the name of the integer object that specifies the length of this object. Make your selection from the displayed list of integer objects that are defined as siblings of the current object, and occur before it in the structure of the message. For information about reordering elements, see "Reordering objects" on page 2900.

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. The length is given in bytes. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`* or *`Length Reference`* property. The default is `Bytes`.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • `1 Bytes`. The default value. • `2 Bytes` • `4 Bytes` • `8 Bytes` • `16 Bytes`
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.

Property	Type	Meaning
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *`Repeat Reference`* is specified, it overrides any setting for the *`Max Occurs`* logical property when parsing and writing the message, but not for validation of the message.

CWF properties for compound element Boolean types:

Byte alignment and occurrences.

The Custom Wire Format properties described here apply to:

- Objects: Compound elements

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • `1 Bytes`. The default value. • `2 Bytes` • `4 Bytes` • `8 Bytes` • `16 Bytes`
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *`Repeat Reference`* is specified, it overrides any setting for the *`Max Occurs`* logical property when parsing and writing the message, but not for validation of the message.

"Deprecated message model object properties" on page 6069
Some objects in the message model are deprecated, but you can reference the information for their properties.

"Compound element properties" on page 6091
Logical, CWF, XML, TDS, and document properties for a compound element.

"Compound element CWF properties" on page 6077
The properties, and their permissible values, vary according to the object type.

CWF properties for compound element dateTime types:

Physical representation, null values, byte alignment, and occurrences.

The Custom Wire Format properties described here apply to:

- Objects: Compound elements

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Fixed Length String`. The element's length is determined by other length properties as follows. • `Length Encoded String 1`. The first byte of the element contains the length of the string following the length byte in length units. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The element's first 2 bytes contain the length of the string following the two length bytes in length units. The maximum length of a `Length Encoded String 2` element is 65535 length units. The two length bytes are in the format of the WebSphere MQ queue manager Encoding. • `Null Terminated String`. The string ends with the hexadecimal NULL character, `X'00'`. • `Packed Decimal`. The dateTime is coded as a Packed Decimal number. It is valid only if the *`DateTime Format`* property represents numeric-only data. • `Binary`. The dateTime is encoded as a binary sequence of bytes. If you select this option, the range of symbols that you can specify for the Format String property is less than the range of symbols you can specify if you select a string option (see "DateTime formats" on page 6310 for details). • `Time Seconds`. This value supports C time_t and Java Date and Time objects. It is valid only if the *`DateTime Format`* property represents numeric-only data. • `Time Milliseconds`. This value supports C time_t and Java Date and Time objects. It is valid only if the *`DateTime Format`* property represents numeric-only data. The default value is `fixed length string`.
DateTime Format	String	Specify a template for date and time. The default dateTime format is dependent on the logical type of the object. For information about the defaults for the dateTime format according to the logical type, see "DateTime defaults by logical type" on page 6320. See "DateTime formats" on page 6310 for details of date and time formats.
Length	Button and Integer	If you have selected a *`Physical Type`* of `Fixed Length String`, `Packed Decimal`, or `Binary`, and have selected the length to be defined by *`Length`*, enter the number of length units for the element. The minimum value that you can specify is 1 for all three physical types. The maximum value that you can specify is `256` for `Fixed Length String`, `10` for `Packed Decimal`, and `2147483647` for `Binary`. The default value is 0 (zero).
Length Reference	Button and Enumerated type	If you have selected the length to be defined by *`Length Reference`*, select the name of the integer object that specifies the length of this object. Make your selection from the displayed list of integer objects that are defined as siblings of the current object, and occur before it in the structure of the message. For information about reordering elements, see "Reordering objects" on page 2900.

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. The length is given in bytes. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`* or *`Length Reference`* property. The default is `Bytes`.
Signed	Check box	Specify whether the value is signed. This property is applicable only if the *`Physical type`* property is `Packed Decimal`. By default, this check box is cleared, which indicates that the value is not signed.
Justification	Enumerated type	If you have set the *`Physical Type`* property to `Fixed Length String`, select `Left Justify` (the default value) or `Right Justify` from the list. If you have selected another value for *`Physical Type`*, this property is inactive.

Property	Type	Meaning
Padding Character	String	If you have set the *Physical Type* property to Fixed Length String, and the *Justification* property is either Left Justify or Right Justify, this property is applicable. When writing an output message, use the padding character to fill out the remaining character positions when the string length is less than the length implied by the *Length* or *Length Reference* property. Whether the string is padded from the left or the right is governed by the *Justification* property. When parsing an input message, the padding character is trimmed from the end of the string. Whether the string is trimmed from the left or the right is governed by the *Justification* property. Specify this character in one of the following ways: • Select NUL, '0', or SPACE from the displayed list. • Enter a character between quotation marks; for example, "c" or 'c', where c is any alphanumeric character. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form 0xYY, where YY is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, it is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the displayed list. The option that you select determines the value that you must set for the property *Encoding Null Value*: • NULLPadFill. This option is valid only if *Physical Type* is Fixed Length String. The field is filled with the value specified by the *Padding Character*. The default value. • NULLLogicalValue. The *Encoding Null Value* property is first converted to an actual value, and rendered in the way specified for the field. • NULLLiteralValue. This specifies that *Encoding Null Value* contains a value that is directly substituted as if it is a string. Use this option when the value you have set for *Encoding Null Value* to specify a null date is not a dateTime value, or does not conform to the standard dateTime format yyyy-MM-dd 'T'HH:mm:ss. • NULLLiteralFill. The field is filled with the value specified by the *Encoding Null Value*. *Encoding Null Value* must resolve to a single character.
Encoding Null Value	String	If you set the *Encoding Null* property to NULLPadFill, this property is disabled. If you set the *Encoding Null* property to NULLLogicalValue, you must set this property to an ISO8601 dateTime format. These formats are described in "DateTime as string data" on page 6311. For example, specify a value conforming to yyyy-MM-dd'T'HH:mm:ss such as 1970-12-01. If you set the *Encoding Null* property to NULLLiteralValue, you can enter any value that is the same length as the field. If you set the *Encoding Null* property to NULLLiteralFill, the value must resolve to a single character. Set the character in one of the following ways: • Select SPACE, NUL, 0x00 or 0xFF from the displayed list • Enter a character between quotation marks, for example 'c' or "c", where c is any alphanumeric character. • Enter a hexadecimal character code in the form 0xYY where YY is a hexadecimal value. • Enter a decimal character code in the form YY where YY is a decimal value. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal format.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • 1 Bytes. The default value. • 2 Bytes • 4 Bytes • 8 Bytes • 16 Bytes

Property	Type	Meaning
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *`Repeat Reference`* is specified, it overrides any setting for the *`Max Occurs`* logical property when parsing and writing the message, but not for validation of the message.

The properties, and their permissible values, vary according to the object type.

CWF properties for compound element decimal types:

Physical representation, null values, byte alignment, and occurrences.

The Custom Wire Format properties described here apply to:

- Objects: Compound elements

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Integer`. This equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. Equates to the COMP-3 data type in COBOL. • `External Decimal`. Equates to the data type PIC 9 USAGE DISPLAY in COBOL. The representation of numeric elements can be affected by the Encoding and CodedCharSetId attributes that are set for the WebSphere MQ queue manager: • Elements that have *`Physical Type`* set to `Integer` and `Packed Decimal` are represented in the appropriate WebSphere MQ Encoding value. • Elements that have *`Physical Type`* set to `External Decimal` are represented in the WebSphere MQ CodedCharSetId value.
Length	Integer	Enter the number of bytes to specify the element length: • If you set the *`Physical Type`* to `Integer`, select `1`, `2`, or `4` (the default) from the displayed list. • If you set the *`Physical Type`* to `Packed Decimal`, enter a value between 1 and 10. • If you set the *`Physical Type`* to `Extended Decimal`, enter a value between 1 and 256. (Numbers greater than the maximum COBOL PICTURE clause of 18 are assumed to be 18.)

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`*. The default is `Bytes`.
Signed	Check box	Select (the default) or clear this property. This property is used with *`Sign Orientation`*.
Sign EBCDIC Custom Overpunched	Check box	If the *`Physical Type`* is set to `External Decimal` and the *`Signed EBCDIC Custom`* property is set, this indicates that the Sign EBCDIC Custom Overpunched representation is to be used within an ASCII environment. If this check box is not selected (the default), the Sign ASCII representation is used. The setting of the *`Sign EBCDIC Custom Overpunched`* check box is appropriate only if the *`Sign Orientation`* property is set to `Leading` or `Trailing` (indicating that the element/attribute has an embedded sign representation). The check box is not available if the element/attribute is unsigned (for example, if the *`Signed`* check box is not set).

Property	Type	Meaning
Sign Orientation	Enumerated type	If you have set *Physical Type* to External Decimal and you have selected *Signed*, choose from the following options that represent the COBOL options for displaying numeric data: • Leading Overpunched. This option sets a bit in the first byte if the number is negative. No setting is made if the number is positive. For example, the ASCII hexadecimal representation of the number 22 is x'3232'. Using this option, the number +22 would be x'3232' and the number -22 would be x'7232'. The default value. • Leading Separate. This option sets the first byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. • Trailing Overpunched. This option sets a bit in the last byte if the number is negative. No setting is made if the number is positive. Using this option, the number +22 would be x'3232' and the number -22 would be x'3272'. • Trailing Separate. This option sets the last byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. If you have set *Physical Type* to any other value, the value Not Applicable is set for you.
Virtual Decimal Point	Integer	Specify the number of places to the left (for a positive value) or right (for a negative value) that a decimal point is to be moved from its assumed position. For example, a decimal element containing 1234 with a Virtual Decimal value of 3 is 1.234, equivalent to 'V' or 'P' in a COBOL picture clause. There is no C equivalent
Justification	Enumerated type	If you have set the *Physical Type* property to External Decimal, select Left Justify or Right Justify (the default value) from the list. If you have selected another value for *Physical Type*, this property is inactive.

Property	Type	Meaning
Padding Character	String	The padding character is used to fill out the remaining character positions when the string length is less than the specified string size. If you have set the *Physical Type* property to Extended Decimal, and the *Justification* property is either Left Justify or Right Justify, specify this character in one of the following ways: • Select NUL, '0', or SPACE from the displayed list. • Enter a character between quotation marks; for example, "c" or 'c', where c is any alphanumeric character. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form 0xYY, where YY is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, this is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the displayed list: • NULLPadFill. This option is valid only if *Physical Type* is External Decimal. The field is filled with the value specified by the *Padding Character*. *Encoding Null Value* must be set to an empty string. • NULLLogicalValue. The *Encoding Null Value* is transformed to match the required format for the field. The default value. • NULLLiteralValue. The *Encoding Null Value* is directly substituted as if it is a string. You can specify a nonnumeric value for *Encoding Null Value*. • NULLLiteralFill. The field is filled with the value specified by the *Encoding Null Value*. *Encoding Null Value* must resolve to a single character.

Property	Type	Meaning
Encoding Null Value	String	The use of this property depends on the *Encoding Null* property, except for NULLLiteralFill. The default value is zero. If you set the *Encoding Null* property to NULLLiteralFill, the value must resolve to a single character. Set the character in one of the following ways: • Select SPACE, NUL, 0x00 or 0xFF from the displayed list • Enter a character between quotation marks, for example 'c' or "c", where c is any alphanumeric character. • Enter a hexadecimal character in the form 0xYY where YY is a hexadecimal value. • Enter a decimal character code in the form YY where YY is a decimal value. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal format.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • 1 Bytes. The default value. • 2 Bytes • 4 Bytes • 8 Bytes • 16 Bytes
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *Repeat Reference* is specified, it overrides any setting for the *Max Occurs* logical property when parsing and writing the message, but not for validation of the message.

CWF properties for compound element float types:

Physical representation, null values, byte alignment, and occurrences.

The Custom Wire Format properties described here apply to:

- Objects: Compound elements

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Integer`. This equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Float`. This equates to the data type FLOAT or DOUBLE in C or the COMP-1 or COMP-2 data type in COBOL and is the default value. • `Packed Decimal`. Equates to the COMP-3 data type in COBOL. • `External Decimal`. Equates to the data type PIC 9 USAGE DISPLAY in COBOL. The representation of numeric elements can be affected by the Encoding and CodedCharSetId attributes that are set for the WebSphere MQ queue manager: • Elements that have *`Physical Type`* set to `Integer`, `Packed Decimal`, and `Float` are represented in the appropriate WebSphere MQ Encoding value. • Elements that have *`Physical Type`* set to `External Decimal` are represented in the WebSphere MQ CodedCharSetId value.
Length	Integer	Enter the number of bytes to specify the element length: • If you set the *`Physical Type`* to `Float`, select a value from the displayed list. The default value is 8. • If you set the *`Physical Type`* to `Integer`, select `1`, `2`, or `4` (the default) from the displayed list. • If you set the *`Physical Type`* to `Packed Decimal`, enter a value between 1 and 10. • If you set the *`Physical Type`* to `Extended Decimal`, enter a value between 1 and 256. (Numbers greater than the maximum COBOL PICTURE clause of 18 are assumed to be 18.)

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`*. The default is `Bytes`.
Signed	Check box	Select or clear (unsigned, the default) this property. If you have set *`Physical Type`* to `Float`, this is selected. This property is used with *`Sign Orientation`*.
Sign EBCDIC Custom Overpunched	Check box	If the *`Physical Type`* is set to `External Decimal` and the *`Signed EBCDIC Custom`* property is set, this indicates that the Sign EBCDIC Custom Overpunched representation is to be used within an ASCII environment. If this check box is not selected (the default), the Sign ASCII representation is used. The setting of the *`Sign EBCDIC Custom Overpunched`* check box is appropriate only if the *`Sign Orientation`* property is set to `Leading` or `Trailing` (indicating that the element/attribute has an embedded sign representation). The check box is not available if the element/attribute is unsigned (for example, if the *`Signed`* check box is not set).

Property	Type	Meaning
Sign Orientation	Enumerated type	If you have set *Physical Type* to External Decimal and you have selected *Signed*, choose from the following options that represent the COBOL options for displaying numeric data: • Leading Overpunched. This option sets a bit in the first byte if the number is negative. No setting is made if the number is positive. For example, the ASCII hexadecimal representation of the number 22 is x'3232'. Using this option, the number +22 would be x'3232' and the number -22 would be x'7232'. The default value. • Leading Separate. This option sets the first byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. • Trailing Overpunched. This option sets a bit in the last byte if the number is negative. No setting is made if the number is positive. Using this option, the number +22 would be x'3232' and the number -22 would be x'3272'. • Trailing Separate. This option sets the last byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. If you have set *Physical Type* to any other value, the value Not Applicable is set for you.
Virtual Decimal Point	Integer	Specify the number of places to the left (for a positive value) or right (for a negative value) that a decimal point is to be moved from its assumed position. For example, a float element containing 1234 with a Virtual Decimal value of 3 is 1.234. This property is not applicable if you have set *Physical Type* to Float.
Justification	Enumerated type	If you have set the *Physical Type* property to External Decimal, select Left Justify or Right Justify (the default value) from the list. If you have selected another value for *Physical Type*, this property is inactive.

Property	Type	Meaning
Padding Character	String	The padding character is used to fill out the remaining character positions when the string length is less than the specified string size. If you have set the *Physical Type* property to Extended Decimal, and the *Justification* property is either Left Justify or Right Justify, specify this character in one of the following ways: • Select NUL, '0', or SPACE from the displayed list. • Enter a character between quotation marks; for example, "c" or 'c', where c is any alphanumeric character. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form 0xYY, where YY is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, this is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the displayed list: • NULLPadFill. This option is valid only if *Physical Type* is External Decimal. The field is filled with the value specified by the *Padding Character*. *Encoding Null Value* must be set to an empty string. • NULLLogicalValue. The *Encoding Null Value* is transformed to match the required format for the field. The default value. • NULLLiteralValue. The *Encoding Null Value* is directly substituted as if it is a string. You can specify a nonnumeric value for *Encoding Null Value*. • NULLLiteralFill. The field is filled with the value specified by the *Encoding Null Value*. *Encoding Null Value* must resolve to a single character.

Property	Type	Meaning
Encoding Null Value	String	The use of this property depends on the *Encoding Null* property, except for NULLLiteralFill. The default value is zero. If you set the *Encoding Null* property to NULLLiteralFill, the value must resolve to a single character. Set the character in one of the following ways: • Select SPACE, NUL, 0x00 or 0xFF from the displayed list • Enter a character between quotation marks, for example 'c' or "c", where c is any alphanumeric character. • Enter a hexadecimal character in the form 0xYY where YY is a hexadecimal value. • Enter a decimal character code in the form YY where YY is a decimal value. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal format.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • 1 Bytes. The default value. • 2 Bytes • 4 Bytes • 8 Bytes • 16 Bytes
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *Repeat Reference* is specified, it overrides any setting for the *Max Occurs* logical property when parsing and writing the message, but not for validation of the message.

CWF properties for compound element integer types:

Physical representation, null values, byte alignment, and occurrences.

The Custom Wire Format properties described here apply to:

- Objects: Compound elements

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Integer`. This equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. Equates to the COMP-3 data type in COBOL. • `External Decimal`. Equates to the data type PIC 9 USAGE DISPLAY in COBOL. The representation of numeric elements can be affected by the Encoding and CodedCharSetId attributes that are set for the WebSphere MQ queue manager: • Elements that have *`Physical Type`* set to `Integer` and `Packed Decimal` are represented in the appropriate WebSphere MQ Encoding value. • Elements that have *`Physical Type`* set to `External Decimal` are represented in the WebSphere MQ CodedCharSetId value.
Length	Integer	Enter the number of bytes to specify the element length: • If you set the *`Physical Type`* to `Integer`, select `1`, `2`, or `4` (the default) from the displayed list. • If you have set *`Physical Type`* to `Packed Decimal`, enter a value between 1 and 6. • If you have set *`Physical Type`* to `Extended Decimal`, enter a value between 1 and 11.
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`*. The default is `Bytes`.
Signed	Check box	Select (the default) or clear this property. This property is used with *`Sign Orientation`*.

Property	Type	Meaning
Sign EBCDIC Custom Overpunched	Check box	If the *Physical Type* is set to External Decimal and the *Signed EBCDIC Custom* property is set, this indicates that the Sign EBCDIC Custom Overpunched representation is to be used within an ASCII environment. If this check box is not selected (the default), the Sign ASCII representation is used. The setting of the *Sign EBCDIC Custom Overpunched* check box is appropriate only if the *Sign Orientation* property is set to Leading or Trailing (indicating that the element/attribute has an embedded sign representation). The check box is not available if the element/attribute is unsigned (for example, if the *Signed* check box is not set).
Sign Orientation	Enumerated type	If you have set *Physical Type* to External Decimal and you have selected *Signed*, choose from the following options that represent the COBOL options for displaying numeric data: • Leading Overpunched. This option sets a bit in the first byte if the number is negative. No setting is made if the number is positive. For example, the ASCII hexadecimal representation of the number 22 is x'3232'. Using this option, the number +22 would be x'3232' and the number -22 would be x'7232'. The default value. • Leading Separate. This option sets the first byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. • Trailing Overpunched. This option sets a bit in the last byte if the number is negative. No setting is made if the number is positive. Using this option, the number +22 would be x'3232' and the number -22 would be x'3272'. • Trailing Separate. This option sets the last byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. If you have set *Physical Type* to any other value, the value Not Applicable is set for you.
Justification	Enumerated type	If you have set the *Physical Type* property to External Decimal, select Left Justify or Right Justify (the default value) from the list. If you have selected another value for *Physical Type*, this property is inactive.

Property	Type	Meaning
Padding Character	String	The padding character is used to fill out the remaining character positions when the string length is less than the specified string size. If you have set the *Physical Type* property to Extended Decimal, and the *Justification* property is either Left Justify or Right Justify, specify this character in one of the following ways: • Select NUL, '0', or SPACE from the displayed list. • Enter a character between quotation marks; for example, "c" or 'c', where c is any alphanumeric character. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form 0xYY, where YY is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, this is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the displayed list: • NULLPadFill. This option is valid only if *Physical Type* is External Decimal. The field is filled with the value specified by the *Padding Character*. *Encoding Null Value* must be set to an empty string. • NULLLogicalValue. The *Encoding Null Value* is transformed to match the required format for the field. The default value. • NULLLiteralValue. The *Encoding Null Value* is directly substituted as if it is a string. You can specify a nonnumeric value for *Encoding Null Value*. • NULLLiteralFill. The field is filled with the value specified by the *Encoding Null Value*. *Encoding Null Value* must resolve to a single character.

Property	Type	Meaning
Encoding Null Value	String	The use of this property depends on the *Encoding Null* property, except for NULLLiteralFill. The default value is zero. If you set the *Encoding Null* property to NULLLiteralFill, the value must resolve to a single character. Set the character in one of the following ways: • Select SPACE, NUL, 0x00 or 0xFF from the displayed list • Enter a character between quotation marks, for example 'c' or "c", where c is any alphanumeric character. • Enter a hexadecimal character in the form 0xYY where YY is a hexadecimal value. • Enter a decimal character code in the form YY where YY is a decimal value. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal format.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • 1 Bytes. The default value. • 2 Bytes • 4 Bytes • 8 Bytes • 16 Bytes
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *Repeat Reference* is specified, it overrides any setting for the *Max Occurs* logical property when parsing and writing the message, but not for validation of the message.

CWF properties for compound element string types:

Physical representation, null values, byte alignment, and occurrences.

The Custom Wire Format properties described here apply to:

- Objects: Compound elements

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Fixed Length String`. The element's length is determined by other length properties as follows. • `Length Encoded String 1`. The first byte of the element contains the length of the string following the length byte in length units. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The element's first 2 bytes contain the length of the string following the two length bytes in length units. The maximum length of a `Length Encoded String 2` element is 65535 length units. The two length bytes are in the format of the WebSphere MQ queue manager Encoding. • `Null Terminated String`. The string ends with the hexadecimal NULL character, `X'00'`. The default is `Fixed Length String`.
Length	Button and Integer	If you have selected a *`Physical Type`* of `Fixed Length String` or `Binary`, and have selected the length to be defined by *`Length`*, enter the number of length units for the element. The minimum value that you can specify is `0` (zero), the maximum value that you can specify is `2147483647` The default value is `0` (zero).
Length Reference	Button and Enumerated type	If you have selected the length to be defined by *`Length Reference`*, select the name of the integer object that specifies the length of this object. Make your selection from the displayed list of integer objects that are defined as siblings of the current object, and occur before it in the structure of the message. For information about reordering elements, see “Reordering objects” on page 2900.

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. The length is given in bytes. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`* or *`Length Reference`* property. The default is `Bytes`.
Justification	Enumerated type	If you have set the *`Physical Type`* property to `Fixed Length String`, select `Left Justify` (the default value) or `Right Justify` from the list. If you have selected another value for *`Physical Type`*, this property is inactive.

Property	Type	Meaning
Padding Character	String	If you have set the *Physical Type* property to `Fixed Length String`, and the *Justification* property is either `Left Justify` or `Right Justify`, this property is applicable. When writing an output message, use the padding character to fill out the remaining character positions when the string length is less than the length implied by the *Length* or *Length Reference* property. Whether the string is padded from the left or the right is governed by the *Justification* property. When parsing an input message, the padding character is trimmed from the end of the string. Whether the string is trimmed from the left or the right is governed by the *Justification* property. Specify this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the displayed list. • Enter a character between quotation marks; for example, `"c"` or `'c'`, where c is any alphanumeric character. • Enter a Unicode value in the form `U+xxxx` where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, it is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the displayed list: • `NULLPadFill`. This is valid only if *`Physical Type`* is `Fixed Length String`. The field is filled with the value specified by the *`Padding Character`*. *`Encoding Null Value`* must be set to an empty string. • `NULLLogicalValue`. The *`Encoding Null Value`* is transformed to match the required format for the field. The default value. • `NULLLiteralValue`. The *`Encoding Null Value`* is directly substituted as if it is a string. • `NULLLiteralFill`. The field is filled with the value specified by the *`Encoding Null Value`*. *`Encoding Null Value`* must resolve to a single character.
Encoding Null Value	STRING	The use of this property depends on the *`Encoding Null`* property. If specified, its length must be equal to the length of the string element, except for `NULLLiteralFill`. The default value is empty (not set). If you set the *`Encoding Null`* property to `NULLLiteralFill`, the value must resolve to a single character. Set the character in one of the following ways: • Select `SPACE`, `NUL`, `0x00` or `0xFF` from the displayed list • Enter a character between quotation marks, for example `'c'` or `"c"`, where `c` is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY` where `YY` is a hexadecimal value. • Enter a decimal character code in the form `YY` where `YY` is a decimal value. • Enter a Unicode value in the form `U+xxxx` where `xxxx` is a Unicode value specified in hexadecimal format.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • `1 Bytes`. The default value. • `2 Bytes` • `4 Bytes` • `8 Bytes` • `16 Bytes`
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *Repeat Reference* is specified, it overrides any setting for the *Max Occurs* logical property when parsing and writing the message, but not for validation of the message.

Compound element XML properties:

The properties, and their permissible values, vary according to the object type.

The properties that are displayed on the object page, and the values that those properties can take, can vary according to the type of the object. For example, the properties for type *string* are different from those of type *Boolean*. Select the link for the object type from the following table.

Type of object	Properties
Binary types	• ComIbmMrm _BaseValueBinary
Boolean types	• ComIbmMrm _BaseValueBoolean
DateTime types	• ComIbmMrm _BaseValueDateTime
Decimal types	• ComIbmMrm _BaseValueDecimal
Float types	• ComIbmMrm _BaseValueFloat
Integer types	• ComIbmMrm _BaseValueInt
String types	• ComIbmMrm _BaseValueString

XML wire format properties for compound element binary types:

Field identification and physical representation.

The XML Wire Format properties described here apply to:

- Objects: Compound elements

Field identification

A number of the following properties only become active depending on the value that *Render* property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their *XML Name*property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLAttribute`. If you select this value, the object (or type) is rendered as an attribute of the parent XML object. The identity of the child is determined by the attribute name. The value is the attribute value. This is only valid for simple elements. If you select this value for more than one object , you must set their *XML Name* property to different values. This is the default value for attribute objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in *ID Attribute Name* and a value as specified in *ID Attribute Value*. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set *XML Name*, *ID Attribute Name*, *ID Attribute Value* to the same values: – You must also set *Value Attribute Name* to the same value for the two objects. – Both objects must refer to the same element. • `XMLElementAttrVal`. If you specify this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the value of a specified attribute. The name of the attribute is specified in *Value Attribute Name*. • `XMLElementAttrIDVal`. This option combines the two options, `XMLElementAttrID` and `XMLElementAttrVal`. The object is rendered as a child of the parent complex type. The identity of the child is determined by the value of *ID Attribute Name*. The value is the value of *ID Attribute Value*. If you select this value for one object, and set this same value or the value `XMLElementAttrID` for a second object, and set *XML Name*, *ID Attribute Name*, *ID Attribute Value* to the same values: – You must also set *Value Attribute Name* to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.

Property	Type	Meaning
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.
Value Attribute Name	String	Specify the name of the attribute used for the value of the child. This must be a valid XML Attribute Name. This is only used if required by the setting of *Render*. The default value is `val`.
Namespace	String	Enter the namespace associated with the *Value Attribute*.

Physical representation

Property	Type	Meaning
Encoding	String	Select one of the following values from the drop-down list: : • `CDatahex` (the default). Hexadecimal values in this field are specified with the CDATA qualifier, for example <e1><![CDATA[62]]></e1> • `hex`. Hexadecimal values in this field are specified as digits only, for example <e1>62</e1>. • `base64`. Values in this field are specified as digits only, coded in base 64.

XML wire format properties for compound element Boolean types:

Field identification.

The XML Wire Format properties described here apply to:

- Objects: Compound elements

Field identification

A number of the following properties only become active depending on the value that *Render* property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their *`XML Name`*property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLAttribute`. If you select this value, the object (or type) is rendered as an attribute of the parent XML object. The identity of the child is determined by the attribute name. The value is the attribute value. This is only valid for simple elements. If you select this value for more than one object , you must set their *`XML Name`* property to different values. This is the default value for attribute objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in *`ID Attribute Name`* and a value as specified in *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. • `XMLElementAttrVal`. If you specify this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the value of a specified attribute. The name of the attribute is specified in *`Value Attribute Name`*. • `XMLElementAttrIDVal`. This option combines the two options, `XMLElementAttrID` and `XMLElementAttrVal`. The object is rendered as a child of the parent complex type. The identity of the child is determined by the value of *`ID Attribute Name`*. The value is the value of *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrID` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.

Property	Type	Meaning
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.
Value Attribute Name	String	Specify the name of the attribute used for the value of the child. This must be a valid XML Attribute Name. This is only used if required by the setting of *Render*. The default value is `val`.
Namespace	String	Enter the namespace associated with the *Value Attribute*.

XML wire format properties for compound element dateTime types:

Field identification and physical representation.

The XML Wire Format properties described here apply to:

- Objects: Compound elements

Field identification

A number of the following properties only become active depending on the value that *Render* property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their *XML Name*property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLAttribute`. If you select this value, the object (or type) is rendered as an attribute of the parent XML object. The identity of the child is determined by the attribute name. The value is the attribute value. This is only valid for simple elements. If you select this value for more than one object , you must set their *XML Name* property to different values. This is the default value for attribute objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in *ID Attribute Name* and a value as specified in *ID Attribute Value*. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set *XML Name*, *ID Attribute Name*, *ID Attribute Value* to the same values: – You must also set *Value Attribute Name* to the same value for the two objects. – Both objects must refer to the same element. • `XMLElementAttrVal`. If you specify this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the value of a specified attribute. The name of the attribute is specified in *Value Attribute Name*. • `XMLElementAttrIDVal`. This option combines the two options, `XMLElementAttrID` and `XMLElementAttrVal`. The object is rendered as a child of the parent complex type. The identity of the child is determined by the value of *ID Attribute Name*. The value is the value of *ID Attribute Value*. If you select this value for one object, and set this same value or the value `XMLElementAttrID` for a second object, and set *XML Name*, *ID Attribute Name*, *ID Attribute Value* to the same values: – You must also set *Value Attribute Name* to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.

Property	Type	Meaning
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.
Value Attribute Name	String	Specify the name of the attribute used for the value of the child. This must be a valid XML Attribute Name. This is only used if required by the setting of *Render*. The default value is `val`.
Namespace	String	Enter the namespace associated with the *Value Attribute*.

Physical representation

Property	Type	Meaning
DateTime Format	String	Specify a format string that specifies the rendering of the value for dateTime elements. The default dateTime format is dependent on the logical type of the object. For information about the defaults for the dateTime format according to the logical type see “DateTime defaults by logical type” on page 6320. See “DateTime formats” on page 6310 for details of dateTime formats.

Field identification.

The XML Wire Format properties described here apply to:

- Objects: Compound elements

Field identification

A number of the following properties only become active depending on the value that *Render* property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their *`XML Name`*property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLAttribute`. If you select this value, the object (or type) is rendered as an attribute of the parent XML object. The identity of the child is determined by the attribute name. The value is the attribute value. This is only valid for simple elements. If you select this value for more than one object , you must set their *`XML Name`* property to different values. This is the default value for attribute objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in *`ID Attribute Name`* and a value as specified in *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. • `XMLElementAttrVal`. If you specify this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the value of a specified attribute. The name of the attribute is specified in *`Value Attribute Name`*. • `XMLElementAttrIDVal`. This option combines the two options, `XMLElementAttrID` and `XMLElementAttrVal`. The object is rendered as a child of the parent complex type. The identity of the child is determined by the value of *`ID Attribute Name`*. The value is the value of *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrID` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.

Property	Type	Meaning
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.
Value Attribute Name	String	Specify the name of the attribute used for the value of the child. This must be a valid XML Attribute Name. This is only used if required by the setting of *Render*. The default value is `val`.
Namespace	String	Enter the namespace associated with the *Value Attribute*.

Field identification

A number of the following properties only become active depending on the value that *Render* property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their *XML Name*property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLAttribute`. If you select this value, the object (or type) is rendered as an attribute of the parent XML object. The identity of the child is determined by the attribute name. The value is the attribute value. This is only valid for simple elements. If you select this value for more than one object , you must set their *XML Name* property to different values. This is the default value for attribute objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in *ID Attribute Name* and a value as specified in *ID Attribute Value*. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set *XML Name*, *ID Attribute Name*, *ID Attribute Value* to the same values: – You must also set *Value Attribute Name* to the same value for the two objects. – Both objects must refer to the same element. • `XMLElementAttrVal`. If you specify this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the value of a specified attribute. The name of the attribute is specified in *Value Attribute Name*. • `XMLElementAttrIDVal`. This option combines the two options, `XMLElementAttrID` and `XMLElementAttrVal`. The object is rendered as a child of the parent complex type. The identity of the child is determined by the value of *ID Attribute Name*. The value is the value of *ID Attribute Value*. If you select this value for one object, and set this same value or the value `XMLElementAttrID` for a second object, and set *XML Name*, *ID Attribute Name*, *ID Attribute Value* to the same values: – You must also set *Value Attribute Name* to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.

Property	Type	Meaning
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.
Value Attribute Name	String	Specify the name of the attribute used for the value of the child. This must be a valid XML Attribute Name. This is only used if required by the setting of *Render*. The default value is `val`.
Namespace	String	Enter the namespace associated with the *Value Attribute*.

XML wire format properties for compound element integer types:

Field identification.

The XML Wire Format properties described here apply to:

- Objects: Compound elements

Field identification

A number of the following properties only become active depending on the value that *Render* property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their *`XML Name`*property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLAttribute`. If you select this value, the object (or type) is rendered as an attribute of the parent XML object. The identity of the child is determined by the attribute name. The value is the attribute value. This is only valid for simple elements. If you select this value for more than one object , you must set their *`XML Name`* property to different values. This is the default value for attribute objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in *`ID Attribute Name`* and a value as specified in *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. • `XMLElementAttrVal`. If you specify this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the value of a specified attribute. The name of the attribute is specified in *`Value Attribute Name`*. • `XMLElementAttrIDVal`. This option combines the two options, `XMLElementAttrID` and `XMLElementAttrVal`. The object is rendered as a child of the parent complex type. The identity of the child is determined by the value of *`ID Attribute Name`*. The value is the value of *`ID Attribute Value`*. If you select this value for one object, and set this same value or the value `XMLElementAttrID` for a second object, and set *`XML Name`*, *`ID Attribute Name`*, *`ID Attribute Value`* to the same values: – You must also set *`Value Attribute Name`* to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.

Property	Type	Meaning
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.
Value Attribute Name	String	Specify the name of the attribute used for the value of the child. This must be a valid XML Attribute Name. This is only used if required by the setting of *Render*. The default value is `val`.
Namespace	String	Enter the namespace associated with the *Value Attribute*.

XML wire format properties for compound element string types:

Field identification.

The XML Wire Format properties described here apply to:

- Objects: Compound elements

Field identification

A number of the following properties only become active depending on the value that *Render* property is set to.

Property	Type	Meaning
Render	Enumerated type	Specify how the instantiated object or type is rendered (output) in the resulting XML document. Select one of the following values from the drop-down list: • `XMLElement`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the content of the child element. If you select this value for more than one object, and set their *XML Name*property to the same value, both objects must refer to the same element. This is the default value for element objects. • `XMLAttribute`. If you select this value, the object (or type) is rendered as an attribute of the parent XML object. The identity of the child is determined by the attribute name. The value is the attribute value. This is only valid for simple elements. If you select this value for more than one object , you must set their *XML Name* property to different values. This is the default value for attribute objects. • `XMLElementAttrID`. If you select this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the value of a specified attribute of the child. The value is the content of the child element. You must add an attribute to the child element with an attribute name as specified in *ID Attribute Name* and a value as specified in *ID Attribute Value*. If you select this value for one object, and set this same value or the value `XMLElementAttrIDVal` for a second object, and set *XML Name*, *ID Attribute Name*, *ID Attribute Value* to the same values: – You must also set *Value Attribute Name* to the same value for the two objects. – Both objects must refer to the same element. • `XMLElementAttrVal`. If you specify this value, the object (or type) is rendered as a child XML element of the parent complex type. The identity of the child is determined by the tag name of the child. The value is the value of a specified attribute. The name of the attribute is specified in *Value Attribute Name*. • `XMLElementAttrIDVal`. This option combines the two options, `XMLElementAttrID` and `XMLElementAttrVal`. The object is rendered as a child of the parent complex type. The identity of the child is determined by the value of *ID Attribute Name*. The value is the value of *ID Attribute Value*. If you select this value for one object, and set this same value or the value `XMLElementAttrID` for a second object, and set *XML Name*, *ID Attribute Name*, *ID Attribute Value* to the same values: – You must also set *Value Attribute Name* to the same value for the two objects. – Both objects must refer to the same element. "XML rendering options" on page 6262 shows some examples of how these rendering options affect the XML output, and provides usage recommendations.

Property	Type	Meaning
XML Name	String	Enter a value for the XML element name. This property specifies the name for the XML start tag or attribute for the element (or attribute) in an XML document (message). This can be used to provide name mapping when the MRM identifier needs to be different from the XML name, for example because of different namespace rules. It must be a valid XML name. You cannot specify a name that is already used for another element (or attribute) , or for a message. No two elements (or attribute) or messages can have the same XML name. If you do not set a value, it defaults to that of the element's identifier. If the element's identifier is a prefixed identifier, it defaults to the identifier with the caret character (^) replaced by an underscore (_).
ID Attribute Name	String	Specify the name of the attribute used to identify the child. This must be a valid XML Attribute Name. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is `id`.
Namespace	String	Enter the namespace associated with the *ID Attribute*.
ID Attribute Value	String	Specify the value of the attribute used to identify the child. This property is ignored and cannot be changed (the field is disabled) if *Render* is set to `XMLElement`, `XMLAttribute`, or `XMLElementAttrVal`. The default value is the identifier of the child.
Value Attribute Name	String	Specify the name of the attribute used for the value of the child. This must be a valid XML Attribute Name. This is only used if required by the setting of *Render*. The default value is `val`.
Namespace	String	Enter the namespace associated with the *Value Attribute*.

Use the documentation property of an object to add information that describes the function of the object.

TDS properties for compound element binary types:

Field identification and physical representation.

The TDS properties described here apply to:

- Objects: Compound elements

Field identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.

Property	Type	Meaning
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Physical representation

Property	Type	Meaning
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. The default is dependent on the setting of the message set property `Derive default length from logical type`. If `Derive default length from logical type` is selected, the default value is derived from any length or maxLength value constraint (schema facet) on the object's simple type.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

The properties, and their permissible values, vary according to the object type.

TDS properties for compound element Boolean types:

Field identification and physical representation.

The TDS properties described here apply to:

- Objects: Compound elements

Field identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Binary`. The data is in bit string format. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see "Reordering objects" on page 2900.

TDS properties for compound element dateTime types:

Field identification, physical representation, and null values.

The TDS properties described here apply to:

- Objects: Compound elements

Field identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Length Encoded String 1`. The first byte of the data contains the length (in length units) of the data string that follows the length byte. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The first two bytes of the data contain the length (in length units) of the data string that follows the two length bytes. The maximum length of a `Length Encoded String 2` element is 65535 length units. • `Null Terminated String`. The data string ends with the hexadecimal NULL character, `X'00'`. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `Binary`. The data is in bit string format. • `Time Seconds`. This value supports C time_t, and Java Date and Time objects. It is valid only if the `DateTime Format` property represents numeric-only data. • `Time Milliseconds`. This value supports C time_t, and Java Date and Time objects. It is valid only if the `DateTime Format` property represents numeric-only data. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
DateTime Format	String	Specify a template for date and time. The default DateTime format is dependent on the logical type of the object. For information about the defaults for the dateTime format according to the logical type, see “DateTime defaults by logical type” on page 6320. See “DateTime formats” on page 6310 for details of date and time formats.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • `NULLPadFill`. This option is valid only for fixed-length objects and is the default value. • `NULLLogicalValue`. The `Encoding Null Value` property is first converted to an actual value, and rendered in the way specified for the field. • `NULLLiteralValue`. This option specifies that `Encoding Null Value` contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the `Encoding Null Value` property to test or compare the content of the field in the message. • `NULLLiteralFill`. This option specifies that the field is filled with the value specified by the `Encoding Null Value` property. `Encoding Null Value` must resolve to a single character. The option that you select determines the value that you must set for the property `Encoding Null Value`. For full information about using these options, see "TDS Null handling options" on page 6293.
Encoding Null Value	String	The use of this property depends on the `Encoding Null` property. The default value is zero. If you set the `Encoding Null` property for a dateTime object to `NULLLogicalValue`, the value that you set must be in an ISO8601 dateTime format. These formats are described in "DateTime as string data" on page 6311. For example, specify a value that conforms to the `yyyy-MM-dd'T'HH:mm:ss` format; for example, `1970-12-01`.

The properties, and their permissible values, vary according to the object type.

TDS properties for compound element decimal types:

Field identification, physical representation, numeric representation, and null values.

The TDS properties described here apply to:

- Objects: Compound elements

Field identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `TLOG Specific` - this option can be selected only if the `Message Standard` property of the message set is `TLOG`. This option indicates that the format of the data is specific to the TLOG messaging standard. • `Integer`. Equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `External Decimal`. The data is a decimal number that equates to the data type PIC 9 USAGE DISPLAY in COBOL. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. If this property is not set and the message set property `Derive default length from logical type` is selected, and the `Physical type` is 'Character', the default value is derived from any totalDigits value constraint (schema facet) or, if none, any `minInclusive`, `maxInclusive`, `minExclusive`, or `maxExclusive` value constraints (schema facets), on the simple type.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Numeric representation

Property	Type	Meaning
Virtual Decimal Point	Button and Integer	Specify a non-zero integer that represents the position of an implied decimal point within a number, or specify 0, the default, to use the formatting of Float or Decimal numbers as specified by the `Precision` property. If you specify a positive integer, the position of the decimal point is moved left from the right side of the number. For example, if you specify `3`, the decimal value `1234` represents 1.234 If you specify a negative integer, the position of the decimal point is moved right from the right side of the number. For example, if you specify `-3`, the decimal value `1234` represents 1,234,000.
Precision	Button and Integer	This property is applicable only if `Physical Type` is `Text`. It is used if the value of the `Virtual Decimal Point` property is 0, which indicates that the decimal point is present in the data. It deals with truncation, and specifies how many digits are to follow the decimal point. Either specify a number of digits: • If you set `Precision` to 0, data is truncated so that the fractional part is lost. For example, the value `123.45` is truncated to `123`. • If you set `Precision` to a number less than the number of fractional digits, data is truncated. For example, the value `123.4567` is truncated to `123.45` if you set `Precision` to 2. • If you set `Precision` to a number greater than the number of fractional digits, the value is padded with extra zeros. For example, the value `12.345` is padded to `12.34500` if you set `Precision` to 5. Or select one option from the list: • `All Significant Digits - decimal separator only required if fractional digits` (the default): all significant digits are written to the output bit stream, and no decimal separator is written if no fractional digits are present. • `Explicit Decimal Separator - decimal separator always required`: all significant digits are written to the output bit stream and the decimal separator is always included, even when no fractional digits are present. The decimal separator must be present in the input bit stream, even when no fractional digits are present.
Sign Orientation	Enumerated type	The values that you can choose for this property are: • `Leading Separate` • `Trailing Separate` • `Leading Overpunched` • `Trailing Overpunched` This property is enabled only if you have set `Physical Type` to `Text` or `External Decimal`, and you have selected `Signed`. If `Physical Type` is `Text`, the only valid values of `Sign Orientation` are `Leading Separate` and `Trailing Separate`. If `Physical Type` is `External Decimal` and `Sign EBCDIC Customer Overpunched` is selected, the only valid values of `Sign Orientation` are `Leading Overpunched` and `Trailing Overpunched`.
Positive Sign	String	Specify the value that represents the positive symbol. Do not specify a numeric value. If no value is set, "+" is assumed. The positive sign is not written when creating an output message; it is used only to recognize the positive sign when parsing a message bit stream. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.

Property	Type	Meaning
Negative Sign	String	Specify the value that represents the negative symbol. Do not specify a numeric value. If no value is set, "-" is assumed. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • `NULLPadFill`. This option is valid only for fixed-length objects and is the default value. • `NULLLogicalValue`. The `Encoding Null Value` property is first converted to an actual value, and rendered in the way specified for the field. • `NULLLiteralValue`. This option specifies that `Encoding Null Value` contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the `Encoding Null Value` property to test or compare the content of the field in the message. • `NULLLiteralFill`. This option specifies that the field is filled with the value specified by the `Encoding Null Value` property. `Encoding Null Value` must resolve to a single character. The option that you select determines the value that you must set for the property `Encoding Null Value`. For full information about using these options, see "TDS Null handling options" on page 6293.
Encoding Null Value	String	The use of this property depends on the `Encoding Null` property. The default value is zero. If you set the `Encoding Null` property for a dateTime object to `NULLLogicalValue`, the value that you set must be in an ISO8601 dateTime format. These formats are described in "DateTime as string data" on page 6311. For example, specify a value that conforms to the `yyyy-MM-dd'T'HH:mm:ss` format; for example, `1970-12-01`.

TDS properties for compound element float types:

Field identification, physical representation, numeric representation, and null values.

The TDS properties described here apply to:

- Objects: Compound elements

Field identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Float`. Equates to the data type FLOAT or DOUBLE in C, or the COMP-1 or COMP-2 numeric data type in COBOL. • `Integer`. Equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `External Decimal`. The data is a decimal number that equates to the data type PIC 9 USAGE DISPLAY in COBOL. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Numeric representation

Property	Type	Meaning
Virtual Decimal Point	Button and Integer	Specify a non-zero integer that represents the position of an implied decimal point within a number, or specify 0, the default, to use the formatting of Float or Decimal numbers as specified by the `Precision` property. If you specify a positive integer, the position of the decimal point is moved left from the right side of the number. For example, if you specify 3, the decimal value 1234 represents 1.234 If you specify a negative integer, the position of the decimal point is moved right from the right side of the number. For example, if you specify -3, the decimal value 1234 represents 1,234,000.
Precision	Button and Integer	This property is applicable only if `Physical Type` is `Text`. It is used if the value of the `Virtual Decimal Point` property is 0, which indicates that the decimal point is present in the data. It deals with truncation, and specifies how many digits are to follow the decimal point. Either specify a number of digits: • If you set `Precision` to 0, data is truncated so that the fractional part is lost. For example, the value 123.45 is truncated to 123. • If you set `Precision` to a number less than the number of fractional digits, data is truncated. For example, the value 123.4567 is truncated to 123.45 if you set `Precision` to 2. • If you set `Precision` to a number greater than the number of fractional digits, the value is padded with extra zeros. For example, the value 12.345 is padded to 12.34500 if you set `Precision` to 5. Or select one option from the list: • `All Significant Digits - decimal separator only required if fractional digits` (the default): all significant digits are written to the output bit stream, and no decimal separator is written if no fractional digits are present. • `Explicit Decimal Separator - decimal separator always required`: all significant digits are written to the output bit stream and the decimal separator is always included, even when no fractional digits are present. The decimal separator must be present in the input bit stream, even when no fractional digits are present. • `Exponential Notation - Example "1.23456e002"`: data is written out to the bit stream as a signed value having the format `[sign1]a.bbbe[sign2]ccc` where: – `[sign1]` is the value of `Negative Sign` if the value is negative – `a` is a single decimal digit – `bbb` is one or more decimal digits – `[sign2]` is the value of `Negative Sign` if the exponent is negative – `ccc` is exactly three decimal digits (the exponent) `[sign1]` and `[sign2]` are absent if the value and exponent are positive. For example, the value -123.456 is represented as `-1.23456e002` and the value 0.00012 is represented as `1.2e-004` in the output bit stream, assuming that the value of `Negative Sign` is "-", and the value of `Sign Orientation` is `Leading`. The value -0.00012 is represented as `1.2*e*004` if `Negative Sign` is "*" and `Sign Orientation` is `Trailing`.

Property	Type	Meaning
Sign Orientation	Enumerated type	The values that you can choose for this property are: • Leading Separate • Trailing Separate • Leading Overpunched • Trailing Overpunched This property is enabled only if you have set Physical Type to Text or External Decimal, and you have selected Signed. If Physical Type is Text, the only valid values of Sign Orientation are Leading Separate and Trailing Separate. If Physical Type is External Decimal and Sign EBCDIC Customer Overpunched is selected, the only valid values of Sign Orientation are Leading Overpunched and Trailing Overpunched.
Positive Sign	String	Specify the value that represents the positive symbol. Do not specify a numeric value. If no value is set, "+" is assumed. The positive sign is not written when creating an output message; it is used only to recognize the positive sign when parsing a message bit stream. This property is applicable only if Physical Type is Text and Signed is selected.
Negative Sign	String	Specify the value that represents the negative symbol. Do not specify a numeric value. If no value is set, "-" is assumed. This property is applicable only if Physical Type is Text and Signed is selected.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • NULLPadFill. This option is valid only for fixed-length objects and is the default value. • NULLLogicalValue. The Encoding Null Value property is first converted to an actual value, and rendered in the way specified for the field. • NULLLiteralValue. This option specifies that Encoding Null Value contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the Encoding Null Value property to test or compare the content of the field in the message. • NULLLiteralFill. This option specifies that the field is filled with the value specified by the Encoding Null Value property. Encoding Null Value must resolve to a single character. The option that you select determines the value that you must set for the property Encoding Null Value. For full information about using these options, see “TDS Null handling options” on page 6293.
Encoding Null Value	String	The use of this property depends on the Encoding Null property. The default value is zero. If you set the Encoding Null property for a dateTime object to NULLLogicalValue, the value that you set must be in an ISO8601 dateTime format. These formats are described in “DateTime as string data” on page 6311. For example, specify a value that conforms to the yyyy-MM-dd'T'HH:mm:ss format; for example, 1970-12-01.

TDS properties for compound element integer types:

Field identification, physical representation, numeric representation, and null values.

The TDS properties described here apply to:

- Objects: Compound elements

Field identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Integer`. Equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `External Decimal`. The data is a decimal number that equates to the data type PIC 9 USAGE DISPLAY in COBOL. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.

Property	Type	Meaning
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. If this property is not set and the message set property `Derive default length from logical type` is selected, and the `Physical type` is 'Character', the default value is derived from any totalDigits value constraint (schema facet) or, if none, any `minInclusive`, `maxInclusive`, `minExclusive`, or `maxExclusive` value constraints (schema facets), on the simple type.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Numeric representation

Property	Type	Meaning
Sign Orientation	Enumerated type	The values that you can choose for this property are: • Leading Separate • Trailing Separate • Leading Overpunched • Trailing Overpunched This property is enabled only if you have set Physical Type to Text or External Decimal, and you have selected Signed. If Physical Type is Text, the only valid values of Sign Orientation are Leading Separate and Trailing Separate. If Physical Type is External Decimal and Sign EBCDIC Customer Overpunched is selected, the only valid values of Sign Orientation are Leading Overpunched and Trailing Overpunched.
Positive Sign	String	Specify the value that represents the positive symbol. Do not specify a numeric value. If no value is set, "+" is assumed. The positive sign is not written when creating an output message; it is used only to recognize the positive sign when parsing a message bit stream. This property is applicable only if Physical Type is Text and Signed is selected.
Negative Sign	String	Specify the value that represents the negative symbol. Do not specify a numeric value. If no value is set, "-" is assumed. This property is applicable only if Physical Type is Text and Signed is selected.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • NULLPadFill. This option is valid only for fixed-length objects and is the default value. • NULLLogicalValue. The Encoding Null Value property is first converted to an actual value, and rendered in the way specified for the field. • NULLLiteralValue. This option specifies that Encoding Null Value contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the Encoding Null Value property to test or compare the content of the field in the message. • NULLLiteralFill. This option specifies that the field is filled with the value specified by the Encoding Null Value property. Encoding Null Value must resolve to a single character. The option that you select determines the value that you must set for the property Encoding Null Value. For full information about using these options, see “TDS Null handling options” on page 6293.

Property	Type	Meaning
Encoding Null Value	String	The use of this property depends on the `Encoding Null` property. The default value is zero. If you set the `Encoding Null` property for a dateTime object to `NULLLogicalValue`, the value that you set must be in an ISO8601 dateTime format. These formats are described in "DateTime as string data" on page 6311. For example, specify a value that conforms to the `yyyy-MM-dd'T'HH:mm:ss` format; for example, `1970-12-01`.

The properties, and their permissible values, vary according to the object type.

TDS properties for compound element string types:

Field identification, physical representation, and null values.

The TDS properties described here apply to:

- Objects: Compound elements

Field identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.
Interpret Element Value	Enumerated type	Specify whether values stored within this object are interpreted as having significance for the parser and, if so, the type of interpretation that occurs. This interpretation is standard-specific and is therefore hard coded. The possible values for this property are: • `None` (the default value) • `EDIFACT Service String` • `X12 Service String` • `Message Key` • `EDIFACT Syntax Level ID` • `HL7 Service String` • `HL7 Field Separator`
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Length Encoded String 1`. The first byte of the data contains the length (in length units) of the data string that follows the length byte. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The first two bytes of the data contain the length (in length units) of the data string that follows the two length bytes. The maximum length of a `Length Encoded String 2` element is 65535 length units. • `Null Terminated String`. The data string ends with the hexadecimal NULL character, `X'00'`. • `TLOG Specific` - this option can be selected only if the `Message Standard` property of the message set is `TLOG`. This option indicates that the format of the data is specific to the TLOG messaging standard. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. If this property is not set and the message set property `Derive default length from logical type` is selected, and the `Physical type` is 'Character', the default value is derived from any length or maxLength value constraint (schema facet) on the simple type.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • `NULLPadFill`. This option is valid only for fixed-length objects and is the default value. • `NULLLogicalValue`. The `Encoding Null Value` property is first converted to an actual value, and rendered in the way specified for the field. • `NULLLiteralValue`. This option specifies that `Encoding Null Value` contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the `Encoding Null Value` property to test or compare the content of the field in the message. • `NULLLiteralFill`. This option specifies that the field is filled with the value specified by the `Encoding Null Value` property. `Encoding Null Value` must resolve to a single character. The option that you select determines the value that you must set for the property `Encoding Null Value`. For full information about using these options, see "TDS Null handling options" on page 6293.
Encoding Null Value	String	The use of this property depends on the `Encoding Null` property. The default value is zero. If you set the `Encoding Null` property for a dateTime object to `NULLLogicalValue`, the value that you set must be in an ISO8601 dateTime format. These formats are described in "DateTime as string data" on page 6311. For example, specify a value that conforms to the `yyyy-MM-dd'T'HH:mm:ss` format; for example, `1970-12-01`.

More information about the MRM domain.

Embedded simple type logical properties:

The logical properties of an embedded simple type include properties that specify the number of occurrences of the embedded simple type.

Occurrences

Property	Type	Meaning
Min Occurs	Integer	Specify the minimum number of times that the object can repeat. The default value is 1. If the value is set to 0, the object is optional. With the exception of `Max Occurs` being set to -1, if a value is set for `Min Occurs`, it must be less than or equal to the value in `Max Occurs`.
Max Occurs	Integer	Specify the maximum number of times that the object can repeat. The default value is 1. If this property is not set, the object cannot occur more than once. If this property is set to 0, it is interpreted as if the object does not exist in the message. It can also be set to -1, to indicate that the limit is unbounded and there is no maximum to the number of occurrences.

Use the documentation property of an object to add information that describes the function of the object.

CWF properties for embedded simple type binary types:

Physical representation, byte alignment, and occurrences.

The Custom Wire Format properties described here apply to:

- Objects: Embedded simple types

Physical representation

Property	Type	Meaning
Length	Button and Integer	If you have selected the length to be defined by *Length*, enter the number of length units for the element. The minimum value that you can specify is 1. The maximum value that you can specify is 2147483647. The default value is empty (not set).
Length Reference	Button and Enumerated type	If you have selected the length to be defined by *Length Reference*, select the name of the integer object that specifies the length of this object. Make your selection from the displayed list of integer objects that are defined as siblings of the current object, and occur before it in the structure of the message. For information about reordering elements, see “Reordering objects” on page 2900.
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • Bytes. The length is given in bytes. • Characters. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • Character Units. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to Characters. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the Length property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • End of Bitstream. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *Length Count* or *Length Reference* property. The default is Bytes.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • `1 Bytes`. The default value. • `2 Bytes` • `4 Bytes` • `8 Bytes` • `16 Bytes`
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *`Repeat Reference`* is specified, it overrides any setting for the *`Max Occurs`* logical property when parsing and writing the message, but not for validation of the message.

CWF properties for embedded simple type Boolean types:

Byte alignment and occurrences.

The Custom Wire Format properties described here apply to:

- Objects: Embedded simple types

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • `1 Bytes`. The default value. • `2 Bytes` • `4 Bytes` • `8 Bytes` • `16 Bytes`
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *Repeat Reference* is specified, it overrides any setting for the *Max Occurs* logical property when parsing and writing the message, but not for validation of the message.

CWF properties for embedded simple type dateTime types:

Physical representation, null values, byte alignment, and occurrences.

The Custom Wire Format properties described here apply to:

- Objects: Embedded simple types

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Fixed Length String`. The element's length is determined by other length properties as follows. • `Length Encoded String 1`. The first byte of the element contains the length of the string following the length byte in length units. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The element's first 2 bytes contain the length of the string following the two length bytes in length units. The maximum length of a `Length Encoded String 2` element is 65535 length units. The two length bytes are in the format of the WebSphere MQ queue manager Encoding. • `Null Terminated String`. The string ends with the hexadecimal NULL character, `X'00'`. • `Packed Decimal`. The dateTime is coded as a Packed Decimal number. It is valid only if the *`DateTime Format`* property represents numeric-only data. • `Binary`. The dateTime is encoded as a binary sequence of bytes. If you select this option, the range of symbols that you can specify for the Format String property is less than the range of symbols you can specify if you select a string option (see "DateTime formats" on page 6310 for details). • `Time Seconds`. This value supports C time_t and Java Date and Time objects. It is valid only if the *`DateTime Format`* property represents numeric-only data. • `Time Milliseconds`. This value supports C time_t and Java Date and Time objects. It is valid only if the *`DateTime Format`* property represents numeric-only data. The default value is `fixed length string`.
DateTime Format	String	Specify a template for date and time. The default dateTime format is dependent on the logical type of the object. For information about the defaults for the dateTime format according to the logical type, see "DateTime defaults by logical type" on page 6320. See "DateTime formats" on page 6310 for details of date and time formats.
Length	Button and Integer	If you have selected a *`Physical Type`* of `Fixed Length String`, `Packed Decimal`, or `Binary`, and have selected the length to be defined by *`Length`*, enter the number of length units for the element. The minimum value that you can specify is 1 for all three physical types. The maximum value that you can specify is `256` for `Fixed Length String`, `10` for `Packed Decimal`, and `2147483647` for `Binary`. The default value is 0 (zero).
Length Reference	Button and Enumerated type	If you have selected the length to be defined by *`Length Reference`*, select the name of the integer object that specifies the length of this object. Make your selection from the displayed list of integer objects that are defined as siblings of the current object, and occur before it in the structure of the message. For information about reordering elements, see "Reordering objects" on page 2900.

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. The length is given in bytes. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`* or *`Length Reference`* property. The default is `Bytes`.
Signed	Check box	Specify whether the value is signed. This property is applicable only if the *`Physical type`* property is `Packed Decimal`. By default, this check box is cleared, which indicates that the value is not signed.
Justification	Enumerated type	If you have set the *`Physical Type`* property to `Fixed Length String`, select `Left Justify` (the default value) or `Right Justify` from the list. If you have selected another value for *`Physical Type`*, this property is inactive.

Property	Type	Meaning
Padding Character	String	If you have set the *Physical Type* property to `Fixed Length String`, and the *Justification* property is either `Left Justify` or `Right Justify`, this property is applicable. When writing an output message, use the padding character to fill out the remaining character positions when the string length is less than the length implied by the *Length* or *Length Reference* property. Whether the string is padded from the left or the right is governed by the *Justification* property. When parsing an input message, the padding character is trimmed from the end of the string. Whether the string is trimmed from the left or the right is governed by the *Justification* property. Specify this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the displayed list. • Enter a character between quotation marks; for example, `"c"` or `'c'`, where c is any alphanumeric character. • Enter a Unicode value in the form `U+xxxx` where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, it is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the displayed list. The option that you select determines the value that you must set for the property *Encoding Null Value*: • NULLPadFill. This option is valid only if *Physical Type* is Fixed Length String. The field is filled with the value specified by the *Padding Character*. The default value. • NULLLogicalValue. The *Encoding Null Value* property is first converted to an actual value, and rendered in the way specified for the field. • NULLLiteralValue. This specifies that *Encoding Null Value* contains a value that is directly substituted as if it is a string. Use this option when the value you have set for *Encoding Null Value* to specify a null date is not a dateTime value, or does not conform to the standard dateTime format yyyy-MM-dd 'T'HH:mm:ss. • NULLLiteralFill. The field is filled with the value specified by the *Encoding Null Value*. *Encoding Null Value* must resolve to a single character.
Encoding Null Value	String	If you set the *Encoding Null* property to NULLPadFill, this property is disabled. If you set the *Encoding Null* property to NULLLogicalValue, you must set this property to an ISO8601 dateTime format. These formats are described in "DateTime as string data" on page 6311. For example, specify a value conforming to yyyy-MM-dd'T'HH:mm:ss such as 1970-12-01. If you set the *Encoding Null* property to NULLLiteralValue, you can enter any value that is the same length as the field. If you set the *Encoding Null* property to NULLLiteralFill, the value must resolve to a single character. Set the character in one of the following ways: • Select SPACE, NUL, 0x00 or 0xFF from the displayed list • Enter a character between quotation marks, for example 'c' or "c", where c is any alphanumeric character. • Enter a hexadecimal character code in the form 0xYY where YY is a hexadecimal value. • Enter a decimal character code in the form YY where YY is a decimal value. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal format.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • 1 Bytes. The default value. • 2 Bytes • 4 Bytes • 8 Bytes • 16 Bytes

Property	Type	Meaning
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *`Repeat Reference`* is specified, it overrides any setting for the *`Max Occurs`* logical property when parsing and writing the message, but not for validation of the message.

CWF properties for embedded simple type decimal types:

Physical representation, null values, byte alignment, and occurrences.

The Custom Wire Format properties described here apply to:

- Objects: Embedded simple types

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Integer`. This equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. Equates to the COMP-3 data type in COBOL. • `External Decimal`. Equates to the data type PIC 9 USAGE DISPLAY in COBOL. The representation of numeric elements can be affected by the Encoding and CodedCharSetId attributes that are set for the WebSphere MQ queue manager: • Elements that have *`Physical Type`* set to `Integer` and `Packed Decimal` are represented in the appropriate WebSphere MQ Encoding value. • Elements that have *`Physical Type`* set to `External Decimal` are represented in the WebSphere MQ CodedCharSetId value.
Length	Integer	Enter the number of bytes to specify the element length: • If you set the *`Physical Type`* to `Integer`, select `1`, `2`, or `4` (the default) from the displayed list. • If you set the *`Physical Type`* to `Packed Decimal`, enter a value between 1 and 10. • If you set the *`Physical Type`* to `Extended Decimal`, enter a value between 1 and 256. (Numbers greater than the maximum COBOL PICTURE clause of 18 are assumed to be 18.)

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`*. The default is `Bytes`.
Signed	Check box	Select (the default) or clear this property. This property is used with *`Sign Orientation`*.
Sign EBCDIC Custom Overpunched	Check box	If the *`Physical Type`* is set to `External Decimal` and the *`Signed EBCDIC Custom`* property is set, this indicates that the Sign EBCDIC Custom Overpunched representation is to be used within an ASCII environment. If this check box is not selected (the default), the Sign ASCII representation is used. The setting of the *`Sign EBCDIC Custom Overpunched`* check box is appropriate only if the *`Sign Orientation`* property is set to `Leading` or `Trailing` (indicating that the element/attribute has an embedded sign representation). The check box is not available if the element/attribute is unsigned (for example, if the *`Signed`* check box is not set).

Property	Type	Meaning
Sign Orientation	Enumerated type	If you have set *Physical Type* to External Decimal and you have selected *Signed*, choose from the following options that represent the COBOL options for displaying numeric data: • Leading Overpunched. This option sets a bit in the first byte if the number is negative. No setting is made if the number is positive. For example, the ASCII hexadecimal representation of the number 22 is x'3232'. Using this option, the number +22 would be x'3232' and the number -22 would be x'7232'. The default value. • Leading Separate. This option sets the first byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. • Trailing Overpunched. This option sets a bit in the last byte if the number is negative. No setting is made if the number is positive. Using this option, the number +22 would be x'3232' and the number -22 would be x'3272'. • Trailing Separate. This option sets the last byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. If you have set *Physical Type* to any other value, the value Not Applicable is set for you.
Virtual Decimal Point	Integer	Specify the number of places to the left (for a positive value) or right (for a negative value) that a decimal point is to be moved from its assumed position. For example, a decimal element containing 1234 with a Virtual Decimal value of 3 is 1.234, equivalent to 'V' or 'P' in a COBOL picture clause. There is no C equivalent
Justification	Enumerated type	If you have set the *Physical Type* property to External Decimal, select Left Justify or Right Justify (the default value) from the list. If you have selected another value for *Physical Type*, this property is inactive.

Property	Type	Meaning
Padding Character	String	The padding character is used to fill out the remaining character positions when the string length is less than the specified string size. If you have set the *Physical Type* property to Extended Decimal, and the *Justification* property is either Left Justify or Right Justify, specify this character in one of the following ways: • Select NUL, '0', or SPACE from the displayed list. • Enter a character between quotation marks; for example, "c" or 'c', where c is any alphanumeric character. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form 0xYY, where YY is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, this is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the displayed list: • NULLPadFill. This option is valid only if *Physical Type* is External Decimal. The field is filled with the value specified by the *Padding Character*. *Encoding Null Value* must be set to an empty string. • NULLLogicalValue. The *Encoding Null Value* is transformed to match the required format for the field. The default value. • NULLLiteralValue. The *Encoding Null Value* is directly substituted as if it is a string. You can specify a nonnumeric value for *Encoding Null Value*. • NULLLiteralFill. The field is filled with the value specified by the *Encoding Null Value*. *Encoding Null Value* must resolve to a single character.

Property	Type	Meaning
Encoding Null Value	String	The use of this property depends on the *Encoding Null* property, except for NULLLiteralFill. The default value is zero. If you set the *Encoding Null* property to NULLLiteralFill, the value must resolve to a single character. Set the character in one of the following ways: • Select SPACE, NUL, 0x00 or 0xFF from the displayed list • Enter a character between quotation marks, for example 'c' or "c", where c is any alphanumeric character. • Enter a hexadecimal character in the form 0xYY where YY is a hexadecimal value. • Enter a decimal character code in the form YY where YY is a decimal value. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal format.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • 1 Bytes. The default value. • 2 Bytes • 4 Bytes • 8 Bytes • 16 Bytes
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *Repeat Reference* is specified, it overrides any setting for the *Max Occurs* logical property when parsing and writing the message, but not for validation of the message.

- Objects: Embedded simple types

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Integer`. This equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Float`. This equates to the data type FLOAT or DOUBLE in C or the COMP-1 or COMP-2 data type in COBOL and is the default value. • `Packed Decimal`. Equates to the COMP-3 data type in COBOL. • `External Decimal`. Equates to the data type PIC 9 USAGE DISPLAY in COBOL. The representation of numeric elements can be affected by the Encoding and CodedCharSetId attributes that are set for the WebSphere MQ queue manager: • Elements that have *`Physical Type`* set to `Integer`, `Packed Decimal`, and `Float` are represented in the appropriate WebSphere MQ Encoding value. • Elements that have *`Physical Type`* set to `External Decimal` are represented in the WebSphere MQ CodedCharSetId value.
Length	Integer	Enter the number of bytes to specify the element length: • If you set the *`Physical Type`* to `Float`, select a value from the displayed list. The default value is 8. • If you set the *`Physical Type`* to `Integer`, select `1`, `2`, or `4` (the default) from the displayed list. • If you set the *`Physical Type`* to `Packed Decimal`, enter a value between 1 and 10. • If you set the *`Physical Type`* to `Extended Decimal`, enter a value between 1 and 256. (Numbers greater than the maximum COBOL PICTURE clause of 18 are assumed to be 18.)

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`*. The default is `Bytes`.
Signed	Check box	Select or clear (unsigned, the default) this property. If you have set *`Physical Type`* to `Float`, this is selected. This property is used with *`Sign Orientation`*.
Sign EBCDIC Custom Overpunched	Check box	If the *`Physical Type`* is set to `External Decimal` and the *`Signed EBCDIC Custom`* property is set, this indicates that the Sign EBCDIC Custom Overpunched representation is to be used within an ASCII environment. If this check box is not selected (the default), the Sign ASCII representation is used. The setting of the *`Sign EBCDIC Custom Overpunched`* check box is appropriate only if the *`Sign Orientation`* property is set to `Leading` or `Trailing` (indicating that the element/attribute has an embedded sign representation). The check box is not available if the element/attribute is unsigned (for example, if the *`Signed`* check box is not set).

Property	Type	Meaning
Sign Orientation	Enumerated type	If you have set *Physical Type* to External Decimal and you have selected *Signed*, choose from the following options that represent the COBOL options for displaying numeric data: • Leading Overpunched. This option sets a bit in the first byte if the number is negative. No setting is made if the number is positive. For example, the ASCII hexadecimal representation of the number 22 is x'3232'. Using this option, the number +22 would be x'3232' and the number -22 would be x'7232'. The default value. • Leading Separate. This option sets the first byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. • Trailing Overpunched. This option sets a bit in the last byte if the number is negative. No setting is made if the number is positive. Using this option, the number +22 would be x'3232' and the number -22 would be x'3272'. • Trailing Separate. This option sets the last byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. If you have set *Physical Type* to any other value, the value Not Applicable is set for you.
Virtual Decimal Point	Integer	Specify the number of places to the left (for a positive value) or right (for a negative value) that a decimal point is to be moved from its assumed position. For example, a float element containing 1234 with a Virtual Decimal value of 3 is 1.234. This property is not applicable if you have set *Physical Type* to Float.
Justification	Enumerated type	If you have set the *Physical Type* property to External Decimal, select Left Justify or Right Justify (the default value) from the list. If you have selected another value for *Physical Type*, this property is inactive.

Property	Type	Meaning
Padding Character	String	The padding character is used to fill out the remaining character positions when the string length is less than the specified string size. If you have set the *Physical Type* property to Extended Decimal, and the *Justification* property is either Left Justify or Right Justify, specify this character in one of the following ways: • Select NUL, '0', or SPACE from the displayed list. • Enter a character between quotation marks; for example, "c" or 'c', where c is any alphanumeric character. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form 0xYY, where YY is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, this is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the displayed list: • NULLPadFill. This option is valid only if *Physical Type* is External Decimal. The field is filled with the value specified by the *Padding Character*. *Encoding Null Value* must be set to an empty string. • NULLLogicalValue. The *Encoding Null Value* is transformed to match the required format for the field. The default value. • NULLLiteralValue. The *Encoding Null Value* is directly substituted as if it is a string. You can specify a nonnumeric value for *Encoding Null Value*. • NULLLiteralFill. The field is filled with the value specified by the *Encoding Null Value*. *Encoding Null Value* must resolve to a single character.

Property	Type	Meaning
Encoding Null Value	String	The use of this property depends on the *Encoding Null* property, except for NULLLiteralFill. The default value is zero. If you set the *Encoding Null* property to NULLLiteralFill, the value must resolve to a single character. Set the character in one of the following ways: • Select SPACE, NUL, 0x00 or 0xFF from the displayed list • Enter a character between quotation marks, for example 'c' or "c", where c is any alphanumeric character. • Enter a hexadecimal character in the form 0xYY where YY is a hexadecimal value. • Enter a decimal character code in the form YY where YY is a decimal value. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal format.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • 1 Bytes. The default value. • 2 Bytes • 4 Bytes • 8 Bytes • 16 Bytes
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *Repeat Reference* is specified, it overrides any setting for the *Max Occurs* logical property when parsing and writing the message, but not for validation of the message.

CWF properties for embedded simple type integer types:

Physical representation, null values, byte alignment, and occurrences.

The Custom Wire Format properties described here apply to:

- Objects: Embedded simple types

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Integer`. This equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. Equates to the COMP-3 data type in COBOL. • `External Decimal`. Equates to the data type PIC 9 USAGE DISPLAY in COBOL. The representation of numeric elements can be affected by the Encoding and CodedCharSetId attributes that are set for the WebSphere MQ queue manager: • Elements that have *`Physical Type`* set to `Integer` and `Packed Decimal` are represented in the appropriate WebSphere MQ Encoding value. • Elements that have *`Physical Type`* set to `External Decimal` are represented in the WebSphere MQ CodedCharSetId value.
Length	Integer	Enter the number of bytes to specify the element length: • If you set the *`Physical Type`* to `Integer`, select `1`, `2`, or `4` (the default) from the displayed list. • If you have set *`Physical Type`* to `Packed Decimal`, enter a value between 1 and 6. • If you have set *`Physical Type`* to `Extended Decimal`, enter a value between 1 and 11.
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`*. The default is `Bytes`.
Signed	Check box	Select (the default) or clear this property. This property is used with *`Sign Orientation`*.

Property	Type	Meaning
Sign EBCDIC Custom Overpunched	Check box	If the *Physical Type* is set to External Decimal and the *Signed EBCDIC Custom* property is set, this indicates that the Sign EBCDIC Custom Overpunched representation is to be used within an ASCII environment. If this check box is not selected (the default), the Sign ASCII representation is used. The setting of the *Sign EBCDIC Custom Overpunched* check box is appropriate only if the *Sign Orientation* property is set to Leading or Trailing (indicating that the element/attribute has an embedded sign representation). The check box is not available if the element/attribute is unsigned (for example, if the *Signed* check box is not set).
Sign Orientation	Enumerated type	If you have set *Physical Type* to External Decimal and you have selected *Signed*, choose from the following options that represent the COBOL options for displaying numeric data: • Leading Overpunched. This option sets a bit in the first byte if the number is negative. No setting is made if the number is positive. For example, the ASCII hexadecimal representation of the number 22 is x'3232'. Using this option, the number +22 would be x'3232' and the number -22 would be x'7232'. The default value. • Leading Separate. This option sets the first byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. • Trailing Overpunched. This option sets a bit in the last byte if the number is negative. No setting is made if the number is positive. Using this option, the number +22 would be x'3232' and the number -22 would be x'3272'. • Trailing Separate. This option sets the last byte of the element to '+' if the number is positive and to '-' if the number is negative. For this option, the length must include the sign byte. If you have set *Physical Type* to any other value, the value Not Applicable is set for you.
Justification	Enumerated type	If you have set the *Physical Type* property to External Decimal, select Left Justify or Right Justify (the default value) from the list. If you have selected another value for *Physical Type*, this property is inactive.

Property	Type	Meaning
Padding Character	String	The padding character is used to fill out the remaining character positions when the string length is less than the specified string size. If you have set the *Physical Type* property to Extended Decimal, and the *Justification* property is either Left Justify or Right Justify, specify this character in one of the following ways: • Select NUL, '0', or SPACE from the displayed list. • Enter a character between quotation marks; for example, "c" or 'c', where c is any alphanumeric character. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form 0xYY, where YY is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, this is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the displayed list: • NULLPadFill. This option is valid only if *Physical Type* is External Decimal. The field is filled with the value specified by the *Padding Character*. *Encoding Null Value* must be set to an empty string. • NULLLogicalValue. The *Encoding Null Value* is transformed to match the required format for the field. The default value. • NULLLiteralValue. The *Encoding Null Value* is directly substituted as if it is a string. You can specify a nonnumeric value for *Encoding Null Value*. • NULLLiteralFill. The field is filled with the value specified by the *Encoding Null Value*. *Encoding Null Value* must resolve to a single character.

Property	Type	Meaning
Encoding Null Value	String	The use of this property depends on the *Encoding Null* property, except for NULLLiteralFill. The default value is zero. If you set the *Encoding Null* property to NULLLiteralFill, the value must resolve to a single character. Set the character in one of the following ways: • Select SPACE, NUL, 0x00 or 0xFF from the displayed list • Enter a character between quotation marks, for example 'c' or "c", where c is any alphanumeric character. • Enter a hexadecimal character in the form 0xYY where YY is a hexadecimal value. • Enter a decimal character code in the form YY where YY is a decimal value. • Enter a Unicode value in the form U+xxxx where xxxx is a Unicode value specified in hexadecimal format.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • 1 Bytes. The default value. • 2 Bytes • 4 Bytes • 8 Bytes • 16 Bytes
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is 0, the minimum value is 0, and the maximum value is 999999. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *Repeat Reference* is specified, it overrides any setting for the *Max Occurs* logical property when parsing and writing the message, but not for validation of the message.

CWF properties for embedded simple type string types:

Physical representation, null values, byte alignment, and occurrences.

The Custom Wire Format properties described here apply to:

- Objects: Embedded simple types

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select one from the displayed list: • `Fixed Length String`. The element's length is determined by other length properties as follows. • `Length Encoded String 1`. The first byte of the element contains the length of the string following the length byte in length units. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The element's first 2 bytes contain the length of the string following the two length bytes in length units. The maximum length of a `Length Encoded String 2` element is 65535 length units. The two length bytes are in the format of the WebSphere MQ queue manager Encoding. • `Null Terminated String`. The string ends with the hexadecimal NULL character, `X'00'`. The default is `Fixed Length String`.
Length	Button and Integer	If you have selected a *`Physical Type`* of `Fixed Length String` or `Binary`, and have selected the length to be defined by *`Length`*, enter the number of length units for the element. The minimum value that you can specify is `0` (zero), the maximum value that you can specify is `2147483647` The default value is `0` (zero).
Length Reference	Button and Enumerated type	If you have selected the length to be defined by *`Length Reference`*, select the name of the integer object that specifies the length of this object. Make your selection from the displayed list of integer objects that are defined as siblings of the current object, and occur before it in the structure of the message. For information about reordering elements, see “Reordering objects” on page 2900.

Property	Type	Meaning
Length Units	Enumerated type	Select the unit of length for the element or attribute. Select one of the following options from the displayed list (some physical types do not offer all these options): • `Bytes`. The length is given in bytes. • `Characters`. The Length is given in characters. This means that the number of bytes that are processed in the bitstream depends on the code page of the characters that are being processed. – For a single-byte code page (SBCS CCSID) such as "latin-1" (CCSID 850), the number of bytes is equal to the number of characters. – For a double-byte code page (DBCS CCSID) such as "UTF-16" (CCSID 1200), the number of bytes is exactly twice the number of characters. – For a multibyte code page (MBCS CCSID) such as "UTF-8" (CCSID 1208), the number of bytes depends on the bitstream content. The parser reads one character at a time and determines whether the character comprises one or more bytes. • `Character Units`. This option specifies that the size of each character (in bytes) is determined by the code page of the message. – For single-byte and double-byte code pages, this option is identical to `Characters`. – For a multibyte code page, this option provides improved parsing performance by assuming that every character is encoded in the smallest character unit that the code page supports. However, this means that a message must contain only these characters if it is to be processed correctly. For example, in code page "UTF-8" (CCSID 1208), the minimum character unit is 1 byte; therefore, the parser can make a single read (of the number of bytes specified by the `Length` property) to fetch the entire message. The message must contain only characters that are encoded in 1-byte units. • `End of Bitstream`. All data up to the end of the bitstream is processed. This option is valid only if the element is the last in the message. If you select this value, you do not need to enter a value for the *`Length Count`* or *`Length Reference`* property. The default is `Bytes`.
Justification	Enumerated type	If you have set the *`Physical Type`* property to `Fixed Length String`, select `Left Justify` (the default value) or `Right Justify` from the list. If you have selected another value for *`Physical Type`*, this property is inactive.

Property	Type	Meaning
Padding Character	String	If you have set the *Physical Type* property to `Fixed Length String`, and the *Justification* property is either `Left Justify` or `Right Justify`, this property is applicable. When writing an output message, use the padding character to fill out the remaining character positions when the string length is less than the length implied by the *Length* or *Length Reference* property. Whether the string is padded from the left or the right is governed by the *Justification* property. When parsing an input message, the padding character is trimmed from the end of the string. Whether the string is trimmed from the left or the right is governed by the *Justification* property. Specify this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the displayed list. • Enter a character between quotation marks; for example, `"c"` or `'c'`, where c is any alphanumeric character. • Enter a Unicode value in the form `U+xxxx` where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. • Enter a hexadecimal character in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a decimal byte value (from 0 to 255). The choice of which of these padding character forms is used for an MRM element depends on the padding character that is required and whether the padding character is to be subject to data conversion. In most cases, the specification of a padding character in quotation marks is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is being generated. For example, when converting from ASCII to the code page 500, if you have specified U+0008 as your padding character, it is converted from 0x08 to 0x15, the ASCII and EBCDIC representations of 'back space'. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is being generated. If you are converting a message from one code page to another, ensure that the converted value of the padding character is valid for this code page. If the padding character cannot be represented in the target code page, it is replaced by a substitution character. The substitution character is fixed and its value depends on the specified target code page. If a padding character is required that is not subject to data conversion, the hexadecimal or decimal format can be used and you then have the option of specifying an absolute value as a padding character that is inserted directly into the output message. If this format is used, ensure still that this value is valid for the code page of any output messages that are created using these MRM definitions.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the displayed list: • `NULLPadFill`. This is valid only if *`Physical Type`* is `Fixed Length String`. The field is filled with the value specified by the *`Padding Character`*. *`Encoding Null Value`* must be set to an empty string. • `NULLLogicalValue`. The *`Encoding Null Value`* is transformed to match the required format for the field. The default value. • `NULLLiteralValue`. The *`Encoding Null Value`* is directly substituted as if it is a string. • `NULLLiteralFill`. The field is filled with the value specified by the *`Encoding Null Value`*. *`Encoding Null Value`* must resolve to a single character.
Encoding Null Value	STRING	The use of this property depends on the *`Encoding Null`* property. If specified, its length must be equal to the length of the string element, except for `NULLLiteralFill`. The default value is empty (not set). If you set the *`Encoding Null`* property to `NULLLiteralFill`, the value must resolve to a single character. Set the character in one of the following ways: • Select `SPACE`, `NUL`, `0x00` or `0xFF` from the displayed list • Enter a character between quotation marks, for example `'c'` or `"c"`, where `c` is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY` where `YY` is a hexadecimal value. • Enter a decimal character code in the form `YY` where `YY` is a decimal value. • Enter a Unicode value in the form `U+xxxx` where `xxxx` is a Unicode value specified in hexadecimal format.

Byte alignment

Property	Type	Meaning
Byte Alignment	Enumerated type	Specify how the object is aligned from the start of the message. Select one of: • `1 Bytes`. The default value. • `2 Bytes` • `4 Bytes` • `8 Bytes` • `16 Bytes`
Leading Skip Count	Integer	Specify the number of bytes to skip before reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a field defined by C or COBOL data which requires alignment on a 2, 4, 8 or 16 byte boundary. Specify the number of bytes to skip before reading or writing this object. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to the first instance only.
Trailing Skip Count	Integer	Specify the number of bytes to skip after reading or writing this object. The default is `0`, the minimum value is `0`, and the maximum value is `999999`. You can use this value to ignore unwanted fields in a structure, or to model a repeating structure containing fields which require alignment on a 2, 4, 8 or 16 byte boundary. When an output message is written, Skip Count bytes are assigned the value of the message set Byte Alignment Pad property. For repeating objects, this property is applied to all instances.

Occurrences

Property	Type	Meaning
Repeat Reference	Enumerated type	Use this property if the object occurs multiple times, and the number of occurrences is given dynamically by a field earlier in the message. Select an integer object from the displayed list of integer objects that occur before this object in the structure of the message. The value of the selected integer specifies the number of occurrences of this object. If no objects are listed, there are no integer objects before this one in the message structure. If a *Repeat Reference* is specified, it overrides any setting for the *Max Occurs* logical property when parsing and writing the message, but not for validation of the message.

TDS properties for embedded simple type binary types:

Field identification and physical representation.

The TDS properties described here apply to:

- Objects: Embedded simple types

Field identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.

Property	Type	Meaning
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Physical representation

Property	Type	Meaning
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. The default is dependent on the setting of the message set property `Derive default length from logical type`. If `Derive default length from logical type` is selected, the default value is derived from any length or maxLength value constraint (schema facet) on the object's simple type.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see "Reordering objects" on page 2900.

The properties, and their permissible values, vary according to the object type.

TDS properties for embedded simple type Boolean types:

Field identification and physical representation.

The TDS properties described here apply to:

- Objects: Embedded simple types

Field identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Binary`. The data is in bit string format. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see "Reordering objects" on page 2900.

TDS properties for embedded simple type dateTime types:

Field identification, physical representation, and null values.

The TDS properties described here apply to:

- Objects: Embedded simple types

Field identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Length Encoded String 1`. The first byte of the data contains the length (in length units) of the data string that follows the length byte. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The first two bytes of the data contain the length (in length units) of the data string that follows the two length bytes. The maximum length of a `Length Encoded String 2` element is 65535 length units. • `Null Terminated String`. The data string ends with the hexadecimal NULL character, `X'00'`. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `Binary`. The data is in bit string format. • `Time Seconds`. This value supports C time_t, and Java Date and Time objects. It is valid only if the `DateTime Format` property represents numeric-only data. • `Time Milliseconds`. This value supports C time_t, and Java Date and Time objects. It is valid only if the `DateTime Format` property represents numeric-only data. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
DateTime Format	String	Specify a template for date and time. The default DateTime format is dependent on the logical type of the object. For information about the defaults for the dateTime format according to the logical type, see “DateTime defaults by logical type” on page 6320. See “DateTime formats” on page 6310 for details of date and time formats.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • `NULLPadFill`. This option is valid only for fixed-length objects and is the default value. • `NULLLogicalValue`. The `Encoding Null Value` property is first converted to an actual value, and rendered in the way specified for the field. • `NULLLiteralValue`. This option specifies that `Encoding Null Value` contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the `Encoding Null Value` property to test or compare the content of the field in the message. • `NULLLiteralFill`. This option specifies that the field is filled with the value specified by the `Encoding Null Value` property. `Encoding Null Value` must resolve to a single character. The option that you select determines the value that you must set for the property `Encoding Null Value`. For full information about using these options, see "TDS Null handling options" on page 6293.
Encoding Null Value	String	The use of this property depends on the `Encoding Null` property. The default value is zero. If you set the `Encoding Null` property for a dateTime object to `NULLLogicalValue`, the value that you set must be in an ISO8601 dateTime format. These formats are described in "DateTime as string data" on page 6311. For example, specify a value that conforms to the `yyyy-MM-dd'T'HH:mm:ss` format; for example, `1970-12-01`.

The properties, and their permissible values, vary according to the object type.

TDS properties for embedded simple type decimal types:

Field identification, physical representation, numeric representation, and null values.

The TDS properties described here apply to:

- Objects: Embedded simple types

Field identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `TLOG Specific` - this option can be selected only if the `Message Standard` property of the message set is `TLOG`. This option indicates that the format of the data is specific to the TLOG messaging standard. • `Integer`. Equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `External Decimal`. The data is a decimal number that equates to the data type PIC 9 USAGE DISPLAY in COBOL. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. If this property is not set and the message set property `Derive default length from logical type` is selected, and the `Physical type` is 'Character', the default value is derived from any totalDigits value constraint (schema facet) or, if none, any `minInclusive`, `maxInclusive`, `minExclusive`, or `maxExclusive` value constraints (schema facets), on the simple type.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Numeric representation

Property	Type	Meaning
Virtual Decimal Point	Button and Integer	Specify a non-zero integer that represents the position of an implied decimal point within a number, or specify 0, the default, to use the formatting of Float or Decimal numbers as specified by the `Precision` property. If you specify a positive integer, the position of the decimal point is moved left from the right side of the number. For example, if you specify 3, the decimal value `1234` represents 1.234 If you specify a negative integer, the position of the decimal point is moved right from the right side of the number. For example, if you specify `-3`, the decimal value `1234` represents 1,234,000.
Precision	Button and Integer	This property is applicable only if `Physical Type` is `Text`. It is used if the value of the `Virtual Decimal Point` property is 0, which indicates that the decimal point is present in the data. It deals with truncation, and specifies how many digits are to follow the decimal point. Either specify a number of digits: • If you set `Precision` to 0, data is truncated so that the fractional part is lost. For example, the value `123.45` is truncated to `123`. • If you set `Precision` to a number less than the number of fractional digits, data is truncated. For example, the value `123.4567` is truncated to `123.45` if you set `Precision` to 2. • If you set `Precision` to a number greater than the number of fractional digits, the value is padded with extra zeros. For example, the value `12.345` is padded to `12.34500` if you set `Precision` to 5. Or select one option from the list: • `All Significant Digits - decimal separator only required if fractional digits` (the default): all significant digits are written to the output bit stream, and no decimal separator is written if no fractional digits are present. • `Explicit Decimal Separator - decimal separator always required`: all significant digits are written to the output bit stream and the decimal separator is always included, even when no fractional digits are present. The decimal separator must be present in the input bit stream, even when no fractional digits are present.
Sign Orientation	Enumerated type	The values that you can choose for this property are: • `Leading Separate` • `Trailing Separate` • `Leading Overpunched` • `Trailing Overpunched` This property is enabled only if you have set `Physical Type` to `Text` or `External Decimal`, and you have selected `Signed`. If `Physical Type` is `Text`, the only valid values of `Sign Orientation` are `Leading Separate` and `Trailing Separate`. If `Physical Type` is `External Decimal` and `Sign EBCDIC Customer Overpunched` is selected, the only valid values of `Sign Orientation` are `Leading Overpunched` and `Trailing Overpunched`.
Positive Sign	String	Specify the value that represents the positive symbol. Do not specify a numeric value. If no value is set, "+" is assumed. The positive sign is not written when creating an output message; it is used only to recognize the positive sign when parsing a message bit stream. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.

Property	Type	Meaning
Negative Sign	String	Specify the value that represents the negative symbol. Do not specify a numeric value. If no value is set, "-" is assumed. This property is applicable only if `Physical Type` is `Text` and `Signed` is selected.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • `NULLPadFill`. This option is valid only for fixed-length objects and is the default value. • `NULLLogicalValue`. The `Encoding Null Value` property is first converted to an actual value, and rendered in the way specified for the field. • `NULLLiteralValue`. This option specifies that `Encoding Null Value` contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the `Encoding Null Value` property to test or compare the content of the field in the message. • `NULLLiteralFill`. This option specifies that the field is filled with the value specified by the `Encoding Null Value` property. `Encoding Null Value` must resolve to a single character. The option that you select determines the value that you must set for the property `Encoding Null Value`. For full information about using these options, see “TDS Null handling options” on page 6293.
Encoding Null Value	String	The use of this property depends on the `Encoding Null` property. The default value is zero. If you set the `Encoding Null` property for a dateTime object to `NULLLogicalValue`, the value that you set must be in an ISO8601 dateTime format. These formats are described in “DateTime as string data” on page 6311. For example, specify a value that conforms to the `yyyy-MM-dd'T'HH:mm:ss` format; for example, `1970-12-01`.

TDS properties for embedded simple type float types:

Field identification, physical representation, numeric representation, and null values.

The TDS properties described here apply to:

- Objects: Embedded simple types

Field identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Float`. Equates to the data type FLOAT or DOUBLE in C, or the COMP-1 or COMP-2 numeric data type in COBOL. • `Integer`. Equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `External Decimal`. The data is a decimal number that equates to the data type PIC 9 USAGE DISPLAY in COBOL. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Numeric representation

Property	Type	Meaning
Virtual Decimal Point	Button and Integer	Specify a non-zero integer that represents the position of an implied decimal point within a number, or specify 0, the default, to use the formatting of Float or Decimal numbers as specified by the `Precision` property. If you specify a positive integer, the position of the decimal point is moved left from the right side of the number. For example, if you specify `3`, the decimal value `1234` represents 1.234 If you specify a negative integer, the position of the decimal point is moved right from the right side of the number. For example, if you specify `-3`, the decimal value `1234` represents 1,234,000.
Precision	Button and Integer	This property is applicable only if `Physical Type` is `Text`. It is used if the value of the `Virtual Decimal Point` property is 0, which indicates that the decimal point is present in the data. It deals with truncation, and specifies how many digits are to follow the decimal point. Either specify a number of digits: • If you set `Precision` to 0, data is truncated so that the fractional part is lost. For example, the value `123.45` is truncated to `123`. • If you set `Precision` to a number less than the number of fractional digits, data is truncated. For example, the value `123.4567` is truncated to `123.45` if you set `Precision` to 2. • If you set `Precision` to a number greater than the number of fractional digits, the value is padded with extra zeros. For example, the value `12.345` is padded to `12.34500` if you set `Precision` to 5. Or select one option from the list: • `All Significant Digits - decimal separator only required if fractional digits` (the default): all significant digits are written to the output bit stream, and no decimal separator is written if no fractional digits are present. • `Explicit Decimal Separator - decimal separator always required`: all significant digits are written to the output bit stream and the decimal separator is always included, even when no fractional digits are present. The decimal separator must be present in the input bit stream, even when no fractional digits are present. • `Exponential Notation - Example "1.23456e002"`: data is written out to the bit stream as a signed value having the format `[sign1]a.bbbe[sign2]ccc` where: – `[sign1]` is the value of `Negative Sign` if the value is negative – `a` is a single decimal digit – `bbb` is one or more decimal digits – `[sign2]` is the value of `Negative Sign` if the exponent is negative – `ccc` is exactly three decimal digits (the exponent) `[sign1]` and `[sign2]` are absent if the value and exponent are positive. For example, the value -123.456 is represented as `-1.23456e002` and the value 0.00012 is represented as `1.2e-004` in the output bit stream, assuming that the value of `Negative Sign` is "-", and the value of `Sign Orientation` is `Leading`. The value -0.00012 is represented as `1.2*e*004` if `Negative Sign` is "*" and `Sign Orientation` is `Trailing`.

Property	Type	Meaning
Sign Orientation	Enumerated type	The values that you can choose for this property are: • Leading Separate • Trailing Separate • Leading Overpunched • Trailing Overpunched This property is enabled only if you have set Physical Type to Text or External Decimal, and you have selected Signed. If Physical Type is Text, the only valid values of Sign Orientation are Leading Separate and Trailing Separate. If Physical Type is External Decimal and Sign EBCDIC Customer Overpunched is selected, the only valid values of Sign Orientation are Leading Overpunched and Trailing Overpunched.
Positive Sign	String	Specify the value that represents the positive symbol. Do not specify a numeric value. If no value is set, "+" is assumed. The positive sign is not written when creating an output message; it is used only to recognize the positive sign when parsing a message bit stream. This property is applicable only if Physical Type is Text and Signed is selected.
Negative Sign	String	Specify the value that represents the negative symbol. Do not specify a numeric value. If no value is set, "-" is assumed. This property is applicable only if Physical Type is Text and Signed is selected.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • NULLPadFill. This option is valid only for fixed-length objects and is the default value. • NULLLogicalValue. The Encoding Null Value property is first converted to an actual value, and rendered in the way specified for the field. • NULLLiteralValue. This option specifies that Encoding Null Value contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the Encoding Null Value property to test or compare the content of the field in the message. • NULLLiteralFill. This option specifies that the field is filled with the value specified by the Encoding Null Value property. Encoding Null Value must resolve to a single character. The option that you select determines the value that you must set for the property Encoding Null Value. For full information about using these options, see “TDS Null handling options” on page 6293.
Encoding Null Value	String	The use of this property depends on the Encoding Null property. The default value is zero. If you set the Encoding Null property for a dateTime object to NULLLogicalValue, the value that you set must be in an ISO8601 dateTime format. These formats are described in “DateTime as string data” on page 6311. For example, specify a value that conforms to the yyyy-MM-dd'T'HH:mm:ss format; for example, 1970-12-01.

TDS properties for embedded simple type integer types:

Field identification, physical representation, numeric representation, and null values.

The TDS properties described here apply to:

- Objects: Embedded simple types

Field identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Integer`. Equates to the data type SHORT or LONG in C, or the COMP, COMP-4, COMP-5, or BINARY numeric data type in COBOL. • `Packed Decimal`. The data is a packed decimal number that equates to the COMP-3 data type in COBOL. • `External Decimal`. The data is a decimal number that equates to the data type PIC 9 USAGE DISPLAY in COBOL. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.

Property	Type	Meaning
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. If this property is not set and the message set property `Derive default length from logical type` is selected, and the `Physical type` is 'Character', the default value is derived from any totalDigits value constraint (schema facet) or, if none, any `minInclusive`, `maxInclusive`, `minExclusive`, or `maxExclusive` value constraints (schema facets), on the simple type.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Numeric representation

Property	Type	Meaning
Sign Orientation	Enumerated type	The values that you can choose for this property are: • Leading Separate • Trailing Separate • Leading Overpunched • Trailing Overpunched This property is enabled only if you have set Physical Type to Text or External Decimal, and you have selected Signed. If Physical Type is Text, the only valid values of Sign Orientation are Leading Separate and Trailing Separate. If Physical Type is External Decimal and Sign EBCDIC Customer Overpunched is selected, the only valid values of Sign Orientation are Leading Overpunched and Trailing Overpunched.
Positive Sign	String	Specify the value that represents the positive symbol. Do not specify a numeric value. If no value is set, "+" is assumed. The positive sign is not written when creating an output message; it is used only to recognize the positive sign when parsing a message bit stream. This property is applicable only if Physical Type is Text and Signed is selected.
Negative Sign	String	Specify the value that represents the negative symbol. Do not specify a numeric value. If no value is set, "-" is assumed. This property is applicable only if Physical Type is Text and Signed is selected.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • NULLPadFill. This option is valid only for fixed-length objects and is the default value. • NULLLogicalValue. The Encoding Null Value property is first converted to an actual value, and rendered in the way specified for the field. • NULLLiteralValue. This option specifies that Encoding Null Value contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the Encoding Null Value property to test or compare the content of the field in the message. • NULLLiteralFill. This option specifies that the field is filled with the value specified by the Encoding Null Value property. Encoding Null Value must resolve to a single character. The option that you select determines the value that you must set for the property Encoding Null Value. For full information about using these options, see “TDS Null handling options” on page 6293.

Property	Type	Meaning
Encoding Null Value	String	The use of this property depends on the `Encoding Null` property. The default value is zero. If you set the `Encoding Null` property for a dateTime object to `NULLLogicalValue`, the value that you set must be in an ISO8601 dateTime format. These formats are described in "DateTime as string data" on page 6311. For example, specify a value that conforms to the `yyyy-MM-dd'T'HH:mm:ss` format; for example, `1970-12-01`.

The properties, and their permissible values, vary according to the object type.

TDS properties for embedded simple type string types:

Field identification, physical representation, and null values.

The TDS properties described here apply to:

- Objects: Embedded simple types

Field identification

Property	Type	Meaning
Tag	String	Specify the value that is used to identify the object in a message bit stream. If the object is simple and the `Data Element Separation` property of the complex type or types in which the object is a child is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, this property must contain a non-empty value. If the object is a complex element, and the `Data Element Separation` property of its parent is `Tagged Delimited`, `Tagged Fixed Length`, or `Tagged Encoded Length`, the property can contain an empty value. The value for this property must be unique for every element in the message set; that is, no two elements in the message set can contain the same value for this property.
Data Pattern	String	Specify the regular expression that the parser uses to identify the data in the message to assign to the object. This property is used when the `Data Element Separation` method is set to `Use Data Pattern` in the complex type. For more details, see "Regular expression syntax" on page 6304.
Interpret Element Value	Enumerated type	Specify whether values stored within this object are interpreted as having significance for the parser and, if so, the type of interpretation that occurs. This interpretation is standard-specific and is therefore hard coded. The possible values for this property are: • `None` (the default value) • `EDIFACT Service String` • `X12 Service String` • `Message Key` • `EDIFACT Syntax Level ID` • `HL7 Service String` • `HL7 Field Separator`
Repeating Element Delimiter	String	Specify the delimiter to use between repeating elements. This delimiter is used only when the element repeats and the `Data Element Separation` property of the parent group or complex type is set to `All Elements Delimited` or `Variable Length Elements Delimited`. A default value is provided if the previous conditions are true; if the messaging standard is HL7, the mnemonic <HL7_RS> is used; if the messaging standard is not HL7, and the maximum number of repeats is fixed, the delimiter of the parent group or complex type is used. If none of the previous conditions are true, a default is not applied.

Physical representation

Property	Type	Meaning
Physical Type	Enumerated type	Select the physical type of the object. If the `Messaging Standard` property of the message set is `User Defined Text`, `User Defined Mixed`, `CSV`, or `TLOG`, select one of the following values: • `Text`. The data is in character format. • `Length Encoded String 1`. The first byte of the data contains the length (in length units) of the data string that follows the length byte. The maximum length of a `Length Encoded String 1` element is 255 length units. • `Length Encoded String 2`. The first two bytes of the data contain the length (in length units) of the data string that follows the two length bytes. The maximum length of a `Length Encoded String 2` element is 65535 length units. • `Null Terminated String`. The data string ends with the hexadecimal NULL character, `X'00'`. • `TLOG Specific` - this option can be selected only if the `Message Standard` property of the message set is `TLOG`. This option indicates that the format of the data is specific to the TLOG messaging standard. The default is dependent on the `Messaging Standard` property. For all other `Messaging Standard` values, the `Physical Type` property is set to `Text`.
Length	Integer	Specify the expected length of the object in length units. A non-zero length must be specified if no `Length Reference` is specified. If this property is not set and the message set property `Derive default length from logical type` is selected, and the `Physical type` is 'Character', the default value is derived from any length or maxLength value constraint (schema facet) on the simple type.
Justification	Enumerated type	Specify the justification of the object if the data being written or parsed is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Select one of the following values from the list: • `Not Applicable` • `Left Justify` • `Right Justify`

Property	Type	Meaning
Padding Character	String	Specify the padding character to be inserted or interpreted on the writing or parsing of a fixed-length object, if the data is less than the fixed-length value. This property is used only when a value is written as a fixed-length string. Set this character in one of the following ways: • Select `NUL`, `'0'`, or `SPACE` from the drop-down list. • Enter a character between quotation marks, for example "c" or 'c', where c is any alphanumeric character. • Enter a hexadecimal character code in the form `0xYY`, where `YY` is a hexadecimal value. • Enter a Unicode value in the form `U+xxxx`, where `xxxx` is a Unicode value specified in hexadecimal. The maximum length of the string that you can enter is 10. The choice of which of these padding character forms is used for an MRM element depends on the padding character required and whether the padding character is subject to data conversion. In most cases, the specification of a padding character is sufficient, and when this padding character is used, it is converted to the target code page of the output MRM message that is generated. If a padding character is required that cannot easily be entered in the padding character field, the Unicode mnemonic format can be used to specify the required character. When used, this Unicode value is also converted to the target code page of the MRM message that is generated. If a padding character is required that is not subject to data conversion, the hexadecimal format can be used. This gives the option of specifying a padding character that is inserted directly into the output message. If this format is used, you must ensure that the hexadecimal value is valid for the code page of any output messages that are created using these MRM definitions. If you convert a message from one code page to another, you must ensure that the converted value of the padding character is valid for this code page. For example, when converting from ASCII to code page 500, if you have specified the numeric 8 as your padding character, it is converted from 0x08 to 0x15; the ASCII and EBCDIC representations of Backspace. There is a currently a restriction that the value of your padding character must not be greater than U+007F. If you enter a Unicode mnemonic or numeric value, it is considered to be the character that is represented by that number in UTF-8.
Length Reference	Enumerated type	This property is applicable only if `Physical Type` is `Text`, `Binary`, or `TLOG Specific`. If set, this property takes precedence over any value in the `Length Units` property. Specify the identifier of a sibling integer object, the value of which determines the length of the object in question. The sibling object must be defined before the current object within the message structure. For information about reordering elements, see “Reordering objects” on page 2900.

Representation of null values

Property	Type	Meaning
Encoding Null	Enumerated type	Select one of the following options from the list: • `NULLPadFill`. This option is valid only for fixed-length objects and is the default value. • `NULLLogicalValue`. The `Encoding Null Value` property is first converted to an actual value, and rendered in the way specified for the field. • `NULLLiteralValue`. This option specifies that `Encoding Null Value` contains a value that is directly substituted as if it is a string. For dateTime elements, use this option if you want to use the `Encoding Null Value` property to test or compare the content of the field in the message. • `NULLLiteralFill`. This option specifies that the field is filled with the value specified by the `Encoding Null Value` property. `Encoding Null Value` must resolve to a single character. The option that you select determines the value that you must set for the property `Encoding Null Value`. For full information about using these options, see "TDS Null handling options" on page 6293.
Encoding Null Value	String	The use of this property depends on the `Encoding Null` property. The default value is zero. If you set the `Encoding Null` property for a dateTime object to `NULLLogicalValue`, the value that you set must be in an ISO8601 dateTime format. These formats are described in "DateTime as string data" on page 6311. For example, specify a value that conforms to the `yyyy-MM-dd'T'HH:mm:ss` format; for example, `1970-12-01`.

MRM restrictions:

The MRM parser does not exactly follow the XML Schema 1.0 specification.

However, the XMLNSC domain fully complies with the XML Schema 1.0 specification when validation is enabled. All of the constructs that are mentioned in this topic are supported by the XMLNSC domain.

XML Schema features supported only in the message editor:
The following features can be created and edited using the message editor, but are not honored by the MRM domain.

- *Pattern facet on non-string data types*. The message broker only validates pattern facets that are applied to simple types based on xsd:string.
- *White space facet*. The message broker does not use the white space facet. However, if necessary, white space facets can be included in the message model. You can accurately control the processing of white space by using the settings on the physical formats.
- *ID attribute*. The message model can contain attributes with the name 'id', but these will not be checked for uniqueness.

XML Schema exceptions:

The following features can be created and edited using the message editor, but the MRM domain processes them in a way that differs from the XML Schema specification.

- *Default and fixed values*. The processing of default and fixed values depends on the physical format in which the message is parsed. For details on how each physical format uses these fields, refer to the concept topic *Relationship to the logical model* for the relevant physical format.
- *xsi:type attribute*. The xsi:type attribute is not automatically processed by the message broker. An attribute with the name 'xsi:type' can be included in the message model, and can be processed using a message flow.

Differences in validation:
If validation is enabled in a message flow, the following features or scenarios are not validated in exactly the same way as a validating XML parser would validate them:

- *Any Element or Any Attribute*. If the message model contains a wildcard ('any element' or 'any attribute'), the message broker validates the 'processContents' field as follows:
  - `skip`. No checking is done; any element or attribute is allowed.
  - `lax`. No checking is done; any element or attribute is allowed.
  - `strict`. Any element or attribute in the same message set is allowed.

  Note: If all of the definitions for a namespace are included within the same message set, the validation of 'strict' is the same as by a validating XML parser.
- *Element substitution and 'all' groups*. If an element can be substituted, and it occurs within an 'all' group, the following exceptions apply to the validation of the element:
  - The element is always validated as if it were optional.
  - An input message is not rejected if more than one of the substitutions is used in the same 'all' group.

Data types for elements in an MRM message:

A parser is supplied for the body of a message in the MRM domain; it associates each field with a specific data type.

For details of mapping from XML Schema data types that you have specified for elements in the MRM to data types used by the broker and supported by ESQL, see "ESQL to XML Schema data type mapping" on page 5044. When you create an element, you might find that associated value constraints are created to ensure a more accurate mapping of the XML Schema type.

Simple type - list

In the message tree, a list type will be represented as a name node with an anonymous value child for each list item. This allows repeating lists to be handled without any loss of information. Repeating lists will appear as sibling name elements, each of which has its own anonymous value child nodes for its respective list items.

More information about the MRM domain.

CWF data conversion:

You can convert an MRM message to a different code page or encoding, or both.

To do this, set the CodedCharSetId and Encoding fields in the Properties folder and the message tree to the target value.

The data conversion that is performed is dependent on the simple type of each element:

- Binary schema types: base64Binary, hexBinary objects are not converted.
- Boolean schema types: Boolean objects are not converted.
- DateTime schema types: date, dateTime, gDay, gMonth, gMonthDay, gYear, gYearMonth, time objects are handled as binary, string, packed decimal, timeSeconds, or timeMilliseconds.

  If a dateTime element is defined as binary, it is not converted.

  If it is defined as string, it is converted as a string element (described later in this section).

  If it is defined as a packed decimal value, it is converted as Decimal (described later in this section).

If it is defined as a timeSeconds or timeMilliseconds value, it is converted as Integer (described later in this section).

- Decimal schema types: decimal, integer, negativeInteger, nonNegativeInteger, nonPositiveInteger, positiveInteger, unsignedLong objects with *Physical Type* set to `External Decimal` are converted to the target CodedCharSetId. Elements with other *Physical Type* settings are converted to the target Encoding.
- Float schema types: double, float objects with *Physical Type* set to `External Decimal` are converted to the target CodedCharSetId. Elements with other *Physical Type* settings are converted to the target Encoding.
- Integer schema types: byte, int, long, short, unsignedByte, unsignedInt, unsignedShort objects with *Physical Type* set to `External Decimal` are converted to the target CodedCharSetId. Elements with other *Physical Type* settings are converted to the target Encoding.
- String schema types: anyURI, ENTITIES, ENTITY, ID, IDREF, IDREFS, language, Name, NCName, NMTOKEN, NMTOKENS, normalizedString, NOTATION, QName, string, token objects are converted to the target CodedCharSetId (the length of an object that has *Physical Type* of `Length Encoded String 2` is converted to the target Encoding).

XML Null handling options:

The XML Wire Format supports the handling of null values in messages. `Encoding null` properties for XML are set only on the message set, and apply to all the defined objects in the message set.

You can use the following two properties to represent the numeric and non-numeric encoding for NULL in the XML Wire Format:
- `Encoding Numeric Null`
- `Encoding Non-Numeric Null`

These properties represent the numeric and non-numeric encoding for NULL respectively.
- The numeric data types are:
  - Decimal schema types: decimal, integer, negativeInteger, nonNegativeInteger, nonPositiveInteger, positiveInteger, unsignedLong
  - Float schema types: double, float
  - Integer schema types: byte, int, long, short, unsignedByte, unsignedInt, unsignedShort
- The non-numeric data types are:
  - Binary schema types: base64Binary, hexBinary
  - Boolean schema types: Boolean
  - DateTime schema types: date, dateTime, gDay, gMonth, gMonthDay, gYear, gYearMonth, time
  - String schema types: anyURI, ENTITIES, ENTITY, ID, IDREF, IDREFS, language, Name, NCName, NMTOKEN, NMTOKENS, normalizedString, NOTATION, QName, string, token

Each of these encodings has the following enumerated values:
- NULLEmpty (default)
- NULLValue
- NULLXMLSchema
- NULLValueAttribute
- NULLAttribute (deprecated)
- NULLElement (deprecated)

You do not have to supply additional information for `NULLEmpty`, `NULLXMLSchema`, and `NULLValueAttribute`, but if you select `NULLValue`, `NULLAttribute`, or `NULLElement`, you must define further values to be assigned to represent the NULL condition in the `Encoding Numeric Null Value` and `Encoding Non-Numeric Null Value` message set properties.

The following table shows how each encoding works. For each encoding, the example XML causes the element `myElem` to be given a value NULL.

Encoding Numeric Null Encoding Non-Numeric Null	Encoding Numeric Null Value Encoding Non-Numeric Null Value	Example XML
NULLEmpty		`<myElem/>` `<myElem></myElem>`
NULLValue	zzz	`<myElem>zzz</myElem>`
NULLXMLSchema		`<myElem xsi:nil='true'/>`[1] [5]
NULLValueAttribute		`<myElem></myElem>`[2] `<parent id="myElem"></parent>`[3]
NULLElement	null[4]	`<myElem><null/></myElem>`
NULLAttribute	null[4]	`<myElem null='true'/>`[1]

Notes:

1. The attribute must evaluate to true, so the value must be `true`, `1`, or the `Boolean True Value` property.
2. This value is valid only for `XMLElementAttrVal` element rendering, as specified in "XML rendering options" on page 6262. Marking an element as being rendered in this way, and setting it to null, is equivalent to removing the attribute of the element that provides the element's value.
3. This value is valid only for `XMLElementAttrIdVal` element rendering, as specified in "XML rendering options" on page 6262. Marking an element as being rendered in this way, and setting it to null, is equivalent to removing the attribute of the element that provides the element's value, but not removing the attribute that provides the element's name.
4. Both `NULLElement` and `NULLAttribute` are deprecated. The element or attribute name provided must not include a namespace URI or prefix. If namespaces are enabled for the message set, the name matches any namespace.
5. `xsi:nil` is not supported with complex elements of MRM-XML.

When you set the *Encoding Null Num* property to NULLValue in XML, the value is taken as a literal.

"XML Null representation for Binary data" on page 6262
If you use the *Encoding Null Non-Num Val* field with a binary object in XML, enter the appropriate hex value.

"XML Wire Format message set properties" on page 5400
The following tables define the properties for the XML Wire Format for the message set.

XML Null value:

When you set the *Encoding Null Num* property to NULLValue in XML, the value is taken as a literal.

A direct comparison is done with the text string, and no logical data conversion is performed. This behavior is in contrast to the TDS and CWF formats.

For example, if you set the message set property *Encoding Null Num* to the value NULLValue, and you set *Encoding Null Num Val* to 0, a FLOAT value of 0.0 or a DECIMAL value of +0 does not match NULL.

Seting *Encoding Null Num* to NULLEmpty is equivalent to setting *Encoding Null Num* to NULLValue and *Encoding Null Num Val* to "".

More information about the MRM domain.

"Additional XML information" on page 6257
Options for rendering, and null handling.

"XML Null handling options" on page 6258
The XML Wire Format supports the handling of null values in messages. `Encoding null` properties for XML are set only on the message set, and apply to all the defined objects in the message set.

XML Null element and NullValAttr:
In XML there are two conventions for storing a value:

1. It can be stored as an XML attribute with a local element or element reference property *`Render`* set to `XMLAttribute`, `XMLElement`, `XMLElementAttrID`, `XMLElementAttrVal`, or `XMLElementAttrIDVal`. For example, `<element1 val="12"></element1>`.
2. It can be stored as XML content with a local element or element reference property *`Render`* set to `XMLElement`. For example, `<element1>12</element1>`.

If you set the message set property *`Encoding Null Num`* to `NULLElement`, there is no way to represent a null value for an attribute value. If a null value is present in the tree (from ESQL or another format), an attribute with an empty string is written in the output message.

Conversely, if you have set the message set property *`Encoding Null Num`* or *`Encoding Null Non-Num`* to `NULLValAttr`, there is no way to represent a null value for a value rendered as XML content. If a null value is present in the tree, when writing an empty string, an element with no character content is written out instead.

"XML Null handling options" on page 6258
The XML Wire Format supports the handling of null values in messages. `Encoding null` properties for XML are set only on the message set, and apply to all the defined objects in the message set.

XML rendering options:

You can use four properties on the XML layer that to affect how the XML messages are rendered.

The following table shows examples of the values that you can set for the *`Member Render`* property. In this table, the member element is referred to as *A*, and has the value `value of element`. The parent is referred to as *X*.

The effect of rendering options on XML output

To get XML rendered like this:	Set this Member Render property value:	Set these other property values:
<X> <A>value of element</A> </X>	XMLElement (the default)	Member XML Name = A
<X A='value of element'/>	XMLAttribute	Member XML Name = A
<X> <Field id='A'>value of element</Field> </X>	XMLElementAttrID	Member XML Name = Field Member ID Attribute Name = id Member ID Attribute Value = A
<X> <A val=value of element/> </X>	XMLElementAttrVal	Member XML Name = A Member Value Attribute Name = val
<X> <Field id='A' val='value of element'/> </X>	XMLElementAttrIDVal	Member XML Name = Field Member ID Attribute Name = id Member ID Attribute Value = A Member Value Attribute Name = val

You should not have an element in the model that is rendered as an XML attribute. This can result in incorrect validation of XML documents. Instead the element should be redefined as an attribute in the model.

You should not have an attribute in the model that is rendered as an XML element. This can result in incorrect validation of XML documents. Instead the attribute should be defined as an element in the model.

There is one scenario where this technique is appropriate. When you have created a message model by importing a C header file or a COBOL copybook, it will consist entirely of elements. An XML form of this model can be created by simply adding an XML physical format to the message set. If you are looking for certain elements to appear as XML attributes in the XML form, you can use the `Render` property to achieve this.

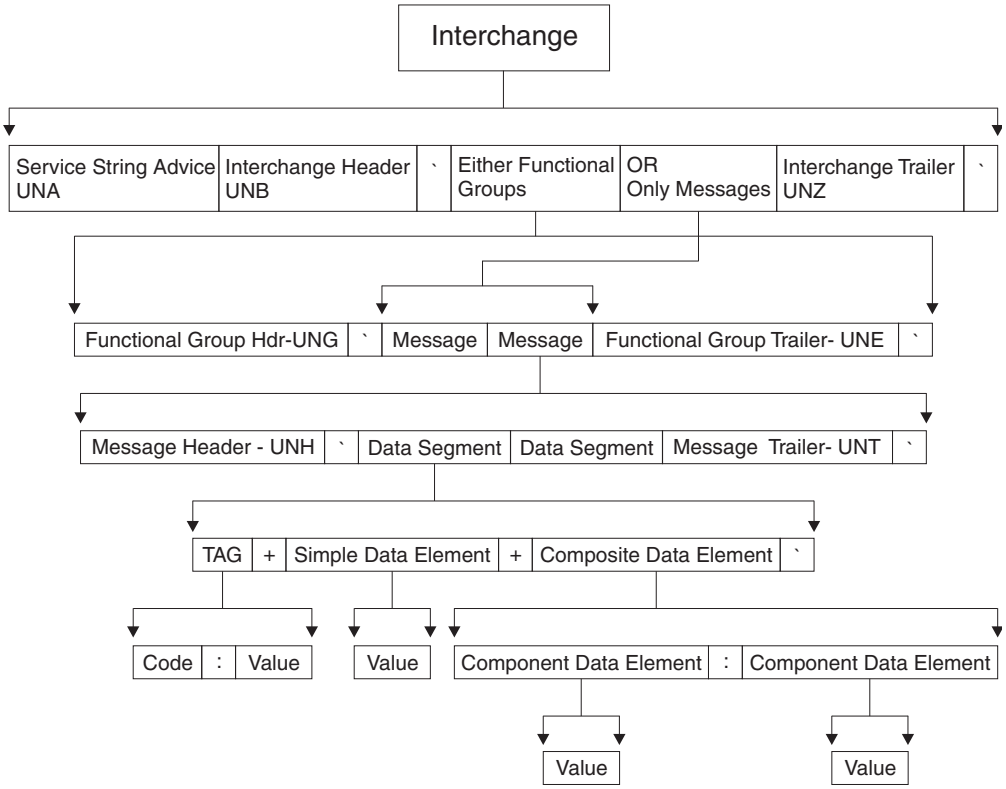
EDIFACT messaging standard:

EDIFACT, an international standard for EDI trading in commercial and non-commercial sectors, has an underlying syntax that is an ISO standard.

Within that syntax, there are directories of data elements, composite data elements, segments, and messages. There are conventions for placing messages in an "envelope" which identifies the sender and receiver and other attributes of a transmission. For more information about the EDIFACT messaging standard, see the United Nations Centre for Trade Facilitation and Electronic Business Web site and click "Standards" on the left side.

EDIFACT messages can be modeled using the MRM Tagged/Delimited String Format (TDS).

The high-level structure of an EDIFACT message is as follows:



You can model the top-level interchange of an EDIFACT message by setting the following properties for the complex type on which the message is based:

Composition = Sequence
Content Validation = Closed
Tag Data Separator = <EDIFACT_TAGDATA_SEP>
Data Element Separation = Tagged Delimited
Delimiter = <EDIFACT_CS>

Within an EDIFACT message, you can define the delimiters to be used in the message itself using the optional Service String Advice element. To enable this element to be recognized as an EDIFACT Service String, you must set the element property *Interpret Element Value* to EDIFACT Service String. You must also set the delimiter values to the mnemonic values that are defaulted when you set the *Message Standard* property to EDIFACT.

A predefined message set solution for EDIFACT can be purchased from IBM.

WebSphere Message Broker supports the ACORD AL3, CSV, EDIFACT, FIX, HL7, SWIFT, TLOG, and X12 standards.

HL7 messaging standard:

The HL7 messaging standard defines the structure and content of messages that are exchanged between systems in various administrative, financial, and clinical activities in the healthcare industry.

HL7 messages can be modeled using the MRM Tagged/Delimited String Format (TDS).

If you are working with HL7 messages you can specify the messaging standard at the message set level and a number of the properties for this standard are set to default settings for HL7 at the message set, complex type, group, and element levels.

Predefined HL7 message sets are available as part of the following Healthcare sample:

- Healthcare

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

SWIFT messaging standard:

SWIFT supplies secure, standardized messaging services and interface software to financial institutions.

SWIFT FIN messages can be modeled using the MRM Tagged/Delimited String Format (TDS).

The high-level block structure of a SWIFT message is shown in the following table.

SWIFT message high level block structure

Block name	Format
Basic header	{1:...}
Application header	{2:...}
User header	{3:...}
Text	{4:...}
Trailer	{5:...}

When they are concatenated in a message, the blocks appear as:
{1:...}{2:...}{3:...}{4:...}{5:...}

You can model this setting the following type properties for the message:

```
Data Element Separation = Tagged Delimited
Group Indicator = {
Delimiter = }{
Group Terminator = }
Tag Data Separator = :
```

Each block is modeled as a complex element with element *Tag* property values of 1,2,3,4, and 5 respectively.

The text body of the message has the following format:

```
{4:
:20:X
:32A:940930USD1,
.....
:72:/A/
-}
```

You can model the complex type of the Text body by setting the following type properties:

```
Data Element Separation = Tagged Delimited
Group Indicator = <CR><LF>:
Delimiter = <CR><LF>:
Group Terminator = <CR><LF>-
Tag Data Separator = :
```

The *Tag* property of the elements within the body has values of 20, 32A, 72, and so on.

A predefined message set solution for SWIFT can be purchased from IBM. See the WebSphere MQ SupportPacs web page.

Swift is a cooperative owned by the financial industry. For more information about the SWIFT messaging standard, see the SWIFT community website.

"TDS Industry standard formats" on page 6265
WebSphere Message Broker supports the ACORD AL3, CSV, EDIFACT, FIX, HL7, SWIFT, TLOG, and X12 standards.

TLOG messaging standard:

In the retail industry, a TLOG is the Point of Sale (POS) Transaction Log.

The TLOG is a complete, detailed record of everything that occurs at the Point of Sale (POS) terminal, including events that are not directly related to a sales transaction. Typically, the precise TLOG record format is unique to a given POS application, but most formats are based on a tagged/delimited string format called Raw TLOG.

Raw TLOG messages can be modeled using the MRM Tagged/Delimited String Format (TDS).

If you are working with TLOG messages you can specify whether fields in the messages are in character format or in a format that is specific to the message. The message format needs the *Messaging Standard* property (at the message set level) to be set to `TLOG`, and that relevant objects that have this non-character based field in the TDS message have the *Physical Type* property set to `TLOG Specific`.

Predefined TLOG message sets are available as part of the following TLOG Processor samples:

- TLOG Processor

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

"TDS Industry standard formats" on page 6265
WebSphere Message Broker supports the ACORD AL3, CSV, EDIFACT, FIX, HL7, SWIFT, TLOG, and X12 standards.

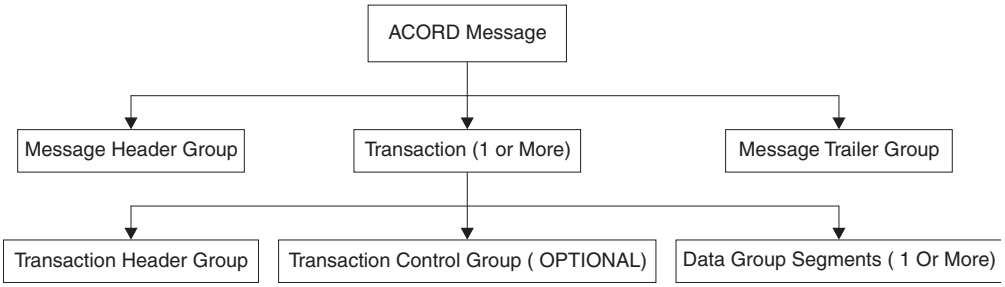
ACORD AL3 messaging standard:

The basic structure of an ACORD AL3 message.



Each group with an ACORD AL3 message has a header consisting of a one-digit number, three letters, plus a three-digit total length count. These first seven characters can be modeled as a tag. The data within the headers is fixed length. Therefore the header type used for the overall message can be modeled as follows:

```
Data Element Separation = Tagged Fixed Length
Length of Tag = 7
```

The Transaction Group contains other groups, and is therefore modeled in the same way as the overall message. The Message Header Group and the Message Trailer group consist of fixed-length elements, therefore the type used can be modeled as:

```
Data Element Separation = Fixed Length
```

Two *Data Element Separation* methods are suited to handling ACORD AL3 messages:

- `Fixed Length AL3` supports basic handling of ACORD AL3 messages, including situations where the message groups conform to a different version of the ACORD AL3 standard. This is deprecated and will be removed in a future version of the product; an alternative will be provided.
- `Tagged Encoded Length` supports handling of more sophisticated situations, including messages containing message groups unknown to the message dictionary.

The following sections describe their use:

- "Using Fixed Length AL3" on page 6273
- "Using Tagged Encoded Length to support reversioning" on page 6274

Using Fixed Length AL3:

Using Fixed Length AL3 is deprecated.

Fixed Length AL3 will be removed in a future version of the product; an alternative will be provided.

You can select the value `Fixed Length AL3` for the *`Data Element Separation`* property for complex types within a message that conforms to the ACORD AL3 standard. Different versions of the ACORD AL3 standard can be supported using the same message set. This value is like the value `Fixed Length` except for the following:

- A question mark (?) in the left-most position of an element means that it is skipped.
- A sequence of question marks is inserted for all missing optional elements.
- Unused trailing optional elements are truncated.
- Any <CR><LF> after the last element is ignored.
- The length field is extracted on input (and *not* put to the tree), and automatically recalculated on output.

"ACORD AL3 messaging standard" on page 6272
The basic structure of an ACORD AL3 message.

Using Tagged Encoded Length to support reversioning:

Parse tags containing groups that are not in the current ACORD AL3 standards.

The incoming message might contain a group that is no longer in use within the current ACORD AL3 standards, and has therefore been deleted from the later version of the standards. Similarly, the incoming bit stream might be from a later version of the ACORD AL3 standards, and might contain a new group that was not defined in earlier versions.

In order to correctly parse this self-defining tag, the TDS parser needs to know the length of the group it is parsing and skip to the end of all data associated with that self-defining tag.

Use the *Data Element Separation* method `Tagged Encoded Length` to handle these situations. You must also set these properties:

- `Length of Tag` or `Tag Data Separator`, so that the TDS parser knows where tags end.
- `Length of Encoded Length`, so that the TDS parser knows the size of the length field.
- `Extra Chars in Encoded Length`, are used to indicate to the TDS parser how many characters, apart from the data itself, are counted in the encoded length field.

"TDS Industry standard formats" on page 6265
WebSphere Message Broker supports the ACORD AL3, CSV, EDIFACT, FIX, HL7, SWIFT, TLOG, and X12 standards.

CSV messaging standard:

The comma separated value (CSV) format is a typical format for describing data in tables or spreadsheets.

The CSV format is used to exchange data between database applications or spreadsheet applications. Although the CSV format is widely used, a definitive specification has not been formally documented. However, these are some of the rules that characterize the CSV format:

- Data fields are separated by commas, and groups of data fields are separated by repeating field delimiters (for example, the <CR><LF> combination of ASCII characters).

  Here is a typical CSV message:

  ```
  12345,Smith,John,"3, North Street"<CR><LF>
  41352,Jones,Ivor,"5, South Road"<CR><LF>
  53421,Edwards,David,"10, East Lane"
  ```

- A comma that occurs within a data field is regarded as part of the data, rather than as a field separator, only if the comma is surrounded by quotation marks (").
- A quotation mark character (") that is within a data field that is enclosed within quotation marks must always be 'escaped' by another instance of the quotation mark character.

  For example, `xx"xx` must be written as `"xx""xx"`, and `"xxxx"` must be written as `"""xxxx"""`.
- In an input message, any variable length data field can be enclosed within quotation mark characters, regardless of whether the field contains any special characters such as quotation mark characters, escape characters, or other reserved characters.

The quotation mark characters must occur at the start and end of the data, are stripped from the data when the field is parsed, and are not added to the output tree. For example, the data `A,"B",C` results in an output tree that contains the values A, B, and C.

- If a data field contains two quotation mark characters and nothing else, the quotation mark characters are removed by the parser and the data field is processed in the same way as an empty field.
- In an output message, any data field that contains a quotation mark character, or any of the special characters that are specified in the TDS message set Reserved Characters property, has quotation mark characters added.

CSV messages can be modeled by using the MRM Tagged/Delimited String Format (TDS). The default message set property values are shown in "Default TDS message set properties" on page 5394.

The following sample is a message set application that shows you how to model some typical CSV message variants, and how to transform the sample CSV messages to and from XML. The XML messages illustrate the logical structure of the data after it has been parsed.

- Comma Separated Value (CSV)

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

You can also import a sample CSV message model by using the New Message Definition File From IBM Supplied Message wizard.

IDoc messaging standard:

Receiving data from SAP systems.

WebSphere Message Broker can receive data from SAP systems in various ways.

Two such ways are:

- ALE IDocs exported from SAP across the WebSphere MQ Link for R3.
- File IDocs exported from SAP to the file system.

Such IDocs are a fixed-length text format, and can be modeled using the MRM domain Tagged/Delimited String Format (TDS).

The IDOC domain is deprecated.

Note: For SAP data that is received from the WebSphere Adapter for SAP, use the DataObject domain.

"TDS Industry standard formats" on page 6265
WebSphere Message Broker supports the ACORD AL3, CSV, EDIFACT, FIX, HL7, SWIFT, TLOG, and X12 standards.

Building the MRM TDS model for an IDoc:

The MRM domain Tagged/Delimited String (TDS) physical format is suitable for parsing and writing SAP ALE IDocs and SAP File IDocs. ALE IDoc messages are exported from SAP across the WebSphere MQ Link for R3. File IDocs are exported from SAP to the file system.

About this task

This topic describes how to build the message model that is required by the MRM parser when parsing and writing SAP ALE and File IDocs using its TDS physical format.

Obtaining the IDoc:
About this task

Create an import file of the required IDoc data for the WebSphere Message Broker Toolkit.

Procedure

1. Log on to an SAP system.
2. Run the supplied transaction `we60`, which extracts the IDoc data as a C header file.
   a. In **Basic Type**, select the IDoc type of interest; for example, `MATMAS02`.

b. Leave the **Control**, **Data**, and **Status** check boxes cleared.
c. Select the **Record types** version. A version 4 IDoc is type **3**.
d. Press **F7** to display a C representation of the IDoc.
e. Click **unconverted**.
f. Select **System** > **List** > **Save** > **Local file**.
g. When prompted, enter a file name and directory for the output from the transaction. The C representation of the IDoc is saved to this C header file.

What to do next

Tip: The exported C header can be imported into the WebSphere Message Broker Toolkit without any further manual processing. This situation was not true in previous releases of WebSphere Message Broker.

Modeling the IDoc:
About this task

Create your message model.

Procedure

1. Switch to the Broker Application Development perspective of the WebSphere Message Broker Toolkit.
2. Use the New Message Set wizard to create a message set for your IDoc. Select text data as the data to use. This action creates a Tagged/Delimited String Format (TDS) physical format, and presets the *Default message domain* property to MRM.
3. Use the Message Set editor to rename the TDS physical format to Text_IDoc.
4. Use the New Message Definition File From IBM supplied message wizard to import a prebuilt model of the overall ALE or File IDoc message structure. This model includes definitions of the DC and DD segments. The prebuilt models are called SAP ALE IDoc and SAP File IDoc. The resultant message definition file is called `ale_idoc.mxsd` or `file_idoc.mxsd`. For information about using the New Message Definition File From IBM supplied message wizard, see "Importing from IBM supplied messages" on page 2942.
5. Use the New Message Definition File From C Header File wizard, or the **`mqsicreatemsgdefs`** command, to import the C representation of the IDoc into the new message set. Specify the following settings:
   - Set the Pre-processing option to SAP ALE IDoc or SAP File IDoc. If this option is not specified, the C header is not imported.
   - Create messages for the segments that appear in the IDoc.
   - Use the `String Encoding` option to import character arrays as fixed-length strings.
   - Use the `Padding Char for String` option to make space (" ") the padding character that is used.

   For information about using the wizard, see "Importing from C" on page 2934.

Using the IDoc message model:
About this task

You can now use your message model to help you to construct a message flow that processes instances of your IDoc message, in the same way as any other message that belongs to the MRM domain.

Tip: SupportPac IA0F contains a more detailed description of the steps involved in building the IDoc message model. You can ignore utilities IDocHeaderTweak and IDocMsgSetTweak because that processing has been incorporated into the New Message Definition File From C Header File wizard.

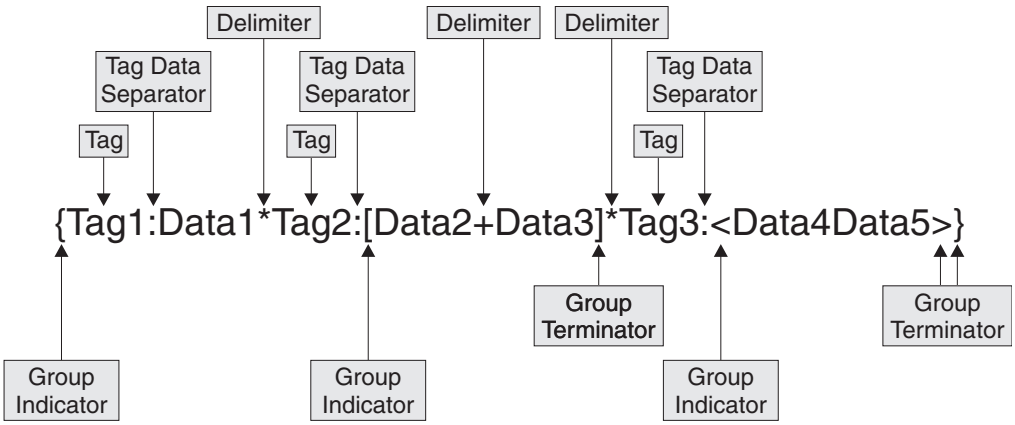
Message characteristics:

Features that are supported by the TDS wire format.

A number of features of text string messages are common across many formats. The following sections give an overview of the main features that are supported by the TDS wire format:

- The text strings in the message can have a tag or a label preceding the data value. The *tag* is a string that uniquely identifies the data value. The TDS format allows you to associate a tag with each element when you define the element in the WebSphere Message Broker Toolkit.
- The message can contain various special characters or strings in addition to the tags and text string data values. The TDS format supports a number of different types of special characters or strings. Some messages have a special character or string that separates each data value from the next. In the TDS format this is a known as a *delimiter*. In formats that have a tag before each data value, the tag can be separated from its data value by a special character or string. In the TDS format this is known as a *tag data separator*.
- A message can be split into a number of substructures in a similar manner to a to COBOL or C structure. You can model each of these substructures separately by defining complex types or elements for each one. Complex types and elements are described in "Message model objects" on page 1174. A substructure can have a special character or string that indicates its start within the data. This is known in the TDS format as a *group indicator*. A substructure can also have a special character or string that indicates its end in the data. In the TDS format, this is known as a *group terminator*. A group indicator and group terminator can also be defined for the whole message. Group indicators and group terminators are optional for the message and each substructure.
- Some text strings within a message can be of fixed length, so a delimiter between each data value is not necessary. This is supported by the TDS format. If you use a fixed length tag, a tagged data separator is not required.
- The TDS property that controls the way text strings are separated is *Data Element Separation*. It has several options that let you choose, for example, if tags are used, if strings lengths are fixed or variable, and what types of text strings are permitted. See "Specifying data element separation methods to model a message" on page 6284.
- The substructures within a message can use different types of *Data Element Separation* and use different special characters. Therefore the TDS format allows you to define different types of data element separation and special characters for each complex type within the message.
- If you use the Use Data Pattern method of *Data Element Separation*, you can use regular expressions to identify parts of the message data to be assigned to subfields. This is done by setting the regular expression in the Data Pattern property. See "Using regular expressions to parse data elements" on page 6301 for further details.

The following figure illustrates the tags and special characters in a TDS message, showing an example data message with each of its components labeled.



- At the top level, each data value has a tag associated with it, each tag is separated from its data value using a tag data separator of colon (:), and the data values are separated from each other using the asterisk delimiter (*).
- The group indicator for the message is the left brace ({) and the group terminator is the right brace (}).
- The data values `Data2` and `Data3` are in a substructure in which there are no tags, and each data element is separated from the next using the delimiter plus (+). The group indicator for this substructure is the left bracket ([) and the group terminator is the right bracket (]).
- The data values `Data4` and `Data5` are in a substructure in which the values are fixed length, and are therefore not separated by a delimiter. The group indicator for this substructure is the less than symbol (<) and the group terminator is the greater than symbol (>).

The following sections describe data element separation and the special characters in more detail:

- "Specifying data element separation methods to model a message" on page 6284
- "Specifying special characters to model a message" on page 6287

Specifying data element separation methods to model a message:

Specify the appropriate method of data element separation to identify data elements in a TDS message.

Elements of data in a TDS message are identified according to the data element separation method that you must specify for the *Data Element Separation* property for a complex type. Depending on the value that you have set for *Data Element Separation*, the properties *Tag Data Separator* and *Delimiter* (for a message set and a complex type) might also be required to identify each element.

The following describes the methods that you can specify for each complex type. The examples given are all based on a complex type that contains three elements of type STRING. The *Tag Data Separator*, where used, is the colon (:), and the *Delimiter*, where used, is the asterisk (*).

Tagged Delimited
Each data value is preceded by a tag that is specified as an element property. If the tag has an associated *Length of Tag*, indicating that the tag has a fixed length, each data value follows immediately after the tag. If the tag is not specified as fixed length, the tag is separated from the next element by a *Tag Data Separator*. Each data value is separated from the next by a *Delimiter*. There is no *Delimiter* after the last element in the complex type.

The following example shows tags of fixed length:

```
tag1data1*tag2data2*tag3data3
```

The following example shows tags of variable length:

```
tag1:data1*tag11:data2*tag111:data3
```

Tagged Fixed Length
This method is the similar to Tagged Delimited, but the data values are always fixed length. Therefore, no delimiter is required after each data value. The tags themselves can be fixed length or variable length, depending the setting of *Tag Data Separator* and *Length of Tag*.

The following example shows tags of fixed length:

```
tag1data1tag2data2tag3data3
```

The following example shows tags of variable length:

```
tag1:data1tag11:data2tag111:data3
```

Tagged Encoded Length
This method has a tag and a length field before the data. It indicates to the parser that following each tag in the bit stream there is data defining the length of data to be associated with that tag. You must set the *Length of Encoded Length* parameter. If the value in *Length of Encoded Length* includes extra characters, you must also set the *Extra Chars in Encoded Length* parameter.

The following example shows a tag of fixed length of four characters (*Length of Tag* has been set to four), a three-character length field (*Length of Encoded Length* has been set to three), and several characters of data. *Extra Chars in Encoded Length* has been set to zero:

```
tagA007dataAAAtagB006dataBBtagC009dataCCCCC
```

Given the bit stream above, the parser finds the tag "tagA" and extracts the length value 7. Because *Extra Chars in Encoded Length* is set to zero, the next seven (7 - 0) characters are the data. Then follow the characters for the next tag "tagB" and the length value of 6, and so on for tag "tagC". In each case in this example, the value in the length field is exactly the length of data.

The following example shows tags with a fixed length of four characters (*Length of Tag* has been set to four), a three-character length field (*Length of Encoded Length* has been set to three), and several characters of data. *Extra Chars in Encoded Length* has been set to three (because in this example the length field value includes the three-character length field as well as the data field):

```
tagA012dataAAAAAtagB010dataBBBtagC016dataCCCCCCCCC
```

Given the bit stream above, after "tagA" the parser extracts the length value 12. But because *Extra Chars in Encoded Length* is set to three, only the next nine (12 - 3) characters are the data. Then follow the characters for "tagB" and length value 10, and so on. In each case in this example, the value in the length field is three more than the actual length of data.

All Elements Delimited

The data values have no tag, but each data value is separated from the next by a delimiter.

The following example shows this:

```
data1*data2*data3
```

Variable Length Elements Delimited

If a data element is fixed length, the next data value follows immediately after it. If the data element is variable length, the next data value is separated from it by the delimiter. There are no tags.

The following example shows element 2 as fixed length, and elements 1 and 3 as variable length:

```
data1*data2data3
```

Use Data Pattern

The data associated with each element is determined by the parser matching the data with the regular expression in the *Data Pattern* property for that element. The TDS parser uses the regular expression in the *Data Pattern* to:

- Determine the length of data to associate with each element.
- Determine if, in the case of a repeating element, another occurrence of an element is present in the bit stream.
- Determine the presence (if the pattern is matched) or absence (if the pattern is not matched) of an element in the bit stream.

There are no delimiters or tags, other than those coded as part of the regular expression patterns. See “Regular expression syntax” on page 6304 for an explanation of how pattern matching works.

The following example shows three elements, each having the regular expression *Data Pattern* shown:

```
First Data Pattern = [A-Z]{1,3}
Second Data Pattern = [0-9]+
Third Data Pattern = [a-z]*

Message data = 'DT31758934information for you'

First element data: 'DT'
Second element data: '31758934'
Third element data: 'information'
```

The first *Data Pattern* means "from one to three characters in the range A to Z", the second means "one or more characters in the range 0 to 9", and the third means "zero or more characters in the range a to z". Notice how each element's data was terminated by the first character that did not match the element's *Data Pattern*.

Fixed Length

All elements are fixed length, and each data value immediately follows the next with no delimiter. There are no tags.

The following example shows this:

```
data1data2data3
```

Fixed Length AL3

This method is the same as Fixed Length, but it also notifies the parser to implement a number of rules in relation to missing elements, length encoding, and versioning that are predefined in the ACORD AL3 standard.

Undefined

This value is set automatically when you set the *Type Composition* property of a complex type to `Message`, and you cannot set it to any other value. You are also unable to set values for the TDS Type properties *Group Indicator*, *Group Terminator*, *Tag Data Separator*, *Length of Tag*, and *Delimiter*.

If you set the *Data Element Separation* method to `Undefined`, you must not set the *Type Composition* property to `Empty`, `Choice`, `Unordered Set`, `Ordered Set`, `Sequence`, or `Simple Unordered Set`.

For more information about *Type Composition* set to `Message`, see "Multipart messages" on page 1191.

Specifying special characters to model a message:

You can specify a number of different types of special character in the WebSphere Message Broker Toolkit.

You can also specify special character values for message sets, types, and type members. The values that you set for a type override the corresponding values that are set for the message set in which it is defined.

You can specify a special character value in one of the following ways:

- As a literal string of one or more characters.
- As a mnemonic value.
- As a combination of both mnemonics and literals.

The types of special character are described in the following table.

Special character type	Description	Set as a property of...
Group Indicator	This is a string that indicates the start of a group or complex type within a message	Message set, complex type
Group Terminator	This is a string that indicates that the end of a group or complex type within a message	Message set, complex type
Tag Data Separator	This is the string that is used to separate a tag from its data.	Message set, complex type
Delimiter	This is the string used to separate data elements from one another	Message set, complex type
Repeating Element Delimiter	This is the string used to separate repeating data elements from one another	Local element or element reference
Tag	This is the string that indicates the start of a piece of data.	Local element or global element
Escape character	This is the character that is used to allow special reserved characters (such as delimiters) to be included as part of data	Message set

Special character type	Description	Set as a property of...
Quotation marks	This is the character that is used to allow special reserved characters (such as delimiters) to be included as part of data.	Message set
Reserved characters	These are characters that have a special meaning; for example, escape characters, quotation marks, delimiters, and group indicators, are all examples of reserved characters.	Message set
Decimal point	This is the character that is used as the separator between the integer and fractional components of a decimal number.	Message set

If you create a complex type and set the `Data Element Separation` property to **`Tagged Delimited`**, the `Group Indicator` property to left brace ({) , the Group Terminator to right brace (}), the Tag Data Separator to colon (:), and the Delimiter to asterisk (*), the bit stream has the following format:

```
{tag1:data1*tag2:data2*tag3:data3}
```

In some message formats, a special character is specified before each element or after each element, as shown in the following two examples:

```
:data1:data2:data3
```

```
data1:data2:data3:
```

You can model these formats by using a combination of the Data Element Separation method, the Delimiter value, the Group Indicator value, and the Group Terminator value.

For the first example, specify **`Data Element Separation`** as All Elements Delimited, Delimiter as colon (:), and Group Indicator as colon (:).

For the second example, specify Data Element Separation as All Elements Delimited, Delimiter as colon (:), and Group Terminator as colon (:).

Using mnemonics for special characters:

A mnemonic is a tag that is delimited by < and >. The broker translates the mnemonic to obtain the actual value of the special character.

Mnemonics can be used in TDS properties Decimal Point, Escape Character, Reserved Characters, Delimiter, Group Indicator, Tag data Separator, Tag, and Repeating Element Delimiter to specify special characters.

There are two types of mnemonic:

- Control code mnemonics, which map to the common non-printing characters.

  These are mapped using the local code page for your system. This is typically an ASCII code page on distributed platforms and an EBCDIC code page on other platforms.

  This means that characters are generally mapped to the 'expected' values for your system. This depends on your code page setting; for more information, refer to your system documentation. If a specific mnemonic is not mapped to the value that you need, you can use the explicit representation (<U+xxxx>, <0xNN>, or <0XNN>) that is described later in this section.
- Message mnemonics for use with specific industry message standards such as X12.

  These are mapped according to their associated message standard. Each mnemonic has a default mapping, but in message standards such as EDIFACT and X12, this default can be overridden by a 'service string' that is specified in the message itself.

Mnemonics can be specified in one of the following ways:

- `<Mnemonic_Name>`, where `Mnemonic_Name` can comprise alphanumeric characters and underscore (_) characters.
- `<U+xxxx>`, where `xxxx` are hexadecimal digits. The mnemonic is interpreted as the Unicode character that corresponds to the value of the digits.
- `<0xNN> or <0XNN>`, where `N` is a hexadecimal digit. The mnemonic is interpreted as the raw byte value given by the digits.

For more details about the supported mnemonics, see "TDS Mnemonics" on page 5391.

TDS Mnemonics:

The Tagged/Delimited String Format (TDS) uses mnemonics for a number of properties for a message set, complex type, or both.

These TDS mnemonics and their associated properties are listed in the following table.

Mnemonic string	Meaning	Default value	Associated property
<EDIFACT_CS>	Component separator in EDIFACT	:	Message set and complex type or group, `Delimiter`
<EDIFACT_DEC_NOTATION>	Decimal notation in EDIFACT	.	Message set, `Decimal Point`
<EDIFACT_DS>	Data element separator in EDIFACT	+	Message set and complex type or group, `Delimiter`
<EDIFACT_ESC_CHAR>	Escape character in EDIFACT	?	Message set, `Escape Character`
<EDIFACT_GROUP_TERM>	Tag terminator in EDIFACT	'	Message set, `Group Terminator`
<EDIFACT_TAGDATA_SEP>	Tag data separator in EDIFACT This is overridden with the same value as that which overrides <EDIFACT_DS>	+	Message set and complex type or group, `Tag Data Separator`
<HL7_CS>	Component separator in HL7	^	Message set and complex type or group, `Delimiter`

Mnemonic string	Meaning	Default value	Associated property
<HL7_FS>	Data element separator in HL7	|	Message set and complex type or group, `Delimiter`
<HL7_RS>	Repeating element delimiter in HL7	~	Local element and element reference, `Repeating Element Delimiter`
<HL7_SCS>	Sub-component separator in HL7	&	Message set and complex type or group, `Delimiter`
<X12_CS>	Component separator for X12	:	Message set and complex type or group, `Delimiter`
<X12_DS>	Data element separator for X12	*	Message set and complex type or group, `Delimiter`
<X12_ERS>	Element repetition separator for X12	{	Local element and element reference, `Repeating Element Delimiter`
<X12_GROUP_TERM>	Tag terminator in X12	!	Message set level, `Group Terminator`

Mnemonics for control characters are shown in the following table.

Mnemonic	Hex value	Unicode	Description
<ACK>	X'06'	<U+0006>	Acknowledge
<BEL>	X'07'	<U+0007>	Bell
<BS>	X'08'	<U+0008>	Backspace
<CAN>	X'18'	<U+0018>	Cancel
<CR>	X'0D'	<U+000D>	Carriage Return
<DC1>	X'11'	<U+0011>	Device Control One
<DC2>	X'12'	<U+0012>	Device Control Two
<DC3>	X'13'	<U+0013>	Device Control Three
<DC4>	X'14'	<U+0014>	Device Control Four
<DLE>	X'10'	<U+0010>	Data Link Escape
<EM>	X'19'	<U+0019>	End of Medium
<ENQ>	X'05'	<U+0005>	Inquiry
<EOT>	X'04'	<U+0004>	End of Transmission
<ESC>	X'1B'	<U+001B>	Escape
<ETB>	X'17'	<U+0017>	End of Transmission Block
<ETX>	X'03'	<U+0003>	End of Text
<FF>	X'0C'	<U+000C>	Form Feed
<FS>	X'1C'	<U+001C>	File Separator
<GS>	X'1D'	<U+001D>	Group Separator
<GT>	X'3E'	<U+003E>	Greater Than
<HT>	X'09'	<U+0009>	Horizontal Tabulation
<LF>	X'0A'	<U+000A>	Line Feed
<LT>	X'3C'	<U+003C>	Less Than

Mnemonic	Hex value	Unicode	Description
<NAK>	X'15'	<U+0015>	Negative Acknowledge
<NUL>	X'00'	<U+0000>	Null-
<RS>	X'1E'	<U+001E>	Record Separator
<SI>	X'0F'	<U+000F>	Locking Shift Zero (Shift In)
<SO>	X'0E'	<U+000E>	Locking Shift One (Shift Out)
<SOH>	X'01'	<U+0001>	Start of Heading
<SP>	X'20'	<U+0020>	Space
<STX>	X'02'	<U+0002>	Start of Text
<SUB>	X'1A'	<U+001A>	Substitute
<SYN>	X'16'	<U+0016>	Synchronous Idle
<US>	X'1F'	<U+001F>	Unit Separator
<VT>	X'0B'	<U+000B>	Vertical Tabulation

These mnemonics were created for characters that cannot be entered into the message editor.

You can enter a mnemonic in the form `<U+NNNN>`, where `NNNN` are hexadecimal digits. None of the characters in this structure are case-sensitive. Do not enclose spaces inside the angle brackets. These numbers represent a Unicode character, not a character in the code page of the input message.

You can enter a mnemonic in the form `<0xNN>`, where `NN` are hexadecimal digits. None of the characters in this structure are case-sensitive. Do not enclose spaces inside the angle brackets. These numbers represent a raw hexadecimal byte value, not a character in the code page of the input message.

If a mnemonic is of the form `<0xNN>`, it is applied directly to the input data, and no code page conversion takes place. Otherwise, a mnemonic is applied to the data after the data has been converted into Unicode from the code page of the input data.

Related tasks:

"Working with physical formats" on page 2847
If you are using the MRM domain to parse and write your messages, when you are developing your message model you might want to add one or more physical format layers to a message set, then configure the properties of these physical formats.

Related reference:

"Message set properties" on page 5371
Message sets have properties that you can set to define their characteristics and the way in which they are processed.

"TDS Format message set properties" on page 5381
The following tables show the properties that you can set for a TDS format message set.

"Default TDS message set properties" on page 5394
The following tables define the defaults for the message set properties for the TDS Format for each of the industry standard messages that you can define.

TDS Null handling options:

TDS supports the handling of null values within messages, provided that the logical Nillable property of the element is set.

You can use the message set property `Boolean Null Representation` to specify the value to be used for Boolean Null representation. You can use the object properties `Encoding Null` and `Encoding Null Value` to control how null handling is represented for individual objects.

You can select the `Encoding Null` property from the enumerated values `NULLPadFill`, `NULLLogicalValue`, `NULLLiteralValue`, and `NULLLiteralFill`:

- Only use the `NULLPadFill` option for fixed length objects. If you select this option for an object of simple type dateTime, a null dateTime is written out, which is an empty tag with a delimiter. (This is equivalent to selecting NullLiteralValue, with the `Encoding Null Value` property set to the empty string "".) If you select this option for an object of another simple type, the object is filled with the value specified by the `Padding Character` property. If you select this option, the `Encoding Null Value` property is disabled.
- If you select the `NULLLogicalValue` option, the value entered for the `Encoding Null Value` property is converted to its logical value. For writing, the logical value is written in the same way as any other value. For parsing, the converted logical value is compared against the converted message data.
- If you select the `NULLLiteralValue` option, the value entered for the `Encoding Null Value` property is directly substituted as if it were a string value. The value is not case sensitive. For fixed length objects, the literal value must be no longer than the length of the object.

  If the literal value is shorter, the `Encoding Null Value` is padded (using `Padding Character`) on output. On input, if the `NULLLiteralValue`'s length does not match the `Length` field, set the message set level `Trim Fix Len String` property so that padded nulls are correctly parsed.
- If you select the `NULLLiteralFill` option, the value entered for the `Encoding Null Value` property is interpreted as a single character string value. Therefore, each character of the value of the element in the bit stream must match exactly the character value specified, to be interpreted as a null value.

The use of the `Encoding Null Value` property is dependent on the value that you select for the `Encoding Null` property described above. Null values are not defined for binary types. The properties `Encoding Null` and `Encoding Null Value` are therefore not set for binary types.

Handling missing fields in a delimited format

When dealing with delimited message formats, it is common for fields to be empty. For example, in a line-oriented format, blank lines might be inserted to separate lines of data.

```
This is Line 1<CR><LF>
<CR><LF>
This is Line 3<CR><LF>
This is Line 4
```

If the TDS property `Suppress Absent Element Delimiters` of the parent complex type is set to `Never`, such a message is successfully parsed, but the blank line does not appear in the message tree:

```
MRM
   - line1 = 'This is Line 1'
   - line3 = 'This is Line 3'
   - line4 = 'This is Line 4'
```

If you need to preserve the blank lines in the message tree, you can use TDS null handling to treat the blank line as NULL. Configure the following properties on the element:

- Select `Nillable` .
- Set `TDS Encoding Null` to `NullLiteralValue`.
- Leave `TDS Encoding Null Value` empty.

The message tree then looks like:

```
MRM
   - line1 = 'This is Line 1'
   - line2 = NULL
   - line3 = 'This is Line 3'
   - line4 = 'This is Line 4'
```

The example above assumes that each line is modeled as an element of simple type string. If each line is modeled as an element of complex type, with each line consisting of a repeating number of word elements, set the three null handling properties on the word element instead, because an element of complex type cannot have a null value.

The message tree then looks like:

```
MRM
   - line1
        - word = 'This'
        - word = 'is'
        - word = 'Line'
        - word = '1'
   - line2
        - word = NULL
   - line3
        - word = 'This'
        - word = 'is'
        - word = 'Line'
        - word = '3'
   - line4
        - word = 'This'
        - word = 'is'
        - word = 'Line'
        - word = '4'
```

General rules: TDS message model integrity:

General rules govern each value that you can set for the *Data Element Separation* property of a type.

Tagged Delimited

- The *Tag* property for every simple child element must contain a non-empty value.

Tagged Encoded Length

- The *Tag* property for every simple child element must contain a non-empty value.
- The *Length Of Encoded Length* property must contain a positive integer greater than zero.

Variable Length Elements Delimited

- The *Delimiter* property must contain a non-empty value.

Use Data Pattern

- Each simple element that is a child of the complex type must have a regular expression specified for *Data Pattern*. See "Regular expression syntax" on page 6304.

All Elements Delimited

- The *Delimiter* property must contain a non-empty value.

Fixed Length

- All simple child elements must specify a length, unless their data type is Boolean (or derived from Boolean).
- All compound child elements must specify a length, unless their data type is Boolean (or derived from Boolean).
- The length can be specified using either the *Length* property, or the *Length Value Of member* property.

Fixed Length AL3

- All complex child elements with a non-Boolean compound element and non-Boolean simple child elements must have either a nonzero value in their *Length* property, or a non-empty value for their *Length Value Of* type member property.

Tagged Fixed Length

- All complex child elements with a non-Boolean compound element and non-Boolean simple child elements must have either a nonzero value in their *Length* property or a non-empty value for their *Length Value Of* type member property.
- The *Tag* property for each and every simple child element must contain a non-empty value.

The following rules also apply:

- If you have set the parent *Type Composition* to Choice, and the parent *Data Element Separation* property to Variable Length Elements Delimited, All Elements Delimited, Fixed Length, or Fixed Length AL3:
  - You must not set the *Type Composition* to Message for any child complex types.
  - You must not set the *Data Element Separation* method to Tagged Delimited or Tagged Fixed Length for any child complex types.

  If you do so, the message set does not deploy successfully.
- If you have set the type's *Data Element Separation* property to Fixed Length, Fixed Length AL3, or Tagged Fixed Length, you must set either the *Length* or *Length Value Of* property for all simple elements under this parent, and also for all complex elements with a simple content and compound elements.
- For a Choice in a fixed-length environment (*Data Element Separation* set to Fixed Length, Tagged Fixed Length, or Fixed Length AL3), length references are not valid. Use element lengths.
- Elements specified in a *Length Value Of* property must be simple elements of type INTEGER, they must exist in the same structure as the referring element, and they must appear before the referring element in that structure.
- Complex types with simple content and Compound elements must have an empty *Length Value Of* type member property. Otherwise, *Length Value Of* element would occur after the referring element in the parent structure, which is disallowed by the previous rule.
- Complex types with simple content cannot have a separation type of Use Data Pattern.
- Compound elements cannot have a separation type of Use Data Pattern.
- Regardless of the setting of the type's *Data Element Separation* property, if the type of a simple element is BINARY, you must set either the *Length* or *Length Value Of* property.
- For fixed-length elements, the *Justification* property must be set to something other than Not Applicable, and the *Padding Character* property cannot be an empty value.
- If any element within a message has its *Interpret Element Value* property set to Message Key, the *Message Key* property must be set for all messages within the message set.
- If you have set the *Repeat* property in the type member to Yes, you must set a value for the *Max Occurs* property in the following two situations:
  - If you have defined an element as a member of a complex type that has the property *Data Element Separation* set to Fixed Length.

– If you have defined a fixed-length element as a member of a complex type that has the property *Data Element Separation* set to `Variable Length Elements Delimited`.

When it is invoked by the broker to interpret an input message, the parser assumes that the number of occurrences of the element is equal to the value that you set for *Max Occurs*. When the parser constructs an output message, if there are fewer elements than the value of *Max Occurs*, the missing elements are inserted with default values.

Restrictions for nesting complex types:

If you include a group within another group or complex type, the *Data Element Separation* property for the nested group must be compatible with the *Data Element Separation* property of the parent group or complex type.

For example, you cannot set the parent property to `Fixed Length` and the child property to `Tagged Delimited`, because the length of the `Tagged Delimited` structure would not be known, and would therefore conflict with the parent definition. If groups are nested to three or more levels, the *Data Element Separation* property for each nested group must be compatible with all of its parent groups.

The rules for compatibility are listed in the following table.

	Parent				
Child	**Tagged Delimited, Tagged Encoded Length**	**All Elements Delimited, Variable Length Elements Delimited**	**Fixed Length, Fixed Length AL3**	**Tagged Fixed Length**	**Use Data Pattern**
Tagged Delimited, Tagged Encoded Length	Allowed	Allowed	Not allowed	Not allowed	Allowed
All Elements Delimited, Variable Length Elements Delimited	Allowed	Allowed	Not allowed	Not allowed	Allowed
Fixed Length, Fixed Length AL3	Allowed	Allowed	Allowed	Allowed	Allowed
Tagged Fixed Length	Allowed	Allowed	Not allowed[1]	Allowed	Allowed
Use Data Pattern	Allowed	Allowed	Allowed	Allowed	Allowed

Note:

1. `Tagged Fixed Length` cannot exist at the inner level if any outer level has a *`Data Element Separation`* method of `Fixed Length` or `Fixed Length AL3`. This is because an item of `Tagged Fixed Length` can repeat a variable number of times. `Fixed Length` and `Fixed Length AL3` are parsed by moving a set number of bytes: with a variable number of repeats, it is not possible to calculate the number of bytes that need to be parsed.

Omission and truncation of elements:

Omitting and truncating elements depends on the setting of the property *Suppress Absent Element Delimiters*.

See "Complex type TDS properties" on page 5505, "Global group TDS properties" on page 5516, or "Local group TDS properties" on page 5526 for a description of this property.

If you have created a message in which some elements are optional, an input message might not contain all defined elements. If the elements are in a complex type that you have defined with the *Data Element Separation* property of the type set to `All Elements Delimited` or `Variable Length Elements Delimited` (in which the elements are separated by a delimiter and have no tag), any elements that are missing from the end of the complex type must be indicated by the application that creates the message in one of two ways. These ways provide techniques to avoid long sequences of delimiters, and to preserve consistent representation of missing elements.

1. If you have set the *Delimiter* property for the complex type to a value that does not match the value that you have set for the *Delimiter* property for any of the complex type's parent types, the elements at the end of the message can be indicated by the occurrence of a *Delimiter* of one of its parents after the last actual element in the complex type data.

   This is known as the truncation method, in which missing elements are treated as not expected, and both data and delimiters are omitted in the bit stream.

   For example, you define a complex element `C` that has four optional elements. You set the *Delimiter* property to the character plus (+). You define complex element `P`, and set the *Delimiter* property of `P` to asterisk (*). You add three elements to `P`, the first is a string, the second is complex element `C`, and the third is a string.

   When a particular instance of the message is received by the broker, all the elements of `P` are present, but only the first two elements of `C` are present. The data in the message appears as follows if the truncation method is used (where `Pn` are the values of the elements of `P` and `Cn` the values of the elements of `C`):

   ```
   P1*C1+C2*P3
   ```

   When the parser encounters the second asterisk delimiter, it determines that the last two elements of complex element `C` are not present, and the next element is the third element of `P`.

   You can use truncation successfully only when both omission and truncation cause the parser to exhibit the same behavior, unless the elements truncated are fixed length.

2. If the *Delimiter* of the complex type matches that of one of its parents, the truncation method cannot be used. This is because the parser cannot determine whether the delimiter after the last element is for the current complex type, or for one of its parents. Therefore a delimiter must be included in the message data for each missing element to ensure that the parser can match the elements with the model.

   This is known as the omission method, in which missing simple elements are represented by an empty sequence of characters between two delimiters.

For example, you define `P` and `C` as in the previous example, but set the *`Delimiter`* property for `P` to plus (+). When the same message is received by the broker (all elements of `P` are present, the first two elements of `C` are present), the data in the message appears as follows:

```
P1+C1+C2++P3
```

Two delimiter characters have been inserted in the message data for the missing elements of complex element `C`. If the truncation method had been used, the parser would have interpreted the data value `P3` as the value of the third element of complex element `C` and not the third element of complex element `P`.

Using regular expressions to parse data elements:

Use regular expressions to identify parts of an input message that are associated with subfields.

If your input messages can contain subfields whose presence or absence can be determined only by examining the actual value of the data (for example, an optional field of numeric digits followed by one or more alphabetic characters) you must use the Data Element Separation method Use Data Pattern.

This situation is particularly relevant to messages that conform to the SWIFT industry standard. To use this method, you must provide regular expressions to

identify those portions of an input message that are to be associated with subfields. You must provide a regular expression value for the `Data Pattern` property of each child of the complex type.

When parsing, data is matched in turn with each child of the complex type. The parser does this by using the regular expression for the child to determine the number of characters from the message that apply for that child. This number of characters is the length of the longest string, starting from the current position in the message, that matches the regular expression. If the longest string that matches the regular expression is of length zero, the element is present in the message, and the empty string is used for the value. If no string matches the regular expression, the element is not present. This situation might cause a subsequent validation error if the element is required.

After the number of characters from the input message has been determined, normal data conversion, or further parsing in the case of a complex element, is performed on the text of the input message to assign values to elements. This might lead to data overrun or underrun errors if the length identified by the pattern is not appropriate for the definition of the child.

"Regular expression syntax" on page 6304 explains the full syntax rules and how to apply them, but the following table gives a few simple examples of parsing using data patterns. A more complex example appears after the table.

Input message	Data Pattern	Value matched
`"123456ABC"`	`[0-9]*`	`"123456"`
`"123"`	`[A-Z]*`	`""`
`"123"`	`[A-Z]+`	Not present
`"0x2A2B"`	`\x2A+`	X'2A'
`"ABCD123"`	`[A-Z]{1,3}` first field `[A-Z]{2,4}` second field	`"ABC"` - first field (the longest string matching the pattern) Not present - second field (minimum length of two alphabetic characters is not present)
`"ABCDEFGHIJ1234"`	`[A-Z]{1,3}` first field, repeat `[0-9]+` second field	`"ABC"` - first field [1] `"DEF"` - first field [2] `"GHI"` - first field [3] `"J"` - first field [4] `"1234"` - second field (the repeating field is terminated when the data `"1234"` no longer matches the data pattern specified for the first field.)

The following example shows three-field pattern matching.

```
Message definition:
 Complex type: Data Element Separation=Use Data Pattern
 Field1: xsd:string minOccurs=1, maxOccurs=1, Length=5, Pad=SPACE,
    Data Pattern=".{5}"
 Field2: xsd:int minOccurs=0, maxOccurs=1,
    Data Pattern="[0-9]{0,6}"
 Field3: xsd:string minOccurs=1, maxOccurs=1, minLength=3, maxLength=4,
    Data Pattern="[A-Z][A-Za-z0-9]{2,3}"

Input1:  "ABCDE123F12"
Result1:  Field1="ABCDE", Field2="123", Field3="F12"

Input2:  "ABCDEF12"
Result2:  Field1="ABCDE", Field2=not present, Field3="F12"

Input3:  "ABCDE123456XXXX"
Result3:  Field1="ABCDE", Field2="123456", Field3="XXXX"

Input4:  "ABCDE1234567"
Result4:  Field1="ABCDE", Field2="123456", Field3=not present,
    which causes an exception if validation is enabled. One
    character ("7") remains unassigned to any element, which
    also causes an exception.
```

In the case of a repeating child, instances of the child are parsed for as many times as the pattern is matched. This is applied even if *Max Occurs* is specified for the repeating element and the number of occurrences exceeds the upper bound. Therefore some terminating condition must be determinable from the regular expression pattern for the element. The table above includes an example of a repeating element.

When parsing, the data from the input message that matches the *Data Pattern*, and that is assigned to an element, is *not* further scanned for delimiters of a higher level complex type. This behavior is similar to that of *Data Element Separation* method `Fixed Length`. However, you can code a regular expression that will match data to one of a number of possible delimiters.

When writing, if a length is specified for a child, the value is padded as appropriate to that length. This behavior is similar to that of *Data Element Separation* method `Variable Length Elements Delimited`, but without delimiters.

If the message includes a complex type that has *Composition* set to `Choice`, you can set the *Data Element Separation* method to `Use Data Pattern`. In this case, the *Data Pattern* values of the children are used to resolve the choice. Starting with the first child, the first pattern to provide a match determines which child is present. Therefore the order of children in a choice might be important.

A complex type can contain repeating children with *Max Occurs* unbounded. *Length*, and other associated properties such as *Justification* and *Padding*, can optionally be specified for the children.

See "TDS message model integrity" on page 6295 for rules that you must follow when using the *Data Element Separation* method `Use Data Pattern`, and refer to "Combinations of Composition and Content Validation" on page 5612 for details of valid settings of *Composition* and *Content Validation*.

Regular expression syntax:

Regular expression syntax elements and example syntax rules.

A regular expression allows you to specify the conditions that a string must satisfy. For example, you might use a regular expression to specify that a string must contain eight characters and start with an alphabetic character. Use the syntax in the following tables to write regular expressions to specify the sets of strings that are permitted. A regular expression can be made up of one or more branches (choices), each of which can be a string made up of characters, character classes, or parenthesized expressions with modifiers to specify repetition rules.

The regular expression syntax that is supported is a subset of XML Schema regular expressions, with the addition of the \xNN hexadecimal syntax. For the full syntax, see Appendix F in XML Schema Part 2: Datatypes that can be found on the World Wide Web Consortium (W3C) Web site.

The following table lists the supported regular expression syntax elements:

Metacharacter	Meaning
\	escape
.	any single character
*	preceding character 0 or more times
+	preceding character 1 or more times

Metacharacter	Meaning
?	preceding character 0 or 1 time
{...}	occurrences of preceding [1]
[...]	match one of the class contained
[^...]	match one of the class not contained [1]
(...)	group the expressions [1]
|	match either preceding or following
Escape sequence	**Meaning**
\n	new line
\r	carriage return
\t	tab
\e	escape
Class code	**Meaning**
\d	digit [0-9]
\D	non-digit [^0-9] [2]
\s	white space[\t\n\r]
\S	non-whitespace character[^ \t\n\r] [2]
\p{L}	all letters [3]
\p{N}	all numbers, similar to \d [4]
[\p{N}\p{L}]	all numbers and all letters, similar to \w [4]
\P{L}	not letters, equivalent to [^\p{L}]
\P{N}	not numbers, equivalent to [^\p{N}]
\xNN	hexadecimal digits in the range 0 to F (\x00 not supported)
Range	**Meaning**
{n}	exactly n times
{n,}	at least n times
{n,m}	at least n, but no more than m, times
{0,m)	zero to m times

Notes:

1. The ellipsis (...) is used to indicate anything inside the { }, or [ ], or ( ) characters.
2. The caret (^) means "not" when inside the [ ] characters.
3. Consult Appendix F of the document XML Schema Part 2: Datatypes for other characters that can be used in place of L and N.
4. Consult Appendix F of the document XML Schema Part 2: Datatypes for the precise differences.

The following table gives some examples of the syntax rules for regular expression syntax. See “Using regular expressions to parse data elements” on page 6301 for some examples of their use.

Regular expression data pattern	Meaning
a	Match character "a"

Regular expression data pattern	Meaning
`.`	Match any one character
`a+`	Match a string of one or more `"a"`
`a*`	Match a string of zero or more `"a"`
`a?`	Match zero or one `"a"`
`a{3}`	Match a string of exactly three "a", that is `"aaa"`
`a{3,}`	Match a string of three or more `"a"`
`a{2,4}`	Match a string with a minimum of two and a maximum of four occurrences of `"a"`
`[abc]`	Match any one of the characters `"a"`, `"b"`, or `"c"`
`[a-zA-Z]`	Match any one character in the range `"a"` to `"z"`, or in the range `"A"` to `"Z"`. Note that the range of characters matched is based on the Unicodes of the characters specified.
`[^abc]`	Match any character except one of `"a"`, `"b"`, or `"c"`
`(ab)+`	Match one or more repetitions of the string `"ab"`
`(ab)|(cd)`	Match either of the strings `"ab"` or `"cd"`

Using multiple delimiters:

To parse messages in which fields are delimited by one of a set of characters or strings, set *Data Element Separation* to the method Use Data Pattern.

For example, consider a simple message with two numeric fields that can have either of the characters ';' or '/' delimiting them. You can use two approaches:

- Model the delimiter as a data element which is added to the message tree. If the message is rewritten, it looks like the input message.

  Consider this model:

  ```
  Composition = Sequence
  Data Element Separation = Use Data Pattern
     FieldA    Data Pattern = [0-9]*
     Delim     Data Pattern = [;/] optionally with a default value.
     FieldB    Data Pattern = [0-9]*
  ```

  After parsing, the elements FieldA and FieldB each contain any number of the digits 0 - 9, and the element Delim contains either ";" or "/".

- Recognize the delimiter as a delimiter, which is *not* added to the tree. If the message is rewritten, a preferred delimiter (as specified in the model) is used.

  Consider this model:

  ```
  Composition = Choice
  Data Element Separation = Use Data Pattern
    SubType1 Data Pattern = [0-9]*;[0-9]*
    (Composition = Sequence
    Data Element Separation = All Elements Delimited
    Delimiter = ';')
     FieldA
     FieldB
    SubType2 Data Pattern = [0-9]*/[0-9]*
    (Composition = Sequence
    Data Element Separation = All Elements Delimited
    Delimiter = '/')
     FieldA
     FieldB
  ```

  The regular expressions differentiate between the two options that can occur in the message, which are then parsed as a normal delimited structure. After parsing, the elements FieldA and FieldB each contain any number of the digits 0 to 9. The delimiter found in the input message is *not* saved in an element.

  You could refine this approach by using different names for the children, or elements for SubType1 and SubType2, to provide the knowledge of which delimiter is used, or to control which delimiter is included in the output message.

Using a variable number of repeats:

You can use the *Data Element Separation* method `Use Data Pattern` to support a variable number of repetitions in an otherwise fixed length environment, where there is no markup to indicate the end of the repetitions.

However, it relies on the ability to recognize the end of the repetitions based on the data content.

In its simplest form, you can do this by specifying a regular expression `Data Pattern` that matches a fixed number of characters that is terminated by reaching the end of the message bit stream.

For example, consider a message with one fixed length field (length 10), followed by another fixed length field (length 20) that repeats indefinitely to the end of the bit stream:

Message *Data Element Separation*=`Use Data Pattern`
    FieldA *Data Pattern*=`.{10}`
    FieldB Repeat, Min Occurs=1, no Max Occurs, *Data Pattern*=`.{20}`

The following example message contains a fixed length field (length 20) that repeats a variable number of times, and is separated from a second field by the string ";". The pattern specifies a string of 20 characters starting with anything except a semicolon:

Message *Data Element Separation*=`All Elements Delimited`, Delimiter=`;`
    SubType1 *Data Element Separation*=`Use Data Pattern`
        FieldA Repeat, Min Occurs=1, no Max Occurs, *Data Pattern*=`[^;].{19}`
        FieldB

Performance considerations when using regular expressions:

Take care when specifying regular expressions: some forms of regular expression can involve a large amount of work to find the best match, which might degrade performance.

Other expressions might produce a result that you did not expect.

For example, to match text up to and including a delimiter character ';' do *not* use the pattern ".*;", which matches up to the *last* ';' character in the message, including all prior ';' characters in the matched text. Instead, use the pattern "[^;]*;".

Similarly, avoid using the pattern ".*", which always forces a search to the end of the message to try and find the best match, and therefore might result in poor performance. However, you must use the pattern ".*" if you intend to match all remaining data in a message.

For best performance, avoid expressions with redundant nested repeats, such as "([0-9]+)*". Keep the expressions simple, with precise matching criteria. Simple expressions avoid the need to perform multiple searches for the best match.

DateTime formats:

When you create an element or attribute with a simple type of dateTime, you must specify a format string in the object's *Format String* property for each physical format layer (CWF, TDS, XML).

You can use the symbols defined in the following information to control the format in which the dateTime appears in the message data.

You can only use dateTime for Gregorian calendar dates.

DateTime information can appear in a message as:

- String data. This includes XML, and all TDS and CWF physical types except those mentioned in this section. This is described further in "DateTime as string data" on page 6311.
- Binary data. This is for the TDS or CWF Binary physical type. See "DateTime as BINARY data" on page 6318 for more information.
- An offset from an epoch in seconds or milliseconds. This is used if you have set the TDS or CWF *Physical Type* property to `Time Seconds` or `Time Milliseconds` respectively. See "DateTime as encoded values" on page 6319 for details of this option.

The defaults that are set for each message set property that relates to dateTime, for each physical representation (CWF, TDS, XML), are defined in "Message set defaults" on page 6321.

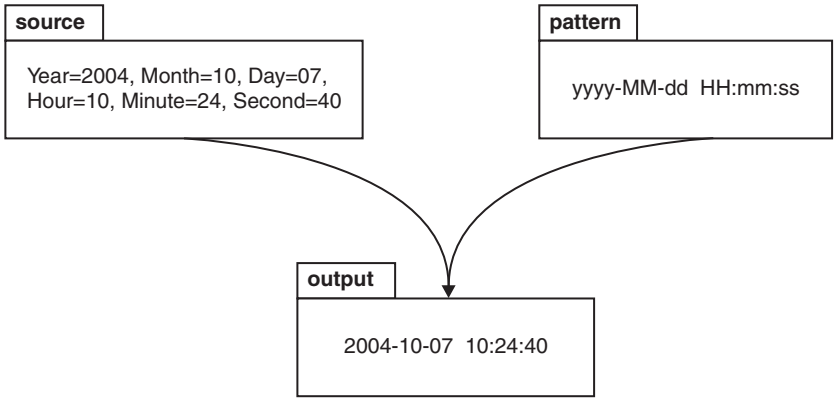
DateTime as string data:

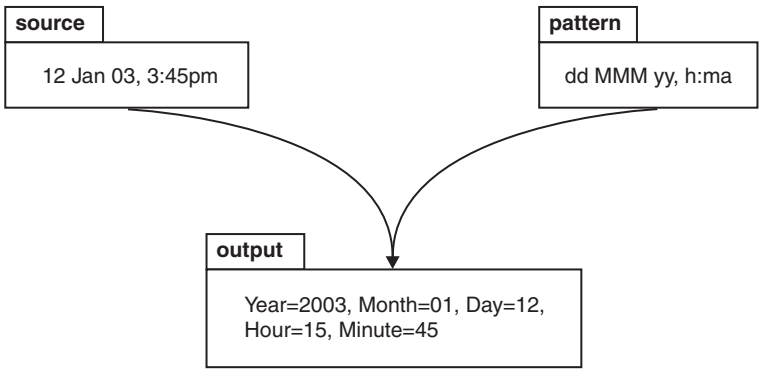
You can use a string of pattern letters to specify the dateTime format.

When you convert a date or time into a string, a format pattern must be applied that directs the conversion. Apply the format pattern to convert a date or time into a string, or to parse a string into a date or time.

During the conversion (for example, of a dateTime into a string), a pattern or a set of tokens is replaced with the equivalent source. The following diagram shows how a pattern is used to format a dateTime source to produce a character string output.



When a string is parsed (for example, when converting the string to a dateTime), the pattern or set of tokens is used to determine which part of the target dateTime is represented by which part of the string. The following diagram shows how this is done.



Syntax

The expression pattern is defined by:

Where:

symbol
is a character in the set **adDeEFGhHIkKmMsSTUwWyYzZ**.

string is a sequence of characters enclosed in single quotation marks. If a single quotation mark is required within the string, use two single quotation marks ('').

Characters for formatting a dateTime as a string

The following table lists the characters that you can use in a pattern for formatting or parsing strings in relation to a dateTime. The table is followed by some notes that explain more about some of the examples in the table.

Symbol	Meaning	Presentation	Examples
a	am or pm marker	Text	Input am, AM, pm, PM. Output AM or PM
d	day in month (1-31)	Number	1, 20
dd	day in month (01-31)	Number	01, 31
D	day in year (1-366)	Number	3, 80, 100
DD	day in year (01-366)	Number	03, 80, 366
DDD	day in year (001-366)	Number	003
e	day in week (1-7)[1]	Number	2
EEE	day in week[1]	Text	Tue
EEEE	day in week[1]	Text	Tuesday

Symbol	Meaning	Presentation	Examples
F	day of week in month (1-5)[2]	Number	2
G	Era	Text	BC or AD
h	hour in am or pm (1-12)	Number	6
hh	hour in am or pm (01-12)	Number	06
H	hour of day in 24 hour form (0-23)[3]	Number	7
HH	hour of day in 24 hour form (00-23)[3]	Number	07
I	ISO8601 Date/Time (up to yyyy-MM-dd'T'HH:mm:ss.SSSZZZ)[4]	Text	2006-10-07T12:06:56.568+01:00
IU	ISO8601 Date/Time (similar to I, but ZZZ with output "Z" if the time zone is +00:00)[4]	Text	2006-10-07T12:06:56.568+01:00, 2003-12 -15T15:42:12.000Z
k	hour of day in 24 hour form (1-24)[3]	Number	8
kk	hour of day in 24 hour form (01-24)[3]	Number	08
K	hour in am or pm (0-11)	Number	9
KK	hour in am or pm (00-11)	Number	09
m	minute	Number	4
mm	minute	Number	04
M	numeric month	Number	5, 12
MM	numeric month	Number	05, 12
MMM	named month	Text	Jan, Feb
MMMM	named month	Text	January, February
s	seconds[10]	Number	5
ss	seconds[10]	Number	05
S	decisecond[5]	Number	7
SS	centisecond[5]	Number	70
SSS	millisecond[5]	Number	700
SSSS	0.0001 second[5]	Number	7000
SSSSS	0.00001 second[5]	Number	70000
SSSSSS	0.000001 second[5]	Number	700000
T	ISO8601 Time (up to HH:mm:ss.SSSZZZ)[4]	Text	12:06:56.568+01:00
TU	ISO8601 Time (similar to T, but a time zone of +00:00 is replaced with 'Z')[4]	Text	12:06:56.568+01:00, 15:42:12.000Z
w	week in year[6]	Number	7, 53
ww	week in year[6]	Number	07, 53
W	week in month[7]	Number	2
yy	year[8]	Number	06

Symbol	Meaning	Presentation	Examples
yyyy	year[8]	Number	2006
YY	year: use with week in year only[6]	Number	06
YYYY	year: use with week in year only[6]	Number	2006
zzz	time zone (abbreviated name)[9]	Text	EST
zzzz	time zone (full name)	Text	Eastern Standard Time
Z	time zone (+/-n)	Text	+3
ZZ	time zone (+/-nn)	Text	+03
ZZZ	time zone (+/-nn:nn)	Text	+03:00
ZZZU	time zone (as ZZZ, "+00:00" is replaced by "Z")	Text	+03:00, Z
ZZZZ	time zone (GMT+/-nn:nn)	Text	GMT+03:00
ZZZZZ	time zone (as ZZZ, but no colon) (+/-nnnn)	Text	+0300
'	escape for text		'User text'
''	(two single quotation marks) single quotation mark within escaped text		'o''clock'

The presentation of the dateTime object depends on the symbols that you specify.

- **Text**: If you specify four or more of the symbols, the full form is presented. If you specify less than four, the short or abbreviated form, if it exists, is presented. For example, `EEEE` produces `Monday`, `EEE` produces `Mon`.
- **Number**: The number of characters for a numeric dateTime component must be within the bounds of the corresponding formatting symbols. Repeat the symbol to specify the minimum number of digits required. The maximum number of digits permitted is the upper bound for a particular symbol. For example, day in month has an upper bound of 31; therefore, a format string of `d` allows the values 2 or 21 to be parsed but does not allow the values 32 or 210 to be parsed. On output, numbers are padded with zeros to the specified length. A year is a special case; see note 8. Fractional seconds are also a special case; see note 5.
- **Lenient dateTime checking**: The parser converts out-of-band dateTime values to the appropriate in-band value. For example, the date 2005-05-32 is converted to 2005-06-01. Output of dateTimes always adheres to the symbol count. For example, a formatting string of `yyyy-MM-dd` (where '-' is the field separator) allows one or more characters to be parsed against `MM` and `dd`. This conversion allows dates such as 2006-01-123 and 2006-011-12, which are not valid, to be input. The value of 2006-01-123 is written as the date 2006-05-03, and the value of 2006-011-12 is written as the date 2006-11-12. The number of occurrences of the time zone formatting symbol Z applies only to the output dateTime format. White space is skipped over.
- **Physical Type**: If you specify the `Physical Type` property of the dateTime object to be `Packed Decimal`, the only pattern formatting symbols that are valid are those that represent numbers; that is, those that have Number in the Presentation column of the table. No other characters are allowed in the format

pattern. For example, yyyyMMdd is valid, but yyyyMMMdd is not valid because MM is a numeric representation of the month, and MMM is a textual representation of the month.

- Any characters in the pattern that are not in the ranges of ['a'..'z'] and ['A'..'Z'] are treated as quoted text. For example, characters like colon (:), comma (,), period (.), the number sign (hash or pound, #), the at sign (@), and space are displayed in the resulting time text even if they are not enclosed within single quotation marks.
- You can create formatting strings that produce unpredictable results; therefore, you must use these symbols with care. For example, if you specify `dMyyyy`, it is impossible to distinguish between day, month, and year. `dMyyyy` tells the broker that a minimum of one character represents the day, a minimum of one character represents the month, and four characters represent the year. Therefore `3112006` might be interpreted as 3/11/2006 or as 31/1/2006.

Notes: The following notes apply to the preceding table.

1. The day in week field is the numeric offset into a week and varies according to the value of the physical message set property `First Day of Week`. For example, the third day in the week is Wednesday if the physical message set property `First Day of Week` is set to Monday.
2. 12th July 2006 is the second Wednesday in July and can be expressed as `2006 July Wednesday 2` using the format string `yyyy MMMM EEEE F`. Note that this format does not represent the Wednesday in week 2 of July 2006, which is 5th July 2006; the format string for this is `yyyy MMMM EEEE W`.
3. 24-hour fields might result in an ambiguous time, if specified with a conflicting am/pm field.
4. See "ISO8601, I and T DateTime tokens" on page 6316.
5. Fractional seconds are represented by uppercase S. The length must implicitly match the number of format symbols on input. The format string `ss SSS` or `ss.SSS`, for example, represents seconds and milliseconds. However, the format string `ss.sss` represents a repeated field (of seconds); the value after the period (.) is taken as a seconds field, not as fractional seconds. The output is truncated to the specified length.
6. The start of a year typically falls in the middle of a week. If the number of days in that week is less than the value specified by the physical message set property `Days in First Week of Year`, the week is considered to be the last week of the previous year; in this case, week 1 starts some days into the new year. Otherwise, the week is considered to be the first week of the new year; in this case, week 1 starts some days before the new year. For example, Monday of week 1 in 2004 (2004 01 Monday, where Days in First Week of Year = 4 and First Day of Week = Monday) using format string `YYYY ww EEEE` is in fact 29th December 2003. If you use `Y`, the day of week (`E`) and week in year (`w`) are adjusted if necessary to indicate that the date falls in the previous year.

   If you use the lowercase `y` symbol, the adjustment is not done and unpredictable results might occur for dates around year end. For example, if the string 2002 01 Monday is formatted:

   - Monday of week 1 in 2002 using format string `YYYY ww EEEE` is correctly interpreted as `31st December 2001`
   - Monday of week 1 in 2002 using format string `yyyy ww EEEE` is incorrectly interpreted as `30th December 2002`

   Use `Y` together with `w` only; if you do not specify `w`, use `y`.

7. The first and last week in a month might include days from neighboring months. For example, Monday 31st July 2006 can be expressed as *Monday in week one of August 2006*, which is `2006 08 1 Monday` using format string `yyyy MM W EEEE`.
8. Year is handled as a special case:
   - On output, if the count of `y` is 2, the year is truncated to 2 digits. For example, if `yyyy` produces `2006`, `yy` produces `06`.
   - On input, for 2-digit years, the physical message set property of `Start of century for 2 digit years` is used to determine the century. For example, if `Start of century for 2 digit years` is set to 53, year 97 is 1997, year 52 is 2052, and year 53 is 1953.
9. Using the `zzz` option can have ambiguous results. For example, `BST` can be interpreted as `Bangladesh Standard Time` or `British Summer Time`. For compatibility reasons, WebSphere Message Broker uses the former interpretation.

   To avoid these problems, use the `zzzz` option with a well-defined name; for example, Europe/London, Asia/Dhaka, or America/Los_Angeles.
10. Seconds `s` & `ss`, must be in the range 0-59. If you need to construct a TIMESTAMP representing the time during a leap second, where the value being created or cast uses the value 60 for seconds, you must handle this case within your ESQL code. The CURRENT_ datetime functions (for example, CURRENT_TIME) within the product never produce a time where the seconds value falls outside of the 0-59 range.

ISO8601, I and T DateTime tokens

If your dateTime values comply with the ISO8601:2000 'Representation of dates and times' standard, consider using the formatting symbols I and T, which match the following subset of the ISO8601 standard.

- The restricted profile as proposed by the W3C at http://www.w3.org/TR/NOTE-datetime
- Truncated representations of calendar dates, as specified in section 5.2.1.3 of ISO8601:2000
  - Basic format (subsections c, e, and f)
  - Extended format (subsections a, b, and d)

Use the formatting symbols I and T only on their own:

- The I formatting symbol matches any dateTime string that conforms to the supported subset.
- The T formatting symbol matches any dateTime string that conforms to the supported subset that consists of a time portion only.

The following table shows how the output form relates to the logical data type.

Logical model data type	ESQL data type	Output form
xsd:dateTime	TIMESTAMP or GMTTIMESTAMP	yyyy-MM-dd'T'HH:mm:ss.SSSZZZ
xsd:date	DATE	yyyy-MM-dd
xsd:gYear	INTERVAL	yyyy
xsd:gYearMonth	INTERVAL	yyyy-MM
xsd:gMonth	INTERVAL	--MM
xsd:gmonthDay	INTERVAL	--MM-dd

Logical model data type	ESQL data type	Output form
xsd:gDay	INTERVAL	---dd
xsd:time	TIME / GMTTIME	'T'HH:mm:ss.SSSZZZ

Note:

- On input, both I and T accept both '+00:00' and 'Z' to indicate a zero time difference from Coordinated Universal Time (UTC), but on output they always generate '+00:00'. If you want 'Z' to always be generated on output, use the IU or TU formatting symbols instead.
- ZZZ always writes '+00:00' to indicate a zero time difference from Coordinated Universal Time (UTC). If you want 'Z' to always be generated on output, use ZZZU instead.

Using the input UTC format on output

An element or attribute of logical type xsd:dateTime or xsd:time that contains a dateTime as a string can specify Coordinated Universal Time (UTC) by using either the Z symbol or time zone +00:00. On input, the MRM parser remembers the UTC format of such elements and attributes. On output, you can specify whether Z or +00:00 is displayed by using the `Default DateTime Format` property of the element or attribute. Alternatively, you can preserve the input UTC format by selecting the message set property `Use input UTC format on output`. If this property is selected, the UTC format is preserved in the output message and overrides the format that is implied by the dateTime format property.

Examples

The following table shows a few examples of dateTime formats.

Format pattern	Result
"yyyy.MM.dd 'at' HH:mm:ss ZZZ"	2006.07.10 at 15:08:56 -05:00
"EEE, MMM d, "yy"	Wed, July 10, '06
"h:mm a"	8:08 PM
"hh o"clock a, ZZZZ"	09 o'clock AM, GMT+09:00
"K:mm a, ZZZ"	9:34 AM, -05:00
"yyyy.MMMMM.dd hh:mm aaa"	1996.July.10 12:08 PM

DateTime as BINARY data:

The count of pattern letters determines the number of bytes used to represent a value. The symbol used in the pattern of letters can be used only in groups of 1, 2, or 4; for example, y, yy, or yyyy.

The following table shows the dateTime symbols for binary data:

Symbol	Meaning	Example
y	year	1996
M	month in year	7
d	day in month	10
H	hour in day (0-23)	13
m	minute in hour	30
s	second in minute	55
S	millisecond	978
X	Ignore on input Pad with zeros on output	

The following example shows the C language structure `tm` with an integer of four bytes:

```
struct tm
{ int tm_sec;      /* seconds after the minute   - [0,59]*/
{ int tm_min;      /* minutes after the hour     - [0,59]*/
{ int tm_hour;     /* hours since midnight       - [0,23]*/
{ int tm_mday;     /* day of the month           - [1,31]*/
{ int tm_mon;      /* months since January       - [0,11]*/
{ int tm_year;     /* years since 1900           */
{ int tm_wday;     /* days since Sunday          - [0,6]*/
{ int tm_yday;     /* days since January 1       - [0,365]*/
{ int tm_isdst;    /* daylight saving time flag */
};
```

You can format this structure by specifying the string "`ssssmmmmHHHHddddMMMM+1yyyy+1900XXXXXXXXXXXX`". The number of pattern letters determines the number of bytes. There are 36 A-Z characters specified in this pattern, which match the 36 byte structure `tm`. A field followed by a plus sign (+) has the succeeding numeric characters added to it. Therefore `MMMM+1` adds one to the month, `yyyy+1900` adds 1900 to the year. `X` expects one byte of input, but ignores its value. On output, it writes the byte as 0.

DateTime as encoded values:

You can represent a dateTime element with the `TimeSeconds` and `TimeMilliSeconds` physical types.

`TimeSeconds`
: A 4 byte integer that represents the number of seconds since the epoch.

`TimeMilliSeconds`
: An 8 byte integer that represents the number of milliseconds since the epoch.

These types provide a way for C time_t and Java dateTime representations to be parsed.

The epoch (time 0) is specified by a format string. To change the epoch you must update the physical properties of your dateTime element:

- In the Physical representation section, you must set the `Physical Type` to either Time Seconds or Time Milliseconds.
- In the `Format` field, set the value to the format of "yyyy-MM-dd'T'HH:mm ZZZ". For example, 2000-01-01T12:59 +00:00.

DateTime defaults by logical type:

The default value that is assigned to the dateTime Format property is dependent on the logical type of the property.

The following table lists the default for each of the logical dateTime types:

Logical Type	Default Format
date	yyyy-MM-dd
dateTime	yyyy-MM-dd'T'HH:mm:ss
gDay	- - -dd
gMonth	- -MM
gMonthDay	- -MM-dd
gYear	yyyy
gYearMonth	yyyy-MM
time	HH:mm:ssZZZ

DateTime component defaults:

Default values are assumed if any part of a dateTime element is not present on input.

For example, the formatting string `yyyy-MM'T'HH:mm` does not contain any information about day in month (d), seconds (s), or milliseconds (S). The following table shows the defaults for all dateTime components.

Component	Default value
Year	1970
Month	First month of year
Day	First day of month
Hour	First hour of day
Minute	Minute 0 of hour
Second	Second 0 of minute
Millisecond	Millisecond 0 of second

Message set defaults:

The default dateTime formatting property settings for the different MRM physical formats.

Message set property	CWF default	TDS default	XML default
Default DateTime Format	See Note 1.	See Note 1.	See Note 1.

Message set property	CWF default	TDS default	XML default
Default Time Zone ID	Use Broker Locale (see Note 2)	Use Broker Locale (see Note 2)	Use Broker Locale (see Note 2)
Century Window	53	53 (80 for SWIFT)	53
Days in First Week of Year	4	Use Broker Locale (see Note 2)	Use Broker Locale (see Note 2)
First Day of Week	Monday	Use Broker Locale (see Note 2)	Use Broker Locale (see Note 2)

Note:

1. You can either set the default dateTime format to be derived from its logical type (the default), or specify the dateTime format that is to be used. This is set at the message set level for each physical format that has been added.
2. The key phrase `Use Broker Locale` causes the broker to get the information from the underlying platform.

You can update all these default values. The CWF defaults are set for all values of the *Physical Type* property. If you change the CWF *Physical Type* to `Binary`, `Packed Decimal`, `TimeSeconds`, or `TimeMilliseconds`, you must update the *Default DateTime Format* property manually to ensure consistent results.

For more information about these message set properties, see "Custom Wire Format message set properties" on page 5375, "TDS Format message set properties" on page 5381, or "XML Wire Format message set properties" on page 5400.

MIME standard header fields:

Check this quick reference to the common MIME headers.

This information does not provide a definitive specification of MIME. In some cases, the MIME parser allows documents that are not strictly valid according to the standard. For example, it does not insist on the presence of a MIME-Version header. All the standard MIME header fields are simply written to the logical tree as they appear in the MIME document. The MIME parser takes special note only of the Content-Type header field.

All MIME headers can include comments enclosed by parentheses, as shown in the example for the MIME-Version header.

MIME header fields

MIME-Version

Example:

```
MIME-version: 1.0 (generated by my-application 1.2)
```

For a MIME document to conform with RFC 2045, this field is required in the top-level header with a value of 1.0. MIME-Version should not be specified on individual parts.

Content-Type

Content-Type is not required for a document to conform with RFC 2045, but a top-level Content-Type is required by the MIME parser. Content-Type defaults to `text/plain`. Content-Type defines the type of data in each part as a type/subtype. The MIME parser accepts most values for Content-Type and stores them in the logical tree. The only exceptions are:

- The MIME parser rejects any Content-Type value with `type = message`.
- The MIME parser assumes that a Content-Type value with `type = multipart` introduces a multipart MIME document, and rejects such a value if it does not contain a valid boundary parameter. The value of the boundary parameter defines the separator between message parts in a multipart message. In a nested multipart message, a unique boundary value is required for each nesting level.

Syntax:

```
Content-Type: type/subtype;parameter
```

where type and subtype define the Content-Type, and all optional parameters are delimited by semicolons.

Example 1:

```
Content-Type: multipart/related;type=text/xml
```

In example 1, the Content-Type is defined as `multipart/related`, and also has an optional parameter definition (`type=text/xml`). Although this structure is syntactically correct, because a valid boundary parameter does not exist, this message is rejected.

Example 2:

```
Content-Type: multipart/related;boundary=Boundary;type=text/xml
```

Example 2 shows a valid Content-Type definition, both in terms of syntax and semantics. The boundary value optionally can be enclosed in quotation marks. When it appears in the MIME body, the value is preceded by the sequence '--', and you must ensure that the resulting value (in this example, --Boundary) cannot appear in the message body. If the message data is encoded as quoted-printable, you must include a boundary that includes a sequence such as “=_”, which cannot appear in a quoted-printable body.

The following table shows some common Content-Type values. Other values are allowed, and stored in the logical tree.

Content-Type	Description
text/plain	Typically used for a typical mail or news message. text/richtext is also common.
text/xml	Typically used with SwA (SOAP with Attachments).
application/octet-stream	Used where the message is an unknown type and contains any kind of data as bytes.
application/xml	Used for application-specific xml data.
x-type	Used for non-standard content type. It must start with the characters x-.

Content-Type	Description
image/jpeg	Used for images. image/jpeg and image/gif are common image formats that are used
multipart/related	Used for multiple related parts in a message. Specifically used with SwA (SOAP with Attachments)
multipart/signed	Used for multiple related parts in a message including signature. Specifically used with S/MIME
multipart/mixed	Used for multiple independent parts in a message

Content-Transfer-Encoding

Optional. Many Content-Types are represented as 8-bit character or binary data, and can include XML, which typically uses UTF-8 or UTF-16 encoding. This type of data cannot be transmitted over some transport protocols, and might be encoded to 7-bit.

The Content-Transfer-Encoding header field is used to indicate the type of transformation that has been used for encoding this type of data into a 7-bit format.

The following values only are allowed by the WS-I Basic Profile:

- 7bit - the default
- 8bit
- binary
- base64
- quoted-printable

The values 7bit, 8bit, and binary all effectively mean that no encoding took place. A MIME conformant mail gateway might use this value to control how it handles the message. For example, encoding it as 7bit before passing routing it over SMTP.

The values base64 and quoted-printable mean that the content has been encoded. The value quoted-printable means that only non-7-bit characters in the original are encoded, and is intended to yield a document which is still human-readable. This setting is most likely to be used in conjunction with a Content-Type of `text/plain`.

Content-ID

Optional. This field enables parts to be labeled, and referenced from other parts of the message. These parts are typically referenced from part 0 (the first) of the message.

Content-Description

Optional. This field enables parts to be described.

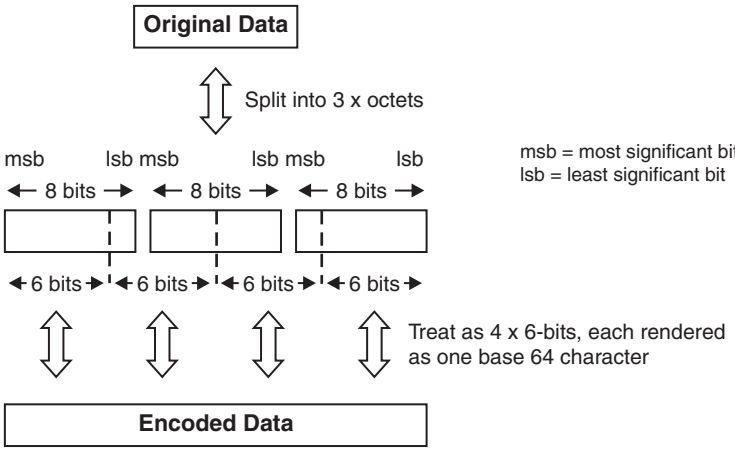
MIME encodings

The following section provides a basic guide to the base64 and quoted-printable encoding; refer to RFC 1521 (linked at the end of this topic) for a definitive specification of MIME encodings.

base64

The original data is broken into groups of 3 octets. Each group is then treated as 4 concatenated 6-bit groups, each of which is translated into a single digit in the base64 alphabet. The base64 alphabet is A-Z, a-z, 0-9,

and / (with A=0 and /=63).



If fewer than 24 bits are available at the end of the data, the encoded data is padded using the "=" character. The maximum line length in the encoded data is 76 characters and line breaks (and all other characters not in the alphabet above) are ignored when decoding.

Examples:

Input	Output
Some data encoded in base64.	U29tZSBkYXRhIGVuY29kZWQgaW4gYmFzZTY0Lg==
life of brian	bGlmZSBvZiBicmlhbg==\012
what	d2hhdA==

quoted-printable

This encoding is appropriate only if most of the data comprises printable characters. Specifically, characters in the ranges 33-60 and 62-126 are typically represented by the corresponding ASCII characters. Control characters and 8-bit data must be represented by the sequence = followed by a pair of hexadecimal digits.

The standard ASCII space <SP> and horizontal tab <HT> represent themselves, unless they appear at the end of an encoded line (without a soft line break), in which case the equivalent hexadecimal format must be used (=09 and =20 respectively).

Line breaks in the data are represented by the RFC 822 line break sequence <CR><LF> and should be encoded as "=0D=0A" if binary data is being encoded.

For base64, the maximum line length in the encoded data is 76 characters. An '=' sign at the end of an encoded line (a 'soft' line break) is used to tell the decoder that the line is to be continued.

MIME parser use and restrictions:

The MIME domain does not support the full MIME standard, but supports specific known uses of MIME. Read this general introduction to the MIME parser, and information about some of the restrictions in its use.

MIME stands for Multipurpose Internet Mail Extensions. A multipart MIME message comprises a number of message parts, each qualified by MIME headers. The MIME domain and parser enable you to parse and write multipart MIME messages.

MIME is used to send email messages. When the email includes attachments, a multipart MIME message is used. Multipart MIME is becoming more widely used as a convenient physical format for sending other kinds of message that have attachments or that consist of multiple separate parts.

Examples are:

- **RosettaNet.** Each part is typically a separate XML document but there might also be non-XML attachments. The MIME parser enables the parsing of MIME messages of the style used by RosettaNet, including nested multipart messages. However, it does not offer specific support for the wider RosettaNet architecture or PIPs (Partner Interface Processes).
- **SOAP with Attachments (SwA).** The first part is a normal SOAP XML message and the other parts contain XML or non-XML attachments.
- **TLOG.** This is a specialized use of SwA in which the attachments are groups of point-of-sale Transaction Log records in either one of two XML forms or a tagged/delimited string form. Different POS devices generate different TLOG record formats such as ACE. In addition, the record can either be processed before it is uploaded or it can be sent unchanged.

Restrictions

The MIME parser is driven by bit streams and has no external metadata; it relies exclusively on bitstream metadata when parsing, and on tree metadata when writing. The parser does not validate MIME messages against a message model and it ignores the tooling Validate property. The parts of a MIME message are handled as BLOBs. You can parse specific MIME parts by using a different parser. If you are using an MRM parser, messages can be validated in the usual way. The MIME parser does not support on-demand parsing and ignores the Parse Timing property.

You can specify the new MIME domain either at run time in an MQRFH2 header (WebSphere MQ only) or statically in their message flow in the tooling (on the input nodes MQGet, HTTPRequest, ResetContentDescriptor, or XSLTransform). The MIME parser is then invoked to own the last child of root (for example, the message body). The MIME domain can be specified with the ESQL CREATE PARSE clause and ASBITSTREAM function to parse and write bit streams. The MIME parser handles documents received both over the HTTP transport (where the Content-Type appears as an HTTP header) and over other transports (where the Content-Type header is part of the message body). In both cases, set the Content-Type value using the ContentType property in the MIME domain. Setting the Content-Type value directly in the MIME tree or HTTP trees can lead to the value being ignored or used inconsistently.

Typically, the MIME parser handles the majority of uses of MIME in application-to-application messaging, including multipart MIME with a single part and non-multipart MIME documents. However, you should use the SOAP domain for SOAP with Attachments (SwA).

Building the message model for the IDOC parser:

The ALE IDoc messages that are sent to, and received from, SAP applications by using the WebSphere MQ Link for R3, can be processed by the IDOC parser, which requires a message model to interpret the data correctly. This topic describes how to build the message model.

Before you begin

The IDOC domain is deprecated. To develop new message flows, use the MRM domain with a TDS physical format when you want to process SAP ALE IDocs that are sent to the broker by SAP R3 clients across the WebSphere MQ link for R3.

Obtaining the IDoc:
About this task

Create an import file of the required IDoc data for the WebSphere Message Broker Toolkit.

Procedure

1. Log on to an SAP system.
2. Run the supplied transaction `we60`, which extracts the IDoc data as a C header file.
   a. In **Basic Type**, select the IDoc type of interest; for example, `MATMAS02`.
   b. Leave the **Control**, **Data**, and **Status** check boxes cleared.
   c. Select the **Record types** version. A version 4 IDoc is type 3.
   d. Press **F7** to display a C representation of the IDoc.
   e. Select **System** > **List** > **Save** > **Local file**.
   f. Click **unconverted**.
   g. When prompted, enter a file name and directory for the output from the transaction. The C representation of the IDoc is saved to this C header file.

What to do next

Tip: The exported C header can be imported into the WebSphere Message Broker Toolkit without any further manual processing.

Modeling the IDoc:
About this task

Create your message model.

Procedure

1. Switch to the Broker Application Development perspective.
2. Use the New Message Set wizard to create a message set for your IDoc. Select binary data as the data to use. This option creates a message set with a Custom Wire Format (CWF) physical format, and presets the `Default message domain` property to MRM.

3. Use the Message Set editor to change the Default message domain property to IDOC.
4. Use the New Message Definition File wizard to import a prebuilt model of the ALE IDoc message structure. To start the wizard, click **File** > **New** > **Message Definition File From**. When the wizard opens, select IBM supplied message, then SAP ALE IDoc. This SAP ALE IDoc prebuilt model includes definitions of the DC and DD segments. The resulting message definition file is called ale_idoc.mxsd. For information about using the New Message Definition File wizard, see "Importing from IBM supplied messages" on page 2942.
5. Use the New Message Definition File wizard, or the **mqsicreatemsgdefs** command, to import the C representation of the IDoc into the new message set. To start the wizard, click **File** > **New** > **Message Definition File From**.

   Specify the following settings:

   - Select C Header file.
   - Set Select the pre-processing option to apply to SAP ALE IDoc. If this option is not specified, the import of the C header fails. If this option is specified, the message prefix preference is ignored.
   - Create messages for the segments that appear in the IDoc.
   - Use the String Encoding option to import character arrays as fixed-length strings.
   - Use the Padding Char for String option to make space (" ") the padding character that is used.

   For information about using the New Message Definition File From C Header File wizard, see "Importing from C" on page 2934.

Using the IDoc message model:
About this task

You can now use your message model to help you to construct a message flow that processes instances of your IDoc message. You can use ESQL or Java to access the fields of the IDoc. You cannot use graphical maps to access the fields of the IDoc because the IDOC domain is not supported by the mapping editor.

When you set the properties of the MQInput node that is to receive your IDoc from the WebSphere MQ Link for R3, the Message Domain property must be IDOC, the Message Set property must be the name of your message set, and the Message Format property must be the name of your Custom Wire Format. You do not need to set a Message Type property on the MQInput node because it is not needed by the IDOC parser.

When your message flow is complete, add the message set and the message flow to a broker archive (BAR) file and deploy the BAR file to a broker execution group.

When an IDoc is received by the MQInput node, the IDOC parser processes the SAP-defined elements in the DC, then, for each DD, processes the SAP-defined elements, and calls the MRM parser to process the user-defined segment data, as described by your exported IDoc, using the CWF physical format. The MRM parser knows the Message Type property to use for the user-defined segment, because it is obtained from the SAP-defined DD field *segnam* by the IDOC parser.

Tip: SupportPac IA0F contains a more detailed description of the steps involved in building the IDoc message model. You can ignore utilities IDocHeaderTweak and IDocMsgSetTweak because that processing has been incorporated into the New Message Definition File From C Header File wizard.

"Field names of the IDOC parser structures" on page 6333
The field names of the Control Structure (DC) and the Data Structure (DD) that are used by the IDOC parser.

Field names of the IDOC parser structures:

The field names of the Control Structure (DC) and the Data Structure (DD) that are used by the IDOC parser.

The field names are documented in the form that they are used in a SET statement of ESQL; for example:

```
SET OutputRoot.Properties = InputRoot.Properties;
SET OutputRoot.MQMD = InputRoot.MQMD;
```

Control structure (DC) fields:
All the fields must be specified and set.

The syntax is:

```
<rootname>.<ParserName>.<foldername>.<fieldname>=
```

For example:

```
SET "OutputRoot"."IDOC"."DC"."docnum" = '0000000000000001';
SET "OutputRoot"."IDOC"."DC"."idoctyp" = 'MATMAS01'
```

The field names, which must be specified in order, are:

1. tabnam
2. mandt
3. docnum
4. docrel
5. status
6. direct
7. outmod
8. exprss
9. test
10. idoctyp
11. cimtyp
12. mestyp
13. mescod
14. mesfct
15. std
16. stdvrs
17. stdmes
18. sndpor
19. sndprt
20. sndpfc
21. sndprn
22. sndsad
23. sndlad
24. rcvpor
25. rcvprt
26. rcvpfc
27. rcvprn
28. rcvsad

29. rcvlad
30. credat
31. cretim
32. refint
33. refgrp
34. refmes
35. arckey
36. serial

Data structure (DD) fields:
To access each DD segment, use the array suffix DD[1], DD[2], and so on.

The syntax is:

```
<rootname>.<ParserName>.DD[1].<fieldname>=
```

For example:

```
SET OutputRoot.IDOC.DD[I].segnam  = 'E2MAKTM001';
SET OutputRoot.IDOC.DD[I].mandt2   = '111';
```

The following list illustrates how the suffix 2 is used to give unique field names to the `mandt` and `docnum` fields.

The field names, which must be supplied in order, are:

1. segnam
2. mandt2
3. docnum2
4. segnum
5. psgnum
6. hlevel

The last 1000 bytes of data in the DD segment are the bytes that are parsed by the MRM domain. The DD `segnam` describes the model that the MRM uses.

Segment fields:
The syntax is:

```
<rootname>.<ParserName>.DD[1].sdatatag.MRM.<fieldname>=
```

For example:

```
SET OutputRoot.IDOC.DD[I].sdatatag.MRM.msgfn = '006'
SET OutputRoot.IDOC.DD[I].sdatatag.MRM.spras_iso = 'EN'
```

The `sdatatag` field indicates to the parser that it is the element that contains the data to be manipulated. The `MRM` field indicates that the MRM handles the transformation.

- msgfn
- spras
- maktx
- msgfn
- spras_iso
- fill954

The `fill954` field is the filler for the segment because an incoming IDoc to SAP must have 1000 byte segments.

The SET statement assigns a value to a variable.

JSON parser use and restrictions

WebSphere Message Broker provides support for the JSON domain.

JSON (JavaScript Object Notation) is a simple data-interchange format based on a subset of the JavaScript programming language. A JSON message consists of objects and arrays, where an object is a set of name-value pairs, and an array is a list of values. A JSON value can be a simple value (string, number, Boolean, or null), an array, or an object.

For more information about the JSON parser and domain, see "JSON parser and domain" on page 1128.

Message modeling and validation

WebSphere Message Broker does not provide support for JSON message modeling. Because of this, the Message Set Editor, Message Mapping Editor, Mapping node, and the XSLTransform node do not support the JSON domain.

Related concepts:

"Parsers" on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

"JSON parser and domain" on page 1128
JSON (JavaScript Object Notation) is a simple data-interchange format based on a subset of the JavaScript programming language.

"JSON message details" on page 1135
A JSON message consists of name-value pairs (objects), and ordered collections of values (arrays). Objects, arrays, or both structures can be nested.

"Manipulating messages in the JSON domain" on page 2617
You can manipulate messages that belong to the JSON domain, which are parsed by the JSON parser.

Message model task list errors that have a quick fix

You can apply a quick fix to some message modeling task list warnings or errors to correct them.

Unresolved references

The following table provides a list of those errors that have references that cannot be resolved:

Error type	Description	Quick Fix
Attribute reference error	The attribute reference cannot be resolved	Allows you to add the missing include or import statement
Attribute group reference error	The attribute group reference cannot be resolved	Allows you to add the missing include or import statement
Attribute type reference	The attribute type reference cannot be resolved	Allows you to add the missing include or import statement
Base type error	The type has an unresolved base type	Allows you to add the missing include or import statement
Element reference error	The element reference cannot be resolved	Allows you to add the missing include or import statement
Element type reference error	The element type reference cannot be resolved	Allows you to add the missing include or import statement
Group reference error	The group reference cannot be resolved	Allows you to add the missing include or import statement
Schema directive error	The schema directive cannot be resolved	Allows you to add the missing include or import statement
Sub group error	The element declaration references a head element which cannot be resolved.	Allows you to add the missing include or import statement

Other errors

The following table provides a list of additional warnings or errors that can be cleared using a quick fix:

Error type	Description	Quick Fix
Message key deprecated warning	TDS property "Message Key" has been superseded by logical property "Message Alias".	Will update your message definition to use "Message Alias" instead. (You should use this if you only have Version 6.0 brokers in your domain.)
Message key enumeration deprecated warning	TDS property "Interpret Element Value = Message Key" has been superseded by logical property "Interpret Value As = Message Identity".	Will update your element definition to use logical property "Interpret Value As = Message Identity" instead. You should use this if you only have Version 6.0 brokers in your domain.)
Repeat count deprecated warning #1	CWF property "Repeat Count" has been superseded by "Max Occurs". Both "Repeat Count" and "Max Occurs" have been set, but do not have the same value.	You will have a choice of two quick fixes: • Will update your definition to unset the "Repeat Count" property. • Will update your definition to set "Max Occurs" to the value of the "Repeat Count" property, and to unset the "Repeat Count" property.
Repeat count deprecated warning #2	CWF property "Repeat Count" has been superseded by "Max Occurs". Both "Repeat Count" and "Max Occurs" have been set and have the same value.	Will update your definition to unset the "Repeat Count" property.
Redefine error	An XML Schema Redefine construct has been found but is not supported.	Will update your message definition file to use an XML Schema Include construct instead. Any redefinitions will be lost.
Value does not match Length facet error	The length of a default value, fixed value or enumeration value does not match the effective Length facet for the simple type.	You will have a choice of two quick fixes: • Will update your simple type definition so that the Length facet is converted to a Max length facet. • Will update all the simple type definitions in your message definition file so that all Length facets are converted to Max Length facets, then save the file to remove all the associated task list errors.

Error type	Description	Quick Fix
Facet not applicable for simple type error	A facet has been found on a simple type, but the facet is either not permitted on that simple type or is a duplicate.	Will update your simple type definition so that all invalid facets and all duplicate facets are removed.

Access property information by property kind, or by object.

Document generation:

The document generator produces a set of HTML pages and any necessary files (for example, images) that are required to display the pages correctly.

Output Files:
There is one page for each message definition file in the message set, and one additional index page linking these pages together.

The index page (*index.html*), is intended to be the "entry point" into the documentation.

"WSDL generation"
Files and other objects are created by the WSDL Generator.

"XML Schema generation" on page 6343
The behavior of XML Schema generation. For example, use the schema generated from a message definition file to validate XML instance documents written by WebSphere Message Broker.

Broker SCA definition generation:

The Broker SCA Definition wizard creates a Broker SCA definition that includes objects that define the binding, interface, and message format information to permit interoperation between WebSphere Message Broker and WebSphere Process Server.

Generated files

The following files are generated:

- A `.outsca` or `.insca` Broker SCA Definition is generated and stored under the Broker SCA Definitions folder in the chosen message set project. The `.outsca` or `.insca` Broker SCA Definition contains a SCA Import or Export, as well as all XSD files and WSDL files referenced directly or indirectly by the SCA Import or Export.
- A WSDL file containing one portType with one or more operations.
- XSD files that correspond to the messages used in the operations defined in the portType.
- If the user has chosen a Web service binding, a WSDL file containing a service and binding that imports the WSDL containing the portType.
- If the user has chosen an MQ binding, the SCA Import or Export contains the binding information.

Related reference:

"Generate Broker SCA Definition wizard" on page 6372
The Generate Broker SCA Definition wizard creates a Broker SCA definition from a message set.

WSDL generation:

Files and other objects are created by the WSDL Generator.

Generated Files

The default file and definition element names are shown in the following table. *Message Set* is the supplied message set name and <*Definition Name*> is the supplied Definition Name solicited by the wizard.

File	File Name	File Extension	Value of name attribute on WSDL <definitions> element
Service File (single-file format)	*Message_Set*	wsdl	<Definition Name>
Service File (multi-file format)	*Message_Set*Service	wsdl	<Definition Name>Service
Binding File	*Message_Set*Binding	wsdl	<Definition Name>Binding
Interface File	*Message_Set*	wsdl	<Definition Name>

If 'Deployable WSDL' is generated, no additional XML schema (xsd) files are generated, and the WSDL refers directly to the broker message definition (mxsd) files; otherwise, separate XML schema (xsd) files are generated, unless you selected 'inline schema'.

Report File

The WSDL generator appends the result of the generation operation to a report file, listing all errors which occurred. The file name is:

Message_Set.wsdlgen.report.txt

WSDL Content

The following tables show the element or attribute values to be set in the generated WSDL. The elements are described top-down as they appear in a conventionally ordered WSDL document. The <schema> section of the WSDL definition is not shown, because this section corresponds directly to the broker message definitions.

Element names are from the WSDL 1.1 namespace except where prefixed by soap: for the WSDL SOAP namespace. Operation elements occur in both the binding and portType sections, so operation is qualified as necessary; for example, portType / operation.

The values shown in the following table apply to the WSDL definition as a whole.

Element	Attribute	Value
definitions	xmlns	Assign namespace prefixes.
definitions	targetNamespace	The WSDL Namespace solicited by the wizard, defaulting to http://tempuri.org/<Message Set>.
message	name	<operation>_<role> where <operation> is the operation name and <role> is in, out, or fault
part	name	The name of the broker message. If Style is set to rpc, the body parts are defined using the type attribute. If not, the body parts are defined using the element attribute.
portType	name	*Message_Set*PortType
binding	name	• "*Message_Set*SOAP_HTTP_ Binding" • "*Message_Set*SOAP_JMS_ Binding"

Element	Attribute	Value
soap:binding	style	From the value of `Style` set in the wizard.

The following values apply to each individual WSDL operation:

Element	Attribute	Value
operation	name	The name of the operation specified in the wizard.
soap:operation	style	From the value of `Style` set in the wizard.
input, output, fault	name	<operation>_<role>, where <operation> is the operation name, and <role> is Input, Output, or Fault.
soap:body	namespace	• If `Style` has been set to rpc, it is the namespace of the corresponding broker message. • If `Style` has been set to document the attribute is not generated.
soap:header, soap:fault, soap:body	use	This element is set to *literal*.

Message Set

The message set provides the basis for many important broker features, including mapping support and ESQL code completion at development time, and validation at run time.

Therefore, the WSDL that you use in the broker at development time (for example, when configuring SOAP nodes) is integrated with the message set, and references the broker message definitions (mxsd) rather than ordinary Schema (xsd) files. This is referred to as *deployable WSDL* and is displayed under the category `Deployable WSDL` in the WebSphere Message Broker Toolkit.

Deployable WSDL is generated when you specify your Message Set Folder (the immediate child of your Message Set Project) as the `destination directory` for your WSDL.

Otherwise, regular WSDL is generated, along with separate XML schema (xsd) files if these were requested. Regular WSDL cannot be used to configure SOAP nodes, but is suitable for consumption by external applications such as .NET.

Assuming that you are generating deployable WSDL for use in a message flow, the flow typically must be able to parse and validate the runtime SOAP messages described by that WSDL. The WSDL generator, therefore, adds additional definitions to your message set:

- For rpc-style WSDL, additional definitions for the WSDL operations themselves are added to your message set
- For the version of the SOAP Envelope used by the WSDL an mxsd file is added – this will be soapenv11.mxsd or soapenv12.mxsd.
- For use by ESQL Content assist and the Mapping editor primarily, a definition of the SOAP_Domain_Msg tree.

XML Schema generation:

The behavior of XML Schema generation. For example, use the schema generated from a message definition file to validate XML instance documents written by WebSphere Message Broker.

Lax generation

Lax generation affects how complex types that have *Content Validation* set to Open or OpenDefined or have *Composition* set to UnorderedSet are rendered in the generated schema. Note that such a validating schema will permit a wider range of messages than MRM parser validation.

Content Validation is set to Open or OpenDefined

Here a complex type (global or anonymous) has its content replaced by a single wildcard element that repeats an unbounded number of times. The following generation pattern is used for complex types with *Content Validation* set to Open:

```
<element name="xmlNameOfMessage">
 <complexType>
  <sequence>
   <any processContent="lax"
   minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
 </complexType>
</element>
```

Where *Content Validation* is set to OpenDefined, the following pattern is used. (The namespaces listed are all those defined in the containing message set.)

```
<element name="xmlNameOfMessage">
 <complexType>
  <sequence>
   <any processContent="lax"
     minOccurs="0" maxOccurs="unbounded"
     namespace="http://www.ns1 http://www.ns2" />
  </sequence>
 </complexType>
</element>
```

Composition is set to UnorderedSet

Where *Composition* is set to UnorderedSet, to mimic the unordered aspect, a choice is inserted with appropriate cardinality. This is shown as follows:

```
<element name="xmlNameOfMessage">
 <complexType>
  <sequence maxOccurs="unbounded"
   minOccurs= "(minOccurs of original sequence) *
          (items in original sequence)">
   <choice>
         .. sequence contents ..
   </choice>
  </sequence>
 </complexType>
</element>
```

Strict generation

Strict generation affects how complex types that have *Content Validation* set to Open or OpenDefined or have *Composition* set to UnorderedSet are rendered in the generated schema. Note that such a validating schema will permit a narrower range of messages than MRM parser validation.

Strict is the default generation option and generates a schema that matches the schema held in the message definition file, without the model extensions.

Content Validation set to Open/OpenDefined

A complex type (global or anonymous) will lose the ability to contain self-defining elements and becomes closed.

Composition set to UnorderedSet

A complex type (global or anonymous) will lose the ability to be unordered and becomes a sequence.

Rendering of xsd:elements

If an XML physical format is specified when generating the schema, the wire format customization is applied to the logical model. These properties control how an element in the model is rendered when it appears in a message for an XML wire format. See “XML rendering options” on page 6262 for the different render options available. The following is a generated schema example showing what is generated for the different render options available for local elements; note these examples do not modify the Namespace of any ID Attribute Name or Value Attribute Name properties and assume that all elements specified in the complexType1 are of schema built-in type string.

```
<xsd:complexType name="complexType1">
    <xsd:sequence>
     <!-- Local element Render = 'XMLElement' -->
        <xsd:element name="localElement1" type="xsd:string"/>
     <!-- Local element Render = 'XMLElementAttrID'
                                    ID Attribute Name = 'id' -->
        <xsd:element name="localElement2">
```

```
            <xsd:complexType>
                <xsd:simpleContent>
                    <xsd:extension base="xsd:string">
                        <xsd:attribute name="id" type="xsd:string"/>
                    </xsd:extension>
                </xsd:simpleContent>
            </xsd:complexType>
        </xsd:element>
     <!-- Local element Render = 'XMLElementAttrVal'
                                  Val Attribute Name = 'val' -->
        <xsd:element name="localElement3">
            <xsd:complexType>
                <xsd:simpleContent>
                    <xsd:extension base="xsd:string">
                        <xsd:attribute name="val" type="xsd:string"/>
                    </xsd:extension>
                </xsd:simpleContent>
            </xsd:complexType>
        </xsd:element>
     <!-- Local element Render = 'XMLElementAttrIDVal'
          ID Attribute Name = 'id' Val Attribute Name = 'val' -->
        <xsd:element name="localElement4">
            <xsd:complexType>
                <xsd:simpleContent>
                    <xsd:extension base="xsd:string">
                        <xsd:attribute name="val" type="xsd:string"/>
                        <xsd:attribute name="id" type="xsd:string"/>
                    </xsd:extension>
                </xsd:simpleContent>
            </xsd:complexType>
        </xsd:element>
    </xsd:sequence>
     <!-- Local element Render = 'XMLAttribute' -->
    <xsd:attribute name="localElement5" type="xsd:string"/>
</xsd:complexType>
```

Rendering of xsd:attributes

The rendering of `xsd:Attributes` is not supported. The user can only change the name of the attribute.

Embedded simple types and Compound Elements

These are deprecated objects that are only encountered if the message set was created using WebSphere MQ Integrator Broker Version 2.1.

They are modeled in the message definition file as elements with both *minOccurs* and *maxOccurs* set to `0` and have one of the predefined ComIbmMrm_xxx types. During the schema generation, the type of such elements is changed to the base type of the respective ComIbmMrm_xxx type.

If there are global simple types that inherit from one of these ComIbmMrm_xxx types, these are changed to inherit from the base type of the corresponding ComIbmMrm_xxx type.

Generated schema files will not have any occurrence of these ComIbmMrm_xxx types.

For example the global element with type defined as follows:

```
<element name="globalElement1" type="ns1:ComIbmMrm_BaseValueBinary"/>
```

will result in the generated schema file and a global element with the corresponding xsd base type defined as follows:

```
<element name="globalElement1" type="hexBinary"/>
```

Importing from C (MRM): supported features:

The C importer uses default values when mapping C data types to message model elements.

The following table shows how the C definitions influence the XML Schema settings in the message model. Some xsd types have '-' after the type. This character indicates that it is an anonymous simple type based on this type. For strings, the purpose of the anonymous type is to add a maximum length restriction; for numeric types, the purpose of the anonymous type is to add either a minimum or a maximum value restriction.

C data type	XML Schema data	Notes
Char	xsd:string-	maxlength=1
Char[10]	xsd:string-	maxlength=10
Char[10][3]	xsd:string-	maxlength=3 maxOccurs=10
Char[10][3][6]	xsd:string-	maxlength=6 maxOccurs=30
Unsigned Char	xsd:unsignedByte	
Unsigned Char[2]	xsd:unsignedByte	maxOccurs=2
Signed Char	xsd:byte	
Signed Char[2]	xsd:byte	maxOccurs=2
Int	xsd:int	
Int[2]	xsd:int	maxOccurs=2
Int[2][3]	xsd:int	maxOccurs=6
Unsigned Int	xsd:unsignedInt	
Short	xsd:short	
Unsigned Short	xsd:unsignedShort	
Long	xsd:int	
Long Long Int	xsd:long	
Float	xsd:float	
Double	xsd:double	
Long Double (see note 1)	xsd:double	
<any pointer type>	xsd:hexBinary-	maxlength=(see note 2)
<any enum>		(see note 3)

The following table shows how C definitions influence the physical MRM CWF characteristics of the elements that are generated in the message model.

C data type	CWF Physical type	CWF Length characteristics	Other CWF characteristics
Char	Fixed Length	Length = 1 Length Units = Bytes	
Char[10]	Fixed Length	Length = 10 Length Units = Bytes	Left justify
Char[10][3]	Fixed Length	Length = 3 (and Max Occurs = 10) Length Units = bytes	Left justify
Char[10][3][6]	Fixed Length	Length =6 (and Max Occurs = 30) Length Units = bytes	Left justify
Unsigned Char	Integer	Length = 1	Signed = no
Unsigned Char[2]	Integer	Length = 1 (and Max Occurs = 2)	Signed = no
Signed Char	Integer	Length = 1	Signed = yes
Signed Char[2]	Integer	Length = 1 (and Max Occurs = 2)	Signed = yes
Int	Integer	Length = 4	Signed = yes
Int[2]	Integer	Length = 4 (and Max Occurs = 2)	Signed = yes
Int[2][3]	Integer	Length = 4 (and Max Occurs = 6)	Signed = yes
Unsigned Int	Integer	Length = 4	Signed = no
Short	Integer	Length = 2	Signed = yes
Unsigned Short	Integer	Length = 2	Signed = no
Long	Integer	Length = 4 (see note 4)	Signed = yes
Long Long Int	Integer	Length = 8	Signed = yes
Float	Float	Length = 4	
Double	Float	Length = 8	
Long Double (see note 1)	Float	Length = 8	
<any pointer type>		(see note 2)	
<any enum>	Integer	(see note 3)	

Notes:

1. Do not set the value of C importer option *size of long double* to 128 bit. This option does not import successfully; use the default 64 bit.
2. The length is affected by the *Address Size* C importer option:
   - For 32 bit, CWF length = 4 bytes.
   - For 64 bit, CWF length = 8 bytes.

3. The type and length of an enum is affected by the *Size of enum* C importer option:
   - For *1*: Logical type = xsd:byte, CWF physical type = Integer, CWF length = 1 byte.
   - For *2*: Logical type = xsd:short, CWF physical type = Integer, CWF length = 2 bytes.
   - For *4*: Logical type = xsd:int, CWF physical type = Integer, CWF length = 4 bytes.
   - For *Compact*: The smallest representation is chosen that the enumeration fits into.
4. The length of a *long* is affected by the *Address Size* C importer option:
   - For 32 bit: CWF length = 4 bytes.
   - For 64 bit: CWF length = 8 bytes.
5. Element names that clash with Java language keywords are modified by prefixing them with a single underscore character.
6. The _Packed keyword is not supported. Only ANSI C declarations are supported.
7. The C long long data type is not supported.
8. C++ object oriented extensions are not supported. Only ANSI C declarations are supported.
9. Pointers will be imported as xsd:integer with CWF length set to 4.
10. Recursive C structures are not supported. If a nested structure contains a structure with a name that is the same as the parent structure, the import succeeds, but the logical definitions are not correct. To avoid this problem, ensure that the name of the nested structure is not the same as that of the outer or parent structure.

Importing from COBOL: supported features:

The COBOL importer uses a set of default values and behaviors when mapping COBOL data types to message model elements.

The following table shows how COBOL definitions influence the XML Schema settings in the message model.

COBOL Clause	XML Schema data type	Notes
PIC A	xsd:string	
PIC G	xsd:string	Set the compile-time locale name to ja_JP in **Window** > **Preferences** > **Importer** > **COBOL** to process this.
PIC N	xsd:string	Set the compile-time locale name to ja_JP in **Window** > **Preferences** > **Importer** > **COBOL** to process this.
PIC X	xsd:string	
PIC 9(n) n = 1-4	xsd:short	DISPLAY, COMP, or COMP-3
PIC 9(n) n = 5-9	xsd:int	DISPLAY, COMP, or COMP-3
PIC 9(n) n = 10-18	xsd:long	DISPLAY, COMP, or COMP-3
PIC 9(n) n = 19-31	xsd:integer	DISPLAY, COMP, or COMP-3
PIC 9(n)V9(m)	xsd:decimal	DISPLAY, COMP, or COMP-3 any virtual decimal point value
COMP-1	xsd:float	
COMP-2	xsd:double	
Any edited string	xsd:string	
Any edited number	xsd:string	For example, a COBOL PICTURE clause that contains any of the following characters: 'Z' '+' '-' '.' ',' 'B' '0' or a currency symbol. If you want your broker logical type to be a numeric one, make sure that the COBOL PICTURE clause does not contain any of these characters.
VALUE	All	Non-88 Level VALUE clauses can be imported as schema default values (option on import wizard).

The following table shows how COBOL definitions influence the physical MRM CWF characteristics of the elements that are generated in the message model.

COBOL Clause	CWF Physical Type	CWF Length Characteristics	Other CWF characteristics
PIC X(n) PIC A(n)	Fixed Length String	Length = n Length Units = Bytes	Justification = Left Justify Padding Character = SPACE

COBOL Clause	CWF Physical Type	CWF Length Characteristics	Other CWF characteristics
PIC G(n) PIC N(n)	Fixed Length String	Length = n Length Units = Characters	Justification = Left Justify Padding Character = SPACE

PIC 9(n) COMP, COMP-4, COMP-5 or BINARY	Integer	Length = 2, 4 or 8 based on n Length Units = Bytes	Signed = Unticked Sign Orientation = Blank
PIC 9(n) COMP-3 n=1-18	Packed Decimal	Length = CEILING((n+1)/2) Length Units = Bytes	Signed = Unticked Sign Orientation = Blank
PIC S9(n) DISPLAY n=1-31	External Decimal	Length = n Length Units = Bytes	Signed = Ticked Sign Orientation = Trailing *See Note 1
PIC S9(n) COMP or COMP-3 n=1-18	Integer or Packed Decimal	Length = See COMP and COMP-3 definitions above Length Units = Bytes	Signed = Ticked Sign Orientation = Blank
PIC 9(m)V9(n) DISPLAY n=1-31	External Decimal	Length = n+m Length Units = Bytes	Signed = Unticked Sign Orientation = Trailing Virtual Decimal Point = n
PIC 9(m)V9(n) COMP or COMP-3	Integer or Packed Decimal	Length = CEILING((n+m+1)/2) for COMP-3 Length = 2, 4 or 8 for COMP Length Units = Bytes	Signed = Unticked Sign Orientation = Blank Virtual Decimal Point = n
COMP-1	Float	Length = 4 Length Units = Bytes	Signed = Ticked Sign Orientation = Blank
COMP-2	Float	Length = 8 Length Units = Bytes	Signed = Ticked Sign Orientation = Blank
SYNC	Float, Integer or Packed Decimal		Leading Skip Count as appropriate Trailing Skip Count as appropriate Byte alignment as appropriate *See note 2

COBOL Clause	CWF Physical Type	CWF Length Characteristics	Other CWF characteristics

Notes:

1. **Sign Orientation** can take one of the following values, based on the SEPARATE, LEADING, or TRAILING keywords in the COBOL definition:
   - Leading
   - Leading Separate
   - Trailing
   - Trailing Separate
2. The SYNC keyword causes the field to be aligned on a 1, 2, 4, or 8-byte boundary. This might cause 'slack bytes' to be added either before or after a field. **Leading Skip Count** is the number of such bytes that are added before a field; **Trailing Skip Count** is the number of such bytes that are added after a field.

   Leading Skip Count and **Trailing Skip Count** are calculated by the importer for each of the imported elements by the importer, irrespective of the SYNC clause. They have non-zero values when the SYNC clause is present.

   Where there is a repeating element, **Leading Skip Count** and **Trailing Skip Count** are used for the first occurrence of the repeating element; for subsequent occurrences, only the **Trailing Skip Count** is used.

   Refer to COBOL reference material for details of fields that require byte alignment.
3. All files that you import must be syntactically correct. Results are unpredictable if the file being imported is not synctactically correct.
4. COBOL data types that have keywords POINTER, COMP-X, INDEX, or PROCEDURE-POINTER, are not supported.
5. COBOL clauses that contain the keyword NATIVE cause an error, and are not imported.
6. COBOL level 66 and level 77 data items are not imported.
7. Hexadecimal binary values cannot be attributed to non-numeric literals. They cannot reside in the LINKAGE SECTIONs that are imported by the COBOL importer. They can reside elsewhere in the COBOL file. Alternatively, you can convert the hexadecimal value to a character string for PIC X, or to a decimal number for PIC 9.
8. If element names clash with Java language keywords, the element names are modified by prefixing the element name with a single underscore character.
9. Object-oriented extensions to COBOL 85 are not supported. For example, OBJECT-REFERENCE is not supported.
10. COBOL OCCURS DEPENDING ON clause. The **Byte Alignment**, **Leading Skip Count**, and **Trailing Skip Count** CWF properties of elements within such a structure are not set up properly. You must correct these using the message editor.
11. When the imported COBOL source file contains QUOTE or QUOTES in the value clause of a picture string, the default behavior is to enter the data with double quotation marks, unless you set the COBOL QUOTE compile option to SINGLE on the Import Options page of the COBOL importer wizard.

Signed external decimal numbers

The MRM Custom Wire Format (CWF) and TDS components of WebSphere Message Broker support the External Decimal (also known as Zoned Decimal) data format for numeric data. Numeric data in this format is stored internally as decimal character data. For example, in a system that uses the EBCDIC code, the number 1234 stored in a 4-byte external decimal field is stored as the character string '1234', and its actual internal hexadecimal representation is 'F1F2F3F4'.

With signed external decimal numbers, the sign can be incorporated into the actual data by modifying the first half of the first or last byte (depending on whether you are using a sign-leading or sign-trailing representation). Typically, '0xC' is used to represent a positive number, '0xD' is used to represent a negative number and '0xF' is used to represent an unsigned number.

Note: In general, any of '0xA', '0xC', '0xE' or '0xF' can be used to indicate a positive value, and '0xB' or '0xD' can be used to indicate a negative value. The actual preferred representation is dependent upon the actual hardware architecture.

On ASCII machines, there are a number of mechanisms for the internal representation of external decimal data. One representation ('Sign ASCII') that is employed by IBM's pSeries machines, uses the normal ASCII codes ('0' [hex 30] to '9' [hex 39]) for the first or last digit of both unsigned and positive numbers, and the characters 'p' [hex 70] to 'y' [hex 79] for negative numbers.

An alternative method (Sign EBCDIC Custom) is used on some other ASCII based machines. This method uses the same characters as an EBCDIC based machine, even though the actual internal hexadecimal representations of them are different. If you use this technique, the character string for both EBCDIC and ASCII platforms is identical. You could potentially receive a message from an EBCDIC platform (created from a COBOL copybook that contains such entries as PIC XXX and PIC S999), and convert the whole message to ASCII, or the other way around. The character string that represents the external decimal field in the message (after the ASCII to EBCDIC, or EBCDIC to ASCII, conversion) maps to the code point that represents the correct sign for the decimal.

This method includes the limitation that curly brace characters are variant (they have different code points in different EBCDIC code pages). This mechanism works only for those EBCDIC code pages where the curly brace characters '{' and '}' (which are used to represent signed 0) have exactly the code points X'C0' and X'D0'. For example, it works for code page 500 but not for code page 871, where the curly braces have code points X'8E' and X'9C.

In an ASCII environment (determined by the CCSID property at run time), the default for both input and output is the 'Sign ASCII' representation. You can specify the applicable representation in the CWF physical layer for local attributes and local elements of types decimal, float, and integer.

Note: This option is appropriate only for those elements or attributes that have an external decimal physical representation, and that have an embedded ('Leading' or 'Trailing') sign (determined by the **Sign Orientation** property).

The following table shows the internal representation (both character and actual hexadecimal value) of the first or last digit for external decimal numbers with an

included (embedded) leading or trailing sign respectively. (The table does not specify the representation for unsigned values, which are 0x30-0x39 for ASCII and 0xF0-0xF9 for EBCDIC.)

	ASCII environment		EBCDIC environment		ASCII environment		EBCDIC environment
	Positively signed values				Negatively signed values		
Digit	Sign ASCII	Sign EBCDIC Custom			Sign ASCII	Sign EBCDIC Custom	
0	0(30)	{(7B)	{(C0)		p(70)	}(7D)	}(D0)
1	1(31)	A(41)	A(C1)		q(71)	J(4A)	J(D1)
2	2(32)	B(42)	B(C2)		r(72)	K(4B)	K(D2)
3	3(33)	C(43)	C(C3)		s(73)	L(4C)	L(D3)
4	4(34)	D(44)	D(C4)		t(74)	M(4D)	M(D4)
5	5(35)	E(45)	E(C5)		u(75)	N(4E)	N(D5)
6	6(36)	F(46)	F(C6)		v(76)	O(4F)	O(D6)
7	7(37)	G(47)	G(C7)		w(77)	P(50)	P(D7)
8	8(38)	H(48)	H(C8)		x(78)	Q(51)	Q(D8)
9	9(39)	I(49)	I(C9)		y(79)	R(52)	R(D9)

The next table gives some examples for a range of simple numbers that are representative of what can be transmitted or received using these approaches.

	Sign leading			Sign trailing		
	ASCII Environment		EBCDIC Environment	ASCII Environment		EBCDIC Environment
Decimal value	Sign ASCII	Sign EBCDIC Custom		Sign ASCII	Sign EBCDIC Custom	
1234	31 32 33 34 "1234"	31 32 33 34 "1234"	F1 F2 F3 F4 "1234"	31 32 33 34 "1234"	31 32 33 34 "1234"	F1 F2 F3 F4 "1234"

Importing from SCA Export or SCA Import: generated objects:

A number of objects are generated when you import from an SCA export or SCA import.

- A Broker SCA definition file. The file extension is `.insca` for an import component, or `.outsca` for an export component. The `.insca` or `.outsca` files are stored in a Broker SCA Definitions folder under the message set project. If multiple SCA Import/Exports are imported into a message set, each has its own `.insca` or `.outsca` file.

  You can drag the Broker SCA Definition onto the Message Flow Editor to create a skeleton flow.

  – Dragging and dropping a `.insca` object onto the Message Flow editor creates a pair of SCAInput and SCAReply nodes if the Broker SCA definition interface contains one or more request-response operations. Otherwise, only the SCAInput node is created.
  – Dragging and dropping a `.outsca` object onto the Message Flow editor creates either a SCARequest node, or a pair of SCAAsyncRequest and SCAAsyncResponse nodes.
- Corresponding message definitions (`.mxsd`) files are created from the XSD types that are used by the messages specified in the WSDL interface in the SCA Import or Export. The message definitions are stored in their respective target namespaces.
- If the SCA Import or SCA Export being imported uses a Web Services Binding type, the deployable WSDL is imported into the message set.
- If the SCA Import or SCA Export being imported uses an MQ Binding type, a deployable WSDL is not imported into the message set.
- A log is created for the import in the log folder under the message set project.

You can create a new message definition file from an SCA import or export.

Importing from WSDL: generated objects and restrictions:

Several objects are generated when you import from WSDL but restrictions might apply.

Generated objects

Files copied by command line import

The **mqsicreatemsgdefsfromwsdl** command copies the WSDL files it needs into the workspace before running the import process. These files are the top level WSDL files and any imports resolved from a relative location. The files are copied under the specified message set into a folder called importFiles.

Report file

The WSDL importer appends the result of the import operation to a report file, listing all errors that occurred during the process. The file name of the report file is *message set*.wsdl.report.txt.

SOAP message definitions

The required SOAP .mxsds files are added to the message set.

To parse SOAP 1.2 instance documents, manually remove the SOAP 1.1 definitions and import the SOAP 1.2 definitions by using the Message Definition File wizard, selecting **IBM supplied message**.

If your message set has TDS or CWF layers, you might find that you get a number of warnings against the imported SOAP definitions. Most of these can be ignored, but take account of the allowed values for Boolean attributes. In SOAP 1.1 the Boolean values are 1 or 0, while in SOAP 1.2 the values are true and false. The XML representation of Boolean values for a message set is specified in the physical properties for the XML physical format, and might need to be set accordingly.

Message definition files

Other message definition file names are created as *input file name*.mxsd and their content depends on the WSDL style.

document-style

WSDL message parts for style="document" (which includes all SOAP header, fault and headerfault parts) refer to an element defined in XML Schema. This element is imported as a global element and broker message in the .xsd or .mxsd file.

The xsi:type output policy on the message is set to "Never".

rpc-style

WSDL message parts for style="rpc" (and exclusively those allocated to the SOAP body) refer to a type defined in XML Schema. In this case, input and output messages are created as shown in the following table.

	An input message	**An output message**
Derived From	The wsdl:input child (if any) of WSDL operation, and the WSDL message and parts that it identifies	The wsdl:output child (if any) of WSDL operation, and the WSDL message and parts that it identifies
Name of Element	The value of the name attribute on the WSDL operation element	The value of the name attribute on the WSDL operation element suffixed by "Response"
Namespace of Element	The value of the namespace attribute on the corresponding soap:body element	The value of the namespace attribute on the corresponding soap:body element

Each message is of local complex type, being a sequence of elements. The name of each element is the value of the name attribute on the WSDL parts

of the message identified by either the input or output element. These elements have no namespace (the underlying schema representation has form="unqualified"), and are locally scoped to avoid name clashes. The type of these local elements is the XML schema type referred to by the type attribute of the corresponding part element. The type is global in the WSDL schema.

If the soap:body element was defined with use="encoded" in the WSDL definition, the message definition includes a reference to the attribute group encodingStyle in the SOAP-ENV namespace and the xsi:type output policy on the message is set to "Follow SOAP encoding rules". Otherwise, the xsi:type output policy on the message is set to "Never".

WSDLs generated using .NET

In some instances, WSDL files that are generated by using .NET include element references to the schema itself; for example:

```
<xsd:complexType>
  <xsd:sequence>
   <xsd:element ref="s:schema"/>
  </xsd:sequence>
</xsd:complexType>
```

For WSDL files of this type to be successfully imported into the WebSphere Message Broker Toolkit without validation errors, you must manually add a namespace import statement to the namespace of the schema; for example:

```
<xsd:import namespace="http://www.w3.org/2001/XMLSchema"/>
```

Place the import statement first in the schema element, and ensure that it appears before any complex type or element definitions. Revalidate the WSDL by right-clicking the updated WSDL and clicking **Validate**.

Restrictions

Restrictions related to importing WSDL definitions exist where the WSDL definitions are not WS-I compliant.

SOAP Arrays

A WSDL 1.1 definition can define a SOAP array (applicable only to the WSDL rpc-encoded style, and not WS-I compliant):

```
<xsd:complexType name="t">
      <xsd:complexContent>
        <xsd:restriction base="SOAP-ENC:Array">
          <xsd:sequence>
            <xsd:element name="item" type="string" maxOccurs="unbounded"/>
          </xsd:sequence>
          <xsd:attribute  ref="SOAP-ENC:arrayType" wsdl:arrayType="xsd:string[]"/>
        </xsd:restriction>
      </xsd:complexContent>
</xsd:complexType>
```

Some uses of SOAP array syntax are not fully supported. Although a useful tree is created during parsing and can be serialized when writing, the following restrictions apply.

- The model does not take any account of the SOAP-ENC:arrayType attribute.
- The model for partially transmitted arrays does not take account of the SOAP-ENC:offset attribute.

For example, the first element of an array specified with offset[2] must be accessed in ESQL, not as InputRoot.MRM.array.item[3], but as InputRoot.MRM.array.item[1].

- The model for multi-dimensional arrays flattens the representation into a single dimension. For example, a 2-dimensional array is accessed in ESQL, not as InputRoot.MRM.array.item[x][y], but as InputRoot.MRM.array.item[i] where the index i has to be calculated appropriately.

Anonymous elements

The WSDL excerpt above describes a SOAP instance document of the following form:

```
<SOAP-ENC:Array SOAP-ENC:arrayType="xsd:string[3]">
   <item xsi:type="xsd:string">A general text string</item>
   <item xsi:type="xsd:token">A restriction of the string type</item>
   <item xsi:type="xsd:Name">ARestrictionOfTheTokenType</item>
</SOAP-ENC:Array>
```

The broker model handles this document as expected, but in SOAP encoding array, elements are also allowed to use the type-elements from the SOAP encoding namespace. Therefore, an application using the same WSDL definition might create an instance document of the following form:

```
<SOAP-ENC:Array SOAP-ENC:arrayType="xsd:string[3]">
   <SOAP-ENC:string>A general text string</SOAP-ENC:string>
   <SOAP-ENC:token>A restriction of the string type</SOAP-ENC:token>
   <SOAP-ENC:Name>ARestrictionOfTheTokenType</ SOAP-ENC:Name>
</SOAP-ENC:Array>
```

To handle this case, you must manually edit the broker model that is created by importing the WSDL, unless it is acceptable to have the parser treat it as a self-defined element.

"Import formats" on page 6346
Supported features of formats that have been imported from C, COBOL, SCA Export, SCA Import, WSDL, or XML Schema.

Importing from XML Schema: unsupported features:

A number of features in XML Schema are not supported, or their support is restricted in some way.

Message sets with namespace support

- Constructs accepted but not supported when importing from an XML Schema.

  When importing an XML Schema into a message set that supports namespaces, the Redefine construct is accepted, but causes an error message to be displayed in the task list because it is not fully supported.

  The following XML shows an example of the Redefine construct:

```
<?xml version="1.0" encoding="UTF-8"?>
<schema xmlns="http://www.w3.org/2001/XMLSchema"
        targetNamespace="http://www.ibm.com" xmlns:ibm="http://www.ibm.com">

 <!-- Unsupported feature: redefine -->
 <redefine schemaLocation="test.xsd"/>

</schema>
```

Message sets without namespace support

- Constructs accepted and ignored when importing from an XML Schema.

  The list of constructs and the action taken is the same as for a message set with namespace support, as described above.

- Target namespaces not qualified with a prefix.

  When importing an XML Schema into a message set that does not support namespaces, you cannot import a schema document that has a target namespace that is not qualified with a prefix. For example:

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
       targetNamespace="http://www.ibm.com" xmlns="http://www.ibm.com">
</xsd:schema>
```

Message model wizards

Wizards help to simplify complex message modeling tasks.

As software grows more complex, wizards are increasingly used to step you through complex tasks or procedures, ensuring that you correctly specify all the parameters that are required, and that you perform the required tasks in the correct order.

This topic provides some additional reference material for those wizards where you might need help in specifying certain parameters.

Each wizard that is documented here has its own high-level topic and a topic for each panel that is displayed by the wizard. The panels are listed in the order that they appear, and the fields on each panel appear in the topic in the same order as they appear on the panel. These topics provide only information about these fields and panels. You can find further information about the wizards in topics that are referenced from the wizard's high-level topic.

The following wizards have additional information:

- "New message definition file wizards"
- "Generate WSDL wizard" on page 6382
- "Export WSDL wizard" on page 6390
- "Configure New Web Service Usage wizard" on page 6392

New message definition file wizard: Create a new message definition file from scratch:

Create a new message definition file by using the New message definition file wizard.

Create a new message definition file from scratch

When you create a new message definition file from scratch, you must set the following fields:

Message sets

Select the target message set
This field lists the message set projects that are available in your workspace. Click the down-arrow and select the appropriate message set from the list displayed. Depending on how you started the New message definition file wizard, a message set might be preselected for you, but this does not prevent you from selecting a different message set if you prefer.

Message definition file name
Specify the name of the message definition file that you are creating.

Schema for Schema settings

Prefix Specifies the namespace prefix to use for the namespace shown in the **Namespace** property.

Namespace
Specifies the namespace to be used.

Target namespace settings

Use target namespace
Selecting this check box allows you to specify a target namespace for the message definition file. You can choose a target namespace only if namespaces have been enabled in the message set.

Prefix Specifies the namespace prefix to use for the namespace shown in the **Namespace** property.

Namespace
Specifies the namespace to be used.

Use this field for the name of the target namespace for the message definition file that you want to create.

Select file from workspace
Choose this option if the COBOL file that you want to add to the message definition file that you are creating is in the current workspace, and select the file from the displayed content of the workspace. COBOL files are filtered to only show artifacts in the active working set.

Select file from outside workspace
Choose this option if the COBOL file that you want to add to the message definition file that you are creating is not in the current workspace, and specify the location of the COBOL file that you want to add.

Copy source file into the 'importFiles' directory of the message set project
Select this check box to copy the source file into the 'importFiles' directory of the message set project.

Create an appropriate physical format if one does not already exist
Select this check box to automatically create the message set physical format that is needed by the pre-canned schema that you have selected for import.

COBOL file options

Preserve case in variable names
Select this check box if you want to preserve the case of the characters that form the names of the variables.

Related reference:

"New message definition file wizards" on page 6360
Use the New message definition file wizards to create message definition files.

"IBM supplied messages that you can import"
You can import IBM supplied messages to create a new message definition file.

IBM supplied messages that you can import:

You can import IBM supplied messages to create a new message definition file.

If the message is to be used with an XML parser, the following points apply:

- If the message set to which you are adding the new message definition file has an XML physical format layer, but does not have namespace support, the imported IBM supplied message is modified to remove namespaces. Therefore, enable namespace support before you import an IBM supplied message.
- If the message set to which you are adding the new message definition file does not have an XML physical format layer, but has namespace support, only the logical information is displayed in the model. The IBM supplied message is not modified to remove namespaces. Add an XML physical format to the message set before you import an IBM supplied message.
- If the message set to which you are adding the new message definition file does not have an XML physical format layer, and does not have namespace support, only the logical information appears in the model and the imported IBM supplied message is modified to remove namespaces.

The IBM supplied messages that you can import are:

SOAP message definitions
These message definitions model the SOAP-defined portions of SOAP XML messages. They are best used with the SOAP parser. The definitions *Soap 1.1 Envelope* and *Soap 1.2 Envelope* model the SOAP envelope structure that is used to wrapper the user-defined body of a SOAP message. The

definitions *Soap 1.1 Encoding* and *Soap 1.2 Encoding* model certain structures for use in "rpc/encoded" style SOAP messages.

An IBM message for the SOAP domain tree is supplied as a schema that provides content-assist in creating a logical model for the SOAP domain by using the ESQL or mapping editor.

Multipart MIME message definitions
These message definitions model the MIME-defined portions of multipart MIME messages and must be used with the message broker's MIME parser. Use the *MIME multipart header* definition for typical multipart MIME messages such as SOAP with Attachments, or RosettaNet. Use the *MIME Nested Multipart header* definition for multipart MIME messages in which the individual parts can themselves be multipart MIME; for example, S/MIME.

SAP IDoc message definitions
These message definitions model the SAP-defined portion of ALE and File IDocs that precede the user-defined content. The ALE IDoc model can be used with the MRM and IDOC parsers. The File IDoc model can be used with the MRM parser only.

Timeout Request message definition
This message definition models the TimeoutRequest message that is used in conjunction with the message broker TimeoutControl and TimeoutNotification nodes. You can use it with any parser.

CSV message definition
This message definition models a CSV (comma separated value) format message. It can be used with the MRM parser.

Related concepts:

"The structure of a SOAP message" on page 1605
A SOAP message is encoded as an XML document, consisting of an `<Envelope>` element, which contains an optional `<Header>` element, and a mandatory `<Body>` element. The `<Fault>` element, contained in `<Body>`, is used for reporting errors.

"MIME messages" on page 1120
A MIME message consists of both data and metadata. MIME metadata consists of HTTP-style headers and MIME boundary delimiters.

The comma separated value (CSV) format is a typical format for describing data in tables or spreadsheets.

New message definition file wizard: Create a new message definition file from an SCA Import or Export:

You can create a new message definition file from an SCA import or export.

Create a new message definition file from an SCA Import or Export

When you create a new message definition file from an SCA import or export file, you must set the following fields:

Select an SCA Import or Export

Message set
Use this field to choose the message set project that is to contain the message definition file that you create.

Message definition file name
Use this field for the name of the message definition file that you want to create.

Select a file or archive from workspace
Choose this option if the SCA import or export file, or the archive that contains the SCA import or export file, that you want to add to the message definition file that you are creating is in the current workspace, and select the file from the displayed content of the workspace. Only files with the following extensions are shown:

.zip (an archive)

.insca (an archive)

.outsca (an archive)

.import

.export

If you select a file with an extension of .insca, .outsca, .import, or .export, only one SCA import or export file is selected.

Select archive from outside workspace
Choose this option if the archive that contains the SCA import or export file that you want to add to the message definition file that you are creating is not in the current workspace, and specify the location of the archive file that you want to add.

Copy source file into the 'importFiles' directory of the message set project
Select this check box to copy the source file into the 'importFiles' directory of the message set project.

Add XMLNSC to supported message domains if it does not exist
Select this check box to add the XMLNSC message domain to the list of supported message domains that the message definition supports.

Create an appropriate physical format if one does not already exist
Select this check box to automatically create an XML wire format for the message set.

Generate Broker SCA Definition wizard:

The Generate Broker SCA Definition wizard creates a Broker SCA definition from a message set.

The following links provide further information in relation to the panels and fields that form the Generate Broker SCA Definition wizard. Some panels only appear if certain conditions are met; such panels are marked as (optional).

Open the Generate Broker SCA Definition wizard

To open the Generate Broker SCA Definition wizard:

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the message set folder from which you want to generate a Broker SCA definition, and select **Generate** > **Broker SCA Definition**. This action starts the Generate Broker SCA Definition wizard.

Generate Broker SCA Definition wizard

The following panels are shown by the Generate Broker SCA Definition wizard:

- Generate a Broker SCA Definition
- Specify the interface used by the Broker SCA Definition
- Create an interface for the Broker SCA Definition
- Configure Web service binding details
- Configure MQ binding details
- Verify the SCA Import or Export definition that will be generated

Related tasks:

Generate Broker SCA Definition wizard: Generate a Broker SCA Definition:

Use this panel to select the message set folder which contains the source of the Broker SCA definition and to specify the type of Broker SCA definition you want to create.

Generate Broker SCA Definition wizard

The following panels are shown by the Generate Broker SCA Definition wizard:

- Generate a Broker SCA Definition
- Specify the interface used by the Broker SCA Definition
- Create an interface for the Broker SCA Definition
- Configure Web service binding details
- Configure MQ binding details
- Verify the SCA Import or Export definition that will be generated

Panel properties

Select the message set folder from which to generate the Broker SCA definition
Specify the message set folder from which to generate the Broker SCA definition.

Select the type of SCA artifact you want to create
Select from:

- **Inbound Broker SCA definition**

  The Broker SCA definition is an SCA import and has a file extension of `.insca`. This is the default.

- **Outbound Broker SCA definition**

  The Broker SCA definition is an SCA export and has a file extension of `.outsca`.

Binding type
Binding type determines which type of binding the Broker SCA definition is to provide. The choices are:

- Web Service
- WebSphere MQ

Broker SCA definition name
Specify a name for the Broker SCA definition.

Related tasks:

"Generating a Broker SCA definition from a message set" on page 2967

Generate Broker SCA Definition wizard: Create an interface for the Broker SCA Definition:

Use this panel to define the operations that you want to add to the WSDL definition that you are creating as the interface for use by this Broker SCA definition.

Generate Broker SCA Definition wizard

The following panels are shown by the Generate Broker SCA Definition wizard:

- Generate a Broker SCA Definition
- Specify the interface used by the Broker SCA Definition
- Create an interface for the Broker SCA Definition
- Configure Web service binding details
- Configure MQ binding details
- Verify the SCA Import or Export definition that will be generated

Panel properties

The panel is divided into two panes.

The top pane is read-only and displays a table that describes the operations that you have defined. The table has four columns with the following headings:

Operation
The name that you have given to the operation.

Input message
The name of the input message.

Output message
The name of the output message. This might be blank if no output message is specified for this operation.

Operation Type
The type of operation. Examples of operation type are:
Request-response
One-way

The bottom pane is where you describe a new operation. The following fields describe the operation:

Name The name that you have given to the operation.

Operation Type
The type of operation. Examples of operation type are:
Request-response
One-way

Input The name of the input message.

Output
The name of the output message. This is omitted for a *One-way* operation.

Fault The name of the fault message. You can specify one or more fault messages.

Related tasks:

"Generating a Broker SCA definition from a message set" on page 2967

"Generate Broker SCA Definition wizard" on page 6372
The Generate Broker SCA Definition wizard creates a Broker SCA definition from a message set.

Generate Broker SCA Definition wizard: Configure Web service binding details:

Use this panel to specify the SOAP/HTTP binding details for the WSDL definition that you are creating for the Broker SCA definition.

Generate Broker SCA Definition wizard

The following panels are shown by the Generate Broker SCA Definition wizard:

- Generate a Broker SCA Definition
- Specify the interface used by the Broker SCA Definition
- Create an interface for the Broker SCA Definition
- Configure Web service binding details
- Configure MQ binding details
- Verify the SCA Import or Export definition that will be generated

Panel properties

The following properties are displayed:

SOAP action
The value for the HTTP SoapAction header. It is possible that an

application might use the SoapAction as a mechanism for relating a SOAP message to an implementation method. This is often true with rpc-style WSDL.

Service name
The value of the name attribute on the service element in the generated WSDL. The exact use of the name depends on products that then use the WSDL such as the SOAP toolkits and UDDI repositories. For example, if you then use a SOAP toolkit to generate Java from your WSDL, the service name is likely to become the Java interface name.

Port name
Port name is the name of a specific WSDL port for this service and would usually be derived from the Service Name. One convention would be to provide a service name of <xyz> Service and a port name of <xyz> Provider.

The value of the name attribute on the port element in the generated WSDL. The exact use of the name depends on products that then use the WSDL such as SOAP toolkits and UDDI repositories. For example if you use a SOAP toolkit to generate Java from your WSDL, the port name could become a Java class name.

Port address
Port address defines the address at which the service is to be made available. It must be a valid URL and it must include the port number, if this is different from the default HTTP port. An example of a port address is: `http://localhost:7800/abcSOAP_HTTP_Service` for an inbound Broker SCA definition.

If you are generating an outbound Broker SCA definition, the port address property expands to present the following additional properties:

- **Module project name**

  The name of the module project in which you intend to place the exported Broker SCA definition in WebSphere Integration Developer.
- **Host name**

  The host name of the server for WebSphere Process Server.
- **Port number**

  The port number of the server for WebSphere Process Server.

The port address is generated for you using the values you provide in **Module project name**, **Host name**, and **Port number** in the format that is required by WebSphere Integration Developer.

Generate Broker SCA Definition wizard: Configure MQ binding details:

Use this panel to specify the MQ binding details for the Broker SCA definition.

Generate Broker SCA Definition wizard

The following panels are shown by the Generate Broker SCA Definition wizard:

- Generate a Broker SCA Definition
- Specify the interface used by the Broker SCA Definition
- Create an interface for the Broker SCA Definition
- Configure Web service binding details
- Configure MQ binding details
- Verify the SCA Import or Export definition that will be generated

Panel properties

Certain properties are displayed only when an outbound binding is being configured. These are indicated in the following list of properties:

Host name
The machine that hosts WebSphere MQ. The default is `localhost`.

Port The port on which to connect to a specific WebSphere MQ queue manager. The default is `1414`.

Channel
The WebSphere MQ channel. The default is `SYSTEM.DEF.SVRCONN`.

Request queue manager
The WebSphere MQ queue manager where the request queue resides.

Request queue
The queue to which request messages are sent.

Response queue
(This property is displayed only if the interface has one at least one request-response operation.) The queue to which response messages are sent.

Response queue manager
(Outbound binding only. This property is displayed only if the interface has one at least one request-response operation.) The WebSphere MQ queue manager where the response queue resides, if different from the request queue manager. This field is optional; if it is left blank, the Response queue manager defaults to the Request queue manager.

Request data binding handler

If the default message domain of the message set in which the Broker SCA definition is to be generated is XMLNSC, XMLNS or XML, the default data binding handler is UTF8XMLDataHandler. Otherwise, the default data binding handler is empty, and you can select one of the following options:

COBOL, C, PL/I language data binding generator

CSVDataHandler

Fixed width

You can enter a custom handler instead; the handler must exist in the WebSphere Integration Developer module.

Response data binding handler
(This property is displayed only if the interface has one at least one request-response operation.) If the default message domain of the message set in which the Broker SCA definition is to be generated is XMLNSC,

XMLNS or XML, the default data binding handler is UTF8XMLDataHandler. Otherwise, the default data binding handler is empty, and you can select one of the following options:

COBOL, C, PL/I language data binding generator

CSVDataHandler

Fixed width

You can enter a custom handler instead; the handler must exist in the WebSphere Integration Developer module.

Response correlation ID options
(Outbound binding only.) The message exchange mechanism used to correlate request messages with their response messages. Choose from `From Request Message ID` (default), or `From Request Correlation ID`.

Generate Broker SCA Definition wizard

The following panels are shown by the Generate Broker SCA Definition wizard:

- Generate a Broker SCA Definition
- Specify the interface used by the Broker SCA Definition
- Create an interface for the Broker SCA Definition
- Configure Web service binding details
- Configure MQ binding details
- Verify the SCA Import or Export definition that will be generated

This panel consists of two panes. The top pane displays summary information about the Broker SCA definition that is to be generated:

Message set
The message set folder from which the Broker SCA Definition is to be generated.

SCA artifact type
The type of Broker SCA definition: inbound or outbound.

- An inbound Broker SCA definition is the WebSphere Message Broker Toolkit representation of an SCA Import and has a file extension of `.insca`.
- An outbound Broker SCA definition is the WebSphere Message Broker Toolkit representation of an SCA Export and has a file extension of `.outsca`.

SCA artifact name
The name of the Broker SCA definition.

Binding type
The binding type of the Broker SCA definition.

The bottom pane allows you to start the Export SCA Import or Export from Broker SCA Definition wizard:

Start Export SCA Import or Export from Broker SCA Definition wizard after generation is finished
Select the check box for the Export SCA Import or Export from Broker SCA Definition wizard to start on completion of this wizard.

When the wizard has finished, the Broker SCA definition which has been created is added to the specified message set project.

Generate WSDL wizard:

The Generate WSDL wizard creates a WSDL definition from a message set.

The following links provide further information in relation to the panels and fields that form the Generate WSDL wizard. Some panels only appear if certain conditions are met. These are marked as (optional).

Open the Generate WSDL wizard

To open the Generate WSDL wizard:

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the folder that contains the message set file from which you want to generate a Web service definition, and select **Generate** > **WSDL Definition**. This starts the Generate WSDL wizard.

Generate WSDL wizard

The following panels are shown by the Generate WSDL wizard:

- Select the action you want to perform
- Select a message set folder and destination directory
- Specify WSDL details
- Add operations to the WSDL definition
- Configure binding details
- Summary of tasks

Related tasks:

To ensure the highest interoperability of your Web services, use the document style of WSDL whenever possible. If rpc style WSDL is necessary, use literal encoding.

Generate WSDL wizard: Select the action you want to perform:

Use this panel to select how you want to generate the WSDL definition.

Generate WSDL wizard

The following panels are shown by the Generate WSDL wizard:

- Select the action you want to perform
- Select a message set folder and destination directory
- Specify WSDL details
- Add operations to the WSDL definition
- Configure binding details

- Summary of tasks

Panel properties

A choice of three options is presented.

Generate a new WSDL definition from existing message definitions
Select this option to generate a new WSDL definition from existing message definitions. This is the default option.

Export an existing WSDL definition to another directory in the workspace or file system.
Select this option to load the Export WSDL wizard.

Generate a new WSDL definition from existing message definitions using message categories (deprecated)
Select this option to generate a new WSDL definition using existing message definitions and message categories. This option is available to provide compatibility with previous releases of WebSphere Message Broker.

Related tasks:

Use Generate WSDL wizard to select both the source of the WSDL definition and where you want the generated WSDL definition to be placed.

Generate WSDL wizard

The following panels are shown by the Generate WSDL wizard:

- Select the action you want to perform
- Select a message set folder and destination directory
- Specify WSDL details
- Add operations to the WSDL definition
- Configure binding details
- Summary of tasks

Panel properties

Select the message set folder from which to generate the WSDL definition:
Specify the message set folder from which to generate the WSDL definition.

Choose one of the following options to select the destination for the generated WSDL definition:

Create in a workspace directory
Select from your workspace directory the message set folder that will contain the generated WSDL definition.

Export to an external directory
Specify the address of the directory, outside your workspace, that you want to contain the generated WSDL definition.

Options
Specify the structure of the generated XML schema

Choose one of the following options to specify the structure of the generated XML schema:

Generate XML schema definitions with current directory structure
Generates the schema definition using the current directory structure; this is the default.

Generate XML schema definitions with flat structure
Generates the schema definition as a single level directory structure.

Related tasks:

Generate WSDL wizard

The following panels are shown by the Generate WSDL wizard:

- Select the action you want to perform
- Select a message set folder and destination directory
- Specify WSDL details
- Add operations to the WSDL definition
- Configure binding details
- Summary of tasks

Panel properties

File Format
Select from:

- **Generate as a single WSDL file**
  The WSDL definition is written to a single file. This format is widely understood by external applications and SOAP toolkits.
- **Generate as a single WSDL file with all XML schema inlined**
  The WSDL definition is written to a single file with the XML added.
- **Generate as three WSDL files (one each for port type, service, and binding)**
  The WSDL definition is split into multiple files. This format offers better reuse of the component files.

WSDL Version
Select the required version of WSDL.

SOAP Version
Select the required version of SOAP

Style The style determines the format of the runtime SOAP messages described by the generated WSDL. The choices are:

- rpc
- document

WSDL Namespace
This must be a valid URI and becomes the target namespace for the WSDL definitions. This value has no particular significance outside of the WSDL definition itself and does not correspond to the namespace of SOAP messages described by the generated WSDL. A default value of http://tempuri.org/<message set name> is set.

RPC Namespace
This field is only enabled if you selected the Style as rpc. It is the namespace for the immediate children of your SOAP body. The value must be a valid URI. A default value of http://tempuri.org/<message set name> is set.

Definition Name
This is used in deriving the names of the WSDL file or files that are created. The default value is the name of your message set.

Documentation
Optional: This text is included as documentation for the PortType element on the generated WSDL. It has no implications for the SOAP messages that are described by the generated WSDL.

Use this panel to define the operations that you want to add to the WSDL definition.

Generate WSDL wizard

The following panels are shown by the Generate WSDL wizard:

- Select the action you want to perform
- Select a message set folder and destination directory
- Specify WSDL details
- Add operations to the WSDL definition
- Configure binding details
- Summary of tasks

Panel properties

The panel is divided into two panes.

The top pane is read-only and displays a table that describes the operations that you have defined. The table has four columns with the following headings:

Operation
The name that you have given to the operation.

Input message
The name of the input message. This might be blank if the operation is a *Notification* type operation.

Output message
The name of the output message. This might be blank if no output message is specified for this operation.

Operation Type
The type of operation. Examples of operation type are:

Request-response

One-way

Solicit-response

Notification

The bottom pane is where you describe a new operation. The following fields describe the operation:

Name The name that you have given to the operation.

Operation Type
The type of operation. Examples of operation type are:

Request-response

One-way

Solicit-response

Notification

Input The name of the input message. This is omitted for a *Notification* operation.

Output
The name of the output message. This is omitted for a *One-way* operation.

Fault The name of the fault message. This is omitted for a *Notification* operation. Otherwise, you can specify one or more fault messages.

- Select the action you want to perform
- Select a message set folder and destination directory

- Specify WSDL details
- Add operations to the WSDL definition
- Configure binding details
- Summary of tasks

Panel properties

Service name
The Service Name is the value of the name attribute on the service element in the generated WSDL. The exact use of the name depends on products that later use the WSDL such as the SOAP toolkits and UDDI repositories. For example if you later use a SOAP toolkit to generate Java from your WSDL, the Service Name is likely to become the Java interface name.

Port name
This property is the name of a specific WSDL port for this service and would typically be derived from the Service Name. One convention would be to provide a Service Name of <xyz> Service and a Port Name of <xyz> Provider.

The Port Name is the value of the name attribute on the port element in the generated WSDL. The exact use of the name depends on products that later use the WSDL such as SOAP toolkits and UDDI repositories. For example if you use a SOAP toolkit to generate Java from your WSDL, the Port Name could become a Java class name.

A choice of two options is presented:

SOAP/HTTP
Select this option to generate a new WSDL definition using existing message definitions with an HTTP transport. This is the default option.

SOAP/JMS
Select this option to generate a new WSDL definition using existing message definitions with a JMS transport.

If you select **SOAP/HTTP**, the following additional properties are displayed:

SOAP action
This property defines the value for the HTTP SoapAction header. It is possible that an application will use the SoapAction as a mechanism for relating a SOAP message to an implementation method. This is often true with rpc-style WSDL.

If the WSDL definition is to contain multiple operations and they use different SOAP actions, you must add the unique SOAP action values to the WSDL after it has been generated. If all operations use the same SOAP action, specify the value here.

Port address
This property defines the address at which the service is made available. It must be a valid URL and it must include the port number, if it is different from the default HTTP port. An example of a port address is:
`http://localhost:9080/wassoap/servlet/router`

If you select **SOAP/JMS**, the following additional properties are displayed:

Destination style
The style in which you specify the destination name of the JMS message. The default value is `jndi`.

Destination name
The name of the destination of the JMS message. This property must be specified according to the `Destination style` property.

JMS provider name
Select a JMS vendor name from the list. When you select a name from the list, the `Initial context factory` property is updated automatically with the relevant Java class. The name must match the name of a configurable service that is defined for the broker to which you deploy the message flow.

Initial context factory

The starting point for a JNDI namespace. A JMS application uses the initial context to obtain and look up the connection factory and queue or topic objects for the JMS provider. When you select a JMS provider name from the list in `JMS provider name`, the `Initial context factory` property is updated automatically with the relevant Java class. The default value is `com.sun.jndi.fscontext.RefFSContextFactory`, which defines the file-based `Initial context factory` for the WebSphere MQ JMS provider.

JNDI connection factory
The name of the connection factory that is used. This name must exist in the bindings file. The `JNDI connection factory` is a JMS QueueConnectionFactory. Alternatively, you can specify the generic JMS ConnectionFactory.

JNDI URL
The JNDI URL for the JMS provider.

Delivery mode
This property controls the persistence mode used for a message. Valid values are:

- `Persistent`: the message survives if the JMS provider has a system failure.
- `Non Persistent`: the message is lost if the JMS provider has a system failure.

Request message lifetime
This property controls the length of time, in seconds, for which the output JMS message is kept. The default value, 0, is used to indicate that the message must not expire.

JMS request message priority

This property assigns relative importance to the message and can be used for message selection by a receiving web service.

Select a value between 0 (lowest priority) and 9 (highest priority). The default value is 4, which indicates medium priority. Priorities in the range 0 - 4 indicate typical delivery. Priorities in the range 5 - 9 indicate faster delivery.

Reply to Name
The name of the JMS destination to which the receiving application must send a reply message. For a reply message to be returned to this JMS destination, the JMS destination name must be known to the domain of the JMS provider that is used by the receiving client.

Specify JNDI parameters
Enter JNDI context parameters, to be included in the generated WSDL URI,

in this table as name-value pairs. If the `Use SOAP/JMS interoperability protocol` check box is cleared, the `JNDI parameters` table is disabled, and its values are not generated in the resultant WSDL.

Specify user parameters
Enter additional user parameters, to be included in the generated WSDL URI, in this table as name-value pairs.

Use SOAP/JMS interoperability protocol
This check box is selected by default. If this check box is selected, the generated SOAP/JMS WSDL is in the W3C format, otherwise it is IBM-style WSDL. If you clear this check box, the `JNDI parameters` table is disabled, and its values are not generated in the resultant WSDL.

Generate WSDL Definition wizard: Summary of tasks:

Generate WSDL Definition wizard: provides a summary of the actions that will occur on finalizing the wizard.

Generate WSDL wizard

The following panels are shown by the Generate WSDL wizard:

- Select the action you want to perform
- Select a message set folder and destination directory
- Specify WSDL details
- Add operations to the WSDL definition
- Configure binding details
- Summary of tasks

Summary information

This panel consists of two panes. The top pane displays a summary of the selections you have made and the bottom pane lists the message definition files generated.

The selected message set
The message set you selected on the Select a message set folder and destination directory panel.

The generated WSDL files will go into:
The destination directory you selected on the Select a message set folder and destination directory panel.

The version of WSDL to be generated
The version you selected on the Specify WSDL details panel.

The version of SOAP to be generated
The version you selected on the Specify WSDL details panel.

The selected style for WSDL generation:
The style you selected on the Specify WSDL details panel.

The WSDL namespace:
The namespace you selected on the Specify WSDL details panel.

If you selected `rpc` as the style there is an entry for **RPC namespace**.

The following bindings are selected:

SOAP over HTTP
See Configure binding details for further details.

SOAP over JMS
See Configure binding details for further details.

The following WSDL files will be generated:
The name of the generated file.

The following links provide further information in relation to the panels and fields that form the Configure New Web Service Usage wizard.

Configure New Web Service Usage wizard

List of panels:

- Configure web service usage
- File generation details

Panel properties

Web service usage

Select from:

- **Expose message flow as Web service**

  The message flow is exposed as a Web service to its clients.
- **Invoke Web service from message flow**

  The Web service is invoked from the message flow.

Web service parameters

Configure the WSDL-related fields:

- **Port type**

  `Port type` must be specified, and lists all the port types defined in the WSDL document.

By default, the drop down is populated with all the port types from the WSDL, in the order in which they appear in the WSDL file. The initially selected port type is the first port type that has at least one `http` binding associated with it.

- **Binding**

  `Binding` must be specified and lists all SOAP bindings with HTTP transport, associated with the selected port type.

  Bindings related to the selected port type are populated in the order in which they appear in the WSDL file. The initially selected binding is the one that has at least one port and one operation associated with it; if there is no such binding, the first binding with at least one port is selected.

  If no binding has ports associated with it, the first binding in the list is selected.

- **Service port**

  Lists all WSDL ports that point to the selected binding.

- **Binding operations**

  Lists all operations defined by the selected port type. Note, that only those operations implemented by the selected binding are selected by default.

  For every selected operation, the subflow generation process produces an output terminal, in the generated subflow.

  If you select an operation, that is not implemented by the selected binding, you receive a warning message; however, you can continue with the selection.

Related tasks:

"Generating a WSDL definition from a message set" on page 2968

Configure New Web Service Usage wizard: File generation details:

Use the Configure New Web Service Usage wizard to specify file generation details.

Configure New Web Service Usage wizard

List of panels:

- Configure web service usage
- File generation details

Panel properties

Flow Generation Details

Only one file is generated, namely the subflow. The subflow name is constructed as follows:

	Format of the generated subflow name
Request operation	`OperationName_WSDLFileName_MainFlow.msgflow`

	Format of the generated subflow name
Extract operation	`WSDLFileName_MainFlow.msgflow`

This page of the wizard lists the name of the file to be generated together with its location.

Typically, this file represents the subflow that is about to be generated. The default subflow name is prefixed by the name of the selected WSDL file, however, you have the option to change the name.

If the file to be generated already exists in the workspace, a warning is issued and the **Finish** button is no longer enabled.

You either have to change the name of the file, or select the **Overwrite existing file** check box.

Node type to be used by the Web service flows

Select from:

- **SOAP nodes**

  Select this option to use the SOAP domain and the SOAP nodes. This is the default option.

  Using SOAP nodes is WSDL driven and allows you to take advantage of various WS_* standards; for example WS_Security and WS_Addressing.

  If the message set does not support the SOAP domain you receive a warning.

- **HTTP nodes**

  Select this option if you want to use HTTP nodes rather than SOAP nodes.

  You can select this option only if the message set supports the XMLNSC, MRM, or XMLNS domains.

  If you select **HTTP nodes**, you see a message explaining the advantages of the SOAP nodes together with a suggestion that you import WSDL files.

  If you use the `ImportFiles` folder as your source, you can only select HTTP node generation.

Details

This pane appears if any additional warnings about the subflow that is generated apply. Possible warnings are as follows:

- When Service Definition is not found in the WSDL file, the URL property is not set on the node.
- You have selected one or more operations that are not implemented by the selected binding.
- When message domain is MRM, but XML wire format not found, message format property is not set on the HTTPInput or Request node.

The Generate WSDL wizard creates a WSDL definition from a message set.

Publish/subscribe

Use the reference information in this section to help you develop publish/subscribe applications.

Publish/subscribe reference information is available for the following topics:
- “Special characters in topics”
- “Topic semantics and usage” on page 6396
- “MQRFH2 header” on page 6397
- “Command messages” on page 6403

Special characters in topics

A topic can contain any character in the Unicode character set, but some characters have a special meaning.

The following three characters have a special meaning:
The topic level separator "/".
The multilevel wildcard "#".
The single-level wildcard "+".

The topic level separator is used to introduce structure into the topic, and can therefore be specified within the topic for that purpose.

The multilevel wildcard and single-level wildcard can be used for subscriptions, but they cannot be used within a topic by the publisher of a message.

However, if a publisher uses the characters "+" or "#" together with other characters in any topic level within a topic, these characters are not treated as wildcards, and they do not have any special meaning.

The topic level separator:
The topic level separator character "/" is used to provide a hierarchical structure to the topic space. It must be used by applications to separate levels within a topic tree. The use of the topic level separator is significant when the two wildcard characters are encountered in topics specified by subscribers.

Topic hierarchy is important in the administration of access control.

The multilevel wildcard:
The multilevel wildcard character "#" is used to match any number of levels within a topic. For example, using the example topic tree shown above, if you subscribe to "USA/Alaska/#", you receive messages on topics "USA/Alaska" and "USA/Alaska/Juneau".

The multilevel wildcard can represent zero or more levels. Therefore, "USA/#" can also match the singular "USA", where # represents zero levels. The topic level separator is meaningless in this context, because there are no levels to separate.

The multilevel wildcard can be specified only on its own or next to the topic level separator character. Therefore, "#" and "USA/#" are valid topics where the "#" character is treated as a wildcard. However, although "USA#" is also a valid topic, the "#" character is not regarded as a wildcard and does not have any special meaning. See “When wildcards are not wild” on page 6396 for more information.

The single-level wildcard:

The single-level wildcard character "+" matches one, and only one, topic level. For example, "USA/+" matches "USA/Alabama", but not "USA/Alabama/Auburn". Also, because the single-level wildcard matches only a single level, "USA/+" does not match "USA".

The single-level wildcard can be used at any level in the topic tree, and in conjunction with the multilevel wildcard. The single-level wildcard must be specified next to the topic level separator, except when it is specified on its own. Therefore, "+" and "USA/+" are valid topics where the "+" character is treated as a wildcard. However, although "USA+" is also a valid topic, the "+" character is not regarded as a wildcard and does not have any special meaning. See "When wildcards are not wild" for more information.

When wildcards are not wild:
The wildcard characters "+" and "#" have no special meaning when they are mixed with other characters (including themselves) in a topic level.

This means that topics that contain "+" or "#" together with other characters in a topic level can be published.

For example, consider the following two topics:

1. level0/level1/+/level4/#
2. level0/level1/#+/level4/level#

In the first example, the characters "+" and "#" are treated as wildcards and are therefore not valid in a topic that is to be published.

In the second example, the characters "+" and "#" are not treated as wildcards and therefore the topic can be both published and subscribed to.

Related reference:

"Topic semantics and usage"

Topic semantics and usage

When you build an application, the design of the topic tree should take into account the following principles of topic name syntax and semantics:

- Topic names are case sensitive.

  For example, "ACCOUNTS" and "Accounts" are two different topics.
- Topic names can include the space character.

  For example, "Accounts payable" is a valid topic.
- A leading "/" creates a distinct topic.

  For example, "/USA" is different from "USA" and "/USA' matches "+/+" and "/+", but not "+".
- A topic name that contains '//' is not a valid name. An attempt to subscribe to a topic with such a name causes an error.
- Do not include the null character (Unicode \x0000) in any topic.
- The wildcard characters "+" and "#" are not treated as wild cards if they are mixed with any other characters (including themselves but excluding the topic level separator "/") within a topic level.

The following principles apply to the construction and content of a topic tree:

- There is no limit to the number of levels in a topic tree.
- There is no limit to the length of the name of a level in a topic tree.

- There can be any number of "root" nodes; that is, there can be any number of topic trees. These are defined below the root "", which is the root of all root nodes. It is referred to as "topicRoot", although there is no corresponding topic name. Applications cannot publish or subscribe to this virtual root.
- The topic trees with roots of "$SYS" and "$ISYS" are reserved for use by WebSphere Message Broker only.

Related reference:

"Special characters in topics" on page 6395
A topic can contain any character in the Unicode character set, but some characters have a special meaning.

MQRFH2 header

The MQRFH2 header is used to pass messages to and from a message broker that belongs to WebSphere Message Broker.

In a message, the MQRFH2 header follows the WebSphere MQ message descriptor (MQMD) and precedes the message body, if present. The MQRFH2 header can be parsed by either the MQRFH2 parser or the MQRFH2C parser.

Other headers, such as the IMS/ESA® or CICS bridge headers, are allowed either before or after the MQRFH2 header, but before the message body.

If you are using the Message Queuing Interface (MQI) to write application programs you need to understand the structure and content of the MQRFH2 header.

For more information, refer to:
- "MQRFH2 structure"
- "Message service folders" on page 6401

Multiple MQRFH2 headers:
A message can have more than one MQRFH2 header.

For example, if an application forwards a message, including its header, to another application, a second MQRFH2 header precedes the header in the message being forwarded.

- Attributes that describe the body of the message, such as the domain, set, type, and format, or the character set ID and encoding, are taken from the *last* MQRFH2 header, which is immediately in front of the body of the message.
- Anything else, such as the topic for a publish/subscribe message, is taken from the *first* MQRFH2 header.

Related reference:

"The MQRFH2 and MQRFH2C parsers" on page 4253
The MQRFH2 header can be parsed using either the MQRFH2 parser or the MQRFH2C compact parser.

"MQInput node" on page 4594
Use the MQInput node to receive messages from clients that connect to the broker by using the WebSphere MQ Enterprise Transport, and that use the MQI and AMI application programming interfaces.

MQRFH2 structure:
The MQRFH2 header contains information about the structure of a message, and its intended consumers, to enable a message broker to process the message and deliver or publish the message to those consumers.

The value 'MQHRF2 ' should be put in the **Format** field of the preceding header (usually the MQMD). The constant *MQFMT_RF_HEADER_2* is defined with this value.

For the C programming language, the constant *MQFMT_RF_HEADER_2_ARRAY* is also defined. This constant has the same value as *MQFMT_RF_HEADER_2*, but it is an array of characters, not a character string.

The character set and encoding of the fields in the MQRFH2 header are as follows:

- Fields other than **NameValueData** are in the character set and encoding defined by the fields **CodedCharSetId** and **Encoding** in the header structure that precedes the MQRFH2 header, or by the same fields in the MQMD structure if the MQRFH2 header is at the start of the application message data. The character set should be one that has single-byte characters for the characters that are valid in queue names.
- **NameValueData** is in the character set defined by the **NameValueCCSID** field. Note that not all Unicode character sets are valid for **NameValueCCSID**; see the description of **NameValueCCSID** for details.

  Some character sets have a representation that is dependent on the encoding. If **NameValueCCSID** defines one of these character sets, **NameValueData** must be in the same encoding as the other fields in the MQRFH2 header.
- The user data (if any) that follows **NameValueData** can be in any supported character set (single-byte, double-byte, or multi-byte), and in any supported encoding.

The MQRFH2 header contains the following fields:

Field Name	Description	Details
StrucId	Structure identifier	The value must be `MQRFH_STRUC_ID`, which is the identifier for the rules and formatting header structure,. WebSphere Message Broker populates this field for you if you are constructing an MQRFH2 header in a message flow. For the C programming language, the constant `MQRFH_STRUC_ID_ARRAY` is also defined; this constant has the same value as `MQRFH_STRUC_ID`, but it is an array of characters, not a character string.
Version	Structure version number	The value must be `MQRFH_VERSION_2`, which is the Version-2 rules and formatting header structure.

Field Name	Description	Details
Struclength	Total length of MQRFH2 (including **NameValueData**)	The initial value of this field is MQRFH_STRUC_LENGTH_FIXED_2, which is the length of the fixed part of the MQRFH2 header structure. This is the length in bytes of the MQRFH2 header structure, including any **NameValueLength** and **NameValueData** fields at the end of the structure. WebSphere Message Broker populates this field for you if you are constructing an MQRFH2 header in a message flow. There might be more than one pair of these fields at the end of the structure, in the sequence: length1, data1, length2, data2, ... The length of any user data that follows the last **NameValueData** field at the end of the structure is not included in **StrucLength**. **Note:** If **Struclength** is not a multiple of four, problems might occur with the data conversion of user data in some operating system environments.
Encoding	Numeric encoding of data that follows **NameValueData**	The initial value of this field is MQENC_NATIVE. This field specifies how numeric values in any data that follows the last **NameValueData** field are represented. This applies to binary integer data, packed decimal integer data and floating-point data.
CodedCharSetId	Character set identifier of data that follows **NameValueData**	The initial value of this field is MQCCSI_INHERIT, which means that the character set identifier is the same as that of the current structure. This field identifies the coded character set for any character strings in the data that follows the last **NameValueData** field.
Format	Format name of data that follows **NameValueData**	The initial value of this field is **MQFMT_NONE**. This field specifies the format name of any data that follows the last **NameValueData** field. The name should be padded with blanks to the length of the field. **Note:** Do not use a null character to terminate the name before the end of the field; the queue manager does not change to a blank character the null character, or any characters that follow the null character, in the MQRFH2 header. **Note:** Do not specify a name with leading or embedded blank characters.
Flags	Flags	The initial value of this field is MQRFH_NONE, which means that there are no flags.

Field Name	Description	Details
NameValueCCSID	Character set identifier of **NameValueData**	The initial value of this field is 1208, which means that the UTF-8 coded character set is used. This field identifies the coded character set for data in the **NameValueData** field. This is different from the character set for other character strings in the MQRFH2 header structure, and might be different from the character set for any character data that follows the last **NameValueData** field. **NameValueCCSID** must have one of the following values: **1200**: UCS-2 open-ended **1208**: UTF-8 **13488**: UCS-2 2.0 subset **17584**: UCS-2 2.1 subset (includes the euro symbol €) For the UCS-2 character sets, the encoding (byte order) of the **NameValueData** field must be the same as the encoding of the other fields in the MQRFH2 header structure. **Note:** Surrogate characters (X'D800' thru X'DFFF') are not supported.
The following two fields are optional, but if present they must occur as a pair. They can be repeated as a pair as many times as required. If these fields occur more than once, they must occur in the sequence ..... length1, data1, length2, data2, ...		
NameValueLength	Length of **NameValueData**	This field specifies the length, in bytes, of the **NameValueData** field that follows this field. WebSphere Message Broker populates this field for you if you are constructing an MQRFH2 header in a message flow. **Note:** If **NameValueLength** is not a multiple of four, there might be a problem with the conversion of the data that follows the **NameValueData** field.
NameValueData	This is a variable-length character string containing data that is encoded using an XML-like structure	The length, in bytes, of this string is given by the **NameValueLength** field that precedes this **NameValueData** field. To avoid the problem described in the note accompanying the description of the **NameValueLength** field, either extend this field with blanks so that its length is a multiple of four, or terminate the field with a null character.

C programming language definition

The following structure is defined in the cmqc.h header file that is supplied with WebSphere MQ. The constants that are used within the **NameValueData** field are defined in the BipRfc.h header file that is supplied with WebSphere Message Broker.

```
typedef struct tagMQRFH2 {
  MQCHAR4  StrucId;         /*  Structure identifier                     */
  MQLONG   Version;         /*  Structure version number                 */
  MQLONG   StrucLength;     /*  Total length of MQRFH2 including
                                NameValueData                            */
  MQLONG   Encoding;        /*  Numeric encoding of data that follows
                                NameValueData                            */
  MQLONG   CodedCharSetId;  /*  Character set identifier of data that
                                follows NameValueData                    */
  MQCHAR8  Format;          /*  Format name of data that follows
                                NameValueData                            */
  MQLONG   Flags;           /*  Flags                                    */
  MQLONG   NameValueCCSID;  /*  Character set identifier of NameValueData   */
 } MQRFH2;
```

Message service folders:

A number of folders are defined for use by WebSphere MQ products.

<mcd>
: Message content descriptor

<psc> Publish/subscribe command

<pscr>
: Publish/subscribe command response

<usr> Application (user) defined properties

<jms> Java Messaging Service

Each folder is contained in a separate **NameValueData** field, each of which is preceded by a **NameValueLength** field.

Independent software vendors can choose other names for their folders. However, you can prefix your chosen folder name with their internet domain name to avoid naming conflicts and problems. For example, a vendor with domain name ourcompany.com might name its folders:

```
com.ourcompany.xxx  or  com.ourcompany.ourData
```

The mcd folder:

The <mcd> folder can contain the following elements that describe the structure of the message data in a WebSphere MQ message. They are all character strings, and are case sensitive.

<Msd> Message service domain

Valid values are:

mrm The message is parsed by the MRM domain.

xmlnsc
: The message is XML and is parsed by the XMLNSC domain.

xmlns The message is XML and is parsed by the XMLNS domain.

xml The message is XML and is parsed by the XML domain.

mime The message uses the MIME standard and is parsed by the MIME domain.

idoc The message is an SAP ALE IDoc from the WebSphere MQ Link for R/3, and is parsed by the IDOC domain.

none The message is treated as an opaque BLOB, and delivered to the recipient without modification.

See "Parsers" on page 1072 for a description of each domain.

<Set> The name of the message set that contains the definition of the message.

If <Msd> is *mrm* or *idoc*, you must use the <Set> element to supply the name of the message set.

If <Msd> is *xmlnsc*, and validation is enabled in the message flow, you must use the <Set> element to supply the name of the message set.

<Type> The name of the message type, in the specified message set, to which this message corresponds. The format of a simple message type is {namespace-uri}:name where name is the name of the message.

The format {namespace-uri}name (that is, with no colon) is also valid to maintain compatibility with previous versions of WebSphere Message Broker.

If <Msd> is *mrm* or *idoc*, you must use the <Type> element to supply the name of the message definition.

<Fmt> The name of a physical format in the specified message set.

If <Msd> is *mrm* or *idoc*, you must use the <Fmt> element to supply the name of the physical format in the message set.

If the message tree contains an MQRFH2 header, any node that modifies the message tree performs the following steps before propagating the message to the next node:

- If there is no <mcd> folder, one is added, and the Msd, Set, Type, and Format fields are populated with values that match the current domain and the current setting in the Properties folder.
- If there is an <mcd> folder, the Msd, Set, Type, and Format fields are overwritten with values that match the current domain and the current settings in the Properties folder.

Tip: If you need to propagate an MQRFH2 header without an <mcd> folder, you can remove the header by using the following ESQL code with a Compute node:

```
CALL CopyEntireMessage();
DELETE FIELD OutputRoot.MQRFH2.mcd;
PROPAGATE FINALIZE NONE; -- Propagate the message without updating the headers
RETURN FALSE; -- Ensure that the message is not propagated again.
```

The psc folder:
The <psc> folder is used to convey publish/subscribe command messages to the broker.

Only one psc folder is allowed in the **NameValueData** field.

See "Command messages" on page 6403 for full details.

The pscr folder:
The <pscr> folder is used to contain information from the broker, in response to publish/subscribe command messages.

Only one pscr folder is present in a response message.

See “Broker Response message” on page 6407 for full details.

The broker ignores this folder in messages that it receives from publish/subscribe applications.

The usr folder:
The content model of the <usr> folder has the following characteristics.

- Any valid XML name that does not contain a colon can be used as an element name.
- Only simple elements, not groups, are allowed.
- All elements take the default type of string.
- All elements are optional, but must not occur more than once in a folder.
- An MQRFH2 instance can contain, at most, one <usr> folder.

The jms folder:
The content model of the <jms> folder contains the following MQRFH2 JMS fields:

- Dst - represents the JMSDestination header field.
- Dlv - represents the JMSDeliveryMode header field.
- Exp - represents the JMSExpiration header field.
- Pri - represents the JMSPriority header field.
- Tms - represents the JMSTimestamp header field.
- Cid - represents the JMSCorrelationID header field.
- Rto - represents the JMSReplyTo header field.

See “JMS message structure” on page 1688 for more information about the content of JMS messages.

Related concepts:

“Parsers” on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

“Message modeling” on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

Related reference:

“JMS message structure” on page 1688
JMS messages have a defined structure that includes headers and payloads.

Command messages

The following command messages can be sent to WebSphere Message Broker in a publish/subscribe application:

- “Delete Publication message” on page 6404
- “Publish message” on page 6405

If you are using the Message Queue Interface (MQI) to write applications that use the publish/subscribe model, you need to understand these messages and the Broker Response message. Refer to:

- “Broker Response message” on page 6407

The commands are contained in a <psc> folder in the **NameValueData** field of the MQRFH2 header.

The message that can be sent by a broker in response to a command message is contained in a <pscr> folder.

Refer to "Message service folders" on page 6401 for details about the message service folders.

The descriptions of each command list the properties that can be contained in a folder. Unless otherwise specified, the properties are optional and can occur no more than once.

Names of properties are shown as <Command>.

Values must be in string format, for example: Publish.

A string constant representing the value of a property is shown in parentheses, for example: (MQPSC_PUBLISH).

String constants are defined in the header file BipRfc.h which is supplied with WebSphere Message Broker.

Delete Publication message:
The *Delete Publication* command message is sent to a broker from a publisher, or from another broker, to tell the broker to delete any retained publications for the specified topics.

This message is sent to the input queue of a message flow that contains a *Publication* node. You must have the authority to put a message onto this queue, and to publish on the topic, or topics, that are specified in the message.

The input queue should be the queue that the original publication was sent to.

If you have the authority for some, but not all, of the topics that are specified in the *Delete Publication* command message, only those topics are deleted. A *Broker Response* message indicates which topics are not deleted.

Similarly, if a **Publish** command contains more than one topic, a **Delete Publication** command matching some, but not all, of those topics deletes only the publications for the topics that are specified in the *Delete Publication* command.

Properties:

<Command> (*MQPSC_COMMAND*)
The value is DeletePub(*MQPSC_DELETE_PUBLICATION*).

This property must be specified.

<Topic> (*MQPSC_TOPIC*)
The value is a string that contains a topic for which retained publications are to be deleted. Wildcard characters can be included in the string to delete publications on more than one topic.

This property must be specified; it can be repeated for as many topics as needed.

<DelOpt> (*MQPSC_DELETE_OPTION*)
The delete options property can take one of the following values:

Local (*MQPSC_LOCAL*)

All retained publications for the specified topics are deleted at the local broker (that is, the broker to which this message is sent), whether they were published with the `Local` option or not.

Publications at other brokers are not affected.

None (*MQPSC_NONE*)

All options take their default values. This has the same effect as omitting the `DelOpt` property. If other options are specified at the same time, `None` is ignored.

The default if this property is omitted is that all retained publications for the specified topics are deleted at all brokers in the network, regardless of whether they were published with the `Local` option.

Example:
Here is an example of **NameValueData** for a **Delete Publication** command message. This is used by the sample application to delete, at the local broker, the retained publication that contains the latest score in the match between Team1 and Team2.

```
<psc>
 <Command>DeletePub</Command>
 <Topic>Sport/Soccer/State/LatestScore/Team1 Team2</Topic>
 <DelOpt>Local</DelOpt>
</psc>
```

Publish message:
The *Publish* command message is sent from a publisher to a broker, or from a broker to a subscriber, to publish information on a specified topic or topics.

This message is sent to the input queue of a message flow that contains a Publication node. Authority to put a message onto this queue, and to publish on the specified topic or topics, is necessary.

If the user has authority on some, but not all, topics, only those topics are published; a warning response indicates which topics are not published.

If a subscriber has any matching subscriptions, the broker forwards the Publish message to the subscriber queues defined in the corresponding **Register Subscriber** command messages.

See "Broker Response message" on page 6407 for details of the message descriptor (MQMD) parameters needed when sending a command message to the broker, and used when a broker forwards a publication to a subscriber.

The broker forwards the Publish message to other brokers in the network that have matching subscriptions, unless it is a local publication.

Publication data, if any, is included in the body of the message. The data can be described in an `<mcd>` folder in the **NameValueData** field of the MQRFH2 header.

Properties:

<Command> (*MQPSC_COMMAND*)
The value is `Publish`(*MQPSC_PUBLISH*).

This property must be specified.

<Topic> (*MQPSC_TOPIC*)
The value is a string that contains a topic that categorizes this publication. No wildcard characters are allowed.

This property must be specified, and can optionally be repeated for as many topics as needed.

<SubPoint> (*MQPSC_SUBSCRIPTION_POINT*)
The subscription point on which the publication is published.

This property should not be included in a publication message sent to the broker but is added automatically to publication messages by the broker before those messages are sent to any appropriate subscribers. The value of the `<SubPoint>` property is the value of the Subscription Point attribute of the Publication node that is handling the publishing.

<PubOpt> (*MQPSC_PUBLICATION_OPTION*)
The publication options property can take the following values:

RetainPub
(*MQPSC_RETAIN_PUB*)

The broker is to retain a copy of the publication. If this option is not set, the publication is deleted as soon as the broker has sent the publication to all its current subscribers.

IsRetainedPub
(*MQPSC_IS_RETAINED_PUB*)

(Can only be set by a broker.) This publication has been retained by the broker. The broker sets this option to notify a subscriber that this publication was published earlier and has been retained, provided that the subscription has been registered with the `InformIfRetained` option. It is set only in response to a **Register Subscriber** or **Request Update** command message. Retained publications that are sent directly to subscribers do not have this option set.

Local
(*MQPSC_LOCAL*)

This option tells the broker that this publication should not be sent to other brokers. All subscribers that registered at this broker receive this publication if they have matching subscriptions.

OtherSubsOnly
(*MQPSC_OTHER_SUBS_ONLY*)

This option allows simpler processing of conference-type applications, where a publisher is also a subscriber to the same topic. It tells the broker not to send the publication to the publisher's subscriber queue even if it has a matching subscription. The publisher's subscriber queue consists of its `QMgrName`, `QName`, and optional `CorrelId`, as described later in this section.

CorrelAsId
(*MQPSC_CORREL_ID_AS_IDENTITY*)

The `CorrelId` in the MQMD (which must not be zero) is part of the publisher's subscriber queue, in applications where the publisher is also a subscriber.

None (*MQPSC_NONE*)

All options take their default values. This has the same effect as omitting the publication options property. If other options are specified at the same time, `None` is ignored.

You can have more than one publication option by introducing additional `<PubOpt>` elements.

The default, if this property is omitted, is that no publication options are set.

<PubTime> (*MQPSC_PUBLISH_TIMESTAMP***)**
The value is an optional publication timestamp set by the publisher. It is 16 characters long with format:

```
YYYYMMDDHHMMSSTH
```

using Universal Time. This information is not checked by the broker before being sent to the subscribers.

<SeqNum> (*MQPSC_SEQUENCE_NUMBER***)**
The value is an optional sequence number set by the publisher.

It should be incremented by 1 with each publication. However, this is not checked by the broker, which merely transmits this information to subscribers.

If publications on the same topic are published to different interconnected brokers, it is the responsibility of the publishers to ensure that sequence numbers, if used, are meaningful.

<QMgrName> (*MQPSC_Q_MGR_NAME***)**
The value is a string containing the name of the queue manager for the publisher's subscriber queue, in applications where the publisher is also a subscriber (see `OtherSubsOnly`).

If this property is omitted, the default is the `ReplyToQMgr` name in the message descriptor (MQMD). If the resulting name is blank, it defaults to the name of the broker's queue manager.

<QName> (*MQPSC_Q_NAME***)**
The value is a string containing the name of the publisher's subscriber queue, in applications where the publisher is also a subscriber (see `OtherSubsOnly`).

If this property is omitted, the default is the `ReplyToQ` name in the message descriptor (MQMD), which must not be blank if `OtherSubsOnly` is set.

Example:
Here are some examples of *NameValueData* for a **Publish** command message.

The first example is for a publication sent by the match simulator in the sample application to indicate that a match has started.

```
<psc>
 <Command>Publish</Command>
 <Topic>Sport/Soccer/Event/MatchStarted</Topic>
</psc>
```

The second example is for a retained publication. The latest score in the match between Team1 and Team2 is published.

```
<psc>
 <Command>Publish</Command>
 <PubOpt>RetainPub</PubOpt>
 <Topic>Sport/Soccer/State/LatestScore/Team1 Team2</Topic>
</psc>
```

Broker Response message:

A *Broker Response* message is sent from a broker to the ReplyToQ of a publisher or a subscriber, to indicate the success or failure of a command message received by the broker if the command message descriptor specified that a response is required.

The response message is contained within the NameValueData field of the MQRFH2 header, in a <pscr> folder.

In the case of a warning or error, the response message contains the <psc> folder from the command message as well as the <pscr> folder. The message data, if any, is not contained in the broker response message. In the case of an error, none of the message that caused an error has been processed; in the case of a warning, some of the message might have been processed successfully.

If there is a failure sending a response:

- For publication messages, the broker tries to send the response to the WebSphere MQ dead-letter queue if the MQPUT fails. This allows the publication to be sent to subscribers even if the response cannot be sent back to the publisher.
- For other messages, or if the publication response cannot be sent to the dead-letter queue, an error is logged and the command message is normally rolled back. Whether this happens depends on how the MQInput node has been configured.

Properties:

<Completion> (*MQPSCR_COMPLETION***)**
The completion code, which can take one of three values:
ok Command completed successfully
warning
Command completed but with warning
error Command failed

<Response> (*MQPSCR_RESPONSE***)**
The response to a command message, if that command produced a completion code of warning or error. It contains a <Reason> property, and might contain other properties that indicate the cause of the warning or error.

In the case of one or more errors, there is only one response folder, indicating the cause of the first error only. In the case of one or more warnings, there is a response folder for each warning.

<Reason> (*MQPSCR_REASON***)**
The reason code qualifying the completion code, if the completion code is a warning or error. It is set to one of the error codes listed later in this section. The <Reason> property is contained within a <Response> folder. The reason code can be followed by any valid property from the <psc> folder (for example, a topic name), indicating the cause of the error or warning.

Examples:
Here are some examples of NameValueData in a **Broker Response** message. A successful response might be the following:

```
<pscr>
  <Completion>ok</Completion>
</pscr>
```

Here is an example of a failure response; the failure is a filter error. The first NameValueData string contains the response; the second contains the original command.

```
<pscr>
  <Completion>error</Completion>
  <Response>
    <Reason>3150</Reason>
  </Reponse>
</pscr>

<psc>
 ...
 command message (to which
 the broker is responding)
 ...
</psc>
```

Here is an example of a warning response (due to unauthorized topics). The first NameValueData string contains the response; the second NameValueData string contains the original command.

```
<pscr>
  <Completion>warning</Completion>
  <Response>
    <Reason>3081</Reason>
    <Topic>topic1</Topic>
  </Reponse>
  <Response>
    <Reason>3081</Reason>
    <Topic>topic2</Topic>
  </Reponse>
</pscr>

<psc>
 ...
 command message (to which
 the broker is responding)
 ...
</psc>
```

Content based filtering

Content based filtering allows a subscriber to filter messages based on their content.

This section contains the following reference information:

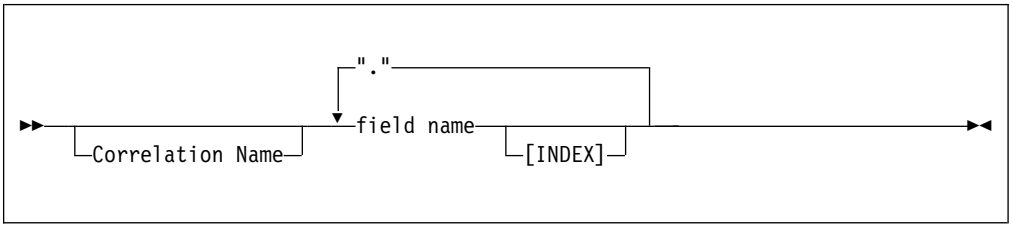
- "Using filters in content-based filtering"
- "Content based filtering examples" on page 6410

For a description of the ESQL language, see "ESQL reference" on page 5019.

Using filters in content-based filtering:

Content based filters are specified as ESQL expressions.

Field references:



The field references that can be used in filters for content based filtering form a subset of those supported by the Filter node. As with the Filter node, to reference a field in a filter, you must specify a path. Each element of the path consists of a, possibly indexed, field name.

The syntax of a field reference is shown above, where `field name` and `Correlation Name` are identifiers. These identifiers represent all messages as a hierarchical syntax element tree. Each path identifies a route through that tree, which leads to a particular syntax element, starting from one of the predefined correlation names that refer to fixed points that every message has. The following correlation names are supported for content based filtering:

Correlation name	Purpose
Root	Identifies the root of a published message.
Properties	Identifies the portion of the message in which the standard properties of a message lie.
Body	Identifies the last child of the root of the message, which is usually, but not always, the application data that follows any headers.

Here are some examples of field references, together with their meanings:

Field reference	Purpose
Body.Person.Address	Refers to the first Address field in the Person entity in the body of the message.
Properties.Topic	Refers to the "Topic" field in the standard properties of a message.
Root.MQMD.UserIdentifier	Refers to the `UserIdentifier` field in the MQMD of the message.

Note that path elements of `"*"` and the array index `"LAST"` are not supported in the filters.

Content based filtering examples:

Some examples of content based filtering.

Content Filter	Explanation
Body.Person.Salary>10000	Filtering against an integer literal
`"Body.Person.Address"[1]NOT LIKE'Blen% 'AND"Body.Person.Salary">15000`	A more complex filter. Note that field identifiers can optionally be surrounded by double quotation marks.

Content Filter	Explanation
Body.Date1='2000-02-14'	Filtering against a date. The date is matched as a string and care must be taken with its layout (see below).
Body.Person.ApprovalFlag	Filtering against a Boolean field.
Body.Person.Salary+Person.Bonus>Body.Person.Limit	An arithmetic filter.
Properties.Topic='employees/marketing'	Filtering on a message property.
Root.MQMD.UserIdentifier='Blair'	Filtering on a message attribute.
Body.Person.HourlyRate = 10.24	Filtering against a float literal
Body.Planet.DistanceFromSun = 0.93E8	Filtering against a float literal in exponential format

User-defined extensions

Reference material that supports the creation and management of your user-defined extensions.

This section contains the following information:

Related concepts:

"User-defined extensions overview" on page 2971
A user-defined extension is an optional component that you design and create to extend the functionality of WebSphere Message Broker.

"Developing user-defined extensions" on page 2970
A user-defined extension is a component that you design and implement to extend the function of WebSphere Message Broker.

Sample node files

Several sample node files are provided on all platforms.

Windows On Windows, the following sample node files are in the *install_dir*\sample\extensions\nodes directory, where *install_dir* is the home directory of your WebSphere Message Broker installation.

Linux On Linux, the following files are in the *install_dir*/sample/extensions/nodes directory, where *install_dir* is the home directory of your WebSphere Message Broker installation.

UNIX On UNIX, the following files are in the *install_dir*/sample/extensions/nodes directory, where *install_dir* is the home directory of your WebSphere Message Broker installation.

z/OS On z/OS, the following files are in the *install_dir*/sample/extensions/nodes directory, where *install_dir* is the home directory of your WebSphere Message Broker installation.

Sample node file	Description
SwitchNode.c	C source file containing a sample implementation of a message processing node that routes a message to one of five output terminals, depending on the content.
SwitchNode.h	The header file for the SwitchNode.c file.
TransformNode.c	C source file containing a sample implementation of a simple fixed transformation of an input message into an output message.
TransformNode.h	The header file for the TransformNode.c file.
BipSampPluginUtil.c	Sample utility functions used by the Switch and Transform nodes.
BipSampPluginUtil.h	The header file for BipSampPluginNode and BipSampPluginUtil.
NodeFactory.c	Common C functions for SwitchNode.c, TransformNode.c, and BipSampPluginUtil.c
NodeFactory.h	The header file for NodeFactory.c
Common.c	Common C functions for SwitchNode.c, TransformNode.c, and BipSampPluginUtil.c
Common.h	The header file for Common.c
PluginSample.add.xml	A sample XML input message that you can use to test the C sample nodes.
PluginSample.change.xml	A sample XML input message that you can use to test the C sample nodes.
PluginSample.delete.xml	A sample XML input message that you can use to test the C sample nodes.
JavaPlugin.add.xml	A sample XML input message that you can use to test the Java sample nodes.
JavaPlugin.change.xml	A sample XML input message that you can use to test the Java sample nodes.

Sample node file	Description
JavaPlugin.delete.xml	A sample XML input message that you can use to test the Java sample nodes.
JavaPlugin.hold.xml	A sample XML input message that you can use to test the Java sample nodes.

Windows On Windows, the following sample node files are in the *install_dir*\sample\extensions\nodes directory, where *install_dir* is the home directory of your WebSphere Message Broker installation.

Linux On Linux, the following files are in the *install_dir*/sample/Javaplugin/com/ibm/samples directory, where *install_dir* is the home directory of your WebSphere Message Broker installation.

UNIX On UNIX, the following files are in the *install_dir*/sample/Javaplugin/com/ibm/samples directory, where *install_dir* is the home directory of your WebSphere Message Broker installation.

z/OS On z/OS, the following files are in the *install_dir*/sample/Javaplugin/com/ibm/samples directory, where *install_dir* is the home directory of your WebSphere Message Broker installation.

Sample node file	Description
JavaSwitchPluginNode.java	Java source file containing a sample implementation of a message processing node that routes a message to one of five output terminals, depending on the content.
JavaTransformPluginNode.java	Java source file containing a sample implementation of a simple fixed transformation of an input message into an output message.

The files that the WebSphere Message Broker Toolkit needs to recognize the Switch node and Transform node are in the *install_dir*\sample\extensions\nodes\com.ibm.samples.nodes directory, where *install_dir* is the home directory of your WebSphere Message Broker installation. You can add this directory to your workspace using the Update Manager, or you can copy it across to your workspace directory and restart the WebSphere Message Broker Toolkit to see the nodes. The help files (HelpContexts.xml, SwitchNode.htm, and TransformNode.htm) demonstrate some features of Eclipse help by adding themselves into the main topic tree, referencing topics in the main tree, and so on.

GIF files that are used to represent the sample nodes in the WebSphere Message Broker Toolkit, which you can use, or replace with your own, are supplied. The GIF files come in three different sizes and can be found in individual directories under the sample\extensions\nodes\com.ibm.samples.nodes\icons\full\ directory.

SupportPacs:
Many other sample nodes are available as SupportPac offerings. For a complete list of available SupportPac offerings see WebSphere MQ SupportPacs web page.

Sample parser files

Several sample parser files are provided on all platforms, to help you to create your own parsers.

Windows On Windows, the following sample parser files are in the *install_dir*\sample\extensions\parser directory, where *install_dir* is the home directory of your WebSphere Message Broker installation.

Linux On Linux, the following sample parser files are in the *install_dir*/sample/extensions/parser directory, where *install_dir* is the home directory of your WebSphere Message Broker installation.

UNIX On UNIX, the following sample parser files are in the *install_dir*/sample/extensions/parser directory, where *install_dir* is the home directory of your WebSphere Message Broker installation.

z/OS On z/OS, the following sample parser files are in the *install_dir*/sample/extensions/parser directory, where *install_dir* is the home directory of your WebSphere Message Broker installation.

Sample parser file	Description
BipSampPluginParser.c	C source file containing sample implementations of a simple pseudo-XML parser.
BipSampPluginParser.h	The header file for the BipSampPluginParser.c file.

SupportPacs:
Many other sample parsers are available as SupportPac offerings. For a complete list of available SupportPacs, see http://www.ibm.com/software/integration/support/supportpacs/.

User-defined nodes

You can define your own nodes to use in WebSphere Message Broker message flows.

User-defined nodes add to the function that is provided by the WebSphere Message Broker built-in nodes. You can also use nodes that are created and supplied by independent software vendors and other companies.

If you create your own editors to handle properties for your nodes, you can access the supported "Property editor API" on page 6686 in this section.

Follow the instructions in "Adding help to the node" on page 3088 to provide help information for user-defined nodes, and how to include that help in this section of the information center.

WebSphere Message Broker provides some additional utilities that user-defined nodes and parsers can use.

"Utility function return codes and values" on page 6686
By convention, the return code output parameter of all utility functions is set to indicate successful completion, or an error. The table lists all return codes with their meanings.

C language user-defined node API

Learn about the different types of call provided by the API.

The C language user-defined node API consists of:

1. A set of implementation functions that provide the functionality of the user-defined node. These functions are called by the broker. The implementation functions are mandatory, and if they are not supplied by the developer, an exception is thrown at run time.
2. A set of utility functions that create resources in the broker, or request a service of the broker. These utility functions are called by a user-defined node.

Most of the utilities are shared by all types of node; however, a few are specific to input nodes. This restriction is marked in the text.

These functions are defined in the `BipCni.h` header file.

This section covers the following topics:

"C node implementation functions"

"C node utility functions" on page 6419

Related concepts:

"Why use a user-defined extension?" on page 2972
Use a user-defined node or parser when the built-in resources do not provide the required functions.

A message processing node is used to process a message in some way, and an output node is used to produce a message as a bit stream.

Related reference:

"C language user-defined parser API" on page 6538
The C language user-defined parser API consists of two complementary sets of functions that you can use to define the function of your parser.

"C Header files" on page 6415
The C interfaces are defined by the following header files.

C node implementation functions:

The user-defined node implements a function interface for the broker to call during runtime operation. This interface includes functions to create a local context whenever a node instance is created, functions to set and retrieve attribute values, the function to perform the processing of the node itself, and functions to examine messages.

The following functions are provided:

Mandatory function

"cniCreateNodeContext" on page 6447

Optional and conditional functions

- "cniDeleteNodeContext" on page 6454
- Either "cniEvaluate" on page 6475 (for message processing and output nodes), or "cniRun" on page 6504 (for input nodes)
- "cniGetAttribute" on page 6482
- "cniGetAttribute2" on page 6484
- "cniGetAttributeName" on page 6485
- "cniGetAttributeName2" on page 6487
- "cniSetAttribute" on page 6511

These implementation functions are called by the broker, and implemented by the node.

For certain implementation functions, you might need to specify the name of a parser that is supplied with WebSphere Message Broker. If so, you must use the correct class name of the parser. The following table provides a summary of the parsers, root element names, and class names for different headers.

Parser	Root element name	Class name
BLOB	BLOB	NONE
IDOC	IDOC	IDOC
JMSMap	JMSMap	JMS_MAP
JMSStream	JMSStream	JMS_STREAM
MIME	MIME	MIME
MQCFH	MQPCF	MQPCF
MQCIH	MQCIH	MQCICS
MQDLH	MQDLH	MQDEAD
MQIIH	MQIIH	MQIMS
MQMD	MQMD	MQHMD
MQMDE	MQMDE	MQHMDE
MQRFH	MQRFH	MQHRF
MQRFH2	MQRFH2	MQHRF2
MQRMH	MQRMH	MQHREF
MQSAPH	MQSAPH	MQHSAP
MQWIH	MQWIH	MQHWIH
MRM	MRM	MRM
Properties	Properties	PropertyParser
SMQ_BMH	SMQ_BMH	SMQBAD
XML	XML	xml
XMLNS	XMLNS	xmlns
XMLNSC	XMLNSC	xmlnsC

Related tasks:

"Creating an input node in C" on page 3027
Create a user-defined input node in C to receive messages into a message flow.

"Creating a message processing or output node in C" on page 3036
A message processing node is used to process a message in some way, and an output node is used to produce a message as a bit stream.

Related reference:

"C node implementation functions" on page 6417
The user-defined node implements a function interface for the broker to call during runtime operation. This interface includes functions to create a local context whenever a node instance is created, functions to set and retrieve attribute values, the function to perform the processing of the node itself, and functions to examine messages.

cniAddAfter:

Use this function to add an unattached syntax element after a specified syntax element. The currently unattached syntax element, and all child elements it possesses, is connected to the syntax element tree after the specified target element.

The added element becomes the *next sibling* of the target element. The target element must be attached to a tree (that is, it must have a parent element).

Syntax:

```
void cniAddAfter(
int*         returnCode,
CciElement*  targetElement,
CciElement*  newElement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
The address of the target syntax element object (input).

newElement
The address of the new syntax element object that is to be added to the tree structure (input).

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Related concepts:

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniAddasFirstChild"
Use this function to add an unattached syntax element as the first child of a specified syntax element. The currently unattached syntax element, and all child elements it possesses, is connected to the syntax element tree as the *first child* of the specified target element. The target element need not be attached to a tree.

"cniAddasLastChild" on page 6423
Use this function to add an unattached syntax element as the last child of a specified syntax element. The currently unattached syntax element, and all child elements it possesses, is connected to the syntax element tree as the *last child* of the specified target element. The new element need not be attached to a tree.

"cniAddBefore" on page 6425
Use this function to add an unattached syntax element before a specified syntax element. The currently unattached syntax element, and all child elements it possesses, is connected to the syntax element tree before the specified target element.

cniAddasFirstChild:

Use this function to add an unattached syntax element as the first child of a specified syntax element. The currently unattached syntax element, and all child elements it possesses, is connected to the syntax element tree as the *first child* of the specified target element. The target element need not be attached to a tree.

Syntax:

```
void cniAddAsFirstChild(
  int*         returnCode,
  CciElement*  targetElement,
  CciElement*  newElement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
The address of the target syntax element object (input).

newElement
The address of the new syntax element object that is to be added to the tree structure (input).

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniAddAfter" on page 6421
Use this function to add an unattached syntax element after a specified syntax element. The currently unattached syntax element, and all child elements it possesses, is connected to the syntax element tree after the specified target element.

"cniAddasFirstChild" on page 6422
Use this function to add an unattached syntax element as the first child of a specified syntax element. The currently unattached syntax element, and all child elements it possesses, is connected to the syntax element tree as the *first child* of the specified target element. The target element need not be attached to a tree.

"cniAddBefore"
Use this function to add an unattached syntax element before a specified syntax element. The currently unattached syntax element, and all child elements it possesses, is connected to the syntax element tree before the specified target element.

cniAddBefore:

Use this function to add an unattached syntax element before a specified syntax element. The currently unattached syntax element, and all child elements it possesses, is connected to the syntax element tree before the specified target element.

The newly added element becomes the *previous sibling* of the target element. The target element must be attached to a tree (that is, it must have a parent element).

Syntax:

```
void cniAddBefore(
  int*         returnCode,
  CciElement*  targetElement,
  CciElement*  newElement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
The address of the target syntax element object (input).

newElement
The address of the new syntax element object that is to be added to the tree structure (input).

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Related concepts:

Use this function to add an unattached syntax element as the first child of a specified syntax element. The currently unattached syntax element, and all child elements it possesses, is connected to the syntax element tree as the *first child* of the specified target element. The target element need not be attached to a tree.

"cniAddasLastChild" on page 6423
Use this function to add an unattached syntax element as the last child of a specified syntax element. The currently unattached syntax element, and all child elements it possesses, is connected to the syntax element tree as the *last child* of the specified target element. The new element need not be attached to a tree.

cniBufferByte:

Use this function to get a single byte from the data buffer associated with (and owned by) the message object specified in the message argument. The value of the index argument indicates which byte in the byte array is to be returned.

Syntax:

```
CciByte cniBufferByte(
  int*         returnCode,
  CciMessage*  message,
  CciSize      index);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_MESSAGE_OBJECT

message
The address of the message object for which the size of the data buffer is to be returned (input).

index
The offset to use as an index into the buffer (input).

Return values:
The requested byte is returned. If an error occurred, the *returnCode* parameter indicates the reason for the error.

"cniBufferPointer"
Use this function to get a pointer to the data buffer associated with (and owned by) the message object specified in the message argument. This function is typically used by output nodes.

"cniBufferSize" on page 6428
Use this function to get the size of the data buffer associated with (and owned by) the message object specified in the message argument.

"cniSetInputBuffer" on page 6520
Use this function to supply a buffer. It is used only by input nodes. The address is specified by the `source` parameter as an input bit stream of the input message to the broker.

"cniWriteBuffer" on page 6537
Use this function to write the syntax element tree associated with the specified message to the data buffer that is owned by the message object. This function is typically used by output nodes.

cniBufferPointer:

Use this function to get a pointer to the data buffer associated with (and owned by) the message object specified in the message argument. This function is typically used by output nodes.

Syntax:

```
const CciByte* cniBufferPointer(
  int*         returnCode,
  CciMessage*  message);
```

Parameters:

`returnCode`
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_MESSAGE_OBJECT

message
The address of the message object for which the address of the data buffer is to be returned (input).

Return values:
If successful, the address of the data buffer is returned. Otherwise, zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

cniBufferSize:

Use this function to get the size of the data buffer associated with (and owned by) the message object specified in the message argument.

Syntax:

```
CciSize cniBufferSize(
  int*         returnCode,
  CciMessage*  message);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_MESSAGE_OBJECT

message
The address of the message object for which the size of the data buffer is to be returned (input).

Return values:
The size of the buffer in bytes, or zero if no buffer exists. If an error occurred, (CCI_FAILURE) is returned, and the *returnCode* parameter indicates the reason for the error.

"cniSetInputBuffer" on page 6520
Use this function to supply a buffer. It is used only by input nodes. The address is specified by the `source` parameter as an input bit stream of the input message to

the broker.

"cniWriteBuffer" on page 6537
Use this function to write the syntax element tree associated with the specified message to the data buffer that is owned by the message object. This function is typically used by output nodes.

cniCopyElementTree:

Use this function to copy a part of the element tree from the source element to the target element. Only the child elements of the source element are copied. All existing child elements of the target element are deleted, and are replaced by the child elements of the source element.

If the target element has not been fully parsed, or represents an unparsed bit stream, the cniCopyElementTree function results in a parse of the target element before its child elements are detached. The function therefore ensures consistency in message-tree formatting so that all references to detached fields by cciElements remain valid. Therefore, if a parsing exception occurs during the execution of the cniCopyElementTree function the cause might be a problem with either the target element or the source element.

Syntax:

```
void cniCopyElementTree(
  int*         returnCode,
  CciElement*  sourceElement,
  CciElement*  targetElement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_MESSAGE_OBJECT

sourceElement
The address of the source syntax element object (input).

targetElement
The address of the target syntax element object (input).

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
cniCopyElementTree(&rc, inRootElement, outRootElement);
```

cniCreateElementAfter:

Use this function to create a new syntax element and insert it after the specified syntax element. The new element becomes the *next sibling* of the specified element.

Do not use cniCreateElementAfter when you create a message body folder (such as XML, XMLNS, MRM, BLOB), because this function does not associate an owning parser with the folder. To create a message body folder, you can use one of the following functions:

cniCreateElementAsFirstChildUsingParser

cniCreateElementAsLastChildUsingParser

cniCreateElementAfterUsingParser

cniCreateElementBeforeUsingParser

When the message body folder has been created, you can use cniCreateElementAfter to create elements under the folder. You can use cniCreateElementAfter because the parser, which is associated with the message body folder, is inherited.

Syntax:

```
CciElement* cniCreateElementAfter(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
The address of the element object (input).

Return values:
If successful, the address of the new element object is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

Related concepts:

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniCreateElementAfterUsingParser"
Use this function to create a syntax element, insert it after the specified syntax element, and associate it with the specified parser class name. The new element becomes the *next sibling* of the specified element.

"cniCreateElementBefore" on page 6442
Use this function to create a new syntax element and insert it before the specified syntax element. The new element becomes the *previous sibling* of the specified element, and shares the same parent element.

"cniCreateElementBeforeUsingParser" on page 6443
Use this function to create a syntax element, insert it before the specified syntax element, and associate it with the specified parser class name. The new element becomes the *previous sibling* of the specified element.

cniCreateElementAfterUsingParser:

Use this function to create a syntax element, insert it after the specified syntax element, and associate it with the specified parser class name. The new element becomes the *next sibling* of the specified element.

A portion of the syntax element tree that is owned by a parser can *only* have its effective root at the first generation of elements (that is, as *immediate children of root*). The user-defined node interface does not restrict the ability to create a subtree that appears to be owned by a different parser. However, it is not possible to serialize these element trees into a bit stream when producing an output message.

If you specify the name of a parser supplied with WebSphere Message Broker, you must use the correct class name of the parser.

The internal name for the BLOB parser is *none*. Therefore, if you use this function to create a BLOB parser folder, the associated parser name should be *none*.

Syntax:

```
CciElement* cniCreateElementAfterUsingParser(
  int*            returnCode,
  CciElement*     targetElement,
  const CciChar*  parserClassName);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_PARSER_NAME

TargetElement
The address of the element object (input).

parserClassName
The name of the parser class (input).

Return values:
If successful, the address of the new element object is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

Related concepts:

"User-defined message processing nodes" on page 2996
A user-defined message processing node is a node that you can create to complement the supplied built-in node types.

"User-defined output nodes" on page 3006

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniCreateElementAfter" on page 6431
Use this function to create a new syntax element and insert it after the specified syntax element. The new element becomes the *next sibling* of the specified element.

"cniCreateElementBefore" on page 6442
Use this function to create a new syntax element and insert it before the specified syntax element. The new element becomes the *previous sibling* of the specified element, and shares the same parent element.

"cniCreateElementBeforeUsingParser" on page 6443
Use this function to create a syntax element, insert it before the specified syntax element, and associate it with the specified parser class name. The new element becomes the *previous sibling* of the specified element.

cniCreateElementAsFirstChild:

Use this function to create a syntax element as the first child of the specified syntax element.

Do not use cniCreateElementAsFirstChild when creating a message body folder (such as XML, XMLNS, MRM, BLOB), because it does not associate an owning parser with the folder. To create a message body folder, you can use one of the following functions:

cniCreateElementAsFirstChildUsingParser

cniCreateElementAsLastChildUsingParser

cniCreateElementAfterUsingParser

cniCreateElementBeforeUsingParser

When the message body folder has been created, you can call cniCreateElementAsFirstChild to create elements under the folder. You can use cniCreateElementAsFirstChild because the parser, which is associated with the message body folder, is inherited.

Syntax:

```
CciElement* cniCreateElementAsFirstChild(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
The address of the element object (input).

Return values:
If successful, the address of the new element object is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

"cniCreateElementAsLastChildUsingParser" on page 6440
Use this function to create a syntax element as the last child of the specified syntax element, and associate it with the specified parser class name.

cniCreateElementAsFirstChildUsingParser:

Use this function to create a syntax element as the first child of the specified syntax element, and associates it with the specified parser class name.

A portion of the syntax element tree that is owned by a parser can *only* have its effective root at the first generation of elements (that is, as *immediate children of root*). The user-defined node interface does not restrict the ability to create a subtree that appears to be owned by a different parser. However, it is not possible to serialize these element trees into a bit stream when producing a message.

If you specify the name of a parser supplied with WebSphere Message Broker, you must use the correct class name of the parser.

The internal name for the BLOB parser is *none*. Therefore, if you use this function to create a BLOB parser folder, the associated parser name should be *none*.

Syntax:

```
CciElement* cniCreateElementAsFirstChildUsingParser(
  int*            returnCode,
  CciElement*     targetElement,
  const CciChar*  parserClassName);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_PARSER_NAME

targetElement
The address of the element object (input).

parserClassName
The name of the parser class (input).

Return values:
If successful, the address of the new element object is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

"cniCreateElementAsLastChildUsingParser" on page 6440
Use this function to create a syntax element as the last child of the specified syntax element, and associate it with the specified parser class name.

cniCreateElementAsLastChild:

Use this function to create a syntax element as the last child of the specified syntax element.

Do not use cniCreateElementAsLastChild when creating a message body folder (such as XML, XMLNS, MRM, BLOB), because it does not associate an owning parser with the folder. To create a message body folder, you can use one of the following functions:

cniCreateElementAsFirstChildUsingParser

cniCreateElementAsLastChildUsingParser

cniCreateElementAfterUsingParser

cniCreateElementBeforeUsingParser

When the message body folder has been created, you can use cniCreateElementAsLastChild to create elements under the folder. You can use cniCreateElementAsLastChild because the parser, which is associated with the message body folder, is inherited.

Syntax:

```
CciElement* cniCreateElementAsLastChild(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
The address of the element object (input).

Return values:
If successful, the address of the new element object is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned and the *returnCode* parameter indicates the reason for the error.

Example:

```
CciElement* lastChild = cniCreateElementAsLastChild(&rc, outRootElement);
cniSetElementName(&rc, lastChild, elementName);
```

Use this function to create a syntax element as the first child of the specified syntax element.

"cniCreateElementAsFirstChildUsingParser" on page 6435
Use this function to create a syntax element as the first child of the specified syntax element, and associates it with the specified parser class name.

"cniCreateElementAsLastChildFromBitstream"
Use this function to create a syntax element tree as the last child of the specified syntax element, and associates it with the specified parser. The syntax element tree is populated by parsing the specified bit stream.

"cniCreateElementAsLastChildUsingParser" on page 6440
Use this function to create a syntax element as the last child of the specified syntax element, and associate it with the specified parser class name.

cniCreateElementAsLastChildFromBitstream:

Use this function to create a syntax element tree as the last child of the specified syntax element, and associates it with the specified parser. The syntax element tree is populated by parsing the specified bit stream.

During the execution of this function, the bit stream is copied, so the caller can free or reuse the memory allocated to hold the original bit stream. You can use this function only to create a message body, that is, the last child of the message property. An output message must already exist.

The root element of this output message should be passed in as the target element parameter. Because this call is designed only to be used to create a message body, you cannot use it to build successive elements. For example, it should not be used to create an MQRFH2 header as the last child of root, then an XML message as the last child of root, after the MQRFH2 header.

Syntax:

```
CciElement* cniCreateElementAsLastChildFromBitstream (
  int*                        returnCode,
  CciElement*                 targetElement,
  const struct CciByteArray* value,
  const CciChar*              parserClassName,
  CciChar*                    messageType,
  CciChar*                    messageSet,
  CciChar*                    messageFormat,
  int                         encoding,
  int                         ccsid,
  int                         options);
```

Parameters:

returnCode
The return code from the function (output). Specifying a NULL pointer signifies that the node will not deal with errors. If input is not NULL, the output signifies the success status of the call. Any exceptions thrown during the execution of this call are re-thrown to the next upstream node in the flow. Call cciGetLastExceptionData for details of the exception.

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_PARSER_NAME
- CCI_INV_DATA_POINTER

targetElement
The syntax element under which the new syntax element tree is created (input). This parameter must be the message property.

parserClassName
The name of the parser class to use to parse the bit stream (input). You must use the same parser that was used to parse the whole bit stream.

value
A pointer to a CciByteArray struct containing a pointer to the bit stream to be parsed, and also the size in CciBytes of this bit stream (output).

messageType
The message type definition used to create the element tree from the bit stream (input). A NULL pointer means that this parameter is ignored. Also, if the parser specified has no interest in this value, for example if it is a generic XML parser, the parameter is ignored.

messageSet
The message set definition used to create the element tree from the bit stream

(input). A NULL pointer means that this parameter is ignored. Also, if the parser specified has no interest in this value, for example if it is a generic XML parser, the parameter is ignored.

messageFormat
The format used to create the element tree from the bit stream (input). A NULL pointer means that this parameter is ignored. Also, if the parser specified has no interest in this value, for example if it is a generic XML parser, the parameter is ignored.

encoding
The encoding to use when parsing the bit stream (input). This parameter is mandatory. You can specify a value of 0 to indicate that the queue manager's encoding should be used.

ccsid
The coded character set identifier to use when parsing the bit stream (input). This parameter is mandatory. You can specify a value of 0 to indicate that the queue manager's ccsid should be used.

options
This is reserved for future use. You must specify a value of 0 to maintain forward compatibility.

Return values:
If successful, the address of the new element object is returned. Otherwise, a value zero (CCI_NULL_ADDR) is returned, and the return code parameter indicates the reason for the error. If an exception occurs during execution, *returnCode* is set to CCI_EXCEPTION

Example:

```
  outMQMD = cniCreateElementAsFirstChildUsingParser(&rc,
                                                    outRootElement,
                                                    CciString("MQHMD",BIP_DEF_COMP_CCSID));
  checkRC(rc);

  cniCopyElementTree(&rc, inMQMD, outMQMD);
  checkRC(rc);

  outBlobRoot = cniCreateElementAsLastChildFromBitstream(
                                                      &rc,
                                                      outRootElement,
                                                      &bitstream,
                                                      inParserClassName,
                                                      messageType,
                                                      messageSet,
                                                      messageFormat,
                                                      encoding,
                                                      ccsid,
                                                      0);

  checkRC(rc);
  ...

  return;
}
```

A message processing node is used to process a message in some way, and an output node is used to produce a message as a bit stream.

Related reference:

"cciGetLastExceptionData" on page 6647
Gets diagnostic information about the last exception generated. Information about the last exception generated on the current thread is returned in a CCI_EXCEPTION_ST output structure. The user-defined extension can use this function to determine whether any recovery is required when a utility function returns an error code.

"cniCreateElementAsFirstChild" on page 6433
Use this function to create a syntax element as the first child of the specified syntax element.

"cniCreateElementAsFirstChildUsingParser" on page 6435
Use this function to create a syntax element as the first child of the specified syntax element, and associates it with the specified parser class name.

"cniCreateElementAsLastChild" on page 6436
Use this function to create a syntax element as the last child of the specified syntax element.

"cniCreateElementAsLastChildUsingParser"
Use this function to create a syntax element as the last child of the specified syntax element, and associate it with the specified parser class name.

cniCreateElementAsLastChildUsingParser:

Use this function to create a syntax element as the last child of the specified syntax element, and associate it with the specified parser class name.

A portion of the syntax element tree that is owned by a parser can *only* have its effective root at the first generation of elements (that is, as *immediate children of root*). The user-defined node interface does not restrict the ability to create a subtree that appears to be owned by a different parser. However, it is not possible to serialize these element trees into a bit stream when producing a message.

If you specify the name of a parser supplied with WebSphere Message Broker, you must use the correct class name of the parser. See "C node implementation functions" on page 6417 for a list of the supplied parsers.

The internal name for the BLOB parser is *none*. Therefore, if you use this function to create a BLOB parser folder, the associated parser name must be *none*.

Syntax:

```
CciElement* cniCreateElementAsLastChildUsingParser(
  int*           returnCode,
  CciElement*    targetElement,
  const CciChar* parserClassName);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_PARSER_NAME

targetElement
The address of the element object (input).

parserClassName
The name of the parser class (input).

Return values:
If successful, the address of the new element object is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

Example:

```
cniElementName(&rc, firstChild, elementName);
CciElementType type = cniElementType(&rc, firstChild);
CciElement* lastChild = cniCreateElementAsLastChildUsingParser(
                                                              &rc,
                                                              outRootElement,
                                                              parserName);
cniSetElementName(&rc, lastChild, elementName);
cniSetElementType(&rc, lastChild, elementType);
```

Use this function to create a syntax element as the first child of the specified syntax element, and associates it with the specified parser class name.

"cniCreateElementAsLastChild" on page 6436
Use this function to create a syntax element as the last child of the specified syntax element.

"cniCreateElementAsLastChildFromBitstream" on page 6437
Use this function to create a syntax element tree as the last child of the specified syntax element, and associates it with the specified parser. The syntax element tree is populated by parsing the specified bit stream.

cniCreateElementBefore:

Use this function to create a new syntax element and insert it before the specified syntax element. The new element becomes the *previous sibling* of the specified element, and shares the same parent element.

DO not use cniCreateElementBefore when creating a message body folder (such as XML, XMLNS, MRM, BLOB), because it does not associate an owning parser with the folder. To create a message body folder, you can use one of the following functions:

cniCreateElementAsFirstChildUsingParser

cniCreateElementAsLastChildUsingParser

cniCreateElementAfterUsingParser

cniCreateElementBeforeUsingParser

When the message body folder has been created, `cniCreateElementBefore` can be used to create elements under the folder. `cniCreateElementBefore` can be used because the parser, which is associated with the message body folder, is inherited.

Syntax:

```
CciElement* cniCreateElementBefore(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters:

`returnCode`
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

`targetElement`
The address of the target element object (input).

Return values:
If successful, the address of the new element object is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

The internal name for the BLOB parser is *none*. Therefore, if you use this function to create a BLOB parser folder, the associated parser name should be *none*.

Syntax:

```
CciElement* cniCreateElementBeforeUsingParser(
  int*            returnCode,
  CciElement*     targetElement,
  const CciChar*  parserClassName);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION

- CCI_INV_ELEMENT_OBJECT
- CCI_INV_PARSER_NAME

targetElement
The address of the element object (input).

parserClassName
The name of the parser class (input).

Return values:
If successful, the address of the new element object is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

Use this function to create a new syntax element and insert it before the specified syntax element. The new element becomes the *previous sibling* of the specified element, and shares the same parent element.

cniCreateInputTerminal:

Use this function to create an input terminal on an instance of a node object and return the address of the terminal object that was created.

The terminal object is destroyed by the broker when its owning node is destroyed. You must call this function only from within the implementation function cniCreateNodeContext.

Syntax:

```
CciTerminal* cniCreateInputTerminal(
  int*      returnCode,
  CciNode*  nodeObject,
  CciChar*  name);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_NODE_OBJECT
- CCI_INV_TERMINAL_NAME

nodeObject
Specifies the address of the instance of the node object on which the input terminal is to be created (input). The handle is passed to the cniCreateNodeContext function.

name
Specifies a name for the terminal being created (input).

Return values:
If successful, the address of the node terminal object is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned.

Example:

```
entry->handle = cniCreateInputTerminal(
                                        &rc,
                                        context->nodeObject,
                                        (CciChar*)terminalName);
```

Related reference:

"C node implementation functions" on page 6417
The user-defined node implements a function interface for the broker to call during runtime operation. This interface includes functions to create a local context whenever a node instance is created, functions to set and retrieve attribute values, the function to perform the processing of the node itself, and functions to examine messages.

"cniCreateNodeContext" on page 6447
This function creates a context for an instance of a node object. It is called by the broker whenever an instance of a node object is constructed. Nodes are constructed when a message flow is deployed by the broker, or when the execution group is started.

"cniCreateOutputTerminal" on page 6450
Use this function to create an output terminal on an instance of a node object and return the address of the terminal object that was created.

cniCreateMessage:

Use this function to create an output message object. For every call to this function, you must include a matching call to cniDeleteMessage to return allocated resources when the processing on the output message has been completed.

Syntax:

```
CciMessage* cniCreateMessage(
  int*                returnCode,
  CciMessageContext*  messageContext);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_FAILURE
- CCI_EXCEPTION
- CCI_INV_MESSAGE_CONTEXT

messageContext
The address of the context for the message (input). Use cniGetMessageContext to get the context from an incoming message; for example, one received in the cniEvaluate function.

Return values:
If successful, the address of the message object is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

Example:

```
outMsg = cniCreateMessage(&rc, cniGetMessageContext(&rc, message));
```

Related concepts:

"User-defined input nodes" on page 2990
A user-defined input node is an extension to the broker that provides a new input node in addition to the nodes supplied with the product.

A user-defined output node is an extension to the broker that provides a new message flow output node in addition to the nodes supplied with the product.

Related tasks:

"Creating an input node in C" on page 3027
Create a user-defined input node in C to receive messages into a message flow.

"Creating a message processing or output node in C" on page 3036
A message processing node is used to process a message in some way, and an output node is used to produce a message as a bit stream.

Related reference:

"C node utility functions" on page 6419
A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniDeleteMessage" on page 6453
Use this function to delete the specified message object. For every call to the cniCreateMessage function, you must include a matching call to cniDeleteMessage to return allocated resources when the processing on the output message has been completed.

"cniEvaluate" on page 6475
This function performs node processing. The broker calls this function when a message is received on one of the input terminals of an instance of a node object.

"cniFinalize" on page 6479
Use this function to cause the broker to request parsers to perform finalize processing on the specified message. Finalization is a process that fixes header chains and makes the Properties folder match the headers.

"cniGetEnvironmentMessage" on page 6490
Use this function to get the CciMessage object that corresponds to the environment tree for the message flow.

"cniGetMessageContext" on page 6491
Use this function to get the address of the message context that is associated with the specified message. The context of an existing message is used to create an output message; for example, by using the cniCreateMessage function.

"cniPropagate" on page 6501
Use this function to propagate a message to a specified terminal object. If the terminal is not attached to another node by a connector, the message is not propagated, and the function is ignored.

cniCreateNodeContext:

This function creates a context for an instance of a node object. It is called by the broker whenever an instance of a node object is constructed. Nodes are constructed when a message flow is deployed by the broker, or when the execution group is started.

The responsibilities of the node, when created, are to:

1. (Optional) Verify that the name of the node specified in the *nodeName* parameter is supported by the factory.
2. Allocate any node instance specific data areas that might be required (for example: context, attribute data, and terminals).
3. Perform all additional resource acquisition or initialization that might be required for the processing of the node.
4. Return the address of the context to the calling function. Whenever an implementation function for this node instance is called, the appropriate context is passed as an argument to that function. Therefore, a user-defined node developed in C does not have to maintain its own static pointers to per-instance data areas.

Defined In	Type	Member
CNI_VFT	Mandatory	iFpCreateNodeContext

Syntax:

```
CciContext* cniCreateNodeContext(
  CciFactory*  factoryObject,
  CciChar*     nodeName,
  CciNode*     nodeObject);
```

Parameters:

factoryObject
The address of the factory object that owns the node being created (input).

nodeName
The name of the node being created (input).

nodeObject
The address of the node object that has just been created (input).

Return values:
If successful, the address of the node context is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned.

Example:

```
  static char* functionName = (char *)"_Switch_createNodeContext()";
  NODE_CONTEXT_ST* p;

  /* Allocate a pointer to the local context */
  p = (NODE_CONTEXT_ST *)malloc(sizeof(NODE_CONTEXT_ST));

  if (p) {

    /* Clear the context area */
    memset(p, 0, sizeof(NODE_CONTEXT_ST));

    /* Save our node object pointer in our context */
    p->nodeObject = nodeObject;

    /* Save our node name */
    CciCharNCpy((CciChar*) &p->nodeName, nodeName, MAX_NODE_NAME_LEN);
}
  else
  /* Handle errors */
```

This interface includes functions to create a local context whenever a node instance is created, functions to set and retrieve attribute values, the function to perform the processing of the node itself, and functions to examine messages.

"cniDeleteNodeContext" on page 6454
This function deletes any context for an instance of a user-defined node object. It is called by the broker whenever an instance of a node object is destroyed, when a message flow is deleted, or when a configuration is redeployed.

cniCreateNodeFactory:

Use this function to create a node factory in the broker. A single instance of the named message flow node factory is created.

This function must be called only in the initialization function bipGetMessageFlowNodeFactory, which is called when the LIL is loaded by the message broker. If cniCreateNodeFactory is called at any other time, the results are unpredictable.

Syntax:

```
CciFactory* cniCreateNodeFactory(
  int*      returnCode,
  CciChar*  name);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_FAILURE
- CCI_EXCEPTION
- CCI_INV_FACTORY_NAME
- CCI_INV_OBJECT_NAME

name
The name of the factory being created (input).

Return values:
If successful, the address of the node factory object is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

Example:

```
factoryObject = cniCreateNodeFactory(0, (unsigned short *)constPluginNodeFactory);
if (factoryObject == CCI_NULL_ADDR) {

/* Handle errors */
```

cniCreateOutputTerminal:

Use this function to create an output terminal on an instance of a node object and return the address of the terminal object that was created.

The terminal object is destroyed when its owning node is destroyed. You must call this function only from within the implementation function cniCreateNodeContext.

Syntax:

```
CciTerminal* cniCreateOutputTerminal(
  int*      returnCode,
  CciNode*  nodeObject,
  CciChar*  name);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_FAILURE
- CCI_EXCEPTION
- CCI_INV_NODE_OBJECT
- CCI_INV_TERMINAL_NAME

nodeObject
The address of the instance of the node object on which the output terminal is to be created (input). The handle is passed to the cniCreateNodeContext function.

name
The name of the terminal being created (input).

Return values:

If successful, the address of the node terminal object is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned.

Example:

```
entry->handle = cniCreateOutputTerminal(
                                        &rc,
                                        context->nodeObject
                                        (CciChar*)terminalName);
```

Create a user-defined input node in C to receive messages into a message flow.

"Creating a message processing or output node in C" on page 3036
A message processing node is used to process a message in some way, and an output node is used to produce a message as a bit stream.

Related reference:

"C node utility functions" on page 6419
A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniCreateInputTerminal" on page 6444
Use this function to create an input terminal on an instance of a node object and return the address of the terminal object that was created.

"cniCreateNodeContext" on page 6447
This function creates a context for an instance of a node object. It is called by the broker whenever an instance of a node object is constructed. Nodes are constructed when a message flow is deployed by the broker, or when the execution group is started.

"cniIsTerminalAttached" on page 6494
Use this function to check whether a terminal is attached to another node by a connector. It returns an integer value that specifies whether the specified terminal object is attached to one or more terminals on other message flow nodes.

cniDefineNodeClass:

Use this function to define a node class, as specified by the *name* parameter, which is supported by the node factory specified as the*factoryObject* parameter.

This function is called by the node during execution of bipGetMessageFlowNodeFactory, when the LIL file is loaded.

If both cniGetAttribute and cniGetAttribute2, or cniGetAttributeName and cniGetAttributeName2 are implemented, cniDefineNodeClass fails with CCI_INV_IMPL_FUNCTION.

Syntax:

```
void cniDefineNodeClass(
  int*         returnCode,
  CciFactory*  factoryObject,
  CciChar*     name,
  CNI_VFT*     functbl);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_FACTORY_OBJECT
- CCI_INV_NODE_NAME
- CCI_INV_OBJECT_NAME
- CCI_INV_VFTP
- CCI_MISSING_IMPL_FUNCTION
- CCI_NAME_EXISTS

factoryObject
The address of the factory object that supports the named node. The address is returned from cniCreateNodeFactory (input).

name
The name of the node to be defined. The name of the node must end with the word `Node` (input).

For example, if you have assigned the name as Basic in the WebSphere Message Broker Toolkit, the class name of the node must be BasicNode.

functbl
The address of the CNI_VFT structure that contains pointers to the node implementation functions (input). Here is an example of a function table:

```
vftable.iFpCreateNodeContext = _Transform_createNodeContext;
vftable.iFpDeleteNodeContext = _deleteNodeContext;
vftable.iFpGetAttributeName2 = _getAttributeName2;
vftable.iFpSetAttribute      = _setAttribute;
vftable.iFpGetAttribute2     = _getAttribute2;
vftable.iFpEvaluate          = _Transform_evaluate; /* if not an input node */
vftable.iFRun                = _run                 /* if an input node */
```

You would typically define only one of the last 2 entries, that is, you define `vftable.iFpEvaluate = _Transform_evaluate;` for a message processing node, or you define `vftable.iFpRun = _run;` for an input node.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniCreateNodeFactory" on page 6449
Use this function to create a node factory in the broker. A single instance of the named message flow node factory is created.

cniDeleteMessage:

Use this function to delete the specified message object. For every call to the cniCreateMessage function, you must include a matching call to cniDeleteMessage to return allocated resources when the processing on the output message has been completed.

Syntax:

```
void cniDeleteMessage(
  int*         returnCode,
  CciMessage*  message);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_MESSAGE_OBJECT

message
The address of the message object to be deleted (input).

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
cniDeleteMessage(0, outMsg);
```

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniCreateMessage" on page 6446
Use this function to create an output message object. For every call to this function, you must include a matching call to cniDeleteMessage to return allocated resources when the processing on the output message has been completed.

"cniGetEnvironmentMessage" on page 6490
Use this function to get the CciMessage object that corresponds to the environment tree for the message flow.

"cniGetMessageContext" on page 6491
Use this function to get the address of the message context that is associated with the specified message. The context of an existing message is used to create an output message; for example, by using the cniCreateMessage function.

"cniFinalize" on page 6479
Use this function to cause the broker to request parsers to perform finalize processing on the specified message. Finalization is a process that fixes header chains and makes the Properties folder match the headers.

"cniPropagate" on page 6501
Use this function to propagate a message to a specified terminal object. If the terminal is not attached to another node by a connector, the message is not propagated, and the function is ignored.

cniDeleteNodeContext:

This function deletes any context for an instance of a user-defined node object. It is called by the broker whenever an instance of a node object is destroyed, when a message flow is deleted, or when a configuration is redeployed.

A message flow node might also be deleted when reconfiguring or redeploying a broker.

The responsibilities of the node are to:

1. Release all node instance specific data areas (such as context) that were acquired at construction or during node processing.
2. Release all additional resources that might have been acquired for the processing of the node.

Defined In	Type	Member
CNI_VFT	Optional	iFpDeleteNodeContext

Syntax:

```
void cniDeleteNodeContext(CciContext* context);
```

Parameters:

context
The address of the context for the instance of the node, as created and returned by the **cniCreateNodeContext** function (input).

Example:

```
void _deleteNodeContext(
  CciContext* context
){
  static char* functionName = (char *)"_deleteNodeContext()";

  return;
}
```

Related reference:

"C node implementation functions" on page 6417
The user-defined node implements a function interface for the broker to call during runtime operation. This interface includes functions to create a local context whenever a node instance is created, functions to set and retrieve attribute values, the function to perform the processing of the node itself, and functions to examine messages.

"cniCreateNodeContext" on page 6447
This function creates a context for an instance of a node object. It is called by the broker whenever an instance of a node object is constructed. Nodes are constructed when a message flow is deployed by the broker, or when the execution group is started.

cniDetach:

Use this function to detach the specified syntax element from the syntax element tree. The element is detached from its parent and siblings, but all child elements are left attached.

Syntax:

```
void cniDetach(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
The address of the syntax element object to be detached (input).

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Related concepts:

"User-defined message processing nodes" on page 2996
A user-defined message processing node is a node that you can create to complement the supplied built-in node types.

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

cniDispatchThread:

Use this function to dispatch a new message flow thread to call another thread instance to run the user-defined message flow input node.

This message flow thread is allocated from a pool of threads maintained for each message flow, under control of the Additional Instances property of the message flow. If no threads are available because they are all in use, CCI_SUCCESS is returned, and *returnCode* is set to CCI_NO_THREADS_AVAILABLE. This value is not an error, but represents one of the following causes:

- The message flow was not configured to run with additional threads.
- All additional threads configured are currently running.

The cniDispatchThread function can be called only from an input node. If it is called at any other time, CCI_FAILURE is returned and *returnCode* is set to CCI_INV_NODE_ENV.

Syntax:

```
int cniDispatchThread(
  int*        returnCode,
  CciNode*    nodeObject);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_NO_THREADS_AVAILABLE
- CCI_INV_NODE_OBJECT
- CCI_INV_NODE_ENV

nodeObject
The address of the node object that is run when the broker creates or reuses the thread. This parameter is passed to the node when its cniCreateNodeContext implementation function is called (input).

Return values:

- If a thread was successfully allocated, CCI_SUCCESS is returned, and *returnCode* is set to CCI_SUCCESS.
- If a thread could not be dispatched because insufficient threads are available in the message flow thread pool to satisfy the request, CCI_SUCCESS is returned and *returnCode* is set to CCI_NO_THREADS_AVAILABLE.
- If the function was not called in an input node, CCI_FAILURE is returned, and *returnCode* is set to CCI_INV_NODE_ENV.
- For all other error conditions, CCI_FAILURE is returned, and *returnCode* indicates the reason for the error.

Example:

```
cniDispatchThread(&rcDispatch, ((NODE_CONTEXT_ST *)context)->nodeObject);
```

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniCreateNodeContext" on page 6447
This function creates a context for an instance of a node object. It is called by the broker whenever an instance of a node object is constructed. Nodes are constructed when a message flow is deployed by the broker, or when the execution group is started.

cniElementAsBitstream:

Use this function to get the bitstream representation of the specified element.

The parser that is associated with the element serializes the element and all its child elements. The result is copied to memory allocated by the caller. In the special case where all the options that are specified match those of the original bit stream, for example a bit stream that is read from a WebSphere MQ queue by the MQInput node, and the message has not been modified since receiving the original bit stream, this original bit stream is copied into the allocated memory. In this case, the parser is not required to parse and reserialize the message.

The algorithm that is used to generate the bit stream depends on the parser that is used, and the options that are specified. All parsers support the following modes:

- RootBitStream, in which the algorithm that generates the bit stream is the same as that used by an output node. In this mode, a meaningful result is obtained only if the element pointed to is at the head of a subtree with an appropriate structure.
- EmbeddedBitStream, in which not only is the algorithm that generates the bit stream the same as that used by an output node, but also the following elements are determined, if not explicitly specified, in the same way as the output node. Therefore they are determined by searching the previous siblings of *element* on the assumption that these elements represent headers:
  - Encoding
  - CCSID
  - Message set
  - Message type
  - Message format

  In this way, the algorithm for determining these properties is essentially the same as that used for the ESQL BITSTREAM function.

Some parsers also support another mode, FolderBitStream, which generates a meaningful bit stream for any subtree, provided that the field pointed to represents a folder.

Syntax:

```
CciSize cniElementAsBitstream(
  int*                        returnCode,
  CciElement*                 element,
  const struct CciByteArray* value,
  CciChar*                    messageType,
  CciChar*                    messageSet,
  CciChar*                    messageFormat,
  int                         encoding,
  int                         ccsid,
  int                         options);
```

Parameters:

returnCode
The return code from the function (output). If you specify a NULL pointer on input, the value indicates that the node does not handle errors. If input is not NULL, the output signifies the success status of the call. Any exceptions that are produced during the execution of this call are sent to the next upstream node in the flow. Call cciGetLastExceptionData for details of the exception.

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER
- CCI_INV_DATA_BUFLEN
- CCI_INV_BUFFER_TOO_SMALL

element
The syntax element to be serialized (input.)

value
A pointer to a CciByteArray struct that contains a pointer to a region of memory allocated by the caller, and the size in CciBytes of this memory (output).

messageType
The message type definition that is used to create the bit stream from the element tree (input). If you specify a NULL pointer, the parameter is ignored. The parameter is also ignored if the value is not relevant to the parser associated with the element; for example, a generic XML parser.

messageSet
The message set definition that is used to create the bit stream from the element tree (input). If you specify a NULL pointer, the parameter is ignored. The parameter is also ignored if the value is not relevant to the parser associated with the element; for example, a generic XML parser.

messageFormat
The format that is used to create the bit stream from the element tree (input). If you specify a NULL pointer, the parameter is ignored. The parameter is also ignored if the value is not relevant to the parser associated with the element; for example, a generic XML parser.

encoding
The encoding to use when writing the bit stream (input). This parameter is mandatory. You can specify a value of `0` to indicate that the encoding for the queue manager must be used.

ccsid
The coded character set identifier to use when writing the bit stream (input). This parameter is mandatory. If you specify a value of `0`, the CCSID of the queue manager is used. A CCSID of `-1` indicates that the bit stream is generated by using CCSID information contained in the subtree consisting of the field pointed to by the element and its child elements. No supplied parsers support this option.

options
The integer value that specifies which bitstream generation mode must be used. Set one of the following values:

- CCI_BITSTREAM_OPTIONS_ROOT
- CCI_BITSTREAM_OPTIONS_EMBEDDED
- CCI_BITSTREAM_OPTIONS_FOLDER

Return values:

- If successful, the correct size of memory that is required to hold the bit stream is returned.

- If the memory allocated by the caller was insufficient, *returnCode* is CCI_BUFFER_TOO_SMALL.
- If an exception occurs during execution, *returnCode* is CCI_EXCEPTION.

Example:
The following example demonstrates how you can use the options parameter to generate the bit stream for different parts of the message tree.

This code can be copied into the _evaluate function of the sample Transform node. For an input message such as:

```
MQMD
MQRFH2
<test><data><aaa>text</aaa></data></test>
```

the node propagates three messages:

- One that contains a copy of the input message in the BLOB domain
- One that contains a copy of the input MQRFH2 as the message body in the BLOB domain
- One that contains the <data></data> folder as the message body in the BLOB domain

```

"cniElementValueState" on page 6471
Use this function to get the state of the value of the specified syntax element.

"cniElementValueType" on page 6472
Use this function to get the *type* attribute for the value of the specified syntax element. The state of an element after creation is undefined. When the value of the element is set, its state becomes valid.

"cniElementValueValue" on page 6473
Use this function to get the address of the value object owned by the specified syntax element.

"cciGetLastExceptionData" on page 6647
Gets diagnostic information about the last exception generated. Information about the last exception generated on the current thread is returned in a CCI_EXCEPTION_ST output structure. The user-defined extension can use this function to determine whether any recovery is required when a utility function returns an error code.

cniElementName:

Use this function to get the value of the *name* attribute for the specified syntax element. You must sethe syntax element name previously by using cniSetElementName or cpiSetElementName.

Syntax:

```
CciSize cniElementName(
  int*            returnCode,
  CciElement*     targetElement,
  const CciChar*  value,
  Ccisize         length);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER
- CCI_INV_DATA_BUFLEN
- CCI_INV_BUFFER_TOO_SMALL

targetElement
The address of the target syntax element object (input).

value
The address of a buffer into which the element name is copied (input).

length
The length, in characters, specified by the *value* parameter (input).

Return values:

- If successful, the element name is copied into the supplied buffer and the number of `CciChar` characters copied is returned.
- If the buffer is not large enough to contain the attribute value, *returnCode* is set to CCI_BUFFER_TOO_SMALL, and the number of CciChars required is returned.
- For any other failures, CCI_FAILURE is returned, and *returnCode* indicates the reason for the error.

"cniSetElementName" on page 6513
Use this function to set the name of the specified syntax element.

"cpiSetElementName" on page 6598
This function sets the name of the specified syntax element.

cniElementNamespace:

Use this function to get the value of the *namespace* attribute for the specified syntax element.

You must previously have set the syntax element name by using cniSetElementNamespace or cpiSetElementNamespace.

Use this function when you want to convert a message that belongs to a namespace-aware domain to a bit stream.

Syntax:

```
CciSize cniElementNamespace(
 int*           returnCode,
 CciElement*    targetElement,
 const CciChar* value,
 CciSize        length)
```

Parameters:

returnCode
The return code from the function (output). Specifying a NULL pointer signifies that the node does not want to deal with errors. If input is not NULL, the output signifies the success status of the call. All exceptions thrown during the execution of this call are re-thrown to the next upstream node in the flow. Call cciGetLastExceptionData for details of the exception.

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER
- CCI_INV_DATA_BUFLEN
- CCI_INV_BUFFER_TOO_SMALL

targetElement
Specifies the address of the target syntax element object (input).

value
Specifies the address of a buffer into which the element namespace value is copied (output). A string of characters (including a NULL terminator) representing the namespace value is copied into this buffer. The buffer must be a portion of memory previously allocated by the caller.

length
The length, in characters, of the buffer specified by the *value* parameter (input).

Return values:

- If successful, the number of CciChars copied into the buffer is returned.
- If the buffer is not large enough to contain the attribute value, *returnCode* is set to CCI_BUFFER_TOO_SMALL, and the number of CciChars required is returned.
- If an exception occurs during execution, *returnCode* is set to CCI_EXCEPTION.

Example:

```
if (element != 0) {
   /*get name*/
   cniElementName(&rc, element, (CciChar*)&elementName, sizeof(elementName));

   /*get namespace*/
   elementNamespace=(CciChar*)malloc(sizeof(CciChar) * elementNamespaceLength);
   elementNamespaceLength = cniElementNamespace(&rc,
                                                element,
                                                elementNamespace,
                                                elementNamespaceLength);

   if (rc==CCI_BUFFER_TOO_SMALL){
     free(elementNamespace);
     elementNamespace=(CciChar*)malloc(sizeof(CciChar) * elementNamespaceLength);
     elementNamespaceLength = cniElementNamespace(&rc,
                                                  element,
                                                  elementNamespace,
                                                  elementNamespaceLength);
   }
   checkRC(rc);
```

cniElementType:

Use this function to get the value of the *type* attribute for the specified syntax element. You must set the syntax element type previously by using cniSetElementType or cpiSetElementType.

Syntax:

```
CciElementType cniElementType(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
The address of the target syntax element object (input).

Return values:

The value of the target element type is returned. If an error occurs, CCI_FAILURE is returned, and the *returnCode* parameter indicates the reason for the error.

"cniSetElementType" on page 6515
Use this function to set the type of the specified syntax element.

"cpiSetElementType" on page 6601
This function sets the type of the specified syntax element.

cniElementValue group:

Use one or more of the functions in this group to retrieve the value of the specified syntax element.

Specify the appropriate function from this group that matches the type of data to be retrieved:

- cniElementBitArrayValue
- cniElementBooleanValue
- cniElementByteArrayValue

- cniElementCharacterValue
- cniElementDateValue
- cniElementDecimalValue
- cniElementGmtTimestampValue
- cniElementGmtTimeValue
- cniElementIntegerValue
- cniElementRealValue
- cniElementTimestampValue
- cniElementTimeValue

Syntax:

```
CciSize cniElementBitArrayValue(
  int*           returnCode,
  CciElement*    targetElement,
  const struct   CciBitArray* value);

CciBool cniElementBooleanValue(
  int*           returnCode,
  CciElement*    targetElement);

CciSize cniElementByteArrayValue(
  int*           returnCode,
  CciElement*    targetElement,
  const struct   CciByteArray* value);

CciSize cniElementCharacterValue(
  int*           returnCode,
  CciElement*    targetElement,
  const CciChar* value,
  CciSize        length);

struct CciDate cniElementDateValue(
  int*           returnCode,
  CciElement*    targetElement);

CciSize cniElementDecimalValue(
  int*           returnCode,
  CciElement*    targetElement,
  const CciChar* value,
  CciSize        length);

struct CciTimestamp cniElementGmtTimestampValue(
  int*           returnCode,
  CciElement*    targetElement);

struct CciTime cniElementGmtTimeValue(
  int*           returnCode,
  CciElement*    targetElement);

CciInt cniElementIntegerValue(
  int*           returnCode,
  CciElement*    targetElement);

CciReal cniElementRealValue(
  int*           returnCode,
  CciElement*    targetElement);

struct CciTimestamp cniElementTimestampValue(
  int*           returnCode,
  CciElement*    targetElement);

struct CciTime cniElementTimeValue(
  int*           returnCode,
  CciElement*    targetElement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER
- CCI_INV_DATA_BUFLEN
- CCI_INV_BUFFER_TOO_SMALL

targetElement
The address of the target syntax element object (input).

value
The address of an output buffer into which the value of the syntax element is stored (input). Used on relevant function calls only.

length
The length of the output buffer, in characters, specified by the *value* parameter (input). Used on relevant function calls only.

Return values:

- If successful, the value of the target element is returned.
- If the size of an element's data can vary, the correct data size is returned.
- If the specified length is too small, the error code is set to CCI_BUFFER_TOO_SMALL.
- If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
 numberOfChars = cniElementCharacterValue(
      &rc, firstChild, (CciChar*)&elementValue, sizeof(elementValue)
      );

if (rc==CCI_BUFFER_TOO_SMALL) {
    free(elementValue);
    elementValue      = (CciChar*)malloc(numberOfChars * sizeof(CciChar));
    numberOfChars     = cniElementCharacterValue(
                  &rc, firstChild, (CciChar*)&elementValue, sizeof(elementValue));
  }
```

cniEvaluate:

This function performs node processing. The broker calls this function when a message is received on one of the input terminals of an instance of a node object.

The function forms the main logic of the message processing node or output node. It is not used with input nodes. You must define a function table before you call this function.

The responsibilities of the node at this point are to:

1. Process the message in accordance with the values of the attributes on the node instance.
2. Process the message based on content, if desired.
3. Propagate the message to any appropriate output terminals.
4. Throw an exception if an error occurs.

Defined In	Type	Member
CNI_VFT	Conditional	iFpEvaluate

Syntax:

```
void cniEvaluate(
  CciContext  *context,
  CciMessage  *localEnvironment,
  CciMessage  *exceptionList,
  CciMessage  *message);
```

Parameters:

context
The address of the context for the instance of the node, as created by the node and returned by the cniCreateNodeContext function (input).

localEnvironment
The address of the input local environment object (input).

For compatibility with earlier versions, you can refer to this parameter as `destinationList`.

exceptionList
The address of the exception list for the message (input).

message
The address of the input message object (input).

A user-defined output node is an extension to the broker that provides a new message flow output node in addition to the nodes supplied with the product.

Related tasks:

"Creating a message processing or output node in C" on page 3036
A message processing node is used to process a message in some way, and an

output node is used to produce a message as a bit stream.

Related reference:

"C node implementation functions" on page 6417
The user-defined node implements a function interface for the broker to call during runtime operation. This interface includes functions to create a local context whenever a node instance is created, functions to set and retrieve attribute values, the function to perform the processing of the node itself, and functions to examine messages.

"cniCreateNodeContext" on page 6447
This function creates a context for an instance of a node object. It is called by the broker whenever an instance of a node object is constructed. Nodes are constructed when a message flow is deployed by the broker, or when the execution group is started.

cniGetComplexAttribute:

Use cniGetComplexAttribute to locate the user-defined properties of the node within the deployment message.

Returns a pointer to the part of the deployment message representing the user-defined properties of the node.

Syntax:

```
CciElement* cniGetComplexAttribute(
  int*                  returnCode,
  CciNode*              nodeObject,
  CciChar*              attributeName);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION

nodeObject
The name of the node for which attributes are required (input).

attributeName
The name and value of the user-defined attribute for the selected node.

Return values:
Returns a syntax element tree that can be navigated to extract the names and values of all user-defined properties for that node, or NULL if no user-defined properties exist for this node. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Related concepts:

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniGetOutputTerminal"
Use cniGetOutputTerminal to locate a named output terminal, it if exists.

"cniGetResourceProperty" on page 6478
Use the `resourceManager` to obtain the value of the property.

cniGetOutputTerminal:

Use cniGetOutputTerminal to locate a named output terminal, it if exists.

Returns a pointer to the named output terminal, or NULL if a terminal of this name does not exist.

Syntax:

```
CciTerminal* cniGetOutputTerminal(
  int*                returnCode,
  CciNode*            nodeObject,
  CciChar*            name);
```

Parameters:

`returnCode`
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION

`nodeObject`
The name of the node (input).

`name`
The name of the output terminal (input).

Return values:
A pointer to the named output terminal, or NULL if a terminal of this name does not exist. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Related concepts:

"User-defined message processing nodes" on page 2996

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniGetComplexAttribute" on page 6476
Use cniGetComplexAttribute to locate the user-defined properties of the node within the deployment message.

"cniGetResourceProperty"
Use the `resourceManager` to obtain the value of the property.

cniGetResourceProperty:

Use the `resourceManager` to obtain the value of the property.

Obtains the value of the property `propertyName` as managed by the `resourceManager`

Syntax:

```
CciSize cniGetResourceProperty(
  int*              returnCode,
  CciChar*          resourceManager,
  CciChar*          propertyName,
  CciChar*          value,
  CciSize           length);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_BUFFER_TOO_SMALL

resourceManager
The address of the resource manager controlling the properties (input).

propertyName
The name of the object for which the value is required.

value
The value of the buffer, already allocated, that you use.

length
The size of the buffer, already allocated, that you use.

If this size is not sufficient, the function fails with *returnCode* set to CCI_BUFFER_TOO_SMALL, and returns the required buffer size; that is, the string length plus one null terminator character.

You should then allocate the required size for the buffer, and call this function again; this function copies the property string into this buffer.

This usage pattern allows you to manage the memory on your system.

This function performs the same task as the **mqsireportproperties** command.

Return values:

None or CCI_BUFFER_TOO_SMALL. If any other error occurs, the *returnCode* parameter indicates the reason for the error.

Related concepts:

"cniGetOutputTerminal" on page 6477
Use cniGetOutputTerminal to locate a named output terminal, it if exists.

"cniGetComplexAttribute" on page 6476
Use cniGetComplexAttribute to locate the user-defined properties of the node within the deployment message.

"**mqsireportproperties** command" on page 3937
Use the **mqsireportproperties** command to display properties that relate to a broker, an execution group, or a configurable service.

cniFinalize:

Use this function to cause the broker to request parsers to perform finalize processing on the specified message. Finalization is a process that fixes header chains and makes the Properties folder match the headers.

The behavior of this processing is specific to each parser. Some parsers do not support finalization processing.

Call cniFinalize before you propagate a message from the node; for example, before you call cniWriteBuffer.

Syntax:

```
void cniFinalize(
  int*         returnCode,
  CciMessage*  message,
  int          options);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_MESSAGE_OBJECT

message
The address of the message object for which the element tree is to be finalized (input).

options
Set this parameter to CCI_FINALIZE_NONE.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
cniFinalize(&rc, outMsg, CCI_FINALIZE_NONE);
retvalue = cniPropagate(
                        &rc,
                        terminalObject,
                        localEnvironment,
                        exceptionList,
                        outMsg);

/* Handle errors */
```

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniCreateMessage" on page 6446
Use this function to create an output message object. For every call to this function, you must include a matching call to cniDeleteMessage to return allocated resources when the processing on the output message has been completed.

"cniDeleteMessage" on page 6453
Use this function to delete the specified message object. For every call to the cniCreateMessage function, you must include a matching call to cniDeleteMessage to return allocated resources when the processing on the output message has been completed.

"cniGetEnvironmentMessage" on page 6490
Use this function to get the CciMessage object that corresponds to the environment tree for the message flow.

"cniGetMessageContext" on page 6491
Use this function to get the address of the message context that is associated with the specified message. The context of an existing message is used to create an output message; for example, by using the cniCreateMessage function.

"cniPropagate" on page 6501
Use this function to propagate a message to a specified terminal object. If the terminal is not attached to another node by a connector, the message is not propagated, and the function is ignored.

"cniWriteBuffer" on page 6537
Use this function to write the syntax element tree associated with the specified message to the data buffer that is owned by the message object. This function is typically used by output nodes.

cniFirstChild:

Use this function to retrieve the address of the syntax element object that is the first child of the specified syntax element.

Syntax:

```
CciElement* cniFirstChild(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
The address of the target syntax element object (input).

Return values:

- If successful, the address of the requested syntax element object is returned.
- If there is no first child, zero is returned, and *returnCode* is set to CCI_SUCCESS.
- If an error occurs, zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

Example:

```
if (element != 0) {
  cniElementName(&rc, element, (CciChar*)&elementName, sizeof(elementName));
  firstChild = cniFirstChild(&rc, element);
```

Related concepts:

"User-defined message processing nodes" on page 2996

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniLastChild" on page 6496
Use this function to retrieve the address of the syntax element object that is the last child of the specified syntax element.

"cniNextSibling" on page 6497
Use this function to retrieve the address of the syntax element object that is the next sibling (right sibling) of the specified syntax element.

"cniParent" on page 6498
Use this function to retrieve the address of the syntax element object that is the parent of the specified syntax element.

"cniPreviousSibling" on page 6499
Use this function to retrieve the address of the syntax element object that is the previous sibling (left sibling) of the specified syntax element.

"cniRootElement" on page 6503
Use this function to get the root syntax element associated with a specified message. It returns the root element that is associated with (and owned by) the message object identified by the *message* parameter. When a message object is constructed by the broker, a root element is automatically created.

"cniSearchElement group" on page 6506
Use one or more of the functions in this group to search previous siblings of the specified element for an element that matches the specified criteria.

cniGetAttribute:

This function gets the value of an attribute on a specific node instance.

Restriction: This function imposes a restriction on the length of the attribute value. This function is provided only for compatibility with earlier versions. You should implement cniGetAttribute2.

This function is invoked by the broker:

- Before the nodes configuration is deployed in order to ascertain default values of any attributes that might override attributes owned by the framework.
- After setting the deployed configuration in order to write the configuration to the broker's database. This call ensures that the configuration persists across shutdown and restarts of the execution group

The responsibilities of the node are to:

1. Return a character representation of the attribute value.
2. Throw an exception if an error occurs.

If both cniGetAttribute and cniGetAttribute2 are implemented, cniDefineNodeClass fails with CCI_INV_IMPL_FUNCTION.

Defined In	Type	Member
CNI_VFT	Optional	iFpGetAttribute

Syntax:

```
int cniGetAttribute(
  CciContext*  context,
  CciChar*     attrName,
  CciChar*     buffer,
  int          bufsize);
```

Parameters:

context
The address of the context for the instance of the node, as created by the node and returned by the **cniCreateNodeContext** function (input).

attrName
The name of the attribute for which the value is to be retrieved (input).

buffer
The address of a buffer into which the attribute value is copied (output).

bufsize
The length, in bytes, of the buffer specified in the *buffer* parameter (input).

Return values:
If successful, zero is returned, and the character representation of the value of the attribute is returned in the specified buffer. If the name of the attribute does not identify one supported by the node, a non-zero value is returned.

"cniCreateNodeContext" on page 6447
This function creates a context for an instance of a node object. It is called by the broker whenever an instance of a node object is constructed. Nodes are constructed when a message flow is deployed by the broker, or when the execution group is started.

"cniGetAttribute2" on page 6484
Use this function to get the value of an attribute on a specific node instance. It is

called by the broker after all the attributes that the user deploys are set.

cniGetAttribute2:

Use this function to get the value of an attribute on a specific node instance. It is called by the broker after all the attributes that the user deploys are set.

The results are written to the broker persistent configuration data to ensure that the node is configured correctly after the execution group process is stopped and started.

The responsibilities of the node are to:

1. Return a character representation of the attribute value.
2. Throw an exception if an error occurs.

If both cniGetAttribute and cniGetAttribute2 functions are implemented, cniDefineNodeClass fails with return code CCI_INV_IMPL_FUNCTION.

Defined In	Type	Member
CNI_VFT	Optional	iFpGetAttribute2

Syntax:

```
CciSize cniGetAttribute2(
  int          returnCode,
  CciContext*  context,
  CciChar*     attrName,
  CciChar*     buffer,
  int          bufsize);
```

Parameters:

context
The address of the context for the instance of the node, as created by the node and returned by the `cniCreateNodeContext` function (input).

returnCode (output)
Pointer to an int. On return, the node must ensure that this int stores a value that describes the status of completion. Possible return codes are:

- CCI_SUCCESS
- CCI_ATTRIBUTE_UNKNOWN
- CCI_BUFFER_TOO_SMALL

attrName
The name of the attribute for which the value is to be retrieved (input).

buffer
The address of a buffer into which the attribute value is copied (output).

bufsize
The length, in `CciChars`, of the buffer specified in the **buffer** parameter (input).

Return values:

- If successful, the attribute value is copied into the supplied buffer and the number of `CciChar` characters copied is returned.
- If the buffer is not large enough to contain the attribute value, *returnCode* is set to CCI_BUFFER_TOO_SMALL, and the number of `CciChars` required is returned.

- If the *attrName* is not known to this node, *returnCode* is set to CCI_ATTRIBUTE_UNKNOWN.

"cniGetAttributeName2" on page 6487
This function returns the name of a node attribute specified by an index. It is called by the broker when the broker requires the names of the attributes that are supported by an instance of a node.

cniGetAttributeName:

This functions returns the name of a node attribute specified by an index.

Restriction: This function imposes a restriction on the length of the attribute value. This function is provided only for compatibility with earlier versions. You should implement cniGetAttributeName2.

This function is invoked by the message broker when the broker requires the names of attributes supported by a particular instance of a node. The function must guarantee to return the attributes in a known, defined order, and to return the attribute name represented by the index parameter.

If both cniGetAttributeName and cniGetAttributeName2 are implemented, cniDefineNodeClass fails with CCI_INV_IMPL_FUNCTION.

Defined In	Type	Member
CNI_VFT	Optional	iFpGetAttributeName

Syntax:

```
int cniGetAttributeName(
  CciContext*  context,
  int          index,
  CciChar*     buffer,
  int          bufsize);
```

Parameters:

context
The address of the context for the instance of the node, as created by the node and returned by the **cniCreateNodeContext** function (input).

index
Specifies the index of the attribute name (input). The index of the attributes starts from zero.

buffer
The address of a buffer into which the attribute name is copied (output).

bufsize
The length, in bytes, of the buffer specified in the *buffer* parameter (input).

Return values:
If successful, zero is returned, and the name of the attribute is returned in the specified buffer. If the end of the list of attributes is reached, a non-zero value is returned.

Related concepts:

This function creates a context for an instance of a node object. It is called by the broker whenever an instance of a node object is constructed. Nodes are constructed when a message flow is deployed by the broker, or when the execution group is

started.

"cniGetAttributeName2"
This function returns the name of a node attribute specified by an index. It is called by the broker when the broker requires the names of the attributes that are supported by an instance of a node.

cniGetAttributeName2:

This function returns the name of a node attribute specified by an index. It is called by the broker when the broker requires the names of the attributes that are supported by an instance of a node.

The function must return the attributes in a known, defined order, and to return the attribute name that is represented by the index parameter.

If both cniGetAttributeName and cniGetAttributeName2 are implemented, cniDefineNodeClass fails with CCI_INV_IMPL_FUNCTION.

Defined In	Type	Member
CNI_VFT	Optional	iFpGetAttributeName2

Syntax:

```
CciSize cniGetAttributeName2(
  int          returnCode,
  CciContext*  context,
  int          index,
  CciChar*     buffer,
  int          bufsize);
```

Parameters:

context
The address of the context for the instance of the node, as created by the node and returned by the **cniCreateNodeContext** function (input).

returnCode (output)
Pointer to an int. On return, the node must ensure that this int stores a value that describes the status of completion. Possible return codes are:

- CCI_SUCCESS
- CCI_ATTRIBUTE_UNKNOWN
- CCI_BUFFER_TOO_SMALL

index
Specifies the index of the attribute name (input). The index of the attributes starts from zero.

buffer
The address of a buffer into which the attribute name is copied (output).

bufsize
The length, in CciChars, of the buffer specified in the **buffer** parameter (input).

Return values:

- If successful, the attribute name is copied into the supplied buffer and the number of `CciChar` characters copied is returned.

- If the buffer is not large enough to contain the attribute name, *returnCode* is set to CCI_BUFFER_TOO_SMALL, and the number of `CciChars` required is returned.
- If the end of the list of attributes is reached, and the attribute name is not found, *returnCode* is set to CCI_ATTRIBUTE_UNKNOWN. For example, when `index` is greater than n-1, where n is the number of attributes for this node.

Use this function to get the value of an attribute on a specific node instance. It is called by the broker after all the attributes that the user deploys are set.

cniGetBrokerInfo:

Use this function to query the current broker environment (for example, for information about broker name and message flow name). The information is returned in a structure of type CNI_BROKER_INFO_ST.

Syntax:

```
void cniGetBrokerInfo(
  int*                returnCode,
  CciNode*            nodeObject,
  CNI_BROKER_INFO_ST* broker_info_st);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_NODE_OBJECT

nodeObject
The message flow processing node for which broker environment information is being requested (input).

broker_info_st
The address of a CNI_BROKER_INFO_ST structure that is used to return a message that represents the input destination (input):

```
typedef struct broker_info_st {
int versionId;   /*Structure version identification*/
CCI_STRING_ST brokerName;  /*The label of the broker*/
CCI_STRING_ST executionGroupName; /*The label of the current execution group*/

int coordinatedTransaction;  /*Flag: coordinatedTransaction: 0=no, 1=yes*/
CCI_STRING_ST dataSourceUserId;  /*The user ID that the broker uses to connect to the data sou
} CNI_BROKER_INFO_ST;
```

Note: The dataSourceUserId parameter returns an empty string. The parameter is included to maintain compatibility with previous versions of WebSphere Message Broker that require a broker database.

Return values:
None. If an error occurs, the **returnCode** parameter indicates the reason for the error.

Example:

```
cniGetBrokerInfo(&rc, nodeObject, &broker_info_st);
```

where nodeObject is of type CciNode*

"C node utility functions" on page 6419
A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

cniGetEnvironmentMessage:

Use this function to get the CciMessage object that corresponds to the environment tree for the message flow.

Syntax:

```
CciMessage ImportExportPrefix * ImportExportSuffix
  cniGetEnvironmentMessage(
    int*         returnCode,
    CciMessage*  message);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_MESSAGE_OBJECT

message
The address of the message object for which the environment is to be obtained. This message might be an input message that has been received as an argument to the cniEvaluate implementation function, or a message created by the cniCreateMessage utility function.

Return values:
If successful, the address of the message object corresponding to the environment tree is returned. Otherwise, a value of zero is returned, and the *returnCode* parameter indicates the reason for the error.

A message processing node is used to process a message in some way, and an output node is used to produce a message as a bit stream.

Related reference:

"C node implementation functions" on page 6417
The user-defined node implements a function interface for the broker to call during runtime operation. This interface includes functions to create a local context whenever a node instance is created, functions to set and retrieve attribute values, the function to perform the processing of the node itself, and functions to examine messages.

"cniCreateMessage" on page 6446
Use this function to create an output message object. For every call to this function, you must include a matching call to cniDeleteMessage to return allocated resources when the processing on the output message has been completed.

"cniDeleteMessage" on page 6453
Use this function to delete the specified message object. For every call to the cniCreateMessage function, you must include a matching call to cniDeleteMessage to return allocated resources when the processing on the output message has been completed.

"cniEvaluate" on page 6475
This function performs node processing. The broker calls this function when a message is received on one of the input terminals of an instance of a node object.

"cniFinalize" on page 6479
Use this function to cause the broker to request parsers to perform finalize processing on the specified message. Finalization is a process that fixes header chains and makes the Properties folder match the headers.

"cniGetMessageContext"
Use this function to get the address of the message context that is associated with the specified message. The context of an existing message is used to create an output message; for example, by using the cniCreateMessage function.

"cniPropagate" on page 6501
Use this function to propagate a message to a specified terminal object. If the terminal is not attached to another node by a connector, the message is not propagated, and the function is ignored.

cniGetMessageContext:

Use this function to get the address of the message context that is associated with the specified message. The context of an existing message is used to create an output message; for example, by using the cniCreateMessage function.

Syntax:

```
CciMessageContext* cniGetMessageContext(
  int*         returnCode,
  CciMessage*  message);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_INV_MESSAGE_OBJECT

message
The address of the message object (input).

Return values:

If successful, the address of the message context is returned. Otherwise, zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

Example:

```
outMsg = cniCreateMessage(&rc, cniGetMessageContext(&rc, message));
```

Use this function to propagate a message to a specified terminal object. If the terminal is not attached to another node by a connector, the message is not propagated, and the function is ignored.

cniGetParserClassName:

Use this function to get the parser class name that is associated with the specified syntax element.

Syntax:

```
CciSize cniGetParserClassName(
  int*           returnCode,
  CciElement*    targetElement,
  const CciChar* value,
  CciSize        length);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER
- CCI_INV_DATA_BUFLEN
- CCI_INV_BUFFER_TOO_SMALL

targetElement
The address of the element for which the parser class name is to be returned (input).

value
The address of an output buffer into which the parser class name is stored (input).

length
The length of the output buffer, expressed as the number of CciChar characters, specified in the *value* parameter (input).

Return values:

- If successful, the *returnCode* parameter indicates CCI_SUCCESS, and the number of characters written to the buffer is returned.
- If the buffer is not large enough to retain the returned name, the *returnCode* parameter indicates CCI_BUFFER_TOO_SMALL, and the returned value indicates the number of characters required to store the name.
- If other errors occur, CCI_FAILURE is returned, and the *returnCode* parameter indicates the reason for the error.

system-provided functions.

cniGetThreadContext:

This function returns the thread context for the current thread.

Syntax:

```
CciThreadContext *cniGetThreadContext(
  int                    *returnCode,
  CciMessageContext      *msgContext);
```

Parameters:

returnCode
This parameter is the return code from the function (output). If the input value is NULL, this value signifies that errors are silently handled, or are ignored by the broker. If the input value is not NULL, the output signifies the success status of the call. If the `msgContext` parameter is not valid, `*returnCode` is set to CCI_INV_MESSAGE_CONTEXT, and a NULL CciThreadContext is returned.

msgContext
This parameter provides the message context from which to acquire the thread-specific context. It is expected that this parameter is obtained by using the cniGetMessageContext utility function.

Return values:
If this function is successful, it returns a handle to the CciThreadContext for the current thread.

The cciMessageContext value must correspond to a cciMessage, where the cciMessage is passed in to the cniEvaluate or cniRun function on the current thread.

Example:

```
CciMessageContext* messageContext = cniGetMessageContext(NULL,message);
CciThreadContext*  threadContext  = cniGetThreadContext(NULL,messageContext);
```

Related reference:

"cciRegisterForThreadStateChange" on page 6656
This function registers a function to be called when the current thread enters a particular state.

"cciRegCallback" on page 6641
This function can be registered as a callback function, and is called when the registered event occurs. The function is registered by providing a function pointer which matches a particular typedef.

cniIsTerminalAttached:

Use this function to check whether a terminal is attached to another node by a connector. It returns an integer value that specifies whether the specified terminal object is attached to one or more terminals on other message flow nodes.

Use this function to test whether a message can be propagated to a terminal; you do not have to call this function before you propagate a message with the cniPropagate utility function. Use the cniIsTerminalAttached function to modify the node behavior when a terminal is not connected.

Syntax:

```
int cniIsTerminalAttached(
  int*          returnCode,
  CciTerminal*  terminalObject);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_TERMINAL_OBJECT

terminalObject
The address of the input or output terminal to be checked for an attached connector (input). The address is returned from cniCreateOutputTerminal.

Return values:

- If the terminal is attached to another node by a connector, a value of 1 is returned.
- If the terminal is not attached, or a failure occurred, a value of zero is returned.
- If a failure occurs, the value of the *returnCode* parameter indicates the reason for the error.

Example:

```
if (terminalObject) {
  if (cniIsTerminalAttached(&rc, terminalObject)) {
    if (rc == CCI_SUCCESS) {
      retvalue = cniPropagate(
                              &rc,
                              terminalObject,
                              localEnvironment,
                              exceptionList,
                              message);
```

Use this function to create an output terminal on an instance of a node object and return the address of the terminal object that was created.

"cniPropagate" on page 6501
Use this function to propagate a message to a specified terminal object. If the terminal is not attached to another node by a connector, the message is not propagated, and the function is ignored.

cniLastChild:

Use this function to retrieve the address of the syntax element object that is the last child of the specified syntax element.

Syntax:

```
CciElement* cniLastChild(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_MESSAGE_OBJECT

targetElement
The address of the target syntax element object (input).

Return values:

- If successful, the address of the requested syntax element object is returned.
- If there is no last child, zero is returned, and *returnCode* is set to CCI_SUCCESS.
- If an error occurs, zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

Example:

```
bodyChild = cniLastChild(&rc, outRootElement);
```

Related concepts:

"cniFirstChild" on page 6481
Use this function to retrieve the address of the syntax element object that is the first child of the specified syntax element.

"cniNextSibling"
Use this function to retrieve the address of the syntax element object that is the next sibling (right sibling) of the specified syntax element.

"cniParent" on page 6498
Use this function to retrieve the address of the syntax element object that is the parent of the specified syntax element.

"cniPreviousSibling" on page 6499
Use this function to retrieve the address of the syntax element object that is the previous sibling (left sibling) of the specified syntax element.

"cniRootElement" on page 6503
Use this function to get the root syntax element associated with a specified message. It returns the root element that is associated with (and owned by) the message object identified by the *message* parameter. When a message object is constructed by the broker, a root element is automatically created.

"cniSearchElement group" on page 6506
Use one or more of the functions in this group to search previous siblings of the specified element for an element that matches the specified criteria.

cniNextSibling:

Use this function to retrieve the address of the syntax element object that is the next sibling (right sibling) of the specified syntax element.

Syntax:

```
CciElement* cniNextSibling(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
The address of the target syntax element object (input).

Return values:

- If successful, the address of the requested syntax element object is returned.
- If there is no next sibling, zero is returned, and *returnCode* is set to CCI_SUCCESS.
- If an error occurs, zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

Example:

```
nextSibling = cniNextSibling(&rc, element);
```

cniParent:

Use this function to retrieve the address of the syntax element object that is the parent of the specified syntax element.

Syntax:

```
CciElement* cniParent(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION

- CCI_INV_ELEMENT_OBJECT

targetElement
The address of the target syntax element object (input).

Return values:

- If successful, the address of the requested syntax element is returned.
- If there is no parent element, zero is returned.
- If an error occurs, zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

Use one or more of the functions in this group to search previous siblings of the specified element for an element that matches the specified criteria.

cniPreviousSibling:

Use this function to retrieve the address of the syntax element object that is the previous sibling (left sibling) of the specified syntax element.

Syntax:

```
CciElement* cniPreviousSibling(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
The address of the target syntax element object (input).

Return values:

- If successful, the address of the requested syntax element object is returned.
- If there is no previous sibling, zero is returned, and *returnCode* is set to CCI_SUCCESS.
- If an error occurs, zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

"cniRootElement" on page 6503
Use this function to get the root syntax element associated with a specified message. It returns the root element that is associated with (and owned by) the message object identified by the *message* parameter. When a message object is constructed by the broker, a root element is automatically created.

"cniSearchElement group" on page 6506
Use one or more of the functions in this group to search previous siblings of the specified element for an element that matches the specified criteria.

cniPropagate:

Use this function to propagate a message to a specified terminal object. If the terminal is not attached to another node by a connector, the message is not propagated, and the function is ignored.

Therefore, you do not have to check whether the terminal is attached before you propagate the message, unless you want the node to take different in this scenario. If required, you can use cniIsTerminalAttached to check whether the terminal is connected before you call this function.

Syntax:

```
int cniPropagate(
  int*          returnCode,
  CciTerminal*  terminalObject,
  CciMessage*   localEnvironment,
  CciMessage*   exceptionList,
  CciMessage*   message);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_TERMINAL_OBJECT
- CCI_INV_MESSAGE_OBJECT

terminalObject
The address of the output terminal to receive the message (input). The address is returned by cniCreateOutputTerminal.

localEnvironment
The address of the local environment object to be sent with the message (input).

This message object is used by the publish/subscribe node supplied by the broker.

For compatibility with earlier versions, you can refer to this parameter as `destinationList`.

exceptionList
The address of the exception list for the message (input).

message
The address of the message object to be sent (input). If the message being sent is the same as the input message, this address is the one passed on the cniEvaluate implementation function.

Return values:
If successful, CCI_SUCCESS is returned. Otherwise, CCI_FAILURE is returned, and the *returnCode* parameter indicates the reason for the error.

Example:

```
if (terminalObject) {
  if (cniIsTerminalAttached(&rc, terminalObject)) {
    if (rc == CCI_SUCCESS) {
      cniPropagate(&rc, terminalObject, destinationList, exceptionList, message);
```

This function performs node processing. The broker calls this function when a message is received on one of the input terminals of an instance of a node object.

"cniFinalize" on page 6479
Use this function to cause the broker to request parsers to perform finalize processing on the specified message. Finalization is a process that fixes header chains and makes the Properties folder match the headers.

"cniGetEnvironmentMessage" on page 6490
Use this function to get the CciMessage object that corresponds to the environment tree for the message flow.

"cniGetMessageContext" on page 6491
Use this function to get the address of the message context that is associated with the specified message. The context of an existing message is used to create an output message; for example, by using the cniCreateMessage function.

"cniIsTerminalAttached" on page 6494
Use this function to check whether a terminal is attached to another node by a connector. It returns an integer value that specifies whether the specified terminal object is attached to one or more terminals on other message flow nodes.

cniRootElement:

Use this function to get the root syntax element associated with a specified message. It returns the root element that is associated with (and owned by) the message object identified by the *message* parameter. When a message object is constructed by the broker, a root element is automatically created.

Syntax:

```
CciElement* cniRootElement(
  int*         returnCode,
  CciMessage*  message);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_MESSAGE_OBJECT

message
The address of the message object (input).

Return values:
If successful, the address of the root element object is returned. Otherwise, zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

Example:

```
inRootElement = cniRootElement(&rc, message);
```

"cniLastChild" on page 6496
Use this function to retrieve the address of the syntax element object that is the last child of the specified syntax element.

"cniNextSibling" on page 6497
Use this function to retrieve the address of the syntax element object that is the next sibling (right sibling) of the specified syntax element.

"cniParent" on page 6498
Use this function to retrieve the address of the syntax element object that is the parent of the specified syntax element.

"cniPreviousSibling" on page 6499
Use this function to retrieve the address of the syntax element object that is the previous sibling (left sibling) of the specified syntax element.

"cniSearchElement group" on page 6506
Use one or more of the functions in this group to search previous siblings of the specified element for an element that matches the specified criteria.

cniRun:

This function declares the node as an input node.

Message processing nodes and output nodes do not use it, and you do not need to call cniEvaluate. The broker allocates a thread, and calls this function on that thread.

Defined In	Type	Member
CNI_VFT	Conditional	iFpRun

Syntax:

```
int cniRun(
  CCiContext*  context,
  CCiMessage*  localEnvironment,
  CciMessage*  exceptionList,
  CciMessage*  message
);
```

Parameters:

context
The address of the context for the instance of the node, as created by the node and returned by the cniCreateNodeContext function (input).

localEnvironment
The address of the input local environment object (input).

For compatibility with earlier versions, you can refer to this parameter as `destinationList`.

exceptionList
The address of the exception list for the message (input).

message
The address of the message object to which the data is attached (input).

The user-defined node can call cniSetInputBuffer to associate a bit stream with this message. Populating the tree of this message is not supported, therefore calls to functions such as cniAddAsLastChild or cniCreateElementAsLastChildFromBitstream do not work. To build parts of the tree, create a new message using cniCreateMessage rather than providing a buffer to be parsed as the whole message.

For example, if you have a bit stream that is to be used as the payload part of the message, and you also want to add a header, take the following steps:

1. Create a new message using cniCreateMessage.
2. Create the header part in this new message by using the Syntax Element Access Utility functions, for example cniCreateElementAsLastChildUsingParser, and passing in the root element of this new message.
3. Add fields to the header by using functions such as cniCreateElementAsLastChild.
4. Create the body of the message by parsing your bit stream through calling cniCreateElementAsLastChildFromBitstream, and passing in the root element of this new message.

Return values:
This function is called by the broker as part of a loop. The meaning of the return value is as follows:

CCI_TIMEOUT
The input node did not receive its input data. This value means that control should be returned to the broker in case message flow reconfiguration is being requested. A user-defined input node should return regularly to give control back to the broker.

CCI_SUCCESS_CONTINUE
A message was successfully processed. The broker performs default transaction commit processing. The input node's cniRun implementation function is called immediately so that the node can continue processing.

CCI_SUCCESS_RETURN
A message has been successfully processed. The broker performs default transaction commit processing. The input node has determined that the thread is not required, and it is returned to the message flow thread pool. If this processing is performed on the only thread, or the last active thread, the broker prevents this last thread being returned to the pool, otherwise no active threads are available to dispatch another thread. In this situation, the broker invokes the cniRun implementation function immediately, as if CCI_SUCCESS_CONTINUE was returned.

CCI_FAILURE_CONTINUE
An error was detected in the processing of a message, and the node is requesting that transaction rollback processing is performed. The input node's cniRun implementation function is called immediately.

CCI_FAILURE_RETURN
An error was detected in the processing of a message, and the node is requesting that transaction rollback processing is performed. However, the input node has determined that the thread is not required and it can be returned to the message flow thread pool. If this processing is performed on the last active thread, the broker prevents this last thread being returned to the

pool, otherwise no active threads are available to dispatch another thread. In this situation the broker invokes the cniRun implementation function immediately, as if CCI_FAILURE_CONTINUE was returned.

Related concepts:

"User-defined input nodes" on page 2990
A user-defined input node is an extension to the broker that provides a new input node in addition to the nodes supplied with the product.

Related tasks:

"Creating an input node in C" on page 3027
Create a user-defined input node in C to receive messages into a message flow.

Related reference:

"C node implementation functions" on page 6417
The user-defined node implements a function interface for the broker to call during runtime operation. This interface includes functions to create a local context whenever a node instance is created, functions to set and retrieve attribute values, the function to perform the processing of the node itself, and functions to examine messages.

cniSearchElement group:

Use one or more of the functions in this group to search previous siblings of the specified element for an element that matches the specified criteria.

The search is performed starting at the syntax element specified in the *targetElement* parameter, and each of the four functions provides a search in a different tree direction:

- cniSearchFirstChild searches the immediate child elements of the starting element from the first child, until either a match is found, or the end of the child element chain is reached.
- cniSearchLastChild searches the immediate child elements of the starting element from the last child, until either a match is found, or the end of the child element chain is reached.
- cniSearchNextSibling searches from the starting element to the next siblings, until either a match is found, or the end of the sibling chain is reached.
- cniSearchPreviousSibling searches from the starting element to the previous siblings, until either a match is found, or the start of the sibling chain is reached.

If you use this command to search for an element within a message that belongs to a namespace-aware domain, the search is performed only on those elements whose namespace is an empty string. If you want to perform a search for elements in all namespaces, use one of the cniSearchElementNamespace functions.

Syntax:

```
CciElement* cniSearchFirstChild(
  int*            returnCode,
  CciElement*     targetElement,
  CciCompareMode* mode,
  CciElementType  type,
  CciChar         name);
CciElement* cniSearchLastChild(
  int*            returnCode,
  CciElement*     targetElement,
  CciCompareMode* mode,
  CciElementType  type,
  CciChar         name);
```

```
CciElement* cniSearchNextSibling(
  int*            returnCode,
  CciElement*     targetElement,
  CciCompareMode* mode,
  CciElementType  type,
  CciChar         name);
CciElement* cniSearchPreviousSibling(
  int*            returnCode,
  CciElement*     targetElement,
  CciCompareMode* mode,
  CciElementType  type,
  CciChar         name);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
The address of the syntax element object from which the search starts (input).

mode
The search mode to use (input). This parameter indicates what combination of element type and element name is to be searched for. The possible values are:

- CCI_COMPARE_MODE_FULL
- CCI_COMPARE_MODE_FULL_TYPE
- CCI_COMPARE_MODE_GENERIC_TYPE
- CCI_COMPARE_MODE_SPECIFIC_TYPE
- CCI_COMPARE_MODE_NAME
- CCI_COMPARE_MODE_NAME_SPECIFIC_TYPE
- CCI_COMPARE_MODE_NAME_GENERIC_TYPE
- CCI_COMPARE_MODE_NAME_FULL_TYPE
- CCI_COMPARE_MODE_NULL

type
The element type to search for (input). Use this parameter only if the search mode involves a match on the type.

name
The element name to search for (input). Use this parameter only if the search mode involves a match on the name.

Example:

```
int rc;
CciElement* firstChild = cniSearchFirstChild(
                                            &rc,
                                             inRootElement,
                                             CCI_COMPARE_MODE_NAME,
                                             elementName,
                                             0);
```

Return values:

- If successful, the address of the requested syntax element object is returned.

- If there is no matching element, zero is returned.
- If an error occurs, zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniFirstChild" on page 6481
Use this function to retrieve the address of the syntax element object that is the first child of the specified syntax element.

"cniLastChild" on page 6496
Use this function to retrieve the address of the syntax element object that is the last child of the specified syntax element.

"cniNextSibling" on page 6497
Use this function to retrieve the address of the syntax element object that is the next sibling (right sibling) of the specified syntax element.

"cniParent" on page 6498
Use this function to retrieve the address of the syntax element object that is the parent of the specified syntax element.

"cniPreviousSibling" on page 6499
Use this function to retrieve the address of the syntax element object that is the previous sibling (left sibling) of the specified syntax element.

"cniRootElement" on page 6503
Use this function to get the root syntax element associated with a specified message. It returns the root element that is associated with (and owned by) the message object identified by the *message* parameter. When a message object is constructed by the broker, a root element is automatically created.

"cniSearchElementInNamespace group"
Use this element to search for an element that matches the specified criteria.

cniSearchElementInNamespace group:

Use this element to search for an element that matches the specified criteria.

The search starts at the syntax element specified in the element argument, and each of the four functions provides a search in a different tree direction:

1. cniSearchFirstChildInNamespace searches the immediate child elements of the starting element from the first child, until either a match is found, or the end of the child element chain is reached.

2. cniSearchLastChildInNamespace searches the immediate child elements of the starting element from the last child, until either a match is found, or the end of the child element chain is reached.
3. cniSearchNextSiblingInNamespace searches from the starting element to the next siblings, until either a match is found, or the end of the sibling chain is reached.
4. cniSearchPreviousSiblingInNamespace searches from the starting element to the previous siblings, until either a match is found, or the start of the sibling chain is reached.

Use this function when you search a message that belongs to a namespace-aware domain.

Syntax:

```
void cniSearchFirstChildInNamespace(
 int*           returnCode,
 CciElement*    targetElement,
 CciCompareMode mode,
 const CciChar* nameSpace,
 const CciChar* name,
 CciElementType type)

void cniSearchLastChildInNamespace(
 int*           returnCode,
 CciElement*    targetElement,
 CciCompareMode mode,
 const CciChar* nameSpace,
 const CciChar* name,
 CciElementType type)

void cniSearchNextSiblingInNamespace(
 int*           returnCode,
 CciElement*    targetElement,
 CciCompareMode mode,
 const CciChar* nameSpace,
 const CciChar* name,
 CciElementType type)

void cniSearchPreviousSiblingInNamespace(
 int*           returnCode,
 CciElement*    targetElement,
 CciCompareMode mode,
 CciElementType type,
 const CciChar* nameSpace,
 const CciChar* name)
```

Parameters:

returnCode

The return code from the function (output). Specifying a NULL pointer signifies that the node does not want to deal with errors. If input is not NULL, the output signifies the success status of the call. All exceptions thrown during the execution of this call are re-thrown to the next upstream node in the flow. Call cciGetLastExceptionData for details of the exception.

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
The address of the syntax element object from which the search starts (input).

mode
The search mode to use (input). This parameter indicates what combination of element namespace, element name, and element type is to be searched for. The possible values are:

- CCI_COMPARE_MODE_SPACE
- CCI_COMPARE_MODE_SPACE_FULL_TYPE
- CCI_COMPARE_MODE_SPACE_GENERIC_TYPE
- CCI_COMPARE_MODE_SPACE_SPECIFIC_TYPE
- CCI_COMPARE_MODE_SPACE_NAME
- CCI_COMPARE_MODE_SPACE_NAME_FULL_TYPE
- CCI_COMPARE_MODE_SPACE_NAME_GENERIC_TYPE
- CCI_COMPARE_MODE_SPACE_NAME_SPECIFIC_TYPE
- CCI_COMPARE_MODE_NULL

When the compare mode does not involve a match on the namespace, all namespaces are searched. This behavior differs from that of the cniSearchElement group, where only the empty string namespace is searched. When you specify one of the valid modes, set the *nameSpace* parameter to the empty string.

type
The element type to search for (input). Use this parameter only if the search mode involves a match on the type.

nameSpace
The namespace to search (input). Use this parameter only if the search mode involves a match on the namespace.

name
The name to search for (input). Use this parameter only if the search mode involves a match on the name.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
mode=CCI_COMPARE_MODE_SPACE ;
...

  if (forward) {
    firstChild = cniSearchFirstChildInNamespace(&rc, element, mode, space, 0,0);
   }else{
    firstChild = cniSearchLastChildInNamespace(&rc, element, mode, space, 0,0);

   }

   if (firstChild) {
     depth++;
     traceElement(firstChild,forward,space);
     depth--;
   }
   currentElement = firstChild;
   do{

     if (forward) {
```

```
      nextSibling = cniSearchNextSiblingInNamespace(&rc, currentElement,mode,space,0,0);
    }else{
      nextSibling = cniSearchPreviousSiblingInNamespace(&rc, currentElement,mode,space,0,0);
    }
    if (nextSibling) {
      traceElement(nextSibling,forward,space);
      currentElement=nextSibling;
    }

  }while (nextSibling) ;

}
```

Use one or more of the functions in this group to search previous siblings of the specified element for an element that matches the specified criteria.

"cniSetElementNamespace" on page 6514
Use this function to set the *namespace* attribute for the specified syntax element when you manipulate a message that belongs to a namespace-aware domain.

"cciGetLastExceptionData" on page 6647
Gets diagnostic information about the last exception generated. Information about the last exception generated on the current thread is returned in a CCI_EXCEPTION_ST output structure. The user-defined extension can use this function to determine whether any recovery is required when a utility function returns an error code.

cniSetAttribute:

This function sets the value of an attribute on a specific node instance. It is called by the broker when a configuration request is received that attempts to set the value of a node attribute, or during initialization of the node.

A node receives requests to set attributes for the base. If an unknown attribute value is received, this function *must* return a non-zero value so that the broker processes the request correctly.

The responsibilities of the node are to:

1. Verify that the value of the attribute is correctly specified. If not, a configuration exception should be thrown using the cciThrowException function.

2. Store the value of the attribute within the context, which should have been allocated in the cniCreateNodeContext function.
3. Throw a configuration exception if an error occurs, by using the cciThrowException function.

Defined In	Type	Member
CNI_VFT	Optional	iFpSetAttribute

Syntax:

```
int cniSetAttribute(
  CciContext*  context,
  CciChar*     attrName,
  CciChar*     attrValue);
```

Parameters:

context
The address of the context for the instance of the node, as created by the node and returned by the **cniCreateNodeContext** function (input).

attrName
The name of the attribute whose value is to be set (input).

attrValue
The value of the attribute (input).

Return values:
If successful, zero is returned. If the name of the attribute does not identify one supported by the node, a non-zero value is returned.

Related concepts:

"User-defined input nodes" on page 2990
A user-defined input node is an extension to the broker that provides a new input node in addition to the nodes supplied with the product.

The user-defined node implements a function interface for the broker to call during runtime operation. This interface includes functions to create a local context whenever a node instance is created, functions to set and retrieve attribute values, the function to perform the processing of the node itself, and functions to examine messages.

"cniCreateNodeContext" on page 6447
This function creates a context for an instance of a node object. It is called by the broker whenever an instance of a node object is constructed. Nodes are constructed when a message flow is deployed by the broker, or when the execution group is started.

"cciThrowException" on page 6666
Use this function to throw an exception. The exception is thrown by the broker interface, and includes the specified arguments as exception data.

cniSetElementName:

Use this function to set the name of the specified syntax element.

Syntax:

```
void cniSetElementName(
  int*            returnCode,
  CciElement*     targetElement,
  const CciChar*  name);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER

targetElement
The address of the target syntax element object (input).

name
The name of the element (input).

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
CciElement* lastChild = cniCreateElementAsLastChild(&rc, outRootElement);
cniSetElementName(&rc, lastChild, elementName);
cniSetElementType(&rc, lastChild, CCI_ELEMENT_TYPE_NAME);
```

"cniElementName" on page 6464
Use this function to get the value of the *name* attribute for the specified syntax element. You must sethe syntax element name previously by using cniSetElementName or cpiSetElementName.

"cniSetElementNamespace"
Use this function to set the *namespace* attribute for the specified syntax element when you manipulate a message that belongs to a namespace-aware domain.

"cniSetElementType" on page 6515
Use this function to set the type of the specified syntax element.

"cniSetElementValue group" on page 6516
Use one or more of the functions in this group to set the value of the specified syntax element.

"cniSetElementValueValue" on page 6519
Use this function to set the value object of the specified syntax element.

cniSetElementNamespace:

Use this function to set the *namespace* attribute for the specified syntax element when you manipulate a message that belongs to a namespace-aware domain.

Syntax:

```
void cniSetElementNamespace(
 int*           returnCode,
 CciElement*    targetElement,
 const CciChar* nameSpace)
```

Parameters:

returnCode
The return code from the function (output). Specifying a NULL pointer signifies that the node does not want to deal with errors. If input is not NULL, the output signifies the success status of the call. Any exceptions thrown during the execution of this call are re-thrown to the next upstream node in the flow. Call cciGetLastExceptionData for details of the exception.

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER

targetElement
Specifies the address of the target syntax element object (input).

value
Specifies the address of a null terminated string of CciChars representing the namespace value (output). An empty string is a valid value for namespace. By default, elements are created in the empty string namespace, so you could specify an empty string as the namespace, but it has an effect only if the element was previously in another namespace and you want to change the namespace value to empty string.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Gets diagnostic information about the last exception generated. Information about the last exception generated on the current thread is returned in a CCI_EXCEPTION_ST output structure. The user-defined extension can use this function to determine whether any recovery is required when a utility function returns an error code.

cniSetElementType:

Use this function to set the type of the specified syntax element.

Syntax:

```
void cniSetElementType(
  int*            returnCode,
  CciElement*     targetElement,
  CciElementType  type);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
The address of the target syntax element object (input).

type
The type of the element (input).

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
CciElement* lastChild = cniCreateElementAsLastChild(&rc, outRootElement);
cniSetElementName(&rc, lastChild, elementName);
cniSetElementType(&rc, lastChild, CCI_ELEMENT_TYPE_NAME);
```

Use this function to set the value object of the specified syntax element.

cniSetElementValue group:

Use one or more of the functions in this group to set the value of the specified syntax element.

Specify the appropriate function from this group that matches the type of data to be retrieved:

- cniSetElementBitArrayValue
- cniSetElementBooleanValue
- cniSetElementByteArrayValue
- cniSetElementCharacterValue
- cniSetElementDateValue
- cniSetElementDecimalValue
- cniSetElementGmtTimestampValue
- cniSetElementGmtTimeValue
- cniSetElementIntegerValue
- cniSetElementRealValue
- cniSetElementTimestampValue

- cniSetElementTimeValue

Syntax:

```
void cniSetElementBitArrayValue(
  int*                       returnCode,
  CciElement*                targetElement,
  const struct CciBitArray* value);

void cniSetElementBooleanValue(
  int*                        returnCode,
  CciElement*                 targetElement,
  CciBool                     value);

void cniSetElementByteArrayValue(
  int*                        returnCode,
  CciElement*                 targetElement,
  const struct CciByteArray* value);

void cniSetElementCharacterValue(
  int*                        returnCode,
  CciElement*                 targetElement,
  const CciChar*              value,
  CciSize                     length);

void cniSetElementDateValue(
  int*                        returnCode,
  CciElement*                 targetElement,
  const struct CciDate*       value);

void cniSetElementDecimalValue(
  int*                        returnCode,
  CciElement*                 targetElement,
  const CciChar*              value);

void cniSetElementGmtTimestampValue(
  int*                        returnCode,
  CciElement*                 targetElement,
  const struct CciTimestamp* value);

void cniSetElementGmtTimeValue(
  int*                        returnCode,
  CciElement*                 targetElement,
  const struct CciTime*       value);

void cniSetElementIntegerValue(
  int*                        returnCode,
  CciElement*                 targetElement,
  CciInt                      value);

void cniSetElementRealValue(
  int*                        returnCode,
  CciElement*                 targetElement,
  CciReal                     value);

void cniSetElementTimestampValue(
  int*                        returnCode,
  CciElement*                 targetElement,
  const struct CciTimestamp* value);

void cniSetElementTimeValue(
  int*                        returnCode,
  CciElement*                 targetElement,
  const struct CciTime*       value);
```

Parameters:

returnCode

The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION

- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER
- CCI_INV_DATA_BUFLEN

targetElement
The address of the target syntax element object (input).

value
The value to store in the syntax element (input).

length
The length of the data value (input). Used on relevant function calls only.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
static char* functionName = (char *)"_Input_run()";
void* buffer;
CciTerminal* terminalObject;
int buflen = 4096;
int rc = CCI_SUCCESS;
int rcDispatch = CCI_SUCCESS;
char xmlData[] = "<A>data</a>";
buffer = malloc(buflen);
memcpy(buffer, &xmlData, sizeof(xmlData));

cniSetInputBuffer(&rc, message, buffer, buflen);
```

Use one or more of the functions in this group to retrieve the value of the specified syntax element.

"cniSetElementName" on page 6513
Use this function to set the name of the specified syntax element.

"cniSetElementType" on page 6515
Use this function to set the type of the specified syntax element.

"cniSetElementValueValue" on page 6519
Use this function to set the value object of the specified syntax element.

cniSetElementValueValue:

Use this function to set the value object of the specified syntax element.

Syntax:

```
void cniSetElementValueValue(
  int*              returnCode,
  CciElement*       targetElement,
  CciElementValue*  value);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER

targetElement
The address of the target syntax element object (input).

value
The address of a value object that is used to set the value of the syntax element specified by the *targetElement* parameter (input). You can get the address of the value object by calling cniElementValueValue.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Use one or more of the functions in this group to set the value of the specified syntax element.

cniSetInputBuffer:

Use this function to supply a buffer. It is used only by input nodes. The address is specified by the `source` parameter as an input bit stream of the input message to the broker.

By supplying a buffer, an input node can read data into the bit stream that represents an input message from an external data source. The broker takes a copy of the data and the caller can free the storage on return.

Syntax:

```
int cniSetInputBuffer(
  void*        returnCode,
  CciMessage*  message,
  Void*        source,
  CCiInt       length);
```

Parameters:

`returnCode`
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_MESSAGE_OBJECT
- CCI_INV_DATA_POINTER
- CCI_INV_DATA_BUFLEN

`message`
The message object that uses the buffer described by the *source* parameter to represent the input bit stream. (input)

`source`
The address of the buffer to be used as input. (input)

`length`
The length of the input buffer described by the *source* parameter. (input)

Return values:
None. If an error occurs, the*returnCode* parameter indicates the reason for the error.

Example:

```
cniSetInputBuffer(&rc, message, buffer, buflen);
```

Related concepts:

"User-defined input nodes" on page 2990
A user-defined input node is an extension to the broker that provides a new input node in addition to the nodes supplied with the product.

Related tasks:

"Creating an input node in C" on page 3027
Create a user-defined input node in C to receive messages into a message flow.

"C node utility functions" on page 6419
A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniBufferByte" on page 6426
Use this function to get a single byte from the data buffer associated with (and owned by) the message object specified in the message argument. The value of the index argument indicates which byte in the byte array is to be returned.

"cniBufferPointer" on page 6427
Use this function to get a pointer to the data buffer associated with (and owned by) the message object specified in the message argument. This function is typically used by output nodes.

"cniBufferSize" on page 6428
Use this function to get the size of the data buffer associated with (and owned by) the message object specified in the message argument.

"cniWriteBuffer" on page 6537
Use this function to write the syntax element tree associated with the specified message to the data buffer that is owned by the message object. This function is typically used by output nodes.

cniSqlCreateModifyablePathExpression:

Use this function to create an SqlPathExpression object that represents the path that is specified by the path argument. When they are navigated, path elements are created if they do not already exist. This function returns a pointer to the PathExpression object, which is used as input to the functions that navigate the path, namely the cniSqlNavigatePath family.

Because an overhead is incurred in creating the expression, if the same path expression is to be used for every message, call this function once, and use the CciSqlPathExpression* that is returned in a call to cniSqlNavigate for each message. You can use the CciSqlPathExpression on threads other than the one on which it was created.

Syntax:

```
CciSqlPathExpression* cniSqlCreateModifiablePathExpression(
 int* returnCode,
 CciNode* nodeObject,
 CciChar* dataSourceName,
 CciChar* path);
```

Parameters:

returnCode (output)
A NULL pointer input signifies that the user-defined node does not handle errors. Any exceptions that are thrown during the execution of this call are re-thrown to the next upstream node in the flow. If input is not NULL, output signifies the success status of the call. If an exception occurs during execution, *returnCode is set to CCI_EXCEPTION on output. Call cciGetLastExceptionData to retrieve details of the exception. If an invalid nodeObject parameter was passed in, *returnCode* is set to CCI_INV_NODE_OBJECT. If an invalid path parameter, such as NULL or an empty string, was passed in, *returnCode* is set to CCI_INV_ESQL_PATH_EXPR.

nodeObject (input)
Specifies the message flow processing node that the ESQL Path Expression is

owned by. This pointer is passed to the cniCreateNodeContext implementation function. This parameter must not be NULL.

dataSourceName (input)
The ODBC data source name to be used if the statement references an external database. This parameter can be NULL.

path (input)
Pointer to a NULL terminated string of CciChars. This parameter specifies the ESQL path expression to be created as defined by the ESQL field reference syntax diagram, except that it cannot include local ESQL variables, ESQL reference variables, user-defined functions, or ESQL namespace constants, because they cannot be declared. This parameter must not be NULL.

Return values:
If successful, the address of the SQLPathExpression object is returned. If an error occurs, CCI_NULL_ADDR is returned, and the return code parameter indicates the reason for the error. When the SQLPathExpression is no longer needed, (typically when the node is deleted) call cniSqlDeletePathExpression to delete it.

Example:
If you add the following code to the Transform node sample, you can create an element, and all necessary ancestor elements, with one function call.

Create the CciSQLPathExpression in the _Transform_createNodeContext function:

```
 {
        CciChar ucsPathExpressionString[32];
        char*   mbPathExpressionString =
                          "OutputRoot.XMLNS.Request.A.B.C.D.E";
        /* convert our path string to unicode*/
        cciMbsToUcs(NULL,
            mbPathExpressionString,
            ucsPathExpressionString,
            32,
            BIP_DEF_COMP_CCSID);

        p->pathExpression =
                     cniSqlCreateModifiablePathExpression(
                                 NULL,
                                 nodeObject,
                                 NULL,/* do not reference Database*/
                                 ucsPathExpressionString);
    }
```

Now use the CciSqlPathExpression later in the _Transform_evaluate function

```
{
      CciElement* newElement =
               cniSqlNavigatePath(
                     NULL,
                    ((NODE_CONTEXT_ST *)context)->pathExpression,
                     message,
                     localEnvironment,
                     exceptionList,
                     outMsg,
                     NULL,/* do not reference OutputLocalEnvironment*/
                     NULL/* do not reference OutputLExceptionList*/);
}
```

Therefore passing in the input message `PluginSample.change.xml`:

```
<Request
type="change">
  <CustomerAccount>01234567</CustomerAccount>
  <CustomerPhone>555-0000</CustomerPhone>
</Request>
```

The following output message is generated:

```
<Request
type="modify">
  <CustomerAccount>01234567</CustomerAccount>
  <CustomerPhone>555-0000</CustomerPhone>
  <A>
    <B>
      <C>
        <D/>
      </C>
    </B>
  </A>
</Request>
```

This approach, rather than using functions such as cniCreateElementAsLastChild, has the following advantages:

- The path is more dynamic: the path string could be determined at deploy time, for example based on a node property (you could create the CciSQLPathExpression in the cniSetAttribute implementation function).
- While navigating to and creating the element, only one function call is made. This technique is more apparent when the target element is deep within the tree structure.

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniCreateNodeContext" on page 6447
This function creates a context for an instance of a node object. It is called by the broker whenever an instance of a node object is constructed. Nodes are constructed when a message flow is deployed by the broker, or when the execution group is started.

"cniSqlDeleteStatement" on page 6530
Use this function to delete an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter.

"cniSqlExecute" on page 6531
Use this function to run an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter. Use this function when the statement does not return data, for example, when a PASSTHRU function is used.

"cniSqlSelect" on page 6535
Use this function to run an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter. If the statement returns data, the data is written into the message specified by the *outputMessage* parameter.

"cniSqlCreateReadOnlyPathExpression"
Use this function to create an SqlPathExpression object that represents the path that is specified by the path argument. The navigated path does not create path elements if they do not already exist. This function returns a pointer to the PathExpression object, which is used as input to the functions that navigate the path, namely the cniSqlNavigatePath family.

"cniSqlNavigatePath" on page 6532
Use this function to run the SQLPathExpression that you have created by calling the cniSqlCreateReadOnlyPathExpression or the cniSqlCreateModifiablePathExpression utility functions, as defined by the *sqlPathExpression* argument.

"cniSqlDeletePathExpression" on page 6529
Use this function to delete the SQLPathExpression that you have created by calling the cniSqlCreateReadOnlyPathExpression or the cniSqlCreateModifiablePathExpression utility functions, as defined by the *sqlPathExpression* argument.

cniSqlCreateReadOnlyPathExpression:

Use this function to create an SqlPathExpression object that represents the path that is specified by the path argument. The navigated path does not create path elements if they do not already exist. This function returns a pointer to the PathExpression object, which is used as input to the functions that navigate the path, namely the cniSqlNavigatePath family.

Because an overhead is incurred in creating the expression, if the same path expression is to be used for every message, call this function once, and use the CciSqlPathExpression* that is returned in a call to cniSqlNavigate for each message. You can use the CciSqlPathExpression* on threads other than the one on which it was created.

Syntax:

```
CciSqlPathExpression* cniSqlCreateReadOnlyPathExpression(
    int*     returnCode,
     CciNode* nodeObject,
     CciChar* dataSourceName,
     CciChar* path );
```

Parameters:

returnCode (output)
A NULL pointer input signifies that the user-defined node does not handle errors. Any exceptions thrown during the execution of this call are re-thrown to the next upstream node in the flow. If input is not NULL, output signifies the success status of the call. If an exception occurs during execution, *returnCode is set to CCI_EXCEPTION on output. A call to

cciGetLastExceptionData provides details of the exception. If an invalid nodeObject parameter was passed in, returnCode is set to CCI_INV_NODE_OBJECT. If an invalid path parameter, such as a NULL or empty string, was passed in, returnCode is set to CCI_INV_ESQL_PATH_EXPR.

nodeObject (input)
Specifies the message flow processing node that owns the ESQL Path Expression. This pointer is passed to the cniCreateNodeContext implementation function. This parameter must not be NULL.

dataSourceName (input)
The ODBC data source name that is used if the statement references an external database. NULL is allowed.

path (input)
Pointer to a NULL terminated string of CciChars. This parameter specifies the ESQL path expression to be created, as defined by the ESQL field reference syntax diagram. It cannot include local ESQL variables, ESQL reference variables, user-defined functions, or ESQL namespace constants, because they cannot be declared. This parameter must not be NULL.

Return values:
If successful, the address of the SQLPathExpression object is returned. If an error occurs, CCI_NULL_ADDR is returned and the return code parameter indicates the reason for the error. When the SQLPathExpression is no longer needed (typically when the node is deleted), call cniSqlDeletePathExpression to delete it.

Example:
The switch node sample shows how to navigate to a syntax element using functions like cniFirstChild. The following code could be used to achieve the same result.

In _Switch_createNodeContext function, create the CciSqlPathExpression for use later.

```
{
        CciChar ucsPathExpressionString[32];
        char*   mbPathExpressionString = "InputBody.Request.type";
        /* convert our path string to unicode*/
        cciMbsToUcs(
                  NULL,
                  mbPathExpressionString,
                  ucsPathExpressionString,
                  32,
                  BIP_DEF_COMP_CCSID);

        p->pathExpression =
                    cniSqlCreateReadOnlyPathExpression(
                            NULL,
                            nodeObject,
                            NULL, /* do not reference Database*/
                            ucsPathExpressionString);
}
```

This code assumes the addition of the field CciSqlPathExpression* pathExpression to the NODE_CONTEXT_ST struct.

Now use the CciSqlPathExpression in the _Switch_evaluate function.

```
CciElement* targetElement = cniSqlNavigatePath(
                             NULL,
                            ((NODE_CONTEXT_ST *)context)->pathExpression,
                             message,
                             localEnvironment,
                             exceptionList,
                             NULL, /* do not reference any output trees*/
                             NULL,
                             NULL);
```

This approach, rather than using functions such as cniFirstChild and cniNextSibling, has the following advantages:

- The path is more dynamic: the path string could be determined at deploy time based on a node property (you could create the CciSqlPathExpression in the cniSetAttribute implementation function).
- While navigating to the element, only one function call is made. This technique is more apparent when the target element is deep within the tree structure.

Use this function to run an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter. If the statement returns data, the data is written into the message specified by the *outputMessage* parameter.

"cniSqlCreateModifyablePathExpression" on page 6521
Use this function to create an SqlPathExpression object that represents the path that is specified by the path argument. When they are navigated, path elements are created if they do not already exist. This function returns a pointer to the PathExpression object, which is used as input to the functions that navigate the path, namely the cniSqlNavigatePath family.

"cniSqlNavigatePath" on page 6532
Use this function to run the SQLPathExpression that you have created by calling the cniSqlCreateReadOnlyPathExpression or the cniSqlCreateModifiablePathExpression utility functions, as defined by the *sqlPathExpression* argument.

"cniSqlDeletePathExpression" on page 6529
Use this function to delete the SQLPathExpression that you have created by calling the cniSqlCreateReadOnlyPathExpression or the cniSqlCreateModifiablePathExpression utility functions, as defined by the *sqlPathExpression* argument.

cniSqlCreateStatement:

Use this function to create an ESQL expression object that represents the statement specified by the statement argument, by using the syntax defined for the Compute node.

You cannot use the following statements:

- CREATE PROCEDURE
- CREATE MODULE
- CREATE SCHEMA
- CREATE FUNCTION

This function returns a pointer to the SQL expression object, which is used as input to the functions that execute the statement, which are cniSqlExecute and cniSqlSelect. You can create multiple SQL expression objects in a single message flow node. Although you can create these objects at any time, you would typically create them when the message flow node is instantiated, within the implementation function cniCreateNodeContext.

Syntax:

```
CciSqlExpression* cniSqlCreateStatement(
  int*               returnCode,
  CciNode*           nodeObject,
  CciChar*           dataSourceName,
  CciSqlTransaction  transaction,
  CciChar*           statement);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_NODE_OBJECT
- CCI_INV_TRANSACTION_TYPE
- CCI_INV_STATEMENT

nodeObject
The message flow processing node that the SQL expression object is owned by (input). This pointer is passed to the cniCreateNodeContext implementation function.

dataSourceName
The ODBC data source name used if the statement references data in an external database (input).

transaction
Specifies whether a database commit is performed after the statement is executed (input). Valid values are:

CCI_SQL_TRANSACTION_AUTO
Specifies that a database commit is performed at the completion of the message flow (that is, as a fully globally coordinated or partially globally coordinated transaction). This value is the default.

CCI_SQL_TRANSACTION_COMMIT
Specifies that a commit is performed after execution of the statement, and in the cniSqlExecute or cniSqlSelect function (that is, the message flow is partially broker coordinated).

statement
The SQL expression to be created, using the syntax as defined for the Compute node (input).

Return values:
If successful, the address of the SQL expression object is returned. If an error occurs, zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

"C node utility functions" on page 6419
A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniCreateNodeContext" on page 6447
This function creates a context for an instance of a node object. It is called by the broker whenever an instance of a node object is constructed. Nodes are constructed when a message flow is deployed by the broker, or when the execution group is started.

"cniSqlDeleteStatement" on page 6530
Use this function to delete an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter.

"cniSqlExecute" on page 6531
Use this function to run an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter. Use this function when the statement does not return data, for example, when a PASSTHRU function is used.

"cniSqlSelect" on page 6535
Use this function to run an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter. If the statement returns data, the data is written into the message specified by the *outputMessage* parameter.

cniSqlDeletePathExpression:

Use this function to delete the SQLPathExpression that you have created by calling the cniSqlCreateReadOnlyPathExpression or the cniSqlCreateModifiablePathExpression utility functions, as defined by the *sqlPathExpression* argument.

Syntax:

```
void cniSqlDeletePathExpression(
        int*                  returnCode,
        CciSqlPathExpression* sqlPathExpression );
```

Parameters:

returnCode (output)
A NULL pointer input signifies that the user-defined node does not want to deal with errors. All exceptions thrown during the execution of this call are re-thrown to the next upstream node in the flow. If input is not NULL, output signifies the success status of the call. If an exception occurs during execution, *returnCode is set to CCI_EXCEPTION on output. Call cciGetLastExceptionData to get details of the exception. If an invalid *sqlPathExpression* parameter is passed in, *returnCode* is set to CCI_INV_SQL_EXPR_OBJECT.

sqlPathExpression (output)
Specifies the *SQLPathExpression* object to be deleted as returned by either cniCreateModifiablePathExpression or cniCreateReadOnlyPathExpression functions. Tyhis parameter cannot be NULL.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error..

Example:
Expanding on the example for cniSqlCreateReadOnlyPathExpression, include the following code in _deleteNodeContext.

```
cniSqlDeletePathExpression(
                    NULL,
                    ((NODE_CONTEXT_ST *)context)->pathExpression);
```

"cniSqlSelect" on page 6535
Use this function to run an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter. If the statement returns data, the data is written into the message specified by the *outputMessage* parameter.

cniSqlDeleteStatement:

Use this function to delete an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter.

Syntax:

```
void cniSqlDeleteStatement(
  int*               returnCode,
  CciSqlExpression*  sqlExpression);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CC_INV_SQL_EXPR_OBJECT

sqlExpression
The SQL expression object to be deleted, as returned by the cniSqlCreateStatement utility function (input).

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniSqlCreateStatement" on page 6527
Use this function to create an ESQL expression object that represents the statement specified by the statement argument, by using the syntax defined for the Compute node.

"cniSqlExecute"
Use this function to run an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter. Use this function when the statement does not return data, for example, when a PASSTHRU function is used.

"cniSqlSelect" on page 6535
Use this function to run an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter. If the statement returns data, the data is written into the message specified by the *outputMessage* parameter.

cniSqlExecute:

Use this function to run an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter. Use this function when the statement does not return data, for example, when a PASSTHRU function is used.

Syntax:

```
void cniSqlExecute(
  int*               returnCode,
  CciSqlExpression*  sqlExpression,
  CciMessage*        localEnvironment,
  CciMessage*        exceptionList,
  CciMessage*        message);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_INV_SQL_EXPR_OBJECT

- CCI_INV_MESSAGE_OBJECT

sqlExpression
The SQL expression object to be executed, as returned by the cniSqlCreateStatement utility function (input).

localEnvironment
The message representing the input local environment (input).

For compatibility with earlier versions, you can refer to this parameter as `destinationList`.

exceptionList
The message representing the input exception list (input).

message
The message representing the input message (input).

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

"cniSqlSelect" on page 6535
Use this function to run an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter. If the statement returns data, the data is written into the message specified by the *outputMessage* parameter.

cniSqlNavigatePath:

Use this function to run the SQLPathExpression that you have created by calling the cniSqlCreateReadOnlyPathExpression or the cniSqlCreateModifiablePathExpression utility functions, as defined by the *sqlPathExpression* argument.

Syntax:

```
CciElement* cniSqlNavigatePath(
 int*                  returnCode,
 CciSqlPathExpression* sqlPathExpression,
 CciMessage*           inputMessageRoot,
 CciMessage*           inputLocalEnvironment,
 CciMessage*           inputExceptionList,
 CciMessage*           outputMessageRoot
 CciMessage*           outputLocalEnvironment,
 CciMessage*           outputExceptionList);
```

Parameters:

returnCode (output)
A NULL pointer input signifies that the user-defined node does not handle errors. Any exceptions that are thrown during the execution of this call are re-thrown to the next upstream node in the flow. If input is not NULL, output signifies the success status of the call. If an exception occurs during execution, *returnCode is set to CCI_EXCEPTION on output. A call to cciGetLastExceptionData provides details of the exception. If an invalid *sqlPathExpression* parameter was passed in, *returnCode* is set to CCI_INV_SQL_EXPR_OBJECT. If an invalid CciMessage* value is passed in, *returnCode* is set to CCI_INV_MESSAGE_OBJECT. If the element could not be navigated to or created, *returnCode* is set to CCI_PATH_NOT_NAVIGABLE.

sqlPathExpression (input)
Specifies the SQLPathExpression object to be executed as returned by either the cniCreateReadOnlyPathExpression or the cniCreateModifyablePathExpression function. This parameter cannot be NULL.

inputMessageRoot (input)
The message representing the input message. This parameter cannot be NULL.

inputLocalEnvironment (input)
The message representing the input local environment. This parameter cannot be NULL.

inputExceptionList (input)
The message representing the input exception list. This parameter cannot be NULL.

outputMessageRoot (input)
The message representing the output message. This parameter can be NULL.

outputLocalEnvironment (input)
The message representing the output local environment. This parameter can be NULL.

outputExceptionList (input)
The message representing the output exception list. This parameter can be NULL.

The following table shows the mapping between the correlation names accepted in the ESQL path expression and the data that is accessed.

Correlation name	Data accessed
Environment	The single Environment tree for the flow. This element is determined by the broker and it is not necessary to specify it with this API.
InputLocalEnvironment	inputLocalEnvironment parameter to cniSqlNavigatePath

Correlation name	Data accessed
OutputLocalEnvironment	outputLocalEnvironment parameter to cniSqlNavigatePath
InputRoot	inputMessageRoot parameter to cniSqlNavigatePath
InputBody	Last child of InputRoot
InputProperties	InputRoot.Properties (InputRoot.Properties is the first child of InputRoot, named "Properties")
OutputRoot	outputMessageRoot parameter to cniSqlNavigatePath
InputExceptionList	inputExceptionList parameter to cniSqlNavigatePath
OutputExceptionList	outputExceptionList parameter to cniSqlNavigatePath
Database	ODBC datasource identified by dataSourceName parameter to cniCreateReadOnlyPathExpression or cniCreateModifyablePathExpression
InputDestinationList	Synonym for InputLocalEnvironment that is compatible with earlier versions
OutputDestinationList	Synonym for OutputLocalEnvironment that is compatible with earlier versions

All other rules regarding the actual navigability and validity of paths are defined in "Correlation names" on page 1069.

Return values:
If the path is navigated successfully, the address of the syntax element is returned. However, if the path is not navigable, a value of zero (CCI_NULL_ADDR) is returned, and the *returnCode* parameter indicates the reason for the error.

Example:
Assuming that you have previously created a SQLPathExpression (see the example for cniSqlCreateReadOnlyPathExpression or cniSqlCreateModifiablePathExpression), you could use the following code to navigate to the target element.

```
CciElement* targetElement = cniSqlNavigatePath(
                            NULL,
                           ((NODE_CONTEXT_ST *)context)->pathExpression,
                            message,
                            localEnvironment,
                            exceptionList,
                            NULL, /* do not reference any output trees*/
                            NULL,
                            NULL);
```

This function creates a context for an instance of a node object. It is called by the broker whenever an instance of a node object is constructed. Nodes are constructed when a message flow is deployed by the broker, or when the execution group is started.

"cniSqlDeleteStatement" on page 6530
Use this function to delete an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter.

"cniSqlExecute" on page 6531
Use this function to run an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter. Use this function when the statement does not return data, for example, when a PASSTHRU function is used.

"cniSqlSelect"
Use this function to run an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter. If the statement returns data, the data is written into the message specified by the *outputMessage* parameter.

"cniSqlCreateReadOnlyPathExpression" on page 6524
Use this function to create an SqlPathExpression object that represents the path that is specified by the path argument. The navigated path does not create path elements if they do not already exist. This function returns a pointer to the PathExpression object, which is used as input to the functions that navigate the path, namely the cniSqlNavigatePath family.

"cniSqlCreateModifyablePathExpression" on page 6521
Use this function to create an SqlPathExpression object that represents the path that is specified by the path argument. When they are navigated, path elements are created if they do not already exist. This function returns a pointer to the PathExpression object, which is used as input to the functions that navigate the path, namely the cniSqlNavigatePath family.

"cniSqlDeletePathExpression" on page 6529
Use this function to delete the SQLPathExpression that you have created by calling the cniSqlCreateReadOnlyPathExpression or the cniSqlCreateModifiablePathExpression utility functions, as defined by the *sqlPathExpression* argument.

cniSqlSelect:

Use this function to run an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter. If the statement returns data, the data is written into the message specified by the *outputMessage* parameter.

Syntax:

```
void cniSqlSelect(
  int*               returnCode,
  CciSqlExpression*  sqlExpression,
  CciMessage*        localEnvironment,
  CciMessage*        exceptionList,
  CciMessage*        message,
  CciMessage*        outputMessage);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_SQL_EXPR_OBJECT
- CCI_INV_MESSAGE_OBJECT

sqlExpression
The SQL expression object to be executed, as returned by the cniSqlCreateStatement utility function (input).

localEnvironment
The message representing the input local environment (input).

For compatibility with earlier versions, you can refer to this parameter as `destinationList`.

exceptionList
The message representing the input exception list (input).

message
The message representing the input message (input).

outputMessage
The message into which any data returned by the statement is written (output).

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Related concepts:

"cniSqlExecute" on page 6531
Use this function to run an SQL statement that you have created by using the cniSqlCreateStatement utility function, as defined by the *sqlExpression* parameter. Use this function when the statement does not return data, for example, when a PASSTHRU function is used.

cniWriteBuffer:

Use this function to write the syntax element tree associated with the specified message to the data buffer that is owned by the message object. This function is typically used by output nodes.

This operation serializes the element tree into a bit stream that can then be processed as a sequence of contiguous bytes. This function should be used when writing the bit stream to a target that is outside the broker.

You must call cniFinalize before this call, or cniWriteBuffer fails.

Syntax:

```
void cniWriteBuffer(
  int*         returnCode,
  CciMessage*  message);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_MESSAGE_OBJECT

message
The address of the message object for which the element tree is to be serialized (input).

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
cniCopyElementTree(&rc, inLastChild, outLastChild);
cniFinalize(&rc, outMessage);
cniWriteBuffer(&rc, outMessage);
```

Related concepts:

A user-defined node created in the C programming language can create or define broker objects, such as node factories, nodes, and terminals by using system-provided functions.

"cniBufferByte" on page 6426
Use this function to get a single byte from the data buffer associated with (and owned by) the message object specified in the message argument. The value of the index argument indicates which byte in the byte array is to be returned.

"cniBufferPointer" on page 6427
Use this function to get a pointer to the data buffer associated with (and owned by) the message object specified in the message argument. This function is typically used by output nodes.

"cniBufferSize" on page 6428
Use this function to get the size of the data buffer associated with (and owned by) the message object specified in the message argument.

"cniFinalize" on page 6479
Use this function to cause the broker to request parsers to perform finalize processing on the specified message. Finalization is a process that fixes header chains and makes the Properties folder match the headers.

"cniSetInputBuffer" on page 6520
Use this function to supply a buffer. It is used only by input nodes. The address is specified by the `source` parameter as an input bit stream of the input message to the broker.

C language user-defined parser API

The C language user-defined parser API consists of two complementary sets of functions that you can use to define the function of your parser.

The two sets of functions are:

1. A set of implementation functions that provide the functionality of the user-defined parser. These functions are called by the broker. Most implementation functions are mandatory and, if not supplied by the developer, cause an exception at run time.
2. A set of utility functions that create resources in the broker or request a service of the broker. These utility functions can be called by a user-defined parser.

These functions are defined in the `BipCpi.h` header file.

This section covers the following topics:

- "C parser implementation functions."
- "C parser utility functions" on page 6539.

C parser implementation functions:

A user-defined parser implements its capability through a function interface which is called by the broker during runtime operation. This interface includes functions to create and delete all local context storage that is associated with a parser object and the parsing operations.

Some implementation functions are mandatory, and must be implemented when you develop your own parser. Other functions are optional, or conditional.

Mandatory functions

- "cpiCreateContext" on page 6553

- "cpiParseNextSibling" on page 6588
- "cpiParsePreviousSibling" on page 6590
- "cpiParseFirstChild" on page 6586
- "cpiParseLastChild" on page 6587

Optional and conditional functions

- "cpiDeleteContext" on page 6559
- "cpiElementValue" on page 6566
- "cpiNextParserClassName" on page 6573
- "cpiNextParserCodedCharSetId" on page 6574
- "cpiNextParserEncoding" on page 6576
- "cpiParseBuffer" on page 6580
- "cpiParseBufferEncoded" on page 6582
- "cpiParseBufferFormatted" on page 6583
- "cpiParserType" on page 6591
- "cpiSetElementValue" on page 6602

- "cpiWriteBuffer" on page 6610
- "cpiWriteBufferEncoded" on page 6612
- "cpiWriteBufferFormatted" on page 6613

C parser utility functions:

A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

These system-provided functions relate to different types of operation of the parser:

Initialization and resource creation

- "cpiCreateParserFactory" on page 6555
- "cpiDefineParserClass" on page 6557

Message buffer access

- "cpiAppendToBuffer" on page 6545

- "cpiSetElementValue group" on page 6604
- "cpiSetElementValueValue" on page 6606
- "cpiSetNameFromBuffer" on page 6607

cpiAddAfter:

This function adds a new (and currently unattached) syntax element to the syntax element tree after the specified target element. The newly added element becomes the *next sibling* of the target element.

Syntax

```
void cpiAddAfter(
  int*         returnCode,
  CciElement*  targetElement,
  CciElement*  newElement);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
Specifies the address of the target syntax element object (input).

newElement
Specifies the address of the new syntax element object that is to be added to the tree structure (input).

Return values

None. If an error occurs, *returnCode* indicates the reason for the error.

Sample

```
void cpiSetElementValue(
  CciParser*       parser,
  CciElement*      element,
  CciElementValue* value
){
  CciElement* newElement;
  int         rc;

  if ((cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_VALUE) ||
      (cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_NAME_VALUE))  {
    cpiSetElementValueValue(&rc, element, value);
  }
  else if (cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_NAME) {
    /* Create a new value element, add after the current value element,
   and set the value */
    newElement = cpiCreateElement(&rc, parser);
    cpiSetElementType(&rc, newElement, CCI_ELEMENT_TYPE_VALUE);
    cpiSetElementValueValue(&rc, newElement, value);
    cpiAddAfter(&rc, element, newElement);
  }
  else {
  }

  return;
}
```

A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiAddAsFirstChild:

This function adds a new (and currently unattached) syntax element to the syntax element tree as the first child of the specified target element.

Syntax

```
void cpiAddAsFirstChild(
  int*         returnCode,
  CciElement*  targetElement,
  CciElement*  newElement);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
Specifies the address of the target syntax element object (input).

newElement
Specifies the address of the new syntax element object that is to be added to the tree structure (input).

Return values

None. If an error occurs, *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
void cpiSetElementValue(
  CciParser*       parser,
  CciElement*      element,
  CciElementValue* value
){
  CciElement* newElement;
  int         rc;

  if ((cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_VALUE) ||
      (cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_NAME_VALUE))  {
    cpiSetElementValueValue(&rc, element, value);
  }
  else if (cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_NAME) {
    /* Create a new value element, add as a first child, and set the value */
    newElement = cpiCreateElement(&rc, parser);
    cpiSetElementType(&rc, newElement, CCI_ELEMENT_TYPE_VALUE);
    cpiSetElementValueValue(&rc, newElement, value);
    cpiAddAsFirstChild(&rc, element, newElement);
  }
  else {
  }

  return;
}
```

A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiAddAsLastChild:

This function adds a new (and currently unattached) syntax element to the syntax element tree as the last child of the specified target element.

Syntax

```
void cpiAddAsLastChild(
  int*         returnCode,
  CciElement*  targetElement,
  CciElement*  newElement);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
Specifies the address of the target syntax element object (input).

newElement
Specifies the address of the new syntax element object that is to be added to the tree structure (input).

Return values

None. If an error occurs, *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
/* Convert the attribute value into broker form */
          data = CciNString((char *)startMarker, markedSize, pc->iCcsid);

/* Create a new name-value element for the attribute */
          newElement = cpiCreateElement(&rc, parser);
          cpiSetElementType(&rc, newElement, CCI_ELEMENT_TYPE_NAME_VALUE);
          cpiSetElementName(&rc, newElement, data);

          /* Free the memory created in CciNString() */
          free((void *)data);

          /* Add the element */
          cpiAddAsLastChild(&rc, element, newElement);
```

A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiAppendToBuffer:

This function appends data to the buffer containing the bit stream representation of a message, for the specified parser object.

Syntax

```
void cpiAppendToBuffer(
  int*        returnCode,
  CciParser*  parser,
  CciByte*    data,
  CciSize     length);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_PARSER_OBJECT
- CCI_INV_DATA_POINTER
- CCI_INV_LENGTH

parser
Specifies the address of the parser object (input).

data
The address of the data to be appended to the buffer (input).

length
The size in bytes of the data to be appended to the buffer (input).

Return values

None. If an error occurs, *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
cpiAppendToBuffer(&rc, parser, (char *)"Some test data", 14);
```

cpiBufferByte:

This function gets a single byte from the buffer containing the bit stream representation of the input message, for the specified parser object. The value of the index argument indicates which byte in the byte array is to be returned.

Syntax

```
CciByte cpiBufferByte(
  int*        returnCode,
  CciParser*  parser,
  CciSize     index);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_PARSER_OBJECT
- CCI_NO_BUFFER_EXISTS

parser
Specifies the address of the parser object (input).

index
Specifies the offset to use as an index into the buffer (input).

Return values

The requested byte is returned. If an error occurs, *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
void advance(
  PARSER_CONTEXT_ST* context,
  CciParser*         parser
){
  int rc = 0;

  /* Advance to the next character */
  context->iIndex++;

  /* Detect and handle the end condition */
  if (context->iIndex == context->iSize) return;
```

```
  /* Obtain the next character from the buffer */
  context->iCurrentCharacter = cpiBufferByte(&rc, parser, context->iIndex);
}
```

cpiBufferPointer:

This function gets a pointer to the buffer containing the bit stream representation of the input message, for the specified parser object.

Syntax

```
const CciByte* cpiBufferPointer(
  int*        returnCode,
  CciParser*  parser);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_PARSER_OBJECT
- CCI_NO_BUFFER_EXISTS

parser
Specifies the address of the parser object (input).

Return values

If successful, the address of the buffer is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned, and *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
int cpiParseBufferEncoded(
  CciParser*  parser,
  CciContext* context,
  int         encoding,
  int         ccsid
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;

cpiCreateAndInitializeElement:

This function creates a syntax element, owned by the specified parser, that is not attached to a syntax tree. The element is partially initialized with the values of the *type*, *name*, *firstChildComplete*, and *lastChildComplete* parameters.

Syntax

```
CciElement* cpiCreateAndInitializeElement(
  int*            returnCode,
  CciParser*      parser,
  CciElementType  type,
  const CciChar*  name,
  CciBool         firstChildComplete,
  CciBool         lastChildComplete);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_FAILURE
- CCI_INV_PARSER_OBJECT

parser
Specifies the address of the parser object (input). This address is passed to the parser as a parameter of the cpiCreateContext implementation function.

type
Specifies the type of the element being created (input).

name
Specifies a descriptive name for the element (input).

firstChildComplete
Specifies a value for the firstChildComplete flag of the syntax element (input).

lastChildComplete
Specifies a value for the lastChildComplete flag of the syntax element (input).

Return values

If successful, the address of the new element object is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned, and *returnCode* indicates the reason for the error.

Sample

```
/* Advance to the end of the value */
          while (pc->iCurrentCharacter != quoteChar) {
            advance( (PARSER_CONTEXT_ST *)context, parser );
          }

          /* Get a pointer to the end of the tag */
          endMarker = (char*)pc->iBuffer+(int)pc->iIndex;

          /* Compute the size of the tag */
          markedSize = (size_t)endMarker-(int)startMarker;

          /* Convert the attribute value into broker form */
          data = CciNString((char *)startMarker, markedSize, pc->iCcsid);

          /* Create a new name-value element for the attribute */
          newElement = cpiCreateAndInitializeElement(&rc, parser, type, name);
          cpiSetElementType(&rc, newElement, CCI_ELEMENT_TYPE_NAME_VALUE);
          cpiSetElementName(&rc, newElement, data);
          if (pc->trace) {
            const char * mbData = mbString(data, pc->iCcsid);
            fprintf(pc->tracefile, "PLUGIN: Created new NAMEVALUE element;
                    object=0x%x type=0x%x name=",
                    newElement, CCI_ELEMENT_TYPE_NAME_VALUE);
            fprintf(pc->tracefile, "%s\n", mbData);
            fflush(pc->tracefile);
            free((void *)mbData);
          }
          /* Free the memory created in CciNString() */

"cpiCreateElement" on page 6554
This function creates a default syntax element that is not attached to a syntax tree. The element is owned by the specified parser. The element is incomplete in that none of its attributes (such as type or name) are set.

"C parser utility functions" on page 6539
A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiCreateContext:

This function creates a user-defined extension context associated with a parser object. It is called by the broker when an instance of a parser object is constructed or allocated. This action occurs when a message flow causes the message data to be parsed; the broker constructs or allocates a parser object to acquire the appropriate section of the message data.

Before this function is called, the broker creates a name element as the effective root element for the parser. However, this element is not named. The parser must name this element in the cpiSetElementName function.

The responsibilities of the extension are to:

1. Allocate all parser-instance specific data areas (such as context) that might be required.
2. Perform all additional resource acquisition or initialization that might be required.
3. Return the address of the context to the calling function. Whenever an implementation function for this parser instance is called, the appropriate context is passed as an argument to that function. Therefore, a user-defined parser developed in C need not maintain its own static pointers to per-instance data areas.

Defined In	Type	Member
CPI_VFT	Mandatory	iFpCreateContext

Syntax

```
void cpiCreateContext(
  CciParser*   parser);
```

Parameters

parser
The address of the parser object (input).

Return values

If successful, the address of the user-defined extension context is returned. Otherwise, a value of zero is returned.

Related concepts:

"User-defined parsers" on page 3010
A user-defined parser is a program that interprets the bit stream of an incoming message and creates an internal representation of the message in a tree structure. A user-defined parser can also regenerate a bit stream for an outgoing message from the internal message tree representation

"C parser implementation functions" on page 6538
A user-defined parser implements its capability through a function interface which is called by the broker during runtime operation. This interface includes functions to create and delete all local context storage that is associated with a parser object and the parsing operations.

cpiCreateElement:

This function creates a default syntax element that is not attached to a syntax tree. The element is owned by the specified parser. The element is incomplete in that none of its attributes (such as type or name) are set.

Syntax

```
CciElement* cpiCreateElement(
  int*        returnCode,
  CciParser*  parser);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_FAILURE
- CCI_INV_PARSER_OBJECT

parser
Specifies the address of the parser object (input).

Return values

If successful, the address of the new element object is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned, and *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
/* Advance to the end of the value */
          while (pc->iCurrentCharacter != quoteChar) {
            advance( (PARSER_CONTEXT_ST *)context, parser );
          }

          /* Get a pointer to the end of the tag */
          endMarker = (char*)pc->iBuffer+(int)pc->iIndex;

          /* Compute the size of the tag */
          markedSize = (size_t)endMarker-(int)startMarker;

          /* Convert the attribute value into broker form */
          data = CciNString((char *)startMarker, markedSize, pc->iCcsid);

          /* Create a new name-value element for the attribute */
          newElement = cpiCreateElement(&rc, parser);
          cpiSetElementType(&rc, newElement, CCI_ELEMENT_TYPE_NAME_VALUE);
          cpiSetElementName(&rc, newElement, data);
          if (pc->trace) {
            const char * mbData = mbString(data, pc->iCcsid);
```

```
    fprintf(pc->tracefile, "PLUGIN: Created new NAMEVALUE element;
            object=0x%x type=0x%x name=",
            newElement, CCI_ELEMENT_TYPE_NAME_VALUE);
    fprintf(pc->tracefile, "%s\n", mbData);
    fflush(pc->tracefile);
    free((void *)mbData);
  }
  /* Free the memory created in CciNString() */
  free((void *)data);
```

A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiCreateParserFactory:

This function creates a single instance of the named parser factory in the broker.

Purpose

It must be called only in the initialization function bipGetParserFactory, which is called when the LIL file is loaded by the broker. If cpiCreateParserFactory is called at a later time, the results are unpredictable.

Syntax

```
CciFactory* cpiCreateParserFactory(
  int*      returnCode,
  CciChar*  name);
```

Parameters

returnCode

Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_FAILURE
- CCI_INV_FACTORY_NAME

- CCI_INV_OBJECT_NAME

name
Specifies the name of the factory being created (input).

Return values

If successful, the address of the parser factory object is returned. Otherwise, a value of zero (CCI_NULL_ADDR) is returned, and *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
void LilFactoryExportPrefix * LilFactoryExportSuffix bipGetParserFactory()
{
  /* Declare variables */
  CciFactory*     factoryObject;
  int             rc;
  static CPI_VFT  vftable = {CPI_VFT_DEFAULT};

  /* Before we proceed we need to initialise all the static constants */
  /* that may be used by the plug-in.                                 */
  initParserConstants();

  /* Setup function table with pointers to parser implementation functions */
  vftable.iFpCreateContext            = cpiCreateContext;
  vftable.iFpParseBufferEncoded       = cpiParseBufferEncoded;
  vftable.iFpParseFirstChild          = cpiParseFirstChild;
  vftable.iFpParseLastChild           = cpiParseLastChild;
  vftable.iFpParsePreviousSibling     = cpiParsePreviousSibling;
  vftable.iFpParseNextSibling         = cpiParseNextSibling;
  vftable.iFpWriteBufferEncoded       = cpiWriteBufferEncoded;
  vftable.iFpDeleteContext            = cpiDeleteContext;
  vftable.iFpSetElementValue          = cpiSetElementValue;
  vftable.iFpElementValue             = cpiElementValue;
  vftable.iFpNextParserClassName      = cpiNextParserClassName;
  vftable.iFpSetNextParserClassName   = cpiSetNextParserClassName;
  vftable.iFpNextParserEncoding       = cpiNextParserEncoding;
  vftable.iFpNextParserCodedCharSetId = cpiNextParserCodedCharSetId;

  /* Create the parser factory for this plugin */
  factoryObject = cpiCreateParserFactory(&rc, constParserFactory);
  if (factoryObject) {
    /* Define the classes of message supported by the factory */
    cpiDefineParserClass(&rc, factoryObject, constPXML, &vftable);
  }
  else {
    /* Error: Unable to create parser factory */
  }

  /* Return address of this factory object to the broker */
  return(factoryObject);
}
```

A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiDefineParserClass:

This function defines the name of a parser class that is supported by a parser factory.

functbl is a pointer to a virtual function table that contains pointers to the C implementation functions; that is, those functions that provide the function of the parser itself.

Syntax

```
void cpiDefineParserClass(
  int*         returnCode,
  CciFactory*  factoryObject,
  CciChar*     name,
  CPI_VFT*     functbl);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_FACTORY_OBJECT
- CCI_INV_PARSER_NAME
- CCI_PARSER_NAME_TOO_LONG
- CCI_INV_OBJECT_NAME
- CCI_INV_VFTP
- CCI_MISSING_IMPL_FUNCTION
- CCI_INV_IMPL_FUNCTION
- CCI_NAME_EXISTS

factoryObject
Specifies the address of the factory object that supports the named parser (input). The address is returned from **cpiCreateParserFactory**.

name
The name of the parser class to be defined (input). The maximum length of a parser class name is 8 characters.

functbl
The address of the CPI_VFT structure that contains pointers to the implementation functions (input).

Return values

None. If an error occurs, *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample parser file BipSampPluginParser.c:

```
void LilFactoryExportPrefix * LilFactoryExportSuffix bipGetParserFactory()
{
  /* Declare variables */
  CciFactory*     factoryObject;
  int             rc;
  static CPI_VFT  vftable = {CPI_VFT_DEFAULT};

  /* Before we proceed we need to initialise all the static constants */
  /* that may be used by the plug-in.                                 */
  initParserConstants();

  /* Setup function table with pointers to parser implementation functions */
  vftable.iFpCreateContext            = cpiCreateContext;
  vftable.iFpParseBufferEncoded       = cpiParseBufferEncoded;
  vftable.iFpParseFirstChild          = cpiParseFirstChild;
  vftable.iFpParseLastChild           = cpiParseLastChild;
  vftable.iFpParsePreviousSibling     = cpiParsePreviousSibling;
  vftable.iFpParseNextSibling         = cpiParseNextSibling;
  vftable.iFpWriteBufferEncoded       = cpiWriteBufferEncoded;
  vftable.iFpDeleteContext            = cpiDeleteContext;
  vftable.iFpSetElementValue          = cpiSetElementValue;
  vftable.iFpElementValue             = cpiElementValue;
  vftable.iFpNextParserClassName      = cpiNextParserClassName;
  vftable.iFpSetNextParserClassName   = cpiSetNextParserClassName;
  vftable.iFpNextParserEncoding       = cpiNextParserEncoding;
  vftable.iFpNextParserCodedCharSetId = cpiNextParserCodedCharSetId;

  /* Create the parser factory for this plugin */
  factoryObject = cpiCreateParserFactory(&rc, constParserFactory);
  if (factoryObject) {
    /* Define the classes of message supported by the factory */
    cpiDefineParserClass(&rc, factoryObject, constPXML, &vftable);
  }
  else {
    /* Error: Unable to create parser factory */
  }

  /* Return address of this factory object to the broker */
  return(factoryObject);
}
```

This function creates a single instance of the named parser factory in the broker.

"C parser utility functions" on page 6539
A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiDeleteContext:

This function deletes the context owned by the parser object. It is invoked by the message broker when an instance of a parser object is destroyed.

The responsibilities of the parser are to:

1. Release all parser-instance specific data areas (such as context) that were acquired at construction or during parser processing.
2. Release all additional resources that might have been acquired for the processing of the parser.

Defined In	Type	Member
CPI_VFT	Optional	iFpDeleteContext

Syntax

```
void cpiDeleteContext(
  CciParser*   parser,
  CciContext*  context);
```

Parameters

parser
The address of the parser object (input).

context
The address of the context owned by the parser object (input).

Return values

None.

Related concepts:

"User-defined parsers" on page 3010
A user-defined parser is a program that interprets the bit stream of an incoming message and creates an internal representation of the message in a tree structure. A user-defined parser can also regenerate a bit stream for an outgoing message from the internal message tree representation

cpiElementCompleteNext:

This function gets the value of the 'next child complete' flag from the target syntax element. This attribute indicates whether the element tree is complete.

Syntax

```
CciBool cpiElementCompleteNext(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
Specifies the address of the target syntax element object (input).

Return values

The value of the attribute is returned. If an error occurs, *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
if ((!cpiElementCompleteNext(&rc, element)) &&
      (cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_NAME)) {

    while ((!cpiElementCompleteNext(&rc, element))     &&
           (!cpiFirstChild(&rc, element)) &&
           (pc->iCurrentElement))
    {
      pc->iCurrentElement = parseNextItem(parser, context, pc->iCurrentElement);
    }
```

cpiElementCompletePrevious:

This function gets the value of the 'previous child complete' flag from the target syntax element. This attribute indicates whether the element tree is complete.

Syntax

```
CciBool cpiElementCompletePrevious(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
Specifies the address of the target syntax element object (input).

Return values

The value of the attribute is returned. If an error occurs, *returnCode* indicates the reason for the error.

Sample

This example is based on code taken from the sample parser file `BipSampPluginParser.c`. In the sample file, the code uses cpiElementCompleteNext.

```
if ((!cpiElementCompletePrevious(&rc, element)) &&
      (cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_NAME)) {

    while ((!cpiElementCompletePrevious(&rc, element))     &&
           (!cpiFirstChild(&rc, element)) &&
           (pc->iCurrentElement))
    {
      pc->iCurrentElement = parsePreviousItem(parser, context, pc->iCurrentElement);
    }
```

"C parser utility functions" on page 6539
A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiElementName:

This function gets the name of the target syntax element. The syntax element name must be set previously by using cniSetElementName or cpiSetElementName.

Syntax

```
Ccisize           cpiElementName(
  int*            returnCode,
  CciElement*     targetElement,
  const CciChar*  value,
  CciSize         length);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER
- CCI_INV_DATA_BUFLEN
- CCI_INV_BUFFER_TOO_SMALL

targetElement
Specifies the address of the target syntax element object (input).

value
Specifies the address of a buffer into which the element name is copied (input).

length
The length, in characters, specified by the *value* parameter (input).

Return values

If successful, the element name is copied into the supplied buffer and the number of *CciChar* characters copied is returned. If the buffer is not large enough to contain the element name, *returnCode* is set to CCI_BUFFER_TOO_SMALL and the number of characters required is returned. For all other failures, CCI_FAILURE is returned

and *returnCode* indicates the reason for the error.

Sample

```
cpiElementName(&rc;, element, (CciChar*)&elementName;, sizeof(elementName));
```

This group of functions retrieve the value of the specified syntax element.

"cpiElementValueValue" on page 6569
This function gets the value object from the specified syntax element. This value object is opaque in that it cannot be interrogated. It can be used to set or derive the value of one element from another, without knowing its type, by using the cpiSetElementValueValue function.

"C parser utility functions" on page 6539
A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiElementNameSpace:

This function retrieves the value of the *namespace* attribute for the specified syntax element.

Defined In	Type	Member
CPI_VFT	Optional	iFpElementValue

Syntax

```
CciSize cpiElementNamespace(
   int*           returnCode,
   CciElement*    targetElement,
   const CciChar* value,
   CciSize        length);
```

Parameters

returnCode

A NULL pointer input signifies that the user-defined node does not want to deal with errors. All exceptions thrown during the execution of this call are re-thrown to the next upstream node in the flow. If input is not NULL, output

signifies the success status of the call. If an exception occurs during execution, *returnCode is set to CCI_EXCEPTION on output. You can call CciGetLastExceptionData to get details of the exception. If the caller did not allocate enough memory to hold the namespace value, *returncode is set to CCI_BUFFER_TOO_SMALL.

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER
- CCI_INV_DATA_BUFLEN
- CCI_INV_BUFFER_TOO_SMALL

targetElement
Specifies the address of the target syntax element object.

value
Specifies the address of a buffer into which the element namespace value is copied. A string of characters (including a NULL terminator) representing the namespace value is copied into this buffer. The buffer must be a portion of memory previously allocated by the caller.

length
The length in CciChars of the buffer specified by the value parameter.

Return values

If successful, the number of CciChars copied into the buffer is returned.

If the buffer is not large enough to contain the attribute value, *returnCode* is set to CCI_BUFFER_TOO_SMALL, and the number of bytes CciChars required is returned.

Sample

```
elementNamespace=(CciChar*)malloc(sizeof(CciChar) * elementNamespaceLength);
    elementNamespaceLength = cpiElementNamespace(&rc;,
                        element,
                        elementNamespace,
                        elementNamespaceLength);

    if (rc==CCI_BUFFER_TOO_SMALL){
      free(elementNamespace);
      elementNamespace=(CciChar*)malloc(sizeof(CciChar) * elementNamespaceLength);
      elementNamespaceLength = cpiElementNamespace(&rc;,
                        element,
                        elementNamespace,
                        elementNamespaceLength);
    }
    checkRC(rc);
```

This function gets the type of the target syntax element. The syntax element type must be set previously by using cniSetElementType or cpiSetElementType.

Syntax

```
CciElementType cpiElementType(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
Specifies the address of the target syntax element object (input).

Return values

The value of the element type is returned. If an error occurs, *returnCode* indicates the reason for the error.

Sample

cpiElementValue:

This function gets the value of a specified element. It is called by the broker when the value of a syntax element is to be retrieved. It provides an opportunity for a user-defined parser to override the behavior for retrieving element values.

Defined In	Type	Member
CPI_VFT	Optional	iFpElementValue

Syntax

```
const CciElementValue* cpiElementValue(
  CciParser*   parser,
  CciElement*  currentElement);
```

Parameters

parser
The address of the parser object (input).

currentElement
The address of the current syntax element (input).

Return values

The value of the target syntax element object is returned. This value has been returned by the cpiElementValueValue function.

Related concepts:

cpiElementValue group:

This group of functions retrieve the value of the specified syntax element.

Specify the appropriate function from this group that matches the type of data to be retrieved:

- cpiElementBitArrayValue
- cpiElementBooleanValue
- cpiElementByteArrayValue
- cpiElementCharacterValue
- cpiElementDateValue
- cpiElementDecimalValue
- cpiElementGmtTimestampValue
- cpiElementGmtTimeValue
- cpiElementIntegerValue
- cpiElementRealValue
- cpiElementTimestampValue
- cpiElementTimeValue

Syntax

```
CciSize cpiElementBitArrayValue(
  int*         returnCode,
  CciElement*  targetElement,
  const struct CciBitArray* value);
CciBool cpiElementBooleanValue(
  int*         returnCode,
  CciElement*  targetElement);
CciSize cpiElementByteArrayValue(
  int*         returnCode,
  CciElement*  targetElement,
  const struct CciByteArray* value);
```

```
CciSize cpiElementCharacterValue(
  int*            returnCode,
  CciElement*     targetElement,
  const CciChar*  value,
  CciSize         length);

struct CciDate cpiElementDateValue(
  int*         returnCode,
  CciElement*  targetElement);

CciSize cpiElementDecimalValue(
  int*            returnCode,
  CciElement*     targetElement,
  const CciChar*  value,
  CciSize         length);

struct CciTimestamp cpiElementGmtTimestampValue(
  int*         returnCode,
  CciElement*  targetElement);

struct CciTime cpiElementGmtTimeValue(
  int*         returnCode,
  CciElement*  targetElement);

CciInt cpiElementIntegerValue(
  int*         returnCode,
  CciElement*  targetElement);

CciReal cpiElementRealValue(
  int*         returnCode,
  CciElement*  targetElement);

struct CciTimestamp cpiElementTimestampValue(
  int*         returnCode,
  CciElement*  targetElement);

struct CciTime cpiElementTimeValue(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER
- CCI_INV_DATA_BUFLEN
- CCI_INV_BUFFER_TOO_SMALL

targetElement
Specifies the address of the target syntax element object (input).

value
The address of an output buffer into which the value of the syntax element is stored (input). Used on relevant function calls only.

length
The length of the output buffer, in characters, specified by the *value* parameter (input). Used on relevant function calls only.

Return values

The value of the element is returned.

In some cases, if the buffer is not large enough to receive the data, the data is not written into the buffer. The size of the required buffer is passed as the return value, and *returnCode* is set to CCI_BUFFER_TOO_SMALL. For example, cpiElementCharacterValue or cpiElementDecimalValue use this technique.

If an error occurs, *returnCode* indicates the reason for the error.

"cpiElementName" on page 6562
This function gets the name of the target syntax element. The syntax element name must be set previously by using cniSetElementName or cpiSetElementName.

"cpiElementType" on page 6565
This function gets the type of the target syntax element. The syntax element type must be set previously by using cniSetElementType or cpiSetElementType.

"cpiElementValueValue"
This function gets the value object from the specified syntax element. This value object is opaque in that it cannot be interrogated. It can be used to set or derive the value of one element from another, without knowing its type, by using the cpiSetElementValueValue function.

"C parser utility functions" on page 6539
A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiElementValueValue:

This function gets the value object from the specified syntax element. This value object is opaque in that it cannot be interrogated. It can be used to set or derive the value of one element from another, without knowing its type, by using the cpiSetElementValueValue function.

This function can be used by parsers that override behavior by calling the implementation functions cpiElementValue and cpiSetElementValue.

Syntax

```
const CciElementValue* cpiElementValueValue(
  int*         returnCode,
  CciElement*  targetElement);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
Specifies the address of the target syntax element object (input).

Return values

The address of the *CciElementValue* object stored in the specified target syntax element is returned. If an error occurs, zero (CCI_NULL_ADDR) is returned and *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
const CciElementValue* cpiElementValue(
  CciParser*  parser,
  CciElement* element
){
  CciElement* firstChild;
  const CciElementValue* value;
  int         rc;

  if ((cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_VALUE) ||
      (cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_NAME_VALUE)) {
    value = cpiElementValueValue(&rc, element);
  }
  else if (cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_NAME) {
    firstChild = cniFirstChild(&rc, element);
    value = cpiElementValueValue(&rc, firstChild);
  }
  else {
  }

  return(value);
}
```

A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiFirstChild:

This function returns the address of the syntax element object that is the first child of the specified target element.

Syntax

```
CciElement* cpiFirstChild(
  int*                returnCode,
  const CciElement*   targetElement);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
Specifies the address of the target syntax element object (input).

Return values

The address of the requested syntax element object is returned, unless there is no child in which case zero is returned. If an error occurs, zero (CCI_NULL_ADDR) is returned and *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample node file `BipSampPluginParser.c`:

```
while ((!cpiElementCompleteNext(&rc, element))     &&
           (!cpiFirstChild(&rc, element)) &&
           (pc->iCurrentElement))
```

This function returns the address of the syntax element object that is the first child of the specified target element.

"C parser utility functions" on page 6539
A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiNextParserClassName:

This function returns the name of the next parser class in the chain, if defined. Use this function to return to the broker the name of the parser class that handles the next section, or remainder, of the message content. Typically, for messages that have a simple format type, only one message content parser is defined.

For messages that have a more complex format type with multiple message parsers, each parser can identify the next one in the chain by returning its name in the *buffer* parameter. The last parser in the chain must return an empty string.

If you specify the name of a parser supplied with WebSphere Message Broker, you must use the correct class name of the parser.

Defined In	Type	Member
CPI_VFT	Optional	iFpNextParserClassName

Syntax

```
void cpiNextParserClassName(
  CciParser*   parser,
  CciContext*  context,
  CciChar*     buffer,
  int          size);
```

Parameters

parser
The address of the parser object (input).

context
The address of the context owned by the parser object (input).

buffer
The address of a buffer into which the parser class name should be put (input).

size
The length, in bytes, of the buffer provided by the broker (input).

Return values

None.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
void cpiNextParserClassName(
  CciParser*  parser,
  CciContext* context,
  CciChar*    buffer,
  int         size
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc = 0;

  if (pc->trace) {
```

```
    fprintf(pc->tracefile, "PLUGIN: -> cpiNextParserClassName() parser=0x%x context=0x%x\n",
            parser, context);
    fflush(pc->tracefile);
  }

  /* Copy the name to the broker */
  CciCharNCpy(buffer, pc->iNextParserClassName, size);

  if (pc->trace) {
    fprintf(pc->tracefile, "PLUGIN: <- cpiNextParserClassName()\n");
    fflush(pc->tracefile);
  }

  return;
}
```

cpiNextSibling:

This function returns the address of the syntax element object that is the next (right) sibling of the specified target element.

Syntax

```
CciElement* cpiNextSibling(
  int*               returnCode,
  const CciElement*  targetElement);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
Specifies the address of the target syntax element object (input).

Return values

The address of the requested syntax element object is returned, unless there is no next sibling in which case zero is returned. If an error occurs, zero (CCI_NULL_ADDR) is returned and *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample node file BipSampPluginParser.c:

```
while ((!cpiElementCompleteNext(&rc, cpiParent(&rc, element))) &&
         (!cpiNextSibling(&rc, element))       &&
         (pc->iCurrentElement))
```

cpiParent:

This function returns the address of the syntax element object that is the parent of the specified target element.

Syntax

```
CciElement* cpiParent(
  int*               returnCode,
  const CciElement*  targetElement);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
Specifies the address of the target syntax element object (input).

Return values

If successful, the address of the requested syntax element is returned. If there is no parent element, zero is returned. If an error occurs, zero (CCI_NULL_ADDR) is returned and the *returnCode* parameter indicates the reason for the error.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
void* parseNextItem(
  CciParser*  parser,
  CciContext* context,
  CciElement* element
){
  void*              endMarker;
  void*              startMarker;
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context;

structure.

Related reference:

"C parser utility functions" on page 6539
A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiParseBuffer:

This function prepares a parser to parse a new message object. It is called the first time (for each message) that the message flow causes the message content to be parsed.

This function is called for each user-defined parser that is used to parse a particular message format to complete the following actions:

- Perform all initialization that is required
- Return the length of the message content that it takes ownership for

The *offset* parameter indicates the offset within the message buffer where parsing is to commence. This indication is required because another parser might own a previous portion of the message (for example, an MQMD header is parsed by an internal parser owned by the broker). The offset must be positive and be less than the size of the buffer. Verify in this function that the offset is valid, to remove problems associated with previous parsers.

The parser must return the size of the remaining buffer for which it takes ownership. The size must be less than or equal to the size of the buffer, less the current offset.

A parser must not attempt to cause parsing of other portions of the syntax element tree, for example, by navigating to the root element and to another branch. This action can cause unpredictable results.

If this implementation function is provided in the CPI_VFT structure, you can call neither cpiParseBufferEncoded() nor cpiParseBufferFormatted(), because the cpiDefineParserClass() function fails with a return code of CCI_INVALID_IMPL_FUNCTION.

Defined In	Type	Member
CPI_VFT	Conditional	iFpParseBuffer

Syntax

```
int cpiParseBuffer(
  CciParser*   parser,
  CciContext*  context,
  int          offset);
```

Parameters

parser
The address of the parser object (input).

context
The address of the context owned by the parser object (input).

offset
The offset into the message buffer at which parsing is to commence (input).

Return values

The size (in bytes) of the remaining portion of the message buffer for which the parser takes ownership.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
int cpiParseBuffer(
  CciParser*  parser,
  CciContext* context,
  int         offset,
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc;

  /* Get a pointer to the message buffer and set the offset */
  pc->iBuffer = (void *)cpiBufferPointer(&rc, parser);
  pc->iIndex = 0;

  /* Save size of the buffer */
  pc->iSize = cpiBufferSize(&rc, parser);

  /* Prime the first byte in the stream */
  pc->iCurrentCharacter = cpiBufferByte(&rc, parser, pc->iIndex);

  /* Set the current element to the root element */
  pc->iCurrentElement = cpiRootElement(&rc, parser);

  /* Reset flag to ensure parsing is reset correctly */
  pc->iInTag = 0;

  if (pc->trace) {
    fprintf(pc->tracefile, "PLUGIN: <- cpiParseBuffer()
    retvalue=%d\n", pc->iSize);
    fflush(pc->tracefile);
  }
```

This function extends the capability of the cpiParseBuffer() implementation function, and provides the encoding and coded character set that the input message is represented in.

If this implementation function is provided in the CPI_VFT structure, you cannot specify either cpiParseBuffer() or cpiParseBufferFormatted(); if you do, the cpiDefineParserClass() function fails with a return code of CCI_INVALID_IMPL_FUNCTION.

Defined In	Type	Member
CPI_VFT	Conditional	iFpParseBufferEncoded

Syntax

```
int cpiParseBufferEncoded(
  CciParser*   parser,
  CciContext*  context,
  int          encoding,
  int          ccsid);
```

Parameters

parser
The address of the parser object (input).

context
The address of the context owned by the parser object (input).

encoding
The encoding of the message buffer (input).

ccsid
The CCSID of the message buffer (input).

Return values

The size (in bytes) of the remaining portion of the message buffer for which the parser takes ownership.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
int cpiParseBufferEncoded(
  CciParser*  parser,
  CciContext* context,
  int         encoding,
  int         ccsid
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc;

  /* Get a pointer to the message buffer and set the offset */
```

```
pc->iBuffer = (void *)cpiBufferPointer(&rc, parser);
pc->iIndex = 0;

/* Save the format of the buffer */
pc->iEncoding = encoding;
pc->iCcsid = ccsid;

/* Save size of the buffer */
pc->iSize = cpiBufferSize(&rc, parser);

/* Prime the first byte in the stream */
pc->iCurrentCharacter = cpiBufferByte(&rc, parser, pc->iIndex);

/* Set the current element to the root element */
pc->iCurrentElement = cpiRootElement(&rc, parser);

/* Reset flag to ensure parsing is reset correctly */
pc->iInTag = 0;

if (pc->trace) {
  fprintf(pc->tracefile, "PLUGIN: <- cpiParseBufferEncoded()
  retvalue=%d\n", pc->iSize);
  fflush(pc->tracefile);
}
```

cpiParseBufferFormatted:

This function extends the capability of the cpiParseBuffer() implementation function, and provides additional information about the input message.

The following additional information is available:

1. The encoding and coded character set that the input message is represented in.
2. The message set, type, and format for the message.

If this implementation function is provided in the CPI_VFT structure, you cannot specify either cpiParseBuffer() or cpiParseBufferEncoded(); if you do, the cpiDefineParserClass() function fails with a return code of CCI_INVALID_IMPL_FUNCTION.

Defined In	Type	Member
CPI_VFT	Conditional	iFpParseBufferFormatted

Syntax

```
int cpiParseBufferFormatted(
  CciParser*     parser,
  CciContext*    context,
  int            encoding,
  int            ccsid,
  CciChar*       set,
  CciChar*       type,
  CciChar*       format);
```

Parameters

parser
The address of the parser object (input).

context
The address of the context owned by the parser object (input).

encoding
The encoding of the message buffer (input).

ccsid
The CCSID of the message buffer (input).

set
The message set to which the message belongs (input).

type
The message type (input).

format
The message format (input).

Return values

The size (in bytes) of the remaining portion of the message buffer for which the parser takes ownership.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
int cpiParseBufferFormatted(
  CciParser*     parser,
  CciContext*    context,
  int            encoding,
  int            ccsid,
  CciChar*       set,
  CciChar*       type,
  CciChar*       format
```

```
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc;

  /* Get a pointer to the message buffer and set the offset */
  pc->iBuffer = (void *)cpiBufferPointer(&rc, parser);
  pc->iIndex = 0;

  /* Save the format of the buffer */
  pc->iEncoding = encoding;
  pc->iCcsid = ccsid;

  /* Save size of the buffer */
  pc->iSize = cpiBufferSize(&rc, parser);

  /* Prime the first byte in the stream */
  pc->iCurrentCharacter = cpiBufferByte(&rc, parser, pc->iIndex);

  /* Set the current element to the root element */
  pc->iCurrentElement = cpiRootElement(&rc, parser);

  /* Reset flag to ensure parsing is reset correctly */
  pc->iInTag = 0;

  if (pc->trace) {
    fprintf(pc->tracefile, "PLUGIN: <- cpiParseBufferFormatted()
    retvalue=%d\n", pc->iSize);
    fflush(pc->tracefile);
  }
```

Create a user-defined parser to interpret messages with a different format and structure.

Related reference:

"cpiParseBuffer" on page 6580
This function prepares a parser to parse a new message object. It is called the first time (for each message) that the message flow causes the message content to be parsed.

"cpiParseBufferEncoded" on page 6582
This function extends the capability of the cpiParseBuffer() implementation function, and provides the encoding and coded character set that the input message is represented in.

"C parser implementation functions" on page 6538
A user-defined parser implements its capability through a function interface which is called by the broker during runtime operation. This interface includes functions to create and delete all local context storage that is associated with a parser object and the parsing operations.

cpiParseFirstChild:

This function parses the first child of a specified syntax element. It is called by the broker when the first child element of the current syntax element is required.

Defined In	Type	Member
CPI_VFT	Mandatory	iFpParseFirstChild

Syntax

```
void cpiParseFirstChild(
  CciParser*   parser,
  CciContext*  context,
  CciElement*  currentElement);
```

Parameters

parser
The address of the parser object (input).

context
The address of the context owned by the parser object (input).

currentElement
The address of the current syntax element (input).

Return values

None.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
void cpiParseFirstChild(
  CciParser*  parser,
  CciContext* context,
  CciElement* element
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc;

  if ((!cpiElementCompleteNext(&rc, element)) &&
      (cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_NAME)) {

    while ((!cpiElementCompleteNext(&rc, element))     &&
           (!cpiFirstChild(&rc, element)) &&
           (pc->iCurrentElement))
    {
      pc->iCurrentElement = parseNextItem(parser, context, pc->iCurrentElement);
    }
  }

  if (pc->trace) {
    fprintf(pc->tracefile, "PLUGIN: <- cpiParseFirstChild()\n");
    fflush(pc->tracefile);
  }

  return;
}
```

A user-defined parser implements its capability through a function interface which is called by the broker during runtime operation. This interface includes functions to create and delete all local context storage that is associated with a parser object and the parsing operations.

cpiParseLastChild:

This function parses the last child of a specified syntax element. It is called by the broker when the last child element of the current syntax element is required.

Defined In	Type	Member
CPI_VFT	Mandatory	iFpParseLastChild

Syntax

```
void cpiParseLastChild(
  CciParser*   parser,
  CciContext*  context,
  CciElement*  currentElement);
```

Parameters

parser
The address of the parser object (input).

context
The address of the context owned by the parser object (input).

currentElement
The address of the current syntax element (input).

Return values

None.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
void cpiParseLastChild(
  CciParser*  parser,
  CciContext* context,
  CciElement* element
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc;

  if ((cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_NAME)) {

    while ((!cpiElementCompleteNext(&rc, element))     &&
           (pc->iCurrentElement))
    {
      pc->iCurrentElement = parseNextItem(parser, context, pc->iCurrentElement);
    }
  }

  if (pc->trace) {
    fprintf(pc->tracefile, "PLUGIN: <- cpiParseLastChild()\n");
    fflush(pc->tracefile);
  }

  return;
}
```

The purpose of this code is to parse children of an element until the last child is reached. You can use this kind of structure in a parser that does not already know the exact offset in the bit stream of the last child of an element.

cpiParseNextSibling:

This function parses the next (right) sibling of a specified syntax element. It is called by the broker when the next (right) sibling element of the current syntax element is required.

Defined In	Type	Member
CPI_VFT	Mandatory	iFpParseNextSibling

Syntax

```
void cpiParseNextSibling(
  CciParser*   parser,
  CciContext*  context,
  CciElement*  currentElement);
```

Parameters

parser
The address of the parser object (input).

context
The address of the context owned by the parser object (input).

currentElement
The address of the current syntax element (input).

Return values

None.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
void cpiParseNextSibling(
  CciParser*  parser,
  CciContext* context,
  CciElement* element
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc;

    while ((!cpiElementCompleteNext(&rc, cpiParent(&rc, element))) &&
         (!cpiNextSibling(&rc, element))       &&
         (pc->iCurrentElement))
  {
    pc->iCurrentElement = parseNextItem(parser, context, pc->iCurrentElement);
  }

  if (pc->trace) {
    fprintf(pc->tracefile, "PLUGIN: <- cpiParseNextSibling()\n");
    fflush(pc->tracefile);
  }

  return;
}
```

A user-defined parser implements its capability through a function interface which is called by the broker during runtime operation. This interface includes functions to create and delete all local context storage that is associated with a parser object and the parsing operations.

cpiParsePreviousSibling:

This function parses the previous (left) sibling of a specified syntax element. It is called by the broker when the previous (left) sibling element of the current syntax element is required.

Defined In	Type	Member
CPI_VFT	Mandatory	iFpParsePreviousSibling

Syntax

```
void cpiParsePreviousSibling(
  CciParser*   parser,
  CciContext*  context,
  CciElement*  currentElement);
```

Parameters

parser
The address of the parser object (input).

context
The address of the context owned by the parser object (input).

currentElement
The address of the current syntax element (input).

Return values

None.

Sample

```
void cpiParsePreviousSibling(
  CciParser*  parser,
  CciContext* context,
  CciElement* element
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc;

  while ((!cpiElementCompletePrevious(&rc, cpiParent(&rc, element))) &&
         (!cpiPreviousSibling(&rc, element))       &&
         (pc->iCurrentElement))
  {
    pc->iCurrentElement = parsePreviousItem(parser, context, pc->iCurrentElement);
```

```
  }

  if (pc->trace) {
    fprintf(pc->tracefile, "PLUGIN: <- cpiParsePreviousSibling()\n");
    fflush(pc->tracefile);
  }

  return;
}
```

The code sample is similar to that used for cpiParseNextSibling. Use cpiParsePreviousSibling as shown in the example when you are parsing the bit stream right to left.

A user-defined parser implements its capability through a function interface which is called by the broker during runtime operation. This interface includes functions to create and delete all local context storage that is associated with a parser object and the parsing operations.

cpiParserType:

This optional function returns whether the parser is an implementation of a *standard* parser.

A standard parser expects the Format field of the preceding header to contain the name of the parser class that follows. *Non-standard* parsers expects the Domain field to contain the parser class name. If the cpiParserType implementation function is not provided, the broker assumes that the parser is a standard parser.

Defined In	Type	Member
CPI_VFT	Optional	iFpParserType

Syntax

```
CciBool cpiParserType(
  CciParser*   parser,
  CciContext*  context);
```

Parameters

parser
The address of the parser object (input).

context
The address of the context owned by the parser object (input).

Return values

If the implementation is of a standard parser, zero is returned. Otherwise, the implementation is assumed to be that of a non-standard parser, nd a non-zero value is returned.

Related concepts:

"User-defined parsers" on page 3010
A user-defined parser is a program that interprets the bit stream of an incoming message and creates an internal representation of the message in a tree structure. A user-defined parser can also regenerate a bit stream for an outgoing message from the internal message tree representation

cpiRootElement:

This function gets the address of the root syntax element of the specified parser object.

Syntax

```
CciElement* cpiRootElement(
  int*        returnCode,
  CciParser*  parser);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_PARSER_OBJECT

parser
Specifies the address of the parser object (input).

Return values

The address of the root syntax element is returned. If an error occurs, zero (CCI_NULL_ADDR) is returned, and *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
int cpiParseBufferEncoded(
  CciParser*  parser,
  CciContext* context,
  int         encoding,
  int         ccsid
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc;

  /* Get a pointer to the message buffer and set the offset */
  pc->iBuffer = (void *)cpiBufferPointer(&rc, parser);
  pc->iIndex = 0;

  /* Save the format of the buffer */
  pc->iEncoding = encoding;
  pc->iCcsid = ccsid;

  /* Save size of the buffer */
  pc->iSize = cpiBufferSize(&rc, parser);

  /* Prime the first byte in the stream */
  pc->iCurrentCharacter = cpiBufferByte(&rc, parser, pc->iIndex);

  /* Set the current element to the root element */
  pc->iCurrentElement = cpiRootElement(&rc, parser);

  /* Reset flag to ensure parsing is reset correctly */
  pc->iInTag = 0;

  /* We will assume ownership of the remainder of the buffer */
  return(pc->iSize);
}
```

cpiSetCharacterValueFromBuffer:

This function sets the value of the specified syntax element.

Syntax

```
void cpiSetCharacterValueFromBuffer(
  int*            returnCode,
  CciElement*     targetElement,
  const CciChar*  value,
  CciSize         length);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER
- CCI_INV_DATA_BUFLEN

targetElement
Specifies the address of the target syntax element object (input).

value
The value to be set in the target element (input).

length
The length of the character string, expressed as the number of `CciChar` characters, specified by the *value* parameter (input).

Return values

None. If an error occurs, *returnCode* indicates the reason for the error.

Sample

```
/* Convert the attribute value into broker form */
          data = CciNString((char *)startMarker, markedSize, pc->iCcsid);

/* Create a new name-value element for the attribute */
          newElement = cpiCreateElement(&rc, parser);
          cpiSetElementType(&rc, newElement, CCI_ELEMENT_TYPE_NAME_VALUE);
          cpiSetCharacterValueFromBuffer(&rc, newElement, data, length);
          if (pc->trace) {
            const char * mbData = mbString(data, pc->iCcsid);
            fprintf(pc->tracefile, "PLUGIN: Created new NAMEVALUE element;
                    object=0x%x type=0x%x name=",
                    newElement, CCI_ELEMENT_TYPE_NAME_VALUE);
            fprintf(pc->tracefile, "%s\n", mbData);
            fflush(pc->tracefile);
            free((void *)mbData);
          }
          /* Free the memory created in CciNString() */
          free((void *)data);

          /* Add the element */
          cpiAddAsLastChild(&rc, element, newElement);
```

cpiSetElementCompleteNext:

This function sets the 'next child complete' flag in the target syntax element to the specified value.

Syntax

```
void cpiSetElementCompleteNext(
  int*         returnCode,
  CciElement*  targetElement,
  CciBool      value);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT

targetElement
Specifies the address of the target syntax element object (input).

value
The value to be set in the flag (input).

Return values

None. If an error occurs, *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
/* Get a pointer to the start of the tag */
        startMarker = (char*)pc->iBuffer+(int)pc->iIndex;

        /* Skip over the tag */
        goToNameEnd( (PARSER_CONTEXT_ST *)context, parser );
```

```
/* Get a pointer to the end of the tag */

A user-defined parser is a program that interprets the bit stream of an incoming message and creates an internal representation of the message in a tree structure. A user-defined parser can also regenerate a bit stream for an outgoing message from the internal message tree representation

"User-defined extensions overview" on page 2971
A user-defined extension is an optional component that you design and create to extend the functionality of WebSphere Message Broker.

"cpiSetElementCompleteNext" on page 6595
This function sets the 'next child complete' flag in the target syntax element to the specified value.

"C parser utility functions" on page 6539
A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiSetElementName:

This function sets the name of the specified syntax element.

Syntax

```
void cpiSetElementName(
  int*            returnCode,
  CciElement*     targetElement,
  const CciChar*  name);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER

targetElement
Specifies the address of the target syntax element object (input).

name
The name to be set in the target element (input).

Return values

None. If an error occurs, *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
/* Convert the attribute value into broker form */
          data = CciNString((char *)startMarker, markedSize, pc->iCcsid);

/* Create a new name-value element for the attribute */
          newElement = cpiCreateElement(&rc, parser);
          cpiSetElementType(&rc, newElement, CCI_ELEMENT_TYPE_NAME_VALUE);
          cpiSetElementName(&rc, newElement, data);
          if (pc->trace) {
            const char * mbData = mbString(data, pc->iCcsid);
            fprintf(pc->tracefile, "PLUGIN: Created new NAMEVALUE element;
                    object=0x%x type=0x%x name=",
                    newElement, CCI_ELEMENT_TYPE_NAME_VALUE);
            fprintf(pc->tracefile, "%s\n", mbData);
            fflush(pc->tracefile);
            free((void *)mbData);
          }
          /* Free the memory created in CciNString() */
          free((void *)data);

          /* Add the element */
          cpiAddAsLastChild(&rc, element, newElement);
```

This function sets the value of the specified syntax element.

"C parser utility functions" on page 6539
A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiSetElementNamespace:

Use this function to set the namespace attribute for the specified syntax element.

Defined In	Type	Member
CPI_VFT	Optional	iFpSetElementValue

Syntax

```
void             cpiSetElementNamespace(
  int*            returnCode,
  CciElement*     targetElement,
  const CciChar*  nameSpace);
```

Parameters

returnCode
A NULL pointer input value indicates that the user-defined node does not want to deal with errors. All exceptions thrown during the execution of this call are rethrown to the next upstream node in the flow. If the input value is not NULL, output signifies the success status of the call. If an exception occurs during execution, *returnCode is set to CCI_EXCEPTION on output. Call CciGetLastExceptionData to obtain details of the exception. (input).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER

currentElement
The address of the current syntax element (input).

targetElement
Specifies the address of the target syntax element object.

value
Specifies the address of a null terminated string of `CciChars` that represents the namespace value. An empty string is a valid value for namespace; elements are created in the empty string namespace by default, therefore if you specify an empty string as the namespace by using this call, the call is effective only if the element was previously in another namespace, and the required effect is to change the namespace value to empty string.

Return values

None.

Sample

```
/* Convert the attribute value into broker form */
          data = CciNString((char *)startMarker, markedSize, pc->iCcsid);

/* Create a new name-value element for the attribute */
          newElement = cpiCreateElement(&rc, parser);
          cpiSetElementType(&rc, newElement, CCI_ELEMENT_TYPE_NAME_VALUE);
          cpiSetElementName(&rc, newElement, data);
          cpiSetElementNamespace(&rc, newElement, data);
          if (pc->trace) {
            const char * mbData = mbString(data, pc->iCcsid);
            fprintf(pc->tracefile, "PLUGIN: Created new NAMESPACEVALUE element;
                    object=0x%x type=0x%x name=",
                    newElement, CCI_ELEMENT_TYPE_NAME_VALUE);
            fprintf(pc->tracefile, "%s\n", mbData);
            fflush(pc->tracefile);
            free((void *)mbData);
          }
          /* Free the memory created in CciNString() */
          free((void *)data);
```

```
/* Add the element */
cpiAddAsLastChild(&rc, element, newElement);
```

cpiSetElementValue:

This optional function sets the value of a specified element.

It called by the broker when the value of a syntax element is to be set. It provides an opportunity for a user-defined parser to override the behavior for setting element values.

Defined In	Type	Member
CPI_VFT	Optional	iFpSetElementValue

Syntax

```
void cpiSetElementValue(
  CciParser*        parser,
  CciElement*       currentElement,
  CciElementValue*  value);
```

Parameters

parser
The address of the parser object (input).

currentElement
The address of the current syntax element (input).

value
The value (input).

Return values

None.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
void cpiSetElementValue(
  CciParser*       parser,
  CciElement*      element,
  CciElementValue* value
){
  CciElement* newElement;
  int         rc;

cpiSetElementValue group:

This group of functions set the value of the specified syntax element.

Specify the appropriate function from this group that matches the type of data to be set:

- cpiSetElementBitArrayValue
- cpiSetElementByteArrayValue
- cpiSetElementBooleanValue
- cpiSetElementCharacterValue
- cpiSetElementDateValue
- cpiSetElementDecimalValue
- cpiSetElementGmtTimestampValue
- cpiSetElementGmtTimeValue
- cpiSetElementIntegerValue
- cpiSetElementRealValue
- cpiSetElementTimestampValue
- cpiSetElementTimeValue

Syntax

```
void cpiSetElementBitArrayValue(
  int*                        returnCode,
  CciElement*                 targetElement,
  const struct CciBitArray*   value);
void cpiSetElementByteArrayValue(

  CciElement*                 targetElement,
  const struct CciByteArray*  value);
void cpiSetElementBooleanValue(
  int*         returnCode,
  CciElement*  targetElement,
  CciBool      value);
void cpiSetElementCharacterValue(
  int*            returnCode,
  CciElement*     targetElement,
  const CciChar*  value,
  CciSize         length);
```

```
void cpiSetElementDateValue(
  int*                   returnCode,
  CciElement*            targetElement,
  const struct CciDate*  value);

void cpiSetElementDecimalValue(
  int*            returnCode,
  CciElement*     targetElement,
  const CciChar*  value);

void cpiSetElementGmtTimestampValue(
  int*                        returnCode,
  CciElement*                 targetElement,  const struct CciTimestamp*  value);

void cpiSetElementGmtTimeValue(
  int*                   returnCode,
  CciElement*            targetElement,
  const struct CciTime*  value);

void cpiSetElementIntegerValue(
  int*         returnCode,
  CciElement*  targetElement,
  CciInt       value);

void cpiSetElementRealValue(
  int*         returnCode,
  CciElement*  targetElement,
  CciReal      value);

void cpiSetElementTimestampValue(
  int*                        returnCode,
  CciElement*                 targetElement,
  const struct CciTimestamp*  value);

void cpiSetElementTimeValue(
  int*                   returnCode,
  CciElement*            targetElement,
  const struct CciTime*  value);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER
- CCI_INV_DATA_BUFLEN

targetElement
Specifies the address of the target syntax element object (input).

value
The value to be set in the target element (input).

length
The length of the data value, expressed as the number of `CciChar` characters. This parameter is used on relevant function calls only.

Return values

None. If an error occurs, *returnCode* indicates the reason for the error.

This function sets the value of the specified syntax element.

Syntax

```
void cpiSetElementValueValue(
  int*              returnCode,
  CciElement*       targetElement,
  CciElementValue*  value);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER

targetElement
Specifies the address of the target syntax element object (input).

value
Specifies the address of the *CciElementValue* object that contains the value to be stored in the specified target element (input).

Return values

None. If an error occurs, *returnCode* indicates the reason for the error.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
void cpiSetElementValue(
  CciParser*       parser,
  CciElement*      element,
  CciElementValue* value
){
  CciElement* newElement;
  int         rc;

  if ((cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_VALUE) ||
      (cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_NAME_VALUE))  {
    cpiSetElementValueValue(&rc, element, value);
  }
  else if (cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_NAME) {
    /* Create a new value element, add as a first child, and set the value */
    newElement = cpiCreateElement(&rc, parser);
    cpiSetElementType(&rc, newElement, CCI_ELEMENT_TYPE_VALUE);
    cpiSetElementValueValue(&rc, newElement, value);
    cpiAddAsFirstChild(&rc, element, newElement);
  }
  else {
  }

  return;
}
```

cpiSetNameFromBuffer:

This function sets the name attribute of the target syntax element using the data supplied in the buffer pointed to by the **name** parameter. The size of the name is specified using the **length** parameter.

Syntax

```
void cpiSetNameFromBuffer(
  int*            returnCode,
  CciElement*     targetElement,
  const CciChar*  name,
  CciSize         length);
```

Parameters

returnCode
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_EXCEPTION
- CCI_INV_ELEMENT_OBJECT
- CCI_INV_DATA_POINTER
- CCI_INV_DATA_BUFLEN

targetElement
Specifies the address of the target syntax element object (input).

name
The address of a buffer containing the name (input).

length
The length of the character string, expressed as the number of `CciChar` characters, specified by the name parameter.

Return values

None. If an error occurs, *returnCode* indicates the reason for the error.

Sample

```
/* Convert the attribute value into broker form */
          data = CciNString((char *)startMarker, markedSize, pc->iCcsid);

/* Create a new name-value element for the attribute */
          newElement = cpiCreateElement(&rc, parser);
          cpiSetElementType(&rc, newElement, CCI_ELEMENT_TYPE_NAME_VALUE);
          cpiSetNameFromBuffer(&rc, newElement, data, length);
          if (pc->trace) {
            const char * mbData = mbString(data, pc->iCcsid);
            fprintf(pc->tracefile, "PLUGIN: Created new NAMEVALUE element;
                    object=0x%x type=0x%x name=",
                    newElement, CCI_ELEMENT_TYPE_NAME_VALUE);
            fprintf(pc->tracefile, "%s\n", mbData);
            fflush(pc->tracefile);
            free((void *)mbData);
          }
          /* Free the memory created in CciNString() */
          free((void *)data);

          /* Add the element */
          cpiAddAsLastChild(&rc, element, newElement);
```

A user-defined parser can call functions provided by the broker to create or define objects, such as message parser factories.

cpiSetNextParserClassName:

This optional function returns the name of the next parser class in the chain.

It is called during finalize processing, and returns to the caller a string that contains the name of the next parser class in the chain. Using this information, a user-defined parser can, during the finalize phase, modify the syntax element tree before the phase that causes serialization of the bit stream.

If you specify the name of a parser supplied with WebSphere Message Broker, you must use the correct class name of the parser.

Defined In	Type	Member
CPI_VFT	Optional	iFpSetNextParserClassName

Syntax

```
void cpiSetNextParserClassName(
  CciParser*   parser,
  CciContext*  context,
  CciChar*     name,
  CciBool      parserType);
```

Parameters

parser
The address of the parser object (input).

context
The address of the context owned by the parser object (input).

name
The name of the next parser as a string of **CciChar** characters.

parserType
Indicates whether the referenced parser is *standard* (`parserType=0`) or *non-standard* (`parserType=non-zero`) (input). A standard parser expects the Format field of the preceding header in the chain to contain the name of the parser class that follows. Non-standard parsers expects the Domain field to contain the parser class name.

Return values

None.

Sample

This example is taken from the sample parser file BipSampPluginParser.c:

```
void cpiSetNextParserClassName(
  CciParser*  parser,
  CciContext* context,
  CciChar*    name,
  CciBool     isHeaderParser
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc = 0;

  /* Save the name in my context */
  CciCharNCpy(pc->iNextParserClassName, name, CciCharLen(name));

  if (pc->trace) {
    fprintf(pc->tracefile, "PLUGIN: <- cpiSetNextParserClassName()\n");
    fflush(pc->tracefile);
  }

  return;
}
```

A user-defined parser implements its capability through a function interface which is called by the broker during runtime operation. This interface includes functions to create and delete all local context storage that is associated with a parser object and the parsing operations.

cpiWriteBuffer:

This function writes a syntax element tree to the message buffer associated with a parser.

It appends data to the bit stream in the message buffer associated with the parser object, using the current syntax element tree as a source. The element tree cannot be modified during the execution of this implementation function. The cpiAppendToBuffer utility function can be used to append the message buffer (bit stream) with data from the element tree.

If this implementation function is provided in the CPI_VFT structure, you cannot specify either cpiWriteBufferEncoded() or cpiWriteBufferFormatted(); if you do, the cpiDefineParserClass() function fails with a return code of CCI_INVALID_IMPL_FUNCTION.

Defined In	Type	Member
CPI_VFT	Conditional	iFpWriteBuffer

Syntax

```
int cpiWriteBuffer(
  CciParser*   parser,
  CciContext*  context);
```

Parameters

parser
The address of the parser object (input).

context
The address of the context owned by the parser object (input).

Return values

The size in bytes of the data appended to the bit stream in the buffer.

Sample

```
int cpiWriteBuffer(
  CciParser*  parser,
  CciContext* context
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                initialSize = 0;
  int                rc = 0;
  const void* a;
  CciByte b;

  initialSize = cpiBufferSize(&rc, parser);
  a = cpiBufferPointer(&rc, parser);
  b = cpiBufferByte(&rc, parser, 0);

  cpiAppendToBuffer(&rc, parser, (char *)"Some test data", 14);

  return cpiBufferSize(0, parser) - initialSize;
}
```

"cpiWriteBufferEncoded"
This function is an extension of the capability provided by the existing **cpiWriteBuffer()** implementation function that provides the encoding and coded character set that the output message should be represented in when the parser serializes its element tree to an output bit stream.

"cpiWriteBufferFormatted" on page 6613
This function extends the capability of the cpiWriteBuffer() implementation function by providing additional information about the output message.

"C parser implementation functions" on page 6538
A user-defined parser implements its capability through a function interface which is called by the broker during runtime operation. This interface includes functions to create and delete all local context storage that is associated with a parser object and the parsing operations.

cpiWriteBufferEncoded:

This function is an extension of the capability provided by the existing **cpiWriteBuffer()** implementation function that provides the encoding and coded character set that the output message should be represented in when the parser serializes its element tree to an output bit stream.

If serialization is not required, for example when the output is based on an input bit stream, and the tree has not been modified, this implementation function is not called by the broker. If this implementation function is provided in the CPI_VFT structure, you cannot specify either cpiWriteBuffer() or cpiWriteBufferFormatted(); if you do, the cpiDefineParserClass() function fails with a return code of CCI_INVALID_IMPL_FUNCTION.

Defined In	Type	Member
CPI_VFT	Conditional	iFpWriteBufferEncoded

Syntax

```
int cpiWriteBufferEncoded(
  CciParser*     parser,
  CciContext*    context,
  int            encoding,
  int            ccsid);
```

Parameters

parser
The address of the parser object (input).

context
The address of the context owned by the parser object (input).

encoding
The encoding of the message buffer (input).

ccsid
The CCSID of the message buffer (input).

Return values

The size in bytes of the data appended to the bit stream in the buffer.

Sample

This example is taken from the sample parser file `BipSampPluginParser.c`:

```
int cpiWriteBufferEncoded(
  CciParser*  parser,
  CciContext* context,
  int         encoding,
  int         ccsid
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                initialSize = 0;
  int                rc = 0;
  const void* a;
  CciByte b;

  initialSize = cpiBufferSize(&rc, parser);
  a = cpiBufferPointer(&rc, parser);
  b = cpiBufferByte(&rc, parser, 0);

  cpiAppendToBuffer(&rc, parser, (char *)"Some test data", 14);

  return cpiBufferSize(0, parser) - initialSize;
}
```

Create a user-defined parser to interpret messages with a different format and structure.

Related reference:

"cpiWriteBuffer" on page 6610
This function writes a syntax element tree to the message buffer associated with a parser.

"cpiWriteBufferFormatted"
This function extends the capability of the cpiWriteBuffer() implementation function by providing additional information about the output message.

"C parser implementation functions" on page 6538
A user-defined parser implements its capability through a function interface which is called by the broker during runtime operation. This interface includes functions to create and delete all local context storage that is associated with a parser object and the parsing operations.

cpiWriteBufferFormatted:

This function extends the capability of the cpiWriteBuffer() implementation function by providing additional information about the output message.

The following additional information is provided:

1. The encoding and coded character set that the output message is represented in when the parser serializes its element tree to an output bit stream.
2. The message set, type, and format for the output message for those parsers which require such information to correctly serialize its element tree to an output bit stream.

If serialization is not required, for example when the output is based on an input bit stream, and the tree has not been modified, this implementation function will not be invoked by the broker.

If this implementation function is provided in the CPI_VFT structure, you cannot specify either cpiWriteBuffer() or cpiWriteBufferEncoded(); if you do, the cpiDefineParserClass() function fails with a return code of CCI_INVALID_IMPL_FUNCTION.

Defined In	Type	Member
CPI_VFT	Conditional	iFpWriteBufferFormatted

Syntax

```
int cpiWriteBufferFormatted(
  CciParser*     parser,
  CciContext*    context,
  int            encoding,
  int            ccsid,
  CciChar*       set,
  CciChar*       type,
  CciChar*       format);
```

Parameters

parser
The address of the parser object (input).

context
The address of the context owned by the parser object (input).

encoding
The encoding of the message buffer (input).

ccsid
The CCSID of the message buffer (input).

set
The message set to which the message belongs (input).

type
The message type (input).

format
The message format (input).

Return values

The size in bytes of the data appended to the bit stream in the buffer.

Sample

```
int cpiWriteBufferFormatted(
  CciParser*  parser,
  CciContext* context,
  int         encoding,
```

```
  int         ccsid
  CciChar*       set,
  CciChar*       type,
  CciChar*       format
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                initialSize = 0;
  int                rc = 0;
  const void* a;
  CciByte b;

  initialSize = cpiBufferSize(&rc, parser);
  a = cpiBufferPointer(&rc, parser);
  b = cpiBufferByte(&rc, parser, 0);

  cpiAppendToBuffer(&rc, parser, (char *)"Some test data", 14);

  return cpiBufferSize(0, parser) - initialSize;
}
```

"C Header files" on page 6415
The C interfaces are defined by the following header files.

bipInitializeUserExits:

bipInitializeUserExits is an implementation function that is exported by the User Exit library (`.lel` file).

This function is called when the execution group starts, just after loading the `.lel` file. When this function runs, your exit code must call cciRegisterUserExit to register each user exit provided by that `.lel` file.

Syntax:

```
void bipInitializeUserExits()
```

Parameters:
None.

Return values:
None.

Example:

```
extern "C"{

void bipInitializeUserExits(){

  int rc = CCI_SUCCESS;
  CCI_UE_VFT myVft = {CCI_UE_VFT_DEFAULT};
  myVft.iFpInputMessageCallback      = myInputMessageCallback;
  myVft.iFpTransactionEventCallback  = myTransactionEventCallback;
  myVft.iFpPropagatedMessageCallback = myPropagatedMessageCallback;
  myVft.iFpNodeCompletionCallback    = myNodeCompletionCallback;
```

```
  cciRegisterUserExit(&rc,
                      MyConstants::myUserExitName,
                      0,
                      myVft);

  /*we should now check the rc for unexpected values*/

  return;
}

}/*end of extern "C" */
```

Related reference:

"cciRegisterUserExit" on page 6638
cciRegisterUserExit is a utility function that can be called by the user's code when bipInitializeUserExits is called.

bipTerminateUserExits:

bipInitializeUserExits is an implementation function exported by the User Exit library (`.lel` file).

This function is called just before unloading the `.lel` file, which typically happens when the execution group process is stopping. When this function runs, your exit code must clean up all resources that were allocated during the bipInitializeUserExits function.

If this function is not exported, the `.lel` file fails to load. You cannot call other utility functions while bipTerminateUserExits is running. This function is started on the same thread as the bipInitializeUserExits function.

Syntax:

```
void bipTerminateUserExits()
```

Parameters:
None.

Return values:
None.

Example:

```
extern "C"{

void bipTerminateUserExits(){
  /*Here, we clean up any resources, e.g.
         spawned threads, file handles, sockets  */
  freeResources();
}

}/*end of extern "C" */
```

Related concepts:

Develop a user exit by declaring it, implementing its behavior, then compiling it.

Related reference:

"bipInitializeUserExits" on page 6617
bipInitializeUserExits is an implementation function that is exported by the User Exit library (`.lel` file).

cciInputMessageCallback:

The cciInputMessageCallback function can be registered as a callback and is called every time a message is read by an input node, and before that message is propagated down the message flow.

The cciInputMessageCallback function is called for every input message that is read in the execution group where the callback is registered, if the user exit state is active. The callback is registered by providing a pointer to the function as the **iFpInputMessageCallback** field of the CCI_UE_VFT struct that is passed to **cciRegisterUserExit**.

Syntax:

```
typedef void (*cciInputMessageCallback)     (
                                CciDataContext*  userContext,
                                CciMessage*      message,
                                CciMessage*      localEnvironment,
                                CciMessage*      exceptionList,
                                CciMessage*      environment,
                                CciMessageOrigin messageOrigin,
                                CciNode*         inputNode);
```

Parameters:

userContext (input)
The value that is passed to the **cciRegisterUserExit** function.

message
A handle to the message object. The user exit code must not update transport headers or Properties elements in this tree. Updating the message can affect performance, particularly if the input message would not otherwise be changed in the message flow.

localEnvironment
A handle to the local environment object.

exceptionList
A handle to the exception list object.

environment
A handle to the environment object for the current message flow.

messageOrigin
Depending on the type of input node, the message might have originated from a bit stream (CCI_MESSAGE_ORIGIN_BITSTREAM) or from a tree (CCI_MESSAGE_ORIGIN_TREE). The user exit can access one of these sources without causing processing by the parser. For example, in the case of the MQInput node, you can access the bitstream safely whereas, in the case of the

JMSInput node, you can access the tree safely. You can access the bit stream by calling **cniBufferPointer**, **cniBufferSize**, or **cniBufferByte**. You can access the tree by calling **cniRootElement** and using the usual syntax element navigation functions (for example, **cniFirstChild**). Although this parameter tells the user exit what it can access safely without causing processing by the parser, the user exit code might ignore this advice and effectively alter the parse timing.

inputNode
A handle to the input node that reads this input message. The handle can be used to make calls to functions such as **cciGetNodeName**, **cciGetNodeType**, and **cniGetBrokerInfo**.

Return values:
None.

Example:

```
void myInputMessageCallback(
                      CciDataContext*  userContext,
                      CciMessage*      message,
                      CciMessage*      localEnvironment,
                      CciMessage*      exceptionList,
                      CciMessage*      environment,
                      CciMessageOrigin messageOrigin,
                      CciNode*         inputNode){
...
...
}
```

Related concepts:

"User exits" on page 3015

Related tasks:

"Developing a user exit" on page 3114
Develop a user exit by declaring it, implementing its behavior, then compiling it.

Related reference:

"cciRegisterUserExit" on page 6638
cciRegisterUserExit is a utility function that can be called by the user's code when bipInitializeUserExits is called.

"cniBufferByte" on page 6426
Use this function to get a single byte from the data buffer associated with (and owned by) the message object specified in the message argument. The value of the index argument indicates which byte in the byte array is to be returned.

"cniBufferPointer" on page 6427
Use this function to get a pointer to the data buffer associated with (and owned by) the message object specified in the message argument. This function is typically used by output nodes.

"cniBufferSize" on page 6428
Use this function to get the size of the data buffer associated with (and owned by) the message object specified in the message argument.

"cniRootElement" on page 6503
Use this function to get the root syntax element associated with a specified message. It returns the root element that is associated with (and owned by) the message object identified by the *message* parameter. When a message object is constructed by the broker, a root element is automatically created.

"cniFirstChild" on page 6481
Use this function to retrieve the address of the syntax element object that is the first child of the specified syntax element.

"cniGetThreadContext" on page 6494
This function returns the thread context for the current thread.

"cciGetNodeName" on page 6630
This function returns the name of the specified node.

"cciGetNodeType" on page 6631
This function returns the type of the specified node.

"cniGetBrokerInfo" on page 6488
Use this function to query the current broker environment (for example, for information about broker name and message flow name). The information is returned in a structure of type CNI_BROKER_INFO_ST.

cciNodeCompletionCallback:

The cciNodeCompletionCallback function can be registered as a callback and is called whenever a node has completed processing of a message and is returning control to its upstream node.

The cciNodeCompletionCallback function is called for every message that is propagated in the execution group where the callback was registered, if the user exit state is active. The callback is registered by providing a pointer to the function as the **iFpNodeCompletionCallback** field of the CCI_UE_VFT struct that is passed to **cciRegisterUserExit**.

If the node completes due to an unhandled exception, it returns with a **reasonCode** of CCI_EXCEPTION, and that exception's details can be obtained by calling **cciGetLastExceptionData**.

If the node completes normally (including handling an exception on the catch or failure terminal), it returns with a **reasonCode** of CCI_SUCCESS. In this case, calling **cciGetLastExceptionData** returns unpredictable results.

Syntax:

```
typedef void (*cciNodeCompletionCallback)   (
                                CciDataContext* userContext,
                                CciMessage*     message,
                                CciMessage*     localEnvironment,
                                CciMessage*     exceptionList,
                                CciMessage*     environment,
                                CciConnection*  connection,
                                int             reasonCode);
```

Parameters:

userContext (input)
The value that is passed to the **cciRegisterUserExit** function.

message
A handle to the current message object. The current message is the message that is propagated to the node plus one or more of the following modifications:

- Modifications that are applied to the input root in the node
- Modifications that are made from a user exit during the preceding propagate callback

- Modifications that are made from a user exit during the downstream node complete callback if the node does not create a new message; for example, output nodes, Compute nodes with a `Compute Mode` that is set to `LocalEnvironment`, `Exception`, or `Exception And LocalEnvironment`, or request nodes with an `Output data location` that is set to `LocalEnvironment`.

The user exit code must not update transport headers or Properties elements in the message tree. Updating the message can affect performance. Changes that are made during this callback are visible only if the upstream node does not cause a new Message to be created.

`localEnvironment`
A handle to the local environment object that is being propagated.

`exceptionList`
A handle to the exception list object that is being propagated.

`environment`
A handle to the environment object for the current message flow.

`connection`
A handle to the connection object between the two nodes. The handle can be used, for example, in calls to **cciGetSourceNode**, **cciGetTargetNode**, **cciGetSourceTerminalName**, and **cciGetTargetTerminalName**. This handle is valid only for the duration of this instance of the user exit function.

`reasonCode`
A reason code that indicates whether the node completes normally (CCI_SUCCESS) or the node completes as the result of an unhandled exception (CCI_EXCEPTION). If the node completes due to an unhandled exception, you can obtain that exception's details by calling **cciGetLastExceptionData**. If the node completes normally (including handling an exception on the catch or failure terminal), the effect of calling **cciGetLastExceptionData** is undetermined.

Return values:
None.

Example:

```
void myNodeCompletionCallback(
                              CciDataContext* userContext,
                              CciMessage*     message,
                              CciMessage*     localEnvironment,
                              CciMessage*     exceptionList,
                              CciMessage*     environment,
                              CciConnection*  connection
                              int             reasonCode){
...
...
}
```

Related concepts:

"User exits" on page 3015
A user exit is user-provided custom software, written in C, to track data passing through message flows.

cciRegisterUserExit is a utility function that can be called by the user's code when bipInitializeUserExits is called.

"cciGetSourceNode" on page 6635
This function returns a handle to the upstream node of a given connection.

"cciGetTargetNode" on page 6637
This function returns a handle to the downstream node of a given connection.

"cciGetSourceTerminalName" on page 6636
This function returns the name of the output terminal of the source node for the specified connection.

"cciGetTargetTerminalName" on page 6637
This function returns the name of the input terminal of the target node for the specified connection.

"cciGetLastExceptionData" on page 6647
Gets diagnostic information about the last exception generated. Information about the last exception generated on the current thread is returned in a CCI_EXCEPTION_ST output structure. The user-defined extension can use this function to determine whether any recovery is required when a utility function returns an error code.

cciPropagatedMessageCallback:

The cciPropagatedMessageCallback function can be registered as a callback and is called whenever a message is propagated from one node to another.

The cciPropagatedMessageCallback function is called for every message that is propagated in the execution group where the callback was registered, if the user exit state is active. The callback is registered by providing a pointer to the function as the **iFpPropagatedMessageCallback** field of the CCI_UE_VFT struct that is passed to **cciRegisterUserExit**.

Syntax:

```
typedef void (*cciPropagatedMessageCallback)(
                                CciDataContext* userContext,
                                CciMessage*     message,
                                CciMessage*     localEnvironment,
                                CciMessage*     exceptionList,
                                CciMessage*     environment,
                                CciConnection*  connection);
```

Parameters:

userContext (input)
The value that is passed to the **cciRegisterUserExit** function.

message
A handle to the message object that is being propagated. The user exit code must not update transport headers or Properties elements in this tree. Updating the message can affect performance, particularly if the input message would not otherwise be changed in the message flow.

localEnvironment
A handle to the local environment object that is being propagated.

exceptionList
A handle to the exception list object that is being propagated.

environment
A handle to the environment object for the current message flow.

connection
A handle to the connection object between the two nodes. The handle can be used, for example, in calls to **cciGetSourceNode**, **cciGetTargetNode**, **cciGetSourceTerminalName**, and **cciGetTargetTerminalName**. This handle is valid only for the duration of this instance of the user exit function.

Return values:
None.

Example:

```
void myPropagatedMessageCallback(
                         CciMessage*    message,
                         CciMessage*    localEnvironment,
                         CciMessage*    exceptionList,
                         CciMessage*    environment,
                         CciConnection* connection){

   int rc = CCI_SUCCESS;
   CciNode* targetNode = cciGetTargetNode(amp rc,
                                          connection);

   CciChar targetNodeName [initialStringBufferLength];
   targetNodeNameLength = cciGetNodeName(amp rc,
                                         targetNode,
                                         targetNodeName,
                                         initialStringBufferLength);
   /*you should now check the rc for unexpected values*/
   /*if rc is CCI_BUFFER_TOO_SMALL, resize and retry*/

}
```

"cciRegisterUserExit" on page 6638
cciRegisterUserExit is a utility function that can be called by the user's code when bipInitializeUserExits is called.

"cciGetSourceNode" on page 6635
This function returns a handle to the upstream node of a given connection.

"cciGetTargetNode" on page 6637
This function returns a handle to the downstream node of a given connection.

"cciGetSourceTerminalName" on page 6636
This function returns the name of the output terminal of the source node for the specified connection.

"cciGetTargetTerminalName" on page 6637
This function returns the name of the input terminal of the target node for the specified connection.

cciTransactionEventCallback:

The cciTransactionEventCallback function can be registered as a callback and is called every time a message flow transaction ends.

This function is called for every message flow transaction within the execution group where the callback was registered, if the user exit state is active. The callback is registered by providing a pointer to the function in the **iFpTransactionEventCallback** field of the CCI_UE_VFT struct passed to **cciRegisterUserExit**.

Syntax:

```
typedef void (*cciTransactionEventCallback) (
                                  CciDataContext*         userContext,
                                  CciTransactionEventType type,
                                  CciMessage*             environment,
                                  CciNode*                inputNode);
```

Parameters:

userContext (input)
This is the value that was passed to the **cciRegisterUserExit** function.

type
This describes the event that occurred. Possible values are:

- CCI_TRANSACTION_EVENT_COMMIT
  A transaction has been successfully committed.
- CCI_TRANSACTION_EVENT_ROLLBACK
  A transaction has been rolled back.

If the transaction was rolled back due to an unhandled exception, you can obtain details of that exception by calling **cciGetLastExceptionData**.

environment
This is a handle to the environment object for the current message flow. Although the user exit can update this tree, it is cleared after returning from this function, so any updates are lost.

inputNode
This is a handle to the input node which reads the input message that triggered the transaction. It can be used to make calls to functions such as **cciGetNodeName**, **cciGetNodeType**, and **cniGetBrokerInfo**.

Return values:
None

Example:

```
void myTransactionEventCallback(
                     CciDataContext*         userContext,
                     CciTransactionEventType type,
                     CciMessage*             environment,
                     CciNode*                inputNode){
...
...
}
```

Related concepts:

"User exits" on page 3015

Related tasks:

"Developing a user exit" on page 3114
Develop a user exit by declaring it, implementing its behavior, then compiling it.

Related reference:

"cciRegisterUserExit" on page 6638
cciRegisterUserExit is a utility function that can be called by the user's code when bipInitializeUserExits is called.

"cciGetLastExceptionData" on page 6647
Gets diagnostic information about the last exception generated. Information about the last exception generated on the current thread is returned in a CCI_EXCEPTION_ST output structure. The user-defined extension can use this function to determine whether any recovery is required when a utility function returns an error code.

"cciGetNodeName" on page 6630
This function returns the name of the specified node.

"cciGetNodeType" on page 6631
This function returns the type of the specified node.

"cniGetBrokerInfo" on page 6488
Use this function to query the current broker environment (for example, for information about broker name and message flow name). The information is returned in a structure of type CNI_BROKER_INFO_ST.

cciOutputMessageCallback:

The cciOutputMessageCallback function can be registered as a callback and is called whenever a message is sent by an output node.

The cciOutputMessageCallback function is called for every output message that is sent successfully in the execution group or message flow where the callback was registered if the user exit state is active. If the node provides WrittenDestination information in the LocalEnvironment tree, the callback is called after this information is created.

Calls are made after the following operations are completed:
- Sending a message from an output or reply node (for WebSphere MQ, JMS, TCPIP, HTTP, or SOAP nodes).
- Sending a message from a request node (TCPIP, HTTP, or SOAP nodes). The callback is made after the reply has been received.
- Writing to a file (FileOutput node).
- Sending an email (EmailOutput node).
- Completing an adapter request (WebSphere Adapters request nodes).

The callback is registered by providing a pointer to the function as the iFpOutputMessageCallback field of the CCI_UE_VFT struct that is passed to cciRegisterUserExit. The iFpOutputMessageCallback field was added in CCI_UE_VFT struct version 2.

When you implement this callback, check the node type by using cciGetNodeType before you perform any node-specific operations.

Syntax:

```
typedef void (*cciOutputMessageCallback)     (
                                CciDataContext*  userContext,
                                CciMessage*      message,
                                CciMessage*      localEnvironment,
```

```
                                        CciMessage*      exceptionList,
                                        CciMessage*      environment,
                                        CciNode*         node);
```

Parameters:

userContext (input)
The value that is passed to the cciRegisterUserExit function.

message (input)
A handle to the message object. You must not update the transport headers or Properties elements in this tree.

You can update the message body. However, because this callback is called after the message has been sent to the transport, any changes do not appear in that message. Changes are visible only to nodes that are connected downstream of the output node. Updating the message can affect performance, particularly if the message tree would not otherwise be changed in the message flow.

localEnvironment (input)
A handle to the local environment object. The handle can contain information about the destination of the message that is written in the WrittenDestination subtree. See each node's documentation for more details.

exceptionList (input)
A handle to the exception list object.

environment (input)
A handle to the environment object for the current message flow.

node (input)
A handle to the node that has sent the output message. You can use the handle to make calls to functions such as cciGetNodeName, cciGetNodeType, and cniGetBrokerInfo.

Return values:
None.

Example:

```
void myOutputMessageCallback(
                      CciDataContext*  userContext,
                      CciMessage*      message,
                      CciMessage*      localEnvironment,
                      CciMessage*      exceptionList,
                      CciMessage*      environment,
                      CciNode*         node){
}
```

"C Header files" on page 6415
The C interfaces are defined by the following header files.

cciGetNodeAttribute:

The cciGetNodeAttribute function returns the value of the specified attribute.

Syntax:

```
CciSize  cciGetNodeAttribute (int*           returnCode,
                              CciNode*       node,
                              CciChar*       name,
                              CciChar*       value,
                              CciSize        length);
```

Parameters:

returnCode (output)
Receives the return code from the function (output).

- CCI_INV_BUFFER_TOO_SMALL
  The provided buffer was not large enough to hold the value of node's type.

node (input)
This is a handle to a node.

name (input)
This is a pointer to a NULL-terminated string of CciChar specifying the name of the node attribute being queried.

value (output)
Address of a buffer, allocated by the caller to hold the value of the attribute.

length
The length, in CciChars, of the buffer allocated by the caller.

Return values:

- If successful, the attribute value is copied into the supplied buffer and the number of CciChar characters copied is returned.
- If the buffer is not large enough to contain the attribute value, **returnCode** is set to CCI_BUFFER_TOO_SMALL, and the number of CciChars required is returned.
- If **name** specifies an attribute name that is not appropriate for the given node, **returnCode** is set to CCI_ATTRIBUTE_UNKOWN.

Example:

```
void myPropagatedMessageCallback(
                        CciMessage*    message,
                        CciMessage*    localEnvironment,
                        CciMessage*    exceptionList,
                        CciMessage*    environment,
                        CciConnection* connection){
   int rc = CCI_SUCCESS;
   CciNode* sourceNode = cciGetSourceNode(&rc,
                                          connection);
   /*you should now check the rc for unexpected values*/
   CciChar   queueNameAttribute[16];
   cciMbsToUcs(&rc,
               "queueName",
```

```
              queueNameAttribute,
              16,
              BIP_DEF_COMP_CCSID);
/*you should now check the rc for unexpected values*/

  CciChar queueName [512];
  sourceNodeQueueNameLength = cciGetNodeType(&rc,
                                     sourceNode,
                                     queueName,
                                     512);
  /*you should now check the rc for unexpected values*/
  /*if rc is CCI_BUFFER_TOO_SMALL, resize and retry*/
/*sourceNodeQueueNameLength will hold the actual or required size */
```

Related concepts:

Related tasks:

"Developing a user exit" on page 3114
Develop a user exit by declaring it, implementing its behavior, then compiling it.

cciGetNodeName:

This function returns the name of the specified node.

The name is assigned internally by the WebSphere Message Broker Toolkit and is unique in the message flow. The label that is assigned to a node by the message flow designer in the Message Flow Editor can be obtained by calling "cciGetNodeAttribute" on page 6629 to read the label attribute.

Syntax:

```
CciSize  getNodeName (int*                  returnCode,
                      CciNode*              node,
                      CciChar*              value,
                      CciSize               length);
```

Parameters:

returnCode (output)
Receives the return code from the function (output)

- CCI_INV_BUFFER_TOO_SMALL

  The provided buffer was not large enough to hold the value of node's name.

node (input)
This is a handle to a node.

value (output)
Address of a buffer, allocated by the caller to hold the value of the node's name.

length
The length, in CciChars, of the buffer allocated by the caller.

Return values:

- If successful, the node name is copied into the supplied buffer and the number of CciChar characters copied is returned.
- If the buffer is not large enough to contain the node name, **returnCode** is set to CCI_BUFFER_TOO_SMALL, and the number of CciChars required is returned.

Example:

```
void myPropagatedMessageCallback(
                        CciMessage*    message,
                        CciMessage*    localEnvironment,
                        CciMessage*    exceptionList,
                        CciMessage*    environment,
                        CciConnection* connection){

  int rc = CCI_SUCCESS;
   CciNode* targetNode = cciGetTargetNode(&rc,
                                          connection);

   CciChar targetNodeName [initialStringBufferLength];
   targetNodeNameLength = cciGetNodeName(&rc,
                                        targetNode,
                                        targetNodeName,
                                        initialStringBufferLength);
   /*you should now check the rc for unexpected values*/
   /*if rc is CCI_BUFFER_TOO_SMALL, resize and retry*/

}
```

cciGetNodeType:

This function returns the type of the specified node.

Syntax:

```
CciSize  cciGetNodeType (int*                    returnCode,
                         CciNode*          node,
                         CciChar*          value,
                         CciSize           length);
```

Parameters:

returnCode (output)
Receives the return code from the function (output).

- CCI_INV_BUFFER_TOO_SMALL

  The provided buffer was not large enough to hold the value of node's type.

node (input)
This is a handle to a node.

value (output)
Address of a buffer, allocated by the caller to hold the value of the node type.

length
The length, in CciChars, of the buffer allocated by the caller.

Return values:

- If the function is successful, the node type is copied into the supplied buffer and the number of CciChar characters copied is returned.

- If the buffer is not large enough to contain the node type, **returnCode** is set to CCI_BUFFER_TOO_SMALL, and the number of CciChars required is returned.

Example:

```
void myPropagatedMessageCallback(
                         CciMessage*    message,
                         CciMessage*    localEnvironment,
                         CciMessage*    exceptionList,
                         CciMessage*    environment,
                         CciConnection* connection){

  int rc = CCI_SUCCESS;
   CciNode* sourceNode = cciGetSourceNode(&rc,
                                          connection);
   /*you should now check the rc for unexpected values*/

   CciChar sourceNodeType[initialStringBufferLength];
   sourceNodeTypeLength = cciGetNodeType(&rc,
                                         sourceNode,
                                         sourceNodeType,
                                         initialStringBufferLength);
   /*you should now check the rc for unexpected values*/
   /*if rc is CCI_BUFFER_TOO_SMALL then you should resize and retry*/
```

"Message flow nodes" on page 1024
A message flow node is a processing step in a message flow. It can be a built-in node, a user-defined node, or a subflow node.

Related reference:

"cciGetNodeType" on page 6631
This function returns the type of the specified node.

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

cciGetSourceNode:

This function returns a handle to the upstream node of a given connection.

Syntax:

```
CciNode*  cciGetSourceNode(int*                    returnCode,
                           CciConnection * connection);
```

Parameters:

returnCode (output)
Receives the return code from the function.

connection
This parameter is a handle to a connection on the output terminal of the requested node.

Return values:
A handle to the node that is on the source side of the connection.

Example:

```
void myPropagatedMessageCallback(
                        CciMessage*    message,
                        CciMessage*    localEnvironment,
                        CciMessage*    exceptionList,
                        CciMessage*    environment,
                        CciConnection* connection){
    ...
    ...

   int rc = CCI_SUCCESS;
   CciNode* sourceNode = cciGetSourceNode(&rc,
                                          connection);
   /*you should now check the rc for unexpected values*/
```

Related concepts:

"User exits" on page 3015
A user exit is user-provided custom software, written in C, to track data passing through message flows.

Related tasks:

"Developing a user exit" on page 3114
Develop a user exit by declaring it, implementing its behavior, then compiling it.

cciGetSourceTerminalName:

This function returns the name of the output terminal of the source node for the specified connection.

Syntax:

```
CciSize  cciGetSourceTerminalName (int*           returnCode,
                                   CciConnection* connection,
                                   CciChar*       value,
                                   CciSize        length);
```

Parameters:

returnCode (output)
Receives the return code from the function (output).

- CCI_BUFFER_TOO_SMALL

  The provided buffer was not large enough to hold the value of node's name.

connection (input)
This parameter is a handle to a connection between two nodes.

value (output)
Address of a buffer, allocated by the caller to hold the value of the terminal's name.

length
The length, in `CciChars`, of the buffer allocated by the caller.

Return values:

- If successful, the terminal name is copied into the supplied buffer, and the number of `CciChar` characters copied is returned.
- If the buffer is not large enough to contain the attribute value, **returnCode** is set to CCI_BUFFER_TOO_SMALL, and the number of `CciChars` required is returned.

Example:

```
void myPropagatedMessageCallback(
                        CciDataContext* userContext,
                        CciMessage*     message,
                        CciMessage*     localEnvironment,
                        CciMessage*     exceptionList,
                        CciMessage*     environment,
                        CciConnection*  connection){
  int rc = CCI_SUCCESS;
   CciChar sourceTerminalName[initialStringBufferLength];
   cciGetSourceTerminalName(&rc,
                            connection,
                            sourceTerminalName,
                            initialStringBufferLength);
}
```

cciGetTargetNode:

This function returns a handle to the downstream node of a given connection.

Syntax:

```
CciNode*  cciGetTargetNode(int*                    returnCode,
                                                CciConnection * connection);
```

Parameters:

returnCode (output)
Receives the return code from the function (output).

connection
This parameter is a handle to a connection on an input terminal of the requested node.

Return values:
A handle to the node that is on the target side of the connection.

Example:

```
void myPropagatedMessageCallback(
                        CciMessage*    message,
                        CciMessage*    localEnvironment,
                        CciMessage*    exceptionList,
                        CciMessage*    environment,
                        CciConnection* connection){
   ...
   ...

   CciNode* targetNode = cciGetTargetNode(&rc,
                                          connection);
```

cciGetTargetTerminalName:

This function returns the name of the input terminal of the target node for the specified connection.

Syntax:

```
CciSize  cciGetTargetTerminalName (int*           returnCode,
                                   CciConnection* connection,
                                   CciChar*       value,
                                   CciSize        length);
```

Parameters:

returnCode (output)
Receives the return code from the function (output).

- CCI_BUFFER_TOO_SMALL

The provided buffer was not large enough to hold the value of node name.

connection (input)
This parameter is a handle to a connection between two nodes.

value (output)
Address of a buffer, allocated by the caller to hold the value of the terminal's name.

length
The length, in CciChars, of the buffer allocated by the caller.

Return values:

- If successful, the terminal name is copied into the supplied buffer, and the number of CciChar characters copied is returned.
- If the buffer is not large enough to contain the terminal name, **returnCode** is set to CCI_BUFFER_TOO_SMALL, and the number of CciChars required is returned.

Example:

```
void myPropagatedMessageCallback(
                        CciDataContext* userContext,
                        CciMessage*     message,
                        CciMessage*     localEnvironment,
                        CciMessage*     exceptionList,
                        CciMessage*     environment,
                        CciConnection*  connection){
   int rc = CCI_SUCCESS;
   CciChar targetTerminalName[initialStringBufferLength];
   cciGetTargetTerminalName(&rc,
                            connection,
                            targetTerminalName,
                            initialStringBufferLength);
   /*you should now check the rc for unexpected values*/
   /*if rc is CCI_BUFFER_TOO_SMALL then you should resize and retry*/
```

Related concepts:

Develop a user exit by declaring it, implementing its behavior, then compiling it.

cciRegisterUserExit:

cciRegisterUserExit is a utility function that can be called by the user's code when bipInitializeUserExits is called.

This function is called by the user's code if the user wants to register functions to be called every time certain events occur.

Syntax:

```
typedef struct cci_UEVft {
    int     reserved;
    char    StrucId[4];
    int     Version;
    cciInputMessageCallback      iFpInputMessageCallback;
    cciTransactionEventCallback  iFpTransactionEventCallback;
    cciPropagatedMessageCallback iFpPropagatedMessageCallback;
```

```
    cciNodeCompletionCallback    iFpNodeCompletionCallback;
    cciOutputMessageCallback     iFpOutputMessageCallback;

} CCI_UE_VFT;

void cciRegisterUserExit (
  int*                            returnCode,
  CciChar*                        name,
  CciDataContext*                 userContext,
  CCI_UE_VFT*                     functionTable);
```

Parameters:

returnCode (output)
Requires the return code from the function. Possible values are:

- CCI_DUP_USER_EXIT_NAME

  The specified name matches the name of a user exit previously registered in the current execution group.
- CCI_INV_USER_EXIT_NAME

  The specified name was invalid. This can be caused if a NULL pointer, empty string or a string containing non-alphanumeric characters was specified.

Name (input)
This parameter must contain a pointer to a NULL-terminated string of CciChars specifying a name for the user exit. The name must be unique across all user exits that can be installed on the same broker. This name is used to identify the user exit in, for example:

- User Trace messages
- Exceptions or syslog messages
- Administration commands (for example, **mqsichangeflowuserexits**)

The name has the following restrictions:

- It must consist of alphanumeric characters only.
- It must be no greater than 255 characters.
- The name must be unique across all user exits that can be installed on the same broker.

userContext (input)
This parameter allows the caller to provide a context pointer that is passed to the callback function when it is called. This parameter can be NULL.

functionTable (input)
This parameter is a pointer to a struct whose fields must contain either pointers to functions matching the correct signatures or contain NULL. A NULL value for any of these fields indicates that the user exit must not be called for that event.

Initialize the structure by using the define CCI_UE_VFT_DEFAULT, which sets the version as CCI_UE_VFT_CURRENT_VERSION. The cciOutputMessageCallback was added at version 2, CCI_UE_VFT_VERSION_2.

Return values:
None. If an error occurs, the **returnCode** parameter indicates the reason for the error.

Example:

```
extern "C"{

void bipInitializeUserExits(){

  int rc = CCI_SUCCESS;
  CCI_UE_VFT myVft = {CCI_UE_VFT_DEFAULT};
  myVft.iFpInputMessageCallback      = myInputMessageCallback;
  myVft.iFpTransactionEventCallback  = myTransactionEventCallback;
  myVft.iFpPropagatedMessageCallback = myPropagatedMessageCallback;
  myVft.iFpNodeCompletionCallback    = myNodeCompletionCallback;
  myVft.iFpOutputMessageCallback     = myOutputMessageCallback;

  cciRegisterUserExit(&rc,
                      MyConstants::myUserExitName,
                      0,
                      &myVft);

  /*you should now check the rc for unexpected values*/

  return;
}

}/*end of extern "C" */
```

The cciPropagatedMessageCallback function can be registered as a callback and is called whenever a message is propagated from one node to another.

"cciNodeCompletionCallback" on page 6621
The cciNodeCompletionCallback function can be registered as a callback and is called whenever a node has completed processing of a message and is returning control to its upstream node.

"cciOutputMessageCallback" on page 6626
The cciOutputMessageCallback function can be registered as a callback and is called whenever a message is sent by an output node.

C common API

The C language common API consists of implementation and utility functions that you can use in user-defined nodes, parsers, and user exits.

All these functions are defined in the `BipCpi.h` header file, see “C Header files” on page 6415.

- “C common implementation functions.”
- “C common utility functions” on page 6643.

Related concepts:

“Developing user-defined extensions” on page 2970
A user-defined extension is a component that you design and implement to extend the function of WebSphere Message Broker.

Related reference:

“C language user-defined node API” on page 6416
Learn about the different types of call provided by the API.

“C language user-defined parser API” on page 6538
The C language user-defined parser API consists of two complementary sets of functions that you can use to define the function of your parser.

“C user exit API” on page 6615
The user exit API defines implementation and utility functions.

C common implementation functions:

You can use the common implementation functions in user-defined nodes and user-defined parsers. All the functions are called by the broker on occurrence of certain events.

These functions are defined in the`BipCci.h` header file.

Optional functions

- cciRegCallback

Related reference:

“cciRegCallback”
This function can be registered as a callback function, and is called when the registered event occurs. The function is registered by providing a function pointer which matches a particular typedef.

cciRegCallback:

This function can be registered as a callback function, and is called when the registered event occurs. The function is registered by providing a function pointer which matches a particular typedef.

Syntax:

```
typedef int (*CciRegCallback)(CciDataContext *, cciCallbackType);
```

Parameters:

`type CciDataContext*`
This parameter is the pointer that is provided by the caller to the registration function.

`type CciCallbackType`
This parameter indicates the reason for the callback. The reason is always one of the CciCallbackType values that is specified on the registration call corresponding to this callback.

Return values:

type CciRegCallbackStatus (defined in BipCci.h)

- CCI_THREAD_STATE_REGISTRATION_RETAIN: This return code is used for a callback that is to remain registered as a callback function on a particular thread.
- CCI_THREAD_STATE_REGISTRATION_REMOVE: This return code is used to signify that the callback is to be de-registered, and that it must not be called again on this thread unless it is reregistered.
- If another value is returned, a warning is written to a log, and CCI_THREAD_STATE_REGISTRATION_RETAIN is assumed.

During execution of this function, it is possible that the node or parser that has registered the function has already been deleted. Therefore, you must not call a node or parser utility function that depends on the existence of a node or parser. The only utility functions that can be called from this callback are:

- cciLog
- cciUserTrace
- cciServiceTrace
- cciUserDebugTrace
- cciServiceDebugTrace
- cciIsTraceActive

For each of these five trace utility functions, the CciObject parameter must be NULL.

Example:
Declare the following struct and function:

```
typedef struct {
    int         id;
}MyContext;

static int registered=0;

CciRegCallbackStatus switchThreadStateChange(CciDataContext *context, CciCallbackType type)
{
  char traceText[256];
  char* typeStr=0;
  MyContext* myContext = (MyContext*)context;

  if (type==CCI_THREAD_STATE_IDLE){
      typeStr = "idle";
  }else if(type==CCI_THREAD_STATE_INSTANCE_END){
      typeStr = "instance end";
  }else if (type==CCI_THREAD_STATE_TERMINATION){
      typeStr = "termination";
  }else{
      typeStr = "unknown";
  }

  memset(traceText,0,256);
  sprintf(traceText,"switchThreadStateChange: context id = %d, thread state %s",myContext->id,typeStr);
  cciServiceTrace(NULL,
                  NULL,
                  traceText);
  return CCI_THREAD_STATE_REGISTRATION_RETAIN;

}
```

Place the following code into the _Switch_evaluate function in the samples to enable you to read service trace, and see when the message processing thread changes state:

```
/*register for thread state change*/
  CciMessageContext* messageContext = cniGetMessageContext(NULL,message);
  CciThreadContext*  threadContext  = cniGetThreadContext(NULL,messageContext);

  static MyContext myContext={1};

  if(registered==0){
    cciRegisterForThreadStateChange(
                  NULL,
                  threadContext,
                  & myContext,
                  switchThreadStateChange,
                  CCI_THREAD_STATE_IDLE |
                  CCI_THREAD_STATE_INSTANCE_END |
                  CCI_THREAD_STATE_TERMINATION);

    registered=1;

  }
```

This example registers only on the first thread that receives a message. If it is necessary to register every thread that receives a message, the user-defined extensions must remember on which threads they have registered.

By using the userContext parameter you can see how data is passed from the code where the callback is registered to the actual callback function.

When registering the callback, a pointer to an instance of the **MyContext** struct is passed in. This pointer is the pointer that is passed back to the callback. To ensure that the pointer is still valid when it is passed back to the callback, an instance of the struct is declared as static. Another technique to ensure that the pointer is valid is to allocate storage on the heap.

In the callback function, the userContext parameter can be cast to a **(MyContext*)**. The original MyContext struct can be referenced through this address. This technique permits the passing of data from the code where the callback is registered to the callback function.

Related reference:

"cciRegisterForThreadStateChange" on page 6656
This function registers a function to be called when the current thread enters a particular state.

C common utility functions:

WebSphere Message Broker provides some additional utilities that user-defined nodes and parsers can use.

These utilities belong to the following categories:

- Exception handling and logging
- Character representation handling

These functions are defined in the BipCci.h header file.

The following exception handling and logging functions are provided for use by a user-defined node or parser:

- "cciGetLastExceptionData" on page 6647
- "cciGetLastExceptionDataW" on page 6649
- "cciLog" on page 6651
- "cciLogW" on page 6653
- "cciRethrowLastException" on page 6659
- "cciThrowException" on page 6666
- "cciThrowExceptionW" on page 6668

The following utilities help you convert between the processing code (in UCS-2) that is used internally by WebSphere Message Broker, and file codes (for example, ASCII).

- "cciMbsToUcs" on page 6655
- "cciUcsToMbs" on page 6672

The following utility functions enable you to determine whether trace is active, and write entries that are appropriate for the trace settings.

- "cciIsTraceActive" on page 6670
- "cciUserTrace" on page 6678
- "cciUserTraceW" on page 6681
- "cciUserDebugTrace" on page 6673
- "cciUserDebugTraceW" on page 6676
- "cciServiceTrace" on page 6663
- "cciServiceTraceW" on page 6664
- "cciServiceDebugTrace" on page 6660
- "cciServiceDebugTraceW" on page 6661

The following utility function is used to register a function that is to be called when the current thread enters a particular state:

- "cciRegisterForThreadStateChange" on page 6656

The following utility functions are available for use with user exits:

- "cciGetBrokerInfo" on page 6645
- "cciGetNodeAttribute" on page 6629
- "cciGetNodeName" on page 6630
- "cciGetNodeType" on page 6631
- "cciGetSourceNode" on page 6635
- "cciGetSourceTerminalName" on page 6636
- "cciGetTargetNode" on page 6637
- "cciGetTargetTerminalName" on page 6637
- "cciInputMessageCallback" on page 6619
- "cciNodeCompletionCallback" on page 6621
- "cciPropagatedMessageCallback" on page 6623
- "cciRegisterUserExit" on page 6638
- "cciTransactionEventCallback" on page 6625

cciGetBrokerInfo:

Use the cciGetBrokerInfo function to query the current broker environment (for example, for information about broker name, execution group name, queue manager name). The information is returned in a structure of type CCI_BROKER_INFO_ST.

This function differs from cniGetBrokerInfo in that you do not have to specify a CciNode* handle, and that it does not return information about a message flow. Therefore, you can call cciGetBrokerInfo from initialization functions; for example, bipInitializeUserExits, bipGetMessageParserFactory, and bipGetMessageFlowNodeFactory.

Syntax:

```
void cciGetBrokerInfo(
                      int*                returnCode,
                      CCI_BROKER_INFO_ST* broker_info_st);
```

Parameters:

returnCode (output)
Receives the return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_INV_BROKER_INFO_ST
- CCI_EXCEPTION

broker_info_st (output)
The address of a CCI_BROKER_INFO_ST structure to be populated with the relevant values on successful completion:

```
typedef struct cci_broker_info_st {
int versionId;   /*Structure version identification*/
CCI_STRING_ST brokerName;  /*The label of the broker*/
CCI_STRING_ST executionGroupName; /*The label of the current execution group*/
CCI_STRING_ST queueManagerName;  /*The name of the MQ Queue Manager for the broker*/
CCI_STRING_ST dataSourceUserId;  /*The userid broker connects to datasource as*/
} CCI_BROKER_INFO_ST;
```

Return values:
None. If an error occurs, the **returnCode** parameter indicates the reason for the error.

Example:

```
int rc = CCI_SUCCESS;

CCI_BROKER_INFO_ST brokerInfo = {CCI_BROKER_INFO_ST_DEFAULT};

#define INTITIAL_STR_LEN 256
CciChar brokerNameStr[INTITIAL_STR_LEN];
CciChar executionGroupNameStr[INTITIAL_STR_LEN];
CciChar queueManagerNameStr[INTITIAL_STR_LEN];

brokerInfo.brokerName.bufferLength = INTITIAL_STR_LEN;
brokerInfo.brokerName.buffer       = brokerNameStr;

brokerInfo.executionGroupName.bufferLength = INTITIAL_STR_LEN;
brokerInfo.executionGroupName.buffer = executionGroupNameStr;

brokerInfo.queueManagerName.bufferLength = INTITIAL_STR_LEN;
brokerInfo.queueManagerName.buffer = queueManagerNameStr;
```

```
cciGetBrokerInfo(&rc,&brokerInfo);

/* just in case any of the buffers were too short*/
if ((brokerInfo.brokerName.bytesOutput         < brokerInfo.brokerName.dataLength)  ||
    (brokerInfo.executionGroupName.bytesOutput < brokerInfo.executionGroupName.dataLength) ||
    (brokerInfo.queueManagerName.bytesOutput   < brokerInfo.queueManagerName.dataLength))  {

  /*at least one of the buffer were too short, need to rerty*/
  /* NOTE this is unlikely given that the initial sizes were reasonably large*/

  brokerInfo.brokerName.bufferLength =
     brokerInfo.brokerName.dataLength;
  brokerInfo.brokerName.buffer       =
    (CciChar*)malloc (brokerInfo.brokerName.bufferLength * sizeof(CciChar));

  brokerInfo.executionGroupName.bufferLength =
    brokerInfo.executionGroupName.dataLength;
  brokerInfo.executionGroupName.buffer       =
    (CciChar*)malloc (brokerInfo.executionGroupName.bufferLength * sizeof(CciChar));

  brokerInfo.queueManagerName.bufferLength =
    brokerInfo.queueManagerName.dataLength;
  brokerInfo.queueManagerName.buffer       =
    (CciChar*)malloc (brokerInfo.queueManagerName.bufferLength * sizeof(CciChar));

  cciGetBrokerInfo(&rc,&brokerInfo);

  /*now do something sensible with these strings before the buffers go out of scope*/
  /* for example call a user written function to copy them away*/
  copyBrokerInfo(brokerInfo.brokerName.buffer,
                 brokerInfo.executionGroupName.buffer,
                 brokerInfo.queueManagerName.buffer);

  free((void*)brokerInfo.brokerName.buffer);
  free((void*)brokerInfo.executionGroupName.buffer);
  free((void*)brokerInfo.queueManagerName.buffer);

}else{
  /*now do something sensible with these strings before the buffers go out of scope*/
  /* for example call a user written function to copy them away*/
  copyBrokerInfo(brokerInfo.brokerName.buffer,
                 brokerInfo.executionGroupName.buffer,
                 brokerInfo.queueManagerName.buffer);
}
```

Related concepts:

"User exits" on page 3015
A user exit is user-provided custom software, written in C, to track data passing through message flows.

Related tasks:

"Developing a user exit" on page 3114
Develop a user exit by declaring it, implementing its behavior, then compiling it.

Related reference:

"cniGetBrokerInfo" on page 6488
Use this function to query the current broker environment (for example, for information about broker name and message flow name). The information is returned in a structure of type CNI_BROKER_INFO_ST.

"bipInitializeUserExits" on page 6617
bipInitializeUserExits is an implementation function that is exported by the User Exit library (`.lel` file).

cciGetLastExceptionData:

Gets diagnostic information about the last exception generated. Information about the last exception generated on the current thread is returned in a CCI_EXCEPTION_ST output structure. The user-defined extension can use this function to determine whether any recovery is required when a utility function returns an error code.

You can call this function when a utility function or user exit callback indicates that an exception has occurred, by setting *returnCode* to CCI_EXCEPTION.

You must call cciGetLastExceptionData() only when CCI_EXCEPTION is indicated; at other times, the function returns unpredictable results.

The *traceText* that is associated with the exception converts to a `char*` if the `char*` is US-ASCII. If the *traceText* is in another language, use cciGetLastExceptionDataW and its associated CCI_EXCEPTION_WIDE_ST structure, which stores the *traceText* as UTF-16.

If the exception has been raised by the broker, or by cciThrowExceptionW, the *traceText* element of the CCI_EXCEPTION_ST structure is an empty string.

Syntax:

```
void* cciGetLastExceptionData(
  int*               returnCode,
  CCI_EXCEPTION_ST*  exception_st);
```

Parameters:

`returnCode`
Receives the return code from the function (output). Possible return codes are:

- CCI_INV_DATA_POINTER
- CCI_NO_EXCEPTION_EXISTS
- CCI_EXCEPTION
- CCI_EXCEPTION_UNKNOWN
- CCI_EXCEPTION_FATAL
- CCI_EXCEPTION_RECOVERABLE
- CCI_EXCEPTION_CONFIGURATION
- CCI_EXCEPTION_PARSER
- CCI_EXCEPTION_CONVERSION
- CCI_EXCEPTION_DATABASE
- CCI_EXCEPTION_USER

`exception_st`
Specifies the address of a CCI_EXCEPTION_ST structure to receive data about the last exception (output). The type value returned in the lower four bits of the `exception_st.type` field is one of the following type values:

- CCI_EXCEPTION_ST_TYPE_EXCEPTION_BASE
- CCI_EXCEPTION_ST_TYPE_EXCEPTION_TERMINATION
- CCI_EXCEPTION_ST_TYPE_EXCEPTION_FATAL
- CCI_EXCEPTION_ST_TYPE_EXCEPTION_RECOVERABLE
- CCI_EXCEPTION_ST_TYPE_EXCEPTION_CONFIGURATION
- CCI_EXCEPTION_ST_TYPE_EXCEPTION_PARSER

- CCI_EXCEPTION_ST_TYPE_EXCEPTION_CONVERSION
- CCI_EXCEPTION_ST_TYPE_EXCEPTION_DATABASE
- CCI_EXCEPTION_ST_TYPE_EXCEPTION_USER

The value returned in the `exception_st.messageNumber` field, for exceptions resulting in a BIP cataloged exception message, contains the message level in the high order bytes and the BIP message number in the lower four bytes.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
typedef struct exception_st {
  int               versionId;     /* Structure version identification */
  int               type;          /* Type of exception */
  int               messageNumber; /* Message number */
  int               insertCount;   /* Number of message inserts */
  CCI_STRING_ST     inserts[CCI_MAX_EXCEPTION_INSERTS];
                                   /* Array of message insert areas */
  const char*       fileName;      /* Source: file name */
  int               lineNumber;    /* Source: line number in file */
  const char*       functionName;  /* Source: function name */
  const char*       traceText;     /* Trace text associated with exception */
  CCI_STRING_ST     objectName;    /* Object name */
  CCI_STRING_ST     objectType;    /* Object type */
} CCI_EXCEPTION_ST;
char msgnumTypeStr[64];

CCI_EXCEPTION_ST exception_st = malloc(sizeof(CCI_EXCEPTION_ST));
int rc = 0;
memset(&exception_st,0,sizeof(exception_st));
cciGetLastExceptionData(&rc, &exception_st);
sprintf(msgnumTypeStr, "MsgNum: %d Type: %d",
(exception_st.messageNumber & 0x0ffff),
(exception_st.type & 0x0f));
```

Reference material that supports the creation and management of your user-defined extensions.

"cciLog" on page 6651
Use cciLog to write an error, warning, or informational event.

"cciRethrowLastException" on page 6659
This function re-throws the last exception that has been generated on the current thread. It is used to pass the exception back to the broker for further handling. The function, like a C **exit** call, does not return to the caller.

"cciThrowException" on page 6666
Use this function to throw an exception. The exception is thrown by the broker interface, and includes the specified arguments as exception data.

cciGetLastExceptionDataW:

Gets diagnostic information about the last exception generated. Information about the last exception generated on the current thread is returned in a CCI_EXCEPTION_WIDE_ST output structure. The user-defined extension uses this function to determine whether any recovery is required when a utility function returns an error code.

You can call this function, when a utility function or user exit callback indicates that an exception has occurred, by setting *returnCode* to CCI_EXCEPTION.

Unless CCI_EXCEPTION is indicated you must not call cciGetLastExceptionDataW() because it returns unpredictable results.

Syntax:

```
void* cciGetLastExceptionDataW(
  int*                    returnCode,
  CCI_EXCEPTION_WIDE_ST*  exception_st);
```

Parameters:

returnCode
Receives the return code from the function (output). Possible return codes are:
- CCI_INV_DATA_POINTER
- CCI_NO_EXCEPTION_EXISTS
- CCI_EXCEPTION
- CCI_EXCEPTION_UNKNOWN
- CCI_EXCEPTION_FATAL
- CCI_EXCEPTION_RECOVERABLE
- CCI_EXCEPTION_CONFIGURATION
- CCI_EXCEPTION_PARSER
- CCI_EXCEPTION_CONVERSION
- CCI_EXCEPTION_DATABASE
- CCI_EXCEPTION_USER

exception_st
Specifies the address of a CCI_EXCEPTION_WIDE_ST structure to receive data about the last exception (output). The type value returned in the lower four bits of the **exception_st.type** field is one of the following type values:
- CCI_EXCEPTION_ST_TYPE_EXCEPTION_BASE
- CCI_EXCEPTION_ST_TYPE_EXCEPTION_TERMINATION
- CCI_EXCEPTION_ST_TYPE_EXCEPTION_FATAL
- CCI_EXCEPTION_ST_TYPE_EXCEPTION_RECOVERABLE
- CCI_EXCEPTION_ST_TYPE_EXCEPTION_CONFIGURATION
- CCI_EXCEPTION_ST_TYPE_EXCEPTION_PARSER

- CCI_EXCEPTION_ST_TYPE_EXCEPTION_CONVERSION
- CCI_EXCEPTION_ST_TYPE_EXCEPTION_DATABASE
- CCI_EXCEPTION_ST_TYPE_EXCEPTION_USER

The value returned in the **exception_st.messageNumber** field, for exceptions resulting in a BIP cataloged exception message, contains the message level in the high order bytes and the BIP message number in the lower four bytes.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
typedef struct exception_wide_st {
  int               versionId;     /* Structure version identification */
  int               type;          /* Type of exception */
  int               messageNumber; /* Message number */
  int               insertCount;   /* Number of message inserts */
  CCI_STRING_ST     inserts[CCI_MAX_EXCEPTION_INSERTS];
                                   /* Array of message insert areas */
  const char*       fileName;     /* Source: file name */
  int               lineNumber;     /* Source: line number in file */
  const char*       functionName;  /* Source: function name */
  CCI_STRING_ST     traceText;     /* Trace text associated with exception */
  CCI_STRING_ST     objectName;    /* Object name */
  CCI_STRING_ST     objectType;    /* Object type */
} CCI_EXCEPTION_WIDE_ST;
char msgnumTypeStr[64];

CCI_EXCEPTION_WIDE_ST exception_st = malloc(sizeof(CCI_EXCEPTION_WIDE_ST));
int rc = 0;
memset(&exception_st,0,sizeof(exception_st));
cciGetLastExceptionDataW(&rc, &exception_st);
sprintf(msgnumTypeStr, "MsgNum: %d Type: %d",
(exception_st.messageNumber & 0x0ffff),
(exception_st.type & 0x0f));
```

Writes a message to service trace, if service trace is active.

"cciServiceDebugTrace" on page 6660
This function is very similar to cciServiceTrace with the only difference being that the entry is written to service trace only when service trace is active at debug level.

"cciIsTraceActive" on page 6670
cciIsTraceActive reports whether trace is active and the level at which trace is active.

"Trace logging from a user-defined C extension" on page 6693
Message processing nodes and parsers that are written to the C programming language API can write entries to trace.

"cciThrowExceptionW" on page 6668
The cciThrowExceptionW exception is thrown by the broker interface and uses the specified arguments as exception data.

"cciLogW" on page 6653
cciLogW logs an error, warning, or informational event. The event is logged by the

broker interface and uses the specified arguments as log data.

"cciUserTraceW" on page 6681
Use cciUserTraceW to write a message from a message catalog (with inserts) to user trace. A message is also written to service trace, if service trace is active.

"cciUserDebugTraceW" on page 6676
Use cciUserDebugTraceW to write a message from a message catalog (with inserts) to user trace when user trace is active at debug level. A message is also written to service trace, if service trace is active.

"cciServiceTraceW" on page 6664
cciServiceTraceW writes a message to service trace, if service trace is active.

"cciServiceDebugTraceW" on page 6661
The function is very similar to cciServiceTraceW with the only difference being that the entry is written to service trace only when service trace is active at debug level.

"User trace" on page 6873
User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

cciLog:

Use cciLog to write an error, warning, or informational event.

The event is logged by the broker interface, and includes the specified arguments as log data.

Syntax:

```
void cciLog(
  int*          returnCode,
  CCI_LOG_TYPE  type,
  char*         file,
  int           line,
  char*         function,
  CciChar*      messageSource,
  int           messageNumber,
  char*         traceText,
                ...);
```

Parameters:

returnCode
The return code from the function (output). Possible return codes are:
- CCI_SUCCESS
- CCI_INV_DATA_POINTER
- CCI_INV_LOG_TYPE

type The type of event, as defined by CCI_LOG_TYPE (input). Valid values are:
- CCI_LOG_ERROR
- CCI_LOG_WARNING
- CCI_LOG_INFORMATION

file The source file name where the function was invoked (input). The value is optional, but it is useful for debugging purposes.

line The line number in the source file where the function was invoked (input). The value is optional, but it is useful for debugging purposes.

function
The function name that invoked the log function (input). The value is optional, but it is useful for debugging purposes.

messageSource
The fully-qualified location and name of the Windows message source or the Linux, UNIX, or z/OS message catalog.

To use the current broker message catalog, specify BIPmsgs on all operating systems. Alternatively, you can create your own message catalog.

messageNumber
The message number identifying the event (input). If *messageNumber* is specified as zero, it is assumed that a message is not available. If *messageNumber* is non-zero, the specified message is written into the broker event log with any inserts provided in the variable argument list.

traceText
Trace information that is written into the broker service trace log (input). The information is optional, but it is useful for debugging purposes.

... A C variable argument list containing any message inserts that accompany the message (input). These inserts are treated as character strings, and the variable arguments are assumed to be of type `pointer to char`.

`char*` characters must be strings in either ASCII (Latin) or EBCDIC (1047).

The last argument in this list must be `(char*)0`.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Use this function to throw an exception. The exception is thrown by the broker interface, and includes the specified arguments as exception data.

cciLogW:

cciLogW logs an error, warning, or informational event. The event is logged by the broker interface and uses the specified arguments as log data.

Syntax:

```
void cciLogW(
  int*              returnCode,
  CCI_LOG_TYPE      type,
  const char*       file,
  int               line,
  const char*       function,
  const CciChar*    messageSource,
  int               messageNumber,
  const CciChar*    traceText,
                    ...
);
```

Parameters:

returnCode
The return code from the function (output). If the *messageSource* parameter is null, the *returnCode* is set to CCI_INV_DATA_POINTER.

type The type of event, as defined by CCI_LOG_TYPE (input). Valid values are:

- CCI_LOG_ERROR
- CCI_LOG_WARNING
- CCI_LOG_INFORMATION

file The source file name where the function was invoked (input). The value is optional, but it is useful for debugging purposes.

line The line number in the source file where the function was invoked (input). The value is optional, but it is useful for debugging purposes.

function
The function name that invoked the log function (input). The value is optional, but it is useful for debugging purposes.

messageSource
The fully-qualified location and name of the Windows message source or the Linux, UNIX, or z/OS message catalog.

To use the current broker message catalog, specify BIPmsgs on all operating systems. Alternatively, you can create your own message catalog.

messageNumber
The message number identifying the event (input). If *messageNumber* is specified as zero, it is assumed that a message is not available. If *messageNumber* is non-zero, the specified message is written into the broker event log with any inserts provided in the variable argument list (see example).

traceText
Trace information that is written into the broker service trace log (input). The information is optional, but it is useful for debugging purposes.

... A C variable argument list containing any message inserts that accompany the message (input). These inserts are treated as character strings and the variable arguments are assumed to be of type `pointer to CciChar`.

The last argument in this list *must* be `(CciChar*)0`.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
void logSomethingWithBroker(CciChar* helpfulText,
                            char* file,
                            int line,
                            char* func
                            ){
  int rc = CCI_SUCCESS;
  /* set up the message catalog name */
  const CciChar* catalog = CciString("BIPmsgs", BIP_DEF_COMP_CCSID);

  cciLogW(&rc,
          CCI_LOG_INFORMATION
          file, line, func,
          catalog, BIP2111,
          helpfulText,
          helpfulText,
          (CciChar*)0
          );

  if(CCI_SUCCESS != rc){
    const CciChar* message = CciString("Failed to log message",
                                       BIP_DEF_COMP_CCSID);
    raiseExceptionWithBroker(message,
                             __FILE__,
                             __LINE__,
                             "logSomethingWithBroker");
  }
}
```

"cciThrowException" on page 6666
Use this function to throw an exception. The exception is thrown by the broker interface, and includes the specified arguments as exception data.

cciMbsToUcs:

Use this function to convert multibyte string data to Universal Character Set (UCS).

Syntax:

```
int cciMbsToUcs(
  int*         returnCode,
  const char*  mbString,
  CciChar*     ucsString,
  int          ucsStringLength,
  int          codePage);
```

Parameters:

returnCode
The return code from the function (output). Possible return codes are:
- CCI_SUCCESS
- CCI_BUFFER_TOO_SMALL
- CCI_INV_CHARACTER
- CCI_FAILURE
- CCI_INV_CODEPAGE

mbString
The string to be converted, expressed as 'file code' (input).

ucsString
The location of the resulting UCS-2 Unicode string (input). This string has a trailing `CciChar` of 0, just as the *mbString* has a trailing byte of 0.

ucsStringLength
The length (in `CciChar`) of the buffer that you have provided (input). Each byte in *mbString* expands to not more than one `CciChar` character, and this defines an upper limit for the buffer size required.

codePage

The code page of the source string (input). The value of the code page must be suitable for the compiler that you are using to compile the user-defined node.

For an ASCII system, a value of 1208 (meaning code page ibm-1208, which is UTF-8 Unicode) is a good choice if you are using cciMbsToUcs to convert string constants for processing by WebSphere Message Broker. 1208 is appropriate for Linux, UNIX, and Windows systems.

On Linux, UNIX systems, `nl_langinfo(CODEPAGE)` gives you the code page that has been selected by `setlocale`.

On z/OS, the default code page for WebSphere MQ, which is 500, must not be used. Instead, use a code page value of 1047.

Return values:
The *returnCode* parameter is set to the converted length in half-words (UCS-2 characters).

"cciUcsToMbs" on page 6672
Use this function to convert Universal Character Set (UCS) data to multibyte string data. This function is, typically, used only for formatting diagnostic messages. Normal processing is best done in UCS-2, which can represent all characters from all languages.

cciRegisterForThreadStateChange:

This function registers a function to be called when the current thread enters a particular state.

Syntax:

```
void cciRegisterForThreadStateChange(
          int               *returnCode,
          CciThreadContext  *threadContext,
          CciDataContext    *userContext,
          CciRegCallback     callback,
          CciCallbackType    type);
```

Parameters:

returnCode
The return code from the function (output). An input value of NULL signifies that errors are silently handled, or are ignored by the broker. If the input value is not NULL, the output value signifies the success status of the call. If the `threadContext` parameter is not valid, `*returnCode` is set to CCI_INV_THREAD_CONTEXT, and the callback is not registered.

threadContext
This parameter provides the thread context in which to register the callback function and associated data. It is assumed that this parameter is obtained by calling cniGetThreadContext() on the current thread. If NULL is supplied as `threadContext`, the thread context is determined by the framework. This method is less efficient than calling cniGetThreadContext.

userContext
This parameter allows the caller to provide a context pointer that is passed to the callback function when it is called. This parameter can be NULL.

callback
This parameter is a pointer to the callback function that is to be called. This function must be of the type `CciRegCallback`.

type
This parameter specifies whether the callback is to be called at the time when the thread is ending, or when the thread is in one of the idle states. The idle states can be one of the following values:

- CCI_THREAD_STATE_IDLE:

  The input node for the current thread is actively polling for data from the input source, but no data is available. Messages are not propagated through the message flow until data becomes available for the input node.
- CCI_THREAD_STATE_INSTANCE_END

  The input node for the current thread has stopped polling for data and the thread has been released. The thread is dispatched again either by the same input node or by another input node in the same message flow. This state is entered when additional instances, which have been deployed for a message flow, have been configured to cope with an influx of input data that has now ceased. The input node continues to poll for input data on a single thread, and the other threads are released.
- CCI_THREAD_STATE_TERMINATION

  The current thread is ending. This action can happen when the broker is shut down, the execution group process is ending in a controlled manner, or when the message flow is being deleted. This state can occur after all nodes and parsers in the flow are deleted.

Alternatively, the `type` parameter can be the result of a bit-wise `OR` operation on two or more of these values. In this case, the specified function is called when the thread enters the relevant state for each individual `type` value.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:
Declaring the struct and function:

```
typedef struct {
    int         id;
}MyContext;
```

```
static int registered=0;

CciRegCallbackStatus switchThreadStateChange(
           CciDataContext *context, CciCallbackType type)
{
  char    traceText[256];
  char*   typeStr=0;
  MyContext* myContext = (MyContext*)context;

  if (type==CCI_THREAD_STATE_IDLE){
      typeStr = "idle";
  }else if(type==CCI_THREAD_STATE_INSTANCE_END){
      typeStr = "instance end";
  }else if (type==CCI_THREAD_STATE_TERMINATION){
      typeStr = "termination";
  }else{
      typeStr = "unknown";
  }

  memset(traceText,0,256);
  sprintf(traceText,"switchThreadStateChange: context id = %d, thread state %s",myContext->id,typeStr);
  cciServiceTrace(NULL,
                  NULL,
                  traceText);
  return CCI_THREAD_STATE_REGISTRATION_RETAIN;

}
```

Place the following code into the `_Switch_evaluate` function in the samples to enable you to read service trace, and to see when the message processing thread changes state:

```
/*register for thread state change*/
  CciMessageContext* messageContext = cniGetMessageContext(NULL,message);
  CciThreadContext*  threadContext  = cniGetThreadContext(NULL,messageContext);

  static MyContext myContext={1};

  if(registered==0){
    cciRegisterForThreadStateChange(
                   NULL,
                   threadContext,
                   & myContext,
                   switchThreadStateChange,
                   CCI_THREAD_STATE_IDLE |
                   CCI_THREAD_STATE_INSTANCE_END |
                   CCI_THREAD_STATE_TERMINATION);
  registered=1;

  }
```

This example registers only on the first thread that receives a message. If it is necessary to register every thread that receives a message, the user-defined extensions must remember on which threads they have registered.

By using the `userContext` parameter, you can see how data is passed from the code where the callback is registered to the actual callback function.

When registering the callback, a pointer to an instance of the **MyContext** struct is passed in. This pointer is the same pointer as is passed back to the callback. To ensure that the pointer is still valid when it is passed back to the callback, an instance of the struct is declared as static. Another technique to ensure that the pointer is valid is to allocate storage on the heap.

In the callback function, the **userContext** parameter can be cast to a **(MyContext*)**. The original **MyContext** struct can be referenced through this address. This technique permits the passing of data from the code where the callback is registered to the callback function.

"cniGetThreadContext" on page 6494
This function returns the thread context for the current thread.

"cciRegCallback" on page 6641
This function can be registered as a callback function, and is called when the registered event occurs. The function is registered by providing a function pointer which matches a particular typedef.

cciRethrowLastException:

This function re-throws the last exception that has been generated on the current thread. It is used to pass the exception back to the broker for further handling. The function, like a C **exit** call, does not return to the caller.

Syntax:

```
void cciRethrowLastException(int* returnCode);
```

Parameters:

returnCode
The return code from the function (output). The possible return code is CCI_NO_EXCEPTION_EXISTS

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
if (rc == CCI_EXCEPTION) {
     cciRethrowLastException(&rc);
   }
```

Create a user-defined parser to interpret messages with a different format and structure.

Related reference:

"User-defined extensions" on page 6411
Reference material that supports the creation and management of your user-defined extensions.

"cciGetLastExceptionData" on page 6647
Gets diagnostic information about the last exception generated. Information about the last exception generated on the current thread is returned in a CCI_EXCEPTION_ST output structure. The user-defined extension can use this function to determine whether any recovery is required when a utility function returns an error code.

"cciLog" on page 6651
Use cciLog to write an error, warning, or informational event.

"cciThrowException" on page 6666
Use this function to throw an exception. The exception is thrown by the broker interface, and includes the specified arguments as exception data.

cciServiceDebugTrace:

This function is very similar to cciServiceTrace with the only difference being that the entry is written to service trace only when service trace is active at debug level.

Syntax:

```
void cciServiceDebugTrace(
  int*           returnCode,
  CciObject*     object,
  const char*    traceText
);
```

Parameters:

returnCode
Receives the return code from the function (output). A NULL pointer input signifies that the user-defined node does not want to deal with errors. Any exceptions thrown during the execution of this call will be re-thrown to the next upstream node in the flow. If input is not NULL, output will signify the success status of the call. If an exception occurs during execution, **returnCode* will be set to CCI_EXCEPTION on output. A call to **CciGetLastExceptionData** will provide details of the exception.

object (input)
The address of the object that is to be associated with the trace entry (input). This object can be a CciNode* or a CciParser*. If it is a CciNode*, the name of that node is written to trace. If it is a CciParser*, the name of the node that created the parser is written to trace. This object is also used to determine if the entry should be written to trace. The entry is only written if trace is active for the node. Currently nodes inherit their trace setting from the message flow.

If this parameter is NULL, the trace level for the execution group is returned.

traceText (input)
A string of characters that ends with NULL (input). This string will be written to service trace and provides an easy way to correlate trace entries with paths through the source code. For example, there could be several paths through the code that result in the same message (*messageSource* and *messageNumber*) being written to trace. *traceText* can be used to distinguish between these different paths. That is, the *traceText* string will be a static literal string in the source and therefore the same string will be in both the source code file and the formatted trace file.

This string must be in ISO-8859-1 (ibm-819) code page for user-defined extensions running on distributed platforms and must be in EBCDIC (1047) for user-defined extensions running on Z/OS See NLS section.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
CciNode*         thisNode = ((NODE_CONTEXT_ST*)context)->nodeObject;

cciServiceTrace(&rc,(CciObject*)thisNode,">>_Switch_evaluate()");
checkRC(rc);
```

"User trace" on page 6873
User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

cciServiceDebugTraceW:

The function is very similar to cciServiceTraceW with the only difference being that the entry is written to service trace only when service trace is active at debug level.

Syntax:

```
void cciServiceDebugTraceW(
  int*           returnCode,
  CciObject*     object,
  const CciChar* traceText
);
```

Parameters:

returnCode
Receives the return code from the function (output). A NULL pointer input signifies that the user-defined node does not want to deal with errors. Any exceptions thrown during the execution of this call will be re-thrown to the next upstream node in the flow. If input is not NULL, output will signify the success status of the call. If an exception occurs during execution, **returnCode* will be set to CCI_EXCEPTION on output. A call to **CciGetLastExceptionData** will provide details of the exception.

object (input)
The address of the object that is to be associated with the trace entry (input).

This object can be a CciNode* or a CciParser*. If it is a CciNode*, the name of that node is written to trace. If it is a CciParser*, the name of the node that created the parser is written to trace. This object is also used to determine if the entry should be written to trace. The entry is only written if trace is active for the node. Currently nodes inherit their trace setting from the message flow.

If this parameter is NULL, the trace level for the execution group is returned.

traceText (input)
A string of characters that ends with NULL (input). This string will be written to service trace and provides an easy way to correlate trace entries with paths through the source code. For example, there could be several paths through the code that result in the same message (*messageSource* and *messageNumber*) being written to trace. *traceText* can be used to distinguish between these different paths. That is, the *traceText* string will be a static literal string in the source and therefore the same string will be in both the source code file and the formatted trace file.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
CciNode* thisNode = ((NODE_CONTEXT_ST*)context)->nodeObject;
CciChar* traceText = CciString(">>_Switch_evaluate()",BIP_DEF_COMP_CCSID");
cciServiceTraceW(&rc,(CciObject*)thisNode,traceText);
checkRC(rc);
```

"cciUserDebugTraceW" on page 6676
Use cciUserDebugTraceW to write a message from a message catalog (with inserts) to user trace when user trace is active at debug level. A message is also written to

service trace, if service trace is active.

"cciServiceTraceW" on page 6664
cciServiceTraceW writes a message to service trace, if service trace is active.

"User trace" on page 6873
User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

cciServiceTrace:

Writes a message to service trace, if service trace is active.

The message that is written to service trace has the following format:

```
<date-time stamp> <threadNumber> +cciServiceTrace <nodeName> <nodeType> <traceText>, <nodeLabel>
```

Syntax:

```
void cciServiceTrace(
  int*           returnCode,
  CciObject*     object,
  const char*    traceText
);
```

Parameters:

returnCode
Receives the return code from the function (output). A NULL pointer input parameter signifies that the user-defined node does not handle errors. Exceptions thrown during the execution of this call are thrown again to the next upstream node in the flow. If the input parameter is not NULL, output signifies the success status of the call. If an exception occurs during execution, **returnCode* is set to CCI_EXCEPTION on output. Use CciGetLastExceptionData to get details of the exception.

object (input)
The address of the object that is to be associated with the trace entry (input). This object can be the address of a CciNode or a CciParser. If you specify a CciNode, the name of that node is written to trace. If you specify a CciParser, the name of the node that created the parser is written to trace. This object is also used to determine if the entry is written to trace. The entry is written only if trace is active for the node. Currently, nodes inherit their trace setting from the message flow.

If this parameter is NULL, the following actions are taken:

- <nodeName>, <nodeType>, <nodeLabel>, and <messageFlowLabel> are omitted from the trace entry.
- The entry is written based on the trace setting of the execution group.

traceText (input)
A string of characters that ends with NULL (input). This string is written to service trace, and you can use it to correlate trace entries with paths through the source code. For example, you might have several paths through the code that result in the same message (*messageSource* and *messageNumber*) being written to trace. *traceText* can be used to distinguish between these different paths. That is, the *traceText* string is a static literal string in the source, and therefore the same string is in both the source code file and the formatted trace file.

This string must be in ISO-8859-1 (ibm-819) code page for user-defined extensions running on distributed platforms, and must be in EBCDIC (1047) for user-defined extensions running on z/OS.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
CciNode*         thisNode = ((NODE_CONTEXT_ST*)context)->nodeObject;

cciServiceTrace(&rc,(CciObject*)thisNode,">>_Switch_evaluate()");
checkRC(rc);
```

User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

"Multicultural support considerations for message catalogs" on page 6694
WebSphere Message Broker converts any message that is loaded from the listed supported code pages into the local code page of the running processes (brokers) before output to the syslog.

cciServiceTraceW:

cciServiceTraceW writes a message to service trace, if service trace is active.

The message that is written to service trace has the following format:

```
<date-time stamp> <threadNumber> +cciServiceTrace <nodeName> <nodeType> <traceText>, <nodeLabel>
```

Syntax:

```
void cciServiceTraceW(
  int*           returnCode,
  CciObject*     object,
  const CciChar* traceText
);
```

Parameters:

returnCode
Receives the return code from the function (output). A NULL pointer input signifies that the user-defined node does not want to deal with errors. Any exceptions thrown during the execution of this call will be re-thrown to the next upstream node in the flow. If input is not NULL, output will signify the success status of the call. If an exception occurs during execution, **returnCode* will be set to CCI_EXCEPTION on output. A call to **CciGetLastExceptionData** will provide details of the exception.

object (input)
The address of the object that is to be associated with the trace entry (input). This object can be a CciNode* or a CciParser*. If it is a CciNode*, the name of that node is written to trace. If it is a CciParser*, the name of the node that created the parser is written to trace. This object is also used to determine if the entry should be written to trace. The entry is only written if trace is active for the node. Currently nodes inherit their trace setting from the message flow.

If this parameter is NULL, the trace level for the execution group is returned.

traceText (input)
A string of characters that ends with NULL (input). This string will be written to service trace and provides an easy way to correlate trace entries with paths through the source code. For example, there could be several paths through the code that result in the same message (*messageSource* and *messageNumber*) being written to trace. *traceText* can be used to distinguish between these different paths. That is, the *traceText* string will be a static literal string in the source and therefore the same string will be in both the source code file and the formatted trace file.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
CciNode*         thisNode = ((NODE_CONTEXT_ST*)context)->nodeObject;
const CciChar*   traceText = CciString(">>_Switch_evaluate()",
                                       BIP_DEF_COMP_CCSID);
cciServiceTraceW(&rc,(CciObject*)thisNode,traceText);
checkRC(rc);
```

"cciUserTraceW" on page 6681
Use cciUserTraceW to write a message from a message catalog (with inserts) to user trace. A message is also written to service trace, if service trace is active.

"cciUserDebugTraceW" on page 6676
Use cciUserDebugTraceW to write a message from a message catalog (with inserts) to user trace when user trace is active at debug level. A message is also written to service trace, if service trace is active.

"cciServiceDebugTraceW" on page 6661
The function is very similar to cciServiceTraceW with the only difference being that the entry is written to service trace only when service trace is active at debug level.

"User trace" on page 6873
User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

cciThrowException:

Use this function to throw an exception. The exception is thrown by the broker interface, and includes the specified arguments as exception data.

Syntax:

```
void cciThrowException(
  int*                returnCode,
  CCI_EXCEPTION_TYPE  type,
  char*               file,
  int                 line,
  char*               function,
  CciChar*            messageSource,
  int                 messageNumber,
  char*               traceText,
                      ...);
```

Parameters:

returnCode
The return code from the function (output). The possible return code is CCI_INV_DATA_POINTER.

type The type of exception (input). Valid values are:

- CCI_FATAL_EXCEPTION
- CCI_RECOVERABLE_EXCEPTION
- CCI_CONFIGURATION_EXCEPTION
- CCI_PARSER_EXCEPTION
- CCI_CONVERSION_EXCEPTION
- CCI_DATABASE_EXCEPTION
- CCI_USER_EXCEPTION

file The source file name where the exception was generated (input). The value is optional, but it is useful for debugging purposes.

line The line number in the source file where the exception was generated (input). The value is optional, but it is useful for debugging purposes.

function
The function name which generated the exception (input). The value is optional, but it is useful for debugging purposes.

messageSource
The fully-qualified location and name of the Windows message source or the Linux, UNIX, or z/OS message catalog.

To use the current broker message catalog, specify BIPmsgs on all operating systems. Alternatively, you can create your own message catalog.

messageNumber
The message number identifying the exception (input). If *messageNumber* is specified as zero, it is assumed that a message is not available. If *messageNumber* is non-zero, the specified message is written into the broker event log with any inserts provided in the variable argument list.

traceText
Trace information that is written into the broker service trace log (input). The information is optional, but it is useful in debugging problems.

... A C variable argument list that contains any message inserts that accompany the message (input). These inserts are treated as character strings and the variable arguments are assumed to be of type `pointer to char`.

`char*` characters must be strings in either ASCII (Latin) or EBCDIC (1047).

The last argument in this list must be `(char*)0`.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Reference material that supports the creation and management of your user-defined extensions.

"cciGetLastExceptionData" on page 6647
Gets diagnostic information about the last exception generated. Information about the last exception generated on the current thread is returned in a CCI_EXCEPTION_ST output structure. The user-defined extension can use this function to determine whether any recovery is required when a utility function returns an error code.

"cciLog" on page 6651
Use cciLog to write an error, warning, or informational event.

"cciRethrowLastException" on page 6659
This function re-throws the last exception that has been generated on the current thread. It is used to pass the exception back to the broker for further handling. The function, like a C **exit** call, does not return to the caller.

cciThrowExceptionW:

The cciThrowExceptionW exception is thrown by the broker interface and uses the specified arguments as exception data.

Syntax:

```
void cciThrowExceptionW(
  int*                returnCode,
  CCI_EXCEPTION_TYPE  type,
  const char*         file,
  int                 line,
  const char*         function,
  const CciChar*      messageSource,
  int                 messageNumber,
  const CciChar*      traceText,
                      ...
);
```

Parameters:

returnCode
The return code from the function (output). If the *messageSource* parameter is null, the *returnCode* is set to CCI_INV_DATA_POINTER.

type The type of exception (input). Valid values are:

- CCI_FATAL_EXCEPTION
- CCI_RECOVERABLE_EXCEPTION
- CCI_CONFIGURATION_EXCEPTION
- CCI_PARSER_EXCEPTION
- CCI_CONVERSION_EXCEPTION
- CCI_DATABASE_EXCEPTION
- CCI_USER_EXCEPTION

file The source file name where the exception was generated (input). The value is optional, but it is useful for debugging purposes.

line The line number in the source file where the exception was generated (input). The value is optional, but it is useful for debugging purposes.

function
The function name which generated the exception (input). The value is optional, but it is useful for debugging purposes.

messageSource
A string that identifies the Windows message source or the Linux and UNIX message catalog. To use the current broker message catalog, specify BIPmsgs on all operating systems.

messageNumber
The message number identifying the exception (input). If *messageNumber* is specified as zero, it is assumed that a message is not available. If *messageNumber* is non-zero, the specified message is written into the broker event log with any inserts provided in the variable argument list.

traceText
Trace information that is written into the service trace log (input). The information is optional, but it is useful in debugging problems.

... A C variable argument list that contains any message inserts that accompany the message (input). These inserts are treated as character strings and the variable arguments are assumed to be of type `pointer to CciChar`.

The last argument in this list *must* be `(Ccichar*)0`.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
void raiseExceptionWithBroker(CciChar* helpfulText,
                              char* file, /* which source file is broken */
                              int line,   /* line in above file */
                              char* func  /* function in above file */
                              ){
  int rc = CCI_SUCCESS;

  /* Set up the message catalog name */
  const char* catalog = "BIPmsgs";

  /* Convert the catalog name to wide characters.
   * BIP_DEF_COMP_CCSID is UTF-8 on distributed and LATIN1 on z/OS
   */
  int maxChars =  strlen(catalog)+1;
  CciChar* wCatalog =(CciChar*)malloc(maxChars*sizeof(CciChar));
  cciMbsToUcs(&rc, catalog, wCatalog, maxChars, BIP_DEF_COMP_CCSID);

  /* The above might have failed, but we are already throwing an exception,
   * so rc is now set to type success. */
  rc = CCI_SUCCESS;

  /* Throw the exception. The explanation will be added as the traceText and
   *  as an insert to the message
   */
  cciThrowExceptionW(&rc,
                     CCI_USER_EXCEPTION,
                     file, line, func,
                     wCatalog, BIP2111,
                     helpfulText,
                     helpfulText,
                     (CciChar*)0
                     );
  /* The above might have failed, but we are already throwing an exception,
   * so the value of rc is not important. */
}
```

Related concepts:

"User-defined extensions overview" on page 2971
A user-defined extension is an optional component that you design and create to extend the functionality of WebSphere Message Broker.

Related tasks:

A message processing node is used to process a message in some way, and an output node is used to produce a message as a bit stream.

"Implementing a user-defined parser" on page 3099
Create a user-defined parser to interpret messages with a different format and structure.

"Using error logging from a user-defined extension" on page 3137
Program user-defined extensions to write entries in the local error log.

Related reference:

"User-defined extensions" on page 6411
Reference material that supports the creation and management of your user-defined extensions.

"cciGetLastExceptionDataW" on page 6649
Gets diagnostic information about the last exception generated. Information about the last exception generated on the current thread is returned in a CCI_EXCEPTION_WIDE_ST output structure. The user-defined extension uses this function to determine whether any recovery is required when a utility function returns an error code.

"cciThrowExceptionW" on page 6668
The cciThrowExceptionW exception is thrown by the broker interface and uses the specified arguments as exception data.

"cciRethrowLastException" on page 6659
This function re-throws the last exception that has been generated on the current thread. It is used to pass the exception back to the broker for further handling. The function, like a C **exit** call, does not return to the caller.

cciIsTraceActive:

cciIsTraceActive reports whether trace is active and the level at which trace is active.

Syntax:

```
CCI_TRACE_TYPE cciIsTraceActive(
  int*          returnCode,
  CciObject*    object);
```

Parameters:

returnCode
Receives the return code from the function (output). A NULL pointer input signifies that the user-defined node does not want to deal with errors. Any exceptions thrown during the execution of this call will be re-thrown to the next upstream node in the flow. If input is not NULL, output will signify the success status of the call. If an exception occurs during execution, *returnCode will be set to CCI_EXCEPTION on output. A call to **CciGetLastExceptionData** will provide details of the exception.

object
The address of the object that is to be associated with the trace entry (input).

This object can be a CciNode* or a CciParser*. If it is a CciNode*, the name of that node is written to trace. If it is a CciParser*, the name of the node that created the parser is written to trace. This object is also used to determine if the entry should be written to trace. The entry is only written if trace is active for the node. Currently nodes inherit their trace setting from the message flow.

If this parameter is NULL, the trace level for the execution group is returned.

Return values:
A CCI_TRACE_TYPE value indicating the level of trace that is currently active. The CCI_TRACE_TYPE type has the following possible values:

- CCI_USER_NORMAL_TRACE
- CCI_USER_DEBUG_TRACE
- CCI_ SERVICE_NORMAL_TRACE
- CCI_SERVICE_DEBUG_TRACE
- CCI_TRACE_NONE

These return values are bitwise values. Combinations of these values are also possible, for example:

- CCI_USER_NORMAL_TRACE + CCI_ SERVICE_NORMAL_TRACE
- CCI_USER_NORMAL_TRACE + CCI_SERVICE_DEBUG_TRACE
- CCI_USER_DEBUG_TRACE + CCI_ SERVICE_NORMAL_TRACE
- CCI_USER_DEBUG_TRACE + CCI_SERVICE_DEBUG_TRACE

CCI_TRACE_NONE is a zero value and all other values are non zero.

Two further values can be used as bitmasks when querying the active level of trace. These are:

- CCI_USER_TRACE
- CCI_SERVICE_TRACE

For example, the expression `(traceLevel & CCI_USER_TRACE)` will evaluate to a non zero value for *traceLevel* for the following return values:

- CCI_USER_NORMAL_TRACE + CCI_ SERVICE_NORMAL_TRACE
- CCI_USER_NORMAL_TRACE + CCI_SERVICE_DEBUG_TRACE
- CCI_USER_DEBUG_TRACE + CCI_ SERVICE_NORMAL_TRACE
- CCI_USER_DEBUG_TRACE + CCI_SERVICE_DEBUG_TRACE
- CCI_USER_NORMAL_TRACE
- CCI_USER_DEBUG_TRACE

The expression `(traceLevel & CCI_USER_TRACE)` will evaluate to zero for *traceLevel* for the following return values:

- CCI_SERVICE_NORMAL_TRACE
- CCI_SERVICE_DEBUG_TRACE
- CCI_TRACE_NONE

Example:

```
CciNode*         thisNode = ((NODE_CONTEXT_ST*)context)->nodeObject;

const CCI_TRACE_TYPE   traceActive = cciIsTraceActive(&rc, (CciObject*)thisNode);
checkRC(rc);
```

Related reference:

"cciUserTrace" on page 6678

"cciUserDebugTrace" on page 6673
Use cciUserDebugTrace to write a message from a message catalog (with inserts) to user trace when user trace is active at debug level.

"cciServiceTrace" on page 6663
Writes a message to service trace, if service trace is active.

"cciServiceDebugTrace" on page 6660
This function is very similar to cciServiceTrace with the only difference being that the entry is written to service trace only when service trace is active at debug level.

"Trace logging from a user-defined C extension" on page 6693
Message processing nodes and parsers that are written to the C programming language API can write entries to trace.

"User trace" on page 6873
User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

cciUcsToMbs:

Use this function to convert Universal Character Set (UCS) data to multibyte string data. This function is, typically, used only for formatting diagnostic messages. Normal processing is best done in UCS-2, which can represent all characters from all languages.

The sample code in `BipSampPluginUtil.c` contains more utilities for processing UCS-2 characters in a portable way.

Syntax:

```
int cciUcsToMbs(
  int*           returnCode,
  const CciChar* ucsString,
  char*          mbString,
  int            mbStringLength,
  int            codePage);
```

Parameters:

returnCode
The return code from the function (output).

Possible return codes are:

- CCI_SUCCESS
- CCI_BUFFER_TOO_SMALL
- CCI_INV_CHARACTER
- CCI_FAILURE
- CCI_INV_CODEPAGE

ucsString
The string to be converted, expressed as UCS-2 Unicode (input).

mbString
The location of the resulting string (input). The string has a trailing byte of 0, just as the Unicode has a trailing `CciChar` of 0.

mbStringLength
The length (in bytes) of the buffer that you have provided (input). Each `CciChar` in the source string expands to one byte (for SBCS code pages), or up to not more than the code page's MB_CUR_MAX value (typically less than five bytes), which defines an upper limit of the buffer size required.

codePage
The code page of the resulting string (input). The value of the code page must be suitable for the compiler that you are using to compile the user-defined node.

For an ASCII system, a value of 1208 (meaning code page ibm-1208, which is UTF-8 Unicode) is a good choice if you are using cciUcsToMbs to convert string constants for processing by WebSphere Message Broker. 1208 is appropriate for Linux, UNIX, and Windows.

On Linux and UNIX systems, `nl_langinfo(CODEPAGE)` gives you the code page that has been selected by the **setlocale** command.

On z/OS, the default code page for WebSphere MQ, which is 500, must not be used. Instead, use a code page value of 1047.

Return values:
The *returnCode* parameter is set to the converted length in bytes.

Related concepts:

"Supported code pages" on page 4176
Application messages must conform to supported code pages.

cciUserDebugTrace:

Use cciUserDebugTrace to write a message from a message catalog (with inserts) to user trace when user trace is active at debug level.

If user trace is not active at debug level, an entry is written to service trace when service trace is active.

Syntax:

```
void cciUserDebugTrace(
  int*           returnCode,
  CciObject*     object,
  const CciChar* messageSource,
  int            messageNumber,
  const char*    traceText,
  ...
);
```

Parameters:

returnCode
Receives the return code from the function (output). A NULL pointer input parameter indicates that the user-defined node does not handle errors. All exceptions that are thrown during the execution of this call are thrown again to the next upstream node in the flow. If the input parameter is not NULL, the output signifies the success status of the call. If an exception occurs during execution, **returnCode* is set to CCI_EXCEPTION on output. Call CciGetLastExceptionData to obtain details of the exception.

object
The address of the object that is to be associated with the trace entry (input). This object can be a CciNode* or a CciParser*. If you specify a CciNode*, the name of that node is written to trace. If you specify a CciParser*, the name of the node that created the parser is written to trace. This object is also used to determine if the entry is written to trace. The entry is written only if trace is active for the node. Nodes inherit their trace setting from the message flow.

If this parameter is NULL, the trace level for the execution group is returned.

messageSource
The fully qualified location and name of the Windows message source or the Linux, UNIX, or z/OS message catalog.

To use the current broker message catalog, specify BIPmsgs on all operating systems. Alternatively, you can create your own message catalog.

When trace is formatted, a message from the NLS version of this catalog is written.

The locale used is that of the environment where the trace is formatted. You can run the broker on one operating system, read the log on that operating system, then format the log on a different operating system. For example, if the broker is running on Linux, UNIX, or z/OS but no `.cat` file is available, you could read the log, then transfer it to Windows where the log can be formatted by using the `.properties` file.

If this parameter is NULL, the effect is the same as specifying an empty string. That is, all other information is written to the log, and the catalog field has an empty string value. Therefore, the log formatter cannot find the message source and fails to format this entry.

messageNumber
The number that identifies the message within the specified *messageSource* (input). If the *messageSource* does not contain a message that corresponds to this *messageNumber*, the log formatter fails to format this entry.

traceText
A string of characters that ends with NULL (input). This string is written to service trace and provides an easy way to correlate trace entries with paths through the source code. For example, you might have several paths through the code that result in the same message (*messageSource* and *messageNumber*) being written to trace. *traceText* can be used to distinguish between these different paths. That is, the *traceText* string is a static literal string in the source and therefore the same string is in both the source code file and the formatted trace file.

...
A C variable argument list that contains other message inserts that accompany the message (input). These inserts are treated as character strings and the variable arguments are assumed to be of type `pointer to char`. The last argument in this list *must* be `(char*)0`.

- For user-defined extensions that are running on distributed platforms, the `char*` arguments must be in ISO-8859-1 (ibm-918) code page.
- For user-defined extensions that are running on z/OS platforms, the `char*` arguments must be in EBCIDIC (1047).

These requirements apply to all char* arguments in **traceText** and the variable argument list of inserts (**...**).

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
const CciChar*   myMessageSource=CciString("SwitchMSG",BIP_DEF_COMP_CCSID);
CciNode*         thisNode = ((NODE_CONTEXT_ST*)context)->nodeObject;

const char* mbElementName  = mbString((CciChar*)&elementName,BIP_DEF_COMP_CCSID);
const char* mbElementValue = mbString((CciChar*)&elementValue,BIP_DEF_COMP_CCSID);
const char* traceTextFormat = "Switch Element: name=%s, value=%s";
char* traceText = (char*)malloc(strlen(traceTextFormat) +
                                strlen(mbElementName) +
                                strlen(mbElementValue));
sprintf(traceText,traceTextFormat,mbElementName,mbElementValue);

cciUserDebugTrace(&rc,
                  (CciObject*)thisNode,
                  myMessageSource,
                  2,
                  traceText,
                  mbElementName,
                  mbElementValue,
                  (char*)0);
free((void*)mbElementName);
free((void*)mbElementValue);
free((void*)traceText);
```

Related tasks:

"Creating message catalogs" on page 3138
Create your own message catalogs to write tailored entries to the local error log.

User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

cciUserDebugTraceW:

Use cciUserDebugTraceW to write a message from a message catalog (with inserts) to user trace when user trace is active at debug level. A message is also written to service trace, if service trace is active.

If user trace is not active at debug level, an entry is written to service trace when service trace is active at any level.

Syntax:

```
void cciUserDebugTraceW(
  int*             returnCode,
  CciObject*       object,
  const CciChar*   messageSource,
  int              messageNumber,
  const CciChar*   traceText,
  ...
);
```

Parameters:

returnCode
Receives the return code from the function (output). A NULL pointer input signifies that the user-defined node does not want to deal with errors. Any exceptions thrown during the execution of this call will be re-thrown to the next upstream node in the flow. If input is not NULL, output will signify the success status of the call. If an exception occurs during execution, *returnCode will be set to CCI_EXCEPTION on output. A call to **CciGetLastExceptionData** will provide details of the exception.

object
The address of the object that is to be associated with the trace entry (input). This object can be a CciNode* or a CciParser*. If it is a CciNode*, the name of that node is written to trace. If it is a CciParser*, the name of the node that created the parser is written to trace. This object is also used to determine if the entry should be written to trace. The entry is only written if trace is active for the node. Currently nodes inherit their trace setting from the message flow.

If this parameter is NULL, the trace level for the execution group is returned.

messageSource
A string that identifies the Windows message source or the Linux and UNIX message catalog (input). When trace is formatted, a message from the NLS version of this catalog is written. The locale used is that of the environment where the trace is formatted. It is possible to run the broker on one type of operating system, read the log on that operating system, then format the log on a different operating system. For example, if the broker is running on Linux or UNIX but no .cat file is available, the user could read the log, then transfer it to Windows where the log can be formatted by using the .properties file.

If this parameter is NULL, the effect is the same as specifying an empty string. That is, all other information will be written to the log, and the catalog field will have an empty string value. Therefore, the log formatter will not be able to find the message source. Consequently, the log formatter will fail to format this entry.

messageNumber
The number that identifies the message within the specified *messageSource* (input). If the *messageSource* does not contain a message that corresponds to this *messageNumber*, the log formatter fails to format this entry.

traceText
A string of characters that ends with NULL (input). This string will be written to service trace and provides an easy way to correlate trace entries with paths through the source code. For example, there could be several paths through the code that result in the same message (*messageSource* and *messageNumber*) being written to trace. *traceText* can be used to distinguish between these different paths. That is, the *traceText* string will be a static literal string in the source and therefore the same string will be in both the source code file and the formatted trace file.

...
A C variable argument list that contains any message inserts that accompany the message (input). These inserts are treated as character strings and the variable arguments are assumed to be of type `pointer to CciChar`.

The last argument in this list *must* be `(CciChar*)0`.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
const CciChar*   myMessageSource=CciString("SwitchMSG",BIP_DEF_COMP_CCSID);
CciNode*         thisNode = ((NODE_CONTEXT_ST*)context)->nodeObject;
const CciChar*   traceText = CciString("Found an element name and value",
                                       BIP_DEF_COMP_CCSID);

cciUserDebugTraceW(&rc,
                   (CciObject*)thisNode,
                   myMessageSource,
                   2,
                   traceText,
                   elementName,
                   elementValue,
                   (CciChar*)0);
```

The cciThrowExceptionW exception is thrown by the broker interface and uses the specified arguments as exception data.

"cciLogW" on page 6653
cciLogW logs an error, warning, or informational event. The event is logged by the broker interface and uses the specified arguments as log data.

"cciUserTraceW" on page 6681
Use cciUserTraceW to write a message from a message catalog (with inserts) to user trace. A message is also written to service trace, if service trace is active.

"cciServiceTraceW" on page 6664
cciServiceTraceW writes a message to service trace, if service trace is active.

"cciServiceDebugTraceW" on page 6661
The function is very similar to cciServiceTraceW with the only difference being that the entry is written to service trace only when service trace is active at debug level.

"User trace" on page 6873
User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

cciUserTrace:

Use cciUserTrace to write a message from a message catalog (with inserts) to user trace. A message is also written to service trace, if service trace is active.

The message written to user trace has the following format:

```
<date-time stamp> <threadNumber> UserTrace <Message text with inserts> <Message Explanation>
```

Syntax:

```
void cciUserTrace(
  int*              returnCode,
  CciObject*        object,
  const CciChar*    messageSource,
  int               messageNumber,
  const char*       traceText,
                    ...
);
```

Parameters:

returnCode
Receives the return code from the function (output). A NULL pointer input signifies that the user-defined node does not want to deal with errors. Any exceptions thrown during the execution of this call are re-thrown to the next upstream node in the flow. If input is not NULL, output signifies the success status of the call. If an exception occurs during execution, *returnCode is set to CCI_EXCEPTION on output. A call to CciGetLastExceptionData provides details of the exception.

object
The address of the object that is to be associated with the trace entry (input). This object can be a CciNode* or a CciParser*. If it is a CciNode*, the name of that node is written to trace. If it is a CciParser*, the name of the node that created the parser is written to trace. This object is also used to determine if the entry should be written to trace. The entry is only written if trace is active for the node. Currently, nodes inherit their trace setting from the message flow.

If this parameter is NULL, the trace level for the execution group is returned.

messageSource
The fully-qualified location and name of the Windows message source, or the Linux, UNIX, or z/OS message catalog (input).

To use the current broker message catalog, specify BIPmsgs on all operating systems. Alternatively, you can create your own message catalog.

When trace is formatted, a message from the NLS version of this catalog is written. The locale used is that of the environment where the trace is formatted.

You can run the broker on one operating system, read the log on that operating system, then format it on a different operating system. For example, if the broker is running on Linux, but no `.cat` file is available, you could read the log, then transfer it to Windows, where the log can be formatted by using the `.properties` file.

If this parameter is NULL, the effect is the same as specifying an empty string. That is, all other information is written to the log, and the catalog field has an empty string value. Therefore, the log formatter cannot find the message source. Consequently, the log formatter fails to format this entry.

messageNumber
The number that identifies the message within the specified *messageSource* (input). If the *messageSource* does not contain a message that corresponds to this *messageNumber*, the log formatter fails to format this entry.

traceText
A string of characters that ends with NULL (input). This string is written to service trace, and provides an easy way to correlate trace entries with paths through the source code. For example, if several paths through the code result in the same message (*messageSource* and *messageNumber*) being written to trace, you can specify *traceText* to distinguish between these different paths. That is, the *traceText* string is a static literal string in the source, and therefore the same string appears in both the source code file and the formatted trace file.

...
A C variable argument list that contains any message inserts that accompany the message (input). These inserts are treated as character strings, and the variable arguments are assumed to be of type `pointer to char`.

The last argument in this list must be `(char*)0`.

- For user-defined extensions that are running on distributed platforms, the `char*` arguments must be in ISO-8859-1 (ibm-918) code page.
- For user-defined extensions that are running on z/OS platforms, the `char*` arguments must be in EBCIDIC (1047).

These requirements include all char* arguments in **traceText** and the variable argument list of inserts (**...**).

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
const CciChar*   myMessageSource=CciString("SwitchMSG",BIP_DEF_COMP_CCSID);
CciNode*          thisNode = ((NODE_CONTEXT_ST*)context)->nodeObject;

cciUserTrace(&rc,
             (CciObject*)thisNode,
              myMessageSource,
              1,
              "propagating to add terminal",
              "add",
              (char*)0);
 checkRC(rc);
```

"Service trace" on page 6875
Service trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Event Log or to user trace. Service trace is inactive by

default; you must activate it explicitly by using a command.

cciUserTraceW:

Use cciUserTraceW to write a message from a message catalog (with inserts) to user trace. A message is also written to service trace, if service trace is active.

The message written to user trace has the following format:

```
<date-time stamp> <threadNumber> UserTrace <Message text with inserts> <Message Explanation>
```

Syntax:

```
void cciUserTraceW(
  int*                returnCode,
  CciObject*          object,
  const CciChar*      messageSource,
  int                 messageNumber,
  const CciChar*      traceText,
                      ...
);
```

Parameters:

returnCode
Receives the return code from the function (output). A NULL pointer input signifies that the user-defined node does not want to deal with errors. Any exceptions that are thrown during the execution of this call are re-thrown to the next upstream node in the flow. If input is not NULL, output indicates the success status of the call. If an exception occurs during execution, *returnCode is set to CCI_EXCEPTION on output. Call CciGetLastExceptionData to obtain details of the exception.

object
The address of the object that is to be associated with the trace entry (input). This object can be a CciNode* or a CciParser*. If you specify a CciNode*, the name of that node is written to trace. If you specify a CciParser*, the name of the node that created the parser is written to trace. This object is also used to determine if the entry should be written to trace. The entry is written only if trace is active for the node. Nodes inherit their trace setting from the message flow.

If this parameter is NULL, the trace level for the execution group is returned.

messageSource
The fully-qualified location and name of the Windows message source or the Linux, UNIX, or z/OS message catalog.

To use the current broker message catalog, specify BIPmsgs on all operating systems. Alternatively, you can create your own message catalog.

When trace is formatted, a message from the NLS version of this catalog is written.

The locale used is that of the environment where the trace is formatted. You can run the broker on one operating system, read the log on that operating system, then format the log on a different operating system. For example, if the broker is running on Linux, UNIX, or z/OS but no `.cat` file is available, you could read the log, then transfer it to Windows where the log can be formatted by using the `.properties` file.

If this parameter is NULL, the effect is the same as specifying an empty string. That is, all other information is written to the log, and the catalog field has an empty string value. Therefore, the log formatter cannot find the message source and fails to format this entry.

messageNumber
The number that identifies the message within the specified *messageSource* (input). If the *messageSource* does not contain a message that corresponds to this *messageNumber*, the log formatter fails to format this entry.

traceText
A string of characters that ends with NULL (input). This string is written to service trace and provides an easy way to correlate trace entries with paths through the source code. For example, there could be several paths through the code that result in the same message (*messageSource* and *messageNumber*) being written to trace. Use *traceText* to distinguish between these different paths. That is, the *traceText* string is a static literal string in the source, and therefore the same string is in both the source code file and the formatted trace file.

...
A C variable argument list that contains any message inserts that accompany the message (input). These inserts are treated as character strings and the variable arguments are assumed to be of type `pointer to CciChar`.

The last argument in this list must be `(CciChar*)0`.

Return values:
None. If an error occurs, the *returnCode* parameter indicates the reason for the error.

Example:

```
const CciChar*   myMessageSource=CciString("SwitchMSG",BIP_DEF_COMP_CCSID);
const CciChar*   text = CciString("propagating to add terminal",
                                  BIP_DEF_COMP_CCSID);
const CciChar*   insert = CciString("add", BIP_DEF_COMP_CCSID);
CciNode*         thisNode = ((NODE_CONTEXT_ST*)context)->nodeObject;
int              rc = CCI_SUCCESS;

cciUserTrace(&rc,
             (CciObject*)thisNode,
             myMessageSource,
             1,
             text,
             insert,
             (CciChar*)0);
checkRC(rc);
```

Utility function return codes and values

By convention, the return code output parameter of all utility functions is set to indicate successful completion, or an error. The table lists all return codes with their meanings.

These return codes are defined in the `BipCci.h` header file.

Return code	Explanation
CCI_BUFFER_TOO_SMALL	The output buffer is not large enough to store the requested data.
CCI_EXCEPTION	An exception occurred.
CCI_EXCEPTION_CONFIGURATION	A configuration exception was detected when invoking the function. [1]
CCI_EXCEPTION_CONVERSION	A conversion exception was detected when invoking the function. [1]
CCI_EXCEPTION_DATABASE	A database exception was detected when invoking the function.
CCI_EXCEPTION_FATAL	A fatal exception was detected when invoking the function. [1]
CCI_EXCEPTION_PARSER	A parser exception was detected when invoking the function. [1]
CCI_EXCEPTION_RECOVERABLE	A recoverable exception was detected when invoking the function. [1]
CCI_EXCEPTION_UNKNOWN	An unknown exception was specified or encountered.
CCI_EXCEPTION_USER	A user exception was detected when invoking the function. [1]
CCI_FAILURE	A function was unsuccessful.
CCI_FAILURE_CONTINUE	cniRun() return value: rollback message processing and continue thread execution
CCI_FAILURE_RETURN	cniRun() return value: rollback message processing and return thread to pool
CCI_INV_CODEPAGE	An invalid code page number was specified.
CCI_INV_CHARACTER	An invalid character was detected in the buffer to be converted.
CCI_INV_DATA_BUFLEN	A data buffer length of zero was specified.
CCI_INV_DATA_POINTER	A null pointer was specified for the address of an output data area.
CCI_INV_ELEMENT_OBJECT	A null pointer was specified for the element object.
CCI_INV_FACTORY_NAME	A factory name that is not valid (blank) was specified.
CCI_INV_FACTORY_OBJECT	A null pointer was specified for the factory object.
CCI_INV_IMPL_FUNCTION	An invalid combination of conditional implementation functions was specified
CCI_INV_LENGTH	A length of zero was specified.
CCI_INV_LOG_TYPE	The specified log type is not valid.
CCI_INV_MESSAGE_CONTEXT	A null pointer was specified for the message context.
CCI_INV_MESSAGE_OBJECT	A null pointer was specified for the message object.
CCI_INV_NODE_ENV	Attempt to dispatch a thread from a non-input node.

Return code	Explanation
CCI_INV_NODE_NAME	A node name that is not valid (blank) was specified.
CCI_INV_NODE_OBJECT	A null pointer was specified for the node object.
CCI_INV_OBJECT_NAME	Characters specified in the object name were not valid.
CCI_INV_PARSER_NAME	A parser class name that is not valid (blank) was specified.
CCI_INV_PARSER_OBJECT	A null pointer was specified for the parser object.
CCI_INV_SQL_EXPR_OBJECT	A null pointer was specified for an SQL expression value.
CCI_INV_STATEMENT	A statement was not specified.
CCI_INV_TERMINAL_NAME	A terminal name that is not valid (blank) was specified.
CCI_INV_TERMINAL_OBJECT	A null pointer was specified for the terminal object.
CCI_INV_TRANSACTION_TYPE	An invalid value was specified for the transaction type.
CCI_INV_VFTP	A null pointer was specified for the address of the user-defined extension virtual function pointer table.
CCI_MISSING_IMPL_FUNCTION	A mandatory implementation function was not defined in the function pointer table.
CCI_NAME_EXISTS	A parser with the same class name already exists.
CCI_NO_BUFFER_EXISTS	No buffer exists for the specified parser object.
CCI_NO_EXCEPTION_EXISTS	No previous exception was found for this thread.
CCI_NO_THREADS_AVAILABLE	No threads were available to be dispatched.
CCI_NULL_ADDR	A function that should return an address was unsuccessful; zero is returned instead.
CCI_PARSER_NAME_TOO_LONG	The name of the parser class is too long.
CCI_SUCCESS	Successful completion.
CCI_SUCCESS_CONTINUE	cniRun() return value: commit message processing and continue thread execution
CCI_SUCCESS_RETURN	cniRun() return value: commit message processing and return thread to pool
CCI_TIMEOUT	cniRun() return value: no message processing but continue thread execution

Note:

1. This return code is returned only by cniGetLastExceptionData to indicate the type of the last exception.

Related reference:

"C common utility functions" on page 6643
WebSphere Message Broker provides some additional utilities that user-defined nodes and parsers can use.

"C Header files" on page 6415
The C interfaces are defined by the following header files.

Available parsers

A parser is called by the broker only when that parser is required. The parser that is called depends upon the parser that has been specified.

For certain implementation functions, it might be necessary to specify the name of a parser supplied with WebSphere Message Broker. For example, functions include:

- cniCreateElementAfterUsingParser
- cniCreateElementAsFirsthChildUsingParser
- cniCreateElementAsLastChildUsingParser
- cniCreateElementAsLastChildFromBitstream
- cniCreateElementBeforeUsingParser

When using these functions, you must specify the correct class name of the parser. The following tables provide a summary of the parsers, root element names, and class names for different headers.

The following table shows the **Body** parsers.

Parser	Root element name	Class name
BLOB	BLOB	NONE
DataObject	DataObject	DataObject
IDOC (deprecated)	IDOC	IDOC
JMSMap	JMSMap	JMS_MAP
JMSStream	JMSStream	JMS_STREAM
MIME	MIME	MIME
MRM	MRM	MRM
SOAP	SOAP	SOAP
XML (deprecated)	XML	xml
XMLNS	XMLNS	xmlns
XMLNSC	XMLNSC	xmlnsC
JSON[1]	JSON	JSON

Note:

1. To enable the JSON parser on a broker, use the **-f** parameter on the **mqsichangebroker** command. For more information, see "**mqsichangebroker** command" on page 3723.

The following table shows the **Header** parsers.

Parser	Root element name	Class name
EmailOutputHeader	EmailOutputHeader	EMAILHDR
HTTPInputHeader	HTTPInputHeader	WSINPHDR

Parser	Root element name	Class name
HTTPReplyHeader	HTTPReplyHeader	WSREPHDR
HTTPRequestHeader	HTTPRequestHeader	WSREQHDR
HTTPResponseHeader	HTTPResponseHeader	WSRSPHDR
JMS header	JMSTransport	jms_transport
MQCFH	MQPCF	MQPCF
MQCIH	MQCIH	MQCICS
MQDLH	MQDLH	MQDEAD
MQIIH	MQIIH	MQIMS
MQMD	MQMD	MQHMD
MQMDE	MQMDE	MQHMDE
MQRFH	MQRFH	MQHRF
MQRFH2	MQRFH2	MQHRF2
MQRFH2C	MQRFH2C	MQHRF2C
MQRMH	MQRMH	MQHREF
MQSAPH	MQSAPH	MQHSAP
MQWIH	MQWIH	MQHWIH
SMQ_BMH	SMQ_BMH	SMQBAD

When using the MQMD parser, the MQMD is assumed to be a V2 MQMD.

The following table shows the **Properties** parser.

Parser	Root element name	Class name
Properties	Properties	PropertyParser

You can also create your own user-defined parsers, or you can make use of user-defined parsers that have been supplied by independent software vendors.

Related concepts:

"User-defined parsers" on page 3010
A user-defined parser is a program that interprets the bit stream of an incoming message and creates an internal representation of the message in a tree structure. A user-defined parser can also regenerate a bit stream for an outgoing message from the internal message tree representation

"User-defined parser life cycle" on page 3011
Various stages exist in the life of a user-defined message flow parser.

"Planning user-defined parsers" on page 3013
Read about the concepts that you should consider before you develop a user-defined parser.

"Parsers" on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

"User-defined extensions" on page 6411
Reference material that supports the creation and management of your user-defined extensions.

Trace logging from a user-defined C extension

Message processing nodes and parsers that are written to the C programming language API can write entries to trace.

You can use two types of trace:

- **Service Trace**: entries usually describe what is happening within the code and are only useful to the owner of the code, such as the user-defined extension developer.
- **User Trace**: entries usually describe what is happening at an external level and are useful to the user of the code. Users of the code include message flow designers, and broker domain administrators.

For each trace type, there are three levels:

- None
- Normal
- Debug

For C user-defined extensions, the following utility functions are available for each trace type:

- **cciServiceTrace** and **cciUserTrace**: these functions write an entry to the respective trace type only when trace has been activated, that is, trace is at normal or debug level.
- **cciServiceDebugTrace** and **cciUserDebugTrace**: these functions write an entry to the respective trace type only when trace is active at debug level.

To help avoid making function calls in the case where no trace is written, the **cciIsTraceActive** utility function is provided. **cciIsTraceActive** reports whether trace is active and the level at which trace is active.

The **cci*Trace** functions can be used by a user-defined extension regardless of the trace settings. The functions determine if trace is active and only write entries which are appropriate for the trace settings. When calling the **cci*Trace** functions, some additional processing can be required. The **cciIsTraceActive** function is provided to allow the user-defined extension to query the trace settings and avoid this extra processing when trace is inactive.

In many cases, it is sufficient to treat the value returned from the **cciIsTraceActive** function as a Boolean value. If the returned value is non zero, trace is active at some level and it is appropriate to call any of the **cci*Trace** functions. The returned value can also be inspected closely in the cases when details of the trace settings are required.

Trace settings can be changed at any time so it is advisable to query them regularly. For example, use **cciIsTraceActive** to query the trace settings when an implementation function is entered.

Trace entries can be associated with certain objects, which allows for further refinement of control for writing trace. A trace entry can be associated with a node or parser and trace is written according to the trace setting for that object. The object's trace setting is inherited from the message flow to which the node or parser belongs. If no object is specified, the trace is associated with the execution group.

Use cciUserDebugTrace to write a message from a message catalog (with inserts) to user trace when user trace is active at debug level.

"cciServiceTrace" on page 6663
Writes a message to service trace, if service trace is active.

"cciServiceDebugTrace" on page 6660
This function is very similar to cciServiceTrace with the only difference being that the entry is written to service trace only when service trace is active at debug level.

"cciIsTraceActive" on page 6670
cciIsTraceActive reports whether trace is active and the level at which trace is active.

"User trace" on page 6873
User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

"Service trace" on page 6875
Service trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Event Log or to user trace. Service trace is inactive by default; you must activate it explicitly by using a command.

Multicultural support considerations for message catalogs

WebSphere Message Broker converts any message that is loaded from the listed supported code pages into the local code page of the running processes (brokers) before output to the syslog.

You must provide symbolic links to your primary message catalogs for all locales that you intend to support. WebSphere Message Broker uses the LC_MESSAGES variable when opening message catalogs.

Multicultural support considerations on Windows:

Windows When you build a message file for Windows that contains multiple locales, ensure that the locale on the computer is set to a western European locale

(for example, English (United Kingdom)) before building the message catalogs. Use the **chcp** (Change Code Page) command to ensure that the code page is 850.

Write or convert all your message files (those with file type .mc) to the following code pages; each message file should be compiled separately by the message compiler with the additional flag that is specified in the following table.

DBCS message files do not need to be in Unicode (no **-U** flag). Use the **RC** command to 'resource compile' all the files, then use the **link** command to build a single message DLL.

Locale	Code page	Additional Flags
English (United States)	437	-U
German (Standard)	850	-U
Spanish (Modern Sort)	850	-U
French (Standard)	850	-U
Italian (Standard)	850	-U
Portuguese (Brazilian)	850	-U
Japan	932	
Simplified Chinese (China)	1381	
Traditional Chinese (Taiwan)	950	
Korean	949	

Multicultural support considerations on Linux and UNIX:
When you build message catalogs for Linux and UNIX systems, ensure that the catalogs are built in the code pages defined in the following table.

Locale	Code page
English	437
German	850
Spanish	850
French	850
Italian	850
Portuguese (Brazilian)	850
Japan	932
Simplified Chinese (China)	1381
Traditional Chinese (Taiwan)	950
Korean	949

Multicultural support considerations on z/OS:
z/OS When you build message catalogs for z/OS systems, ensure that the catalogs are built in the code pages defined in the following table.

Locale	Code page
English	1047
Japan	939
Simplified Chinese (China)	1388

"Using error logging from a user-defined extension" on page 3137
Program user-defined extensions to write entries in the local error log.

Web services external standards

WebSphere Message Broker support for Web services conforms to a number of industry standards and specifications.

This section contains the topics that describe the WebSphere Message Broker support for Web services.

SOAP 1.1 and 1.2

SOAP is a lightweight, XML-based, protocol for exchange of information in a decentralized, distributed environment.

The protocol consists of three parts:

- An envelope that defines a framework for describing what is in a message and how to process it.
- A set of encoding rules for expressing instances of application-defined data types.
- A convention for representing remote procedure calls and responses.

SOAP can be used with other protocols, such as HTTP.

The specifications for SOAP are published by the World Wide Web Consortium (W3C).

- World Wide Web Consortium (W3C)

The specification for SOAP 1.1 is described in:

- Simple Object Access Protocol 1.1

This specification has not been endorsed by the W3C, but forms the basis for the SOAP 1.2 specification. The specification for SOAP 1.1 expands the SOAP acronym to Simple Object Access Protocol.

SOAP 1.2 is a W3C recommendation and is published in two parts:

- Part 1: Messaging Framework.
- Part 2: Adjuncts.

The specification also includes a primer that is intended to provide a tutorial on the features of the SOAP Version 1.2 specification, including usage scenarios. The specification for SOAP 1.2 does not expand the acronym. The primer is published at:

- SOAP 1.2 Primer

WebSphere Message Broker support for Web services conforms to a number of industry standards and specifications.

"What is SOAP?" on page 1604
SOAP is an XML message format used in Web service interactions. SOAP messages are typically sent over HTTP or JMS, but other transport protocols can be used. The use of SOAP in a specific Web service is described by a WSDL definition.

Related information:

http://www.w3.org/

SOAP with Attachments

SOAP with Attachments (SwA) allows you to use SOAP 1.1 or SOAP 1.2 messages wrapped by MIME.

The SOAP with Attachments (SwA) specification is published as a formal submission by the World Wide Web Consortium (W3C):

- World Wide Web Consortium (W3C)

SwA uses the following specifications, described at:

- http://www.w3.org/TR/2000/NOTE-SOAP-attachments-20001211
- http://www.ws-i.org/Profiles/AttachmentsProfile-1.0.html

"What is SOAP?" on page 1604
SOAP is an XML message format used in Web service interactions. SOAP messages are typically sent over HTTP or JMS, but other transport protocols can be used. The use of SOAP in a specific Web service is described by a WSDL definition.

SOAP MTOM

SOAP Message Transmission Optimization Mechanism (MTOM) is one of a related pair of specifications that define conceptually how to optimize the transmission and format of a SOAP message.

MTOM defines:

- How to optimize the transmission of base64binary data in SOAP messages in abstract terms
- How to implement optimized MIME multipart serialization of SOAP messages in a binding independent way using XOP

The implementation of MTOM relies on the related XML-binary Optimized Packaging (XOP) specification. Because these two specifications are so closely linked, they are normally referred to as MTOM/XOP.

The specification is published by the World Wide Web Consortium (W3C) as a W3C Recommendation at SOAP Message Transmission Optimization Mechanism. For further information refer to the following links:

- World Wide Web Consortium (W3C)
- SOAP Message Transmission Optimization Mechanism

"XML-Binary Optimised Packaging (XOP)" on page 6702
XML-binary Optimized Packaging (XOP) is one of a related pair of specifications that define how to efficiently serialize XML Infosets that have certain types of content.

"SOAP Binding for MTOM 1.0" on page 6702
SOAP 1.1 Binding for MTOM 1.0 is a specification that describes how to use the SOAP Message Transmission Optimization Mechanism (MTOM) and XML-binary Optimized Packaging (XOP) specifications with SOAP 1.1.

SOAP over JMS

SOAP over Java Message Service 1.0 is a specification that describes how SOAP can bind to a messaging system that supports the Java Message Service (JMS).

SOAP is transport-independent and can be bound to any protocol. Both SOAP 1.1 and SOAP 1.2 can be bound in this way using the SOAP 1.2 Protocol Binding Framework. SOAP over JMS allows you to use the JMS transport with SOAP messages, and is an alternative messaging mechanism to the standard SOAP over HTTP messaging.

JMS can be used as a transport for SOAP. The specification for SOAP over Java Message Service 1.0 is published as a formal recommendation by the World Wide Web Consortium (W3C):

- SOAP over Java Message Service 1.0 (W3C recommendation)

JMS applications send messages to JMS destinations, which can be queues or topics. Queues are used in point-to-point messaging, and topics are used in publish/subscribe (pub/sub) messaging.

WebSphere Message Broker supports the JMS transport on the SOAP nodes, which are configured by importing WSDL with SOAP/JMS bindings. JMS topic destinations for publish/subscribe messaging are not supported for SOAP nodes in WebSphere Message Broker.

WebSphere Message Broker supports both the W3C standard WSDL format and the IBM proprietary (deprecated) WSDL format. For a summary of differences between these two WSDL formats, see "WSDL URI formats for JMS" on page 1668.

Related concepts:

"What is SOAP?" on page 1604
SOAP is an XML message format used in Web service interactions. SOAP messages are typically sent over HTTP or JMS, but other transport protocols can be used. The use of SOAP in a specific Web service is described by a WSDL definition.

"Processing JMS messages" on page 1679
JMS is the standard J2EE messaging API for building enterprise messaging applications. WebSphere Message Broker provides built-in input and output nodes for its supported protocols.

JMS messages have a defined structure that includes headers and payloads.

"SOAPInput node" on page 4795
Use the SOAPInput node to process client SOAP messages, so that the broker operates as a SOAP Web Services provider.

WSDL Version 1.1

Web Services Description Language (WSDL) is an XML format for describing network services as a set of endpoints operating on messages containing either document-oriented or procedure-oriented information.

The operations and messages are described abstractly, then bound to a concrete network protocol and message format to define an endpoint. Related concrete end points are combined into abstract endpoints (services).

WSDL is extensible to allow the description of endpoints and their messages regardless of what message formats or network protocols are used to communicate. The WSDL 1.1 specification only defines bindings that describe how to use WSDL in conjunction with:

- SOAP 1.1
- HTTP GET
- HTTP POST
- MIME

The specification for WSDL 1.1 is published by the World Wide Web Consortium (W3C) as a W3C Note at WSDL Version 1.1.

- World Wide Web Consortium (W3C)
- WSDL Version 1.1

Related concepts:

"WSDL 1.1 Binding Extension for SOAP 1.2" on page 6701
WSDL 1.1 Binding Extension for SOAP 1.2 is a specification that defines the binding extensions that are required to indicate that Web service messages are bound to the SOAP 1.2 protocol.

"What is SOAP?" on page 1604
SOAP is an XML message format used in Web service interactions. SOAP messages are typically sent over HTTP or JMS, but other transport protocols can be used. The use of SOAP in a specific Web service is described by a WSDL definition.

WS-I Simple SOAP Binding Profile Version 1.0

WS-I Simple SOAP Binding Profile Version 1.0 (SSBP 1.0) is a set of non-proprietary Web services specifications, along with clarifications and amendments to those specifications which promote interoperability.

The SSBP 1.0 is derived from the WS-I Basic Profile 1.0 requirements that relate to the serialization of the envelope and its representation in the message.

WS-I Basic Profile 1.0 is split into two separately published profiles. These profiles are:

- WS-I Basic Profile Version 1.1
- WS-I Simple SOAP Binding Profile Version 1.0

Together these two profiles supersede the WS-I Basic Profile Version 1.0.

The specification for SSBP 1.0 is published by the Web Services Interoperability Organization (WS-I):

- Web Services Interoperability Organization (WS-I)

The specification for SSBP 1.0 can be found at:

- WS-I Simple SOAP Binding Profile Version 1.0

Related concepts:

"Web services external standards" on page 6696
WebSphere Message Broker support for Web services conforms to a number of industry standards and specifications.

"WS-I Basic Profile Version 1.1"
WS-I Basic Profile Version 1.1 (WS-I BP 1.1) is a set of non-proprietary Web services specifications, along with clarifications and amendments to those specifications, which together promote interoperability between different implementations of Web services.

"What is SOAP?" on page 1604
SOAP is an XML message format used in Web service interactions. SOAP messages are typically sent over HTTP or JMS, but other transport protocols can be used. The use of SOAP in a specific Web service is described by a WSDL definition.

"Message flow security and security profiles" on page 788
WebSphere Message Broker provides a security manager for implementing message flow security, so that end-to-end processing of a message through a message flow is secured based on an identity carried in that message instance.

WS-I Basic Profile Version 1.1

WS-I Basic Profile Version 1.1 (WS-I BP 1.1) is a set of non-proprietary Web services specifications, along with clarifications and amendments to those specifications, which together promote interoperability between different implementations of Web services.

The WS-I BP 1.1 is derived from Basic Profile Version 1.0 by incorporating its published errata and separating out the requirements that relate to the serialization of envelopes and their representation in messages. These requirements are now part of the Simple SOAP Binding Profile Version 1.0.

To summarize, the WS-I Basic Profile Version 1.0 is split into two separately published profiles. These profiles are:

- WS-I Basic Profile Version 1.1
- WS-I Simple SOAP Binding Profile Version 1.0

Together these two profiles supersede the WS-I Basic Profile Version 1.0.

The reason for this separation is to enable the Basic Profile 1.1 to be composed with any profile that specifies envelope serialization, including the Simple SOAP Binding Profile 1.0.

The specification for WS-I BP 1.1 is published by the Web Services Interoperability Organization (WS-I):

- Web Services Interoperability Organization (WS-I)

The specification for WS-I BP 1.1 can be found at:

- WS-I Basic Profile Version 1.1

Related concepts:

"Message flow security and security profiles" on page 788

WS-I Simple SOAP Binding Profile Version 1.0 (SSBP 1.0) is a set of non-proprietary Web services specifications, along with clarifications and amendments to those specifications which promote interoperability.

"What is SOAP?" on page 1604
SOAP is an XML message format used in Web service interactions. SOAP messages are typically sent over HTTP or JMS, but other transport protocols can be used. The use of SOAP in a specific Web service is described by a WSDL definition.

WSDL 1.1 Binding Extension for SOAP 1.2

WSDL 1.1 Binding Extension for SOAP 1.2 is a specification that defines the binding extensions that are required to indicate that Web service messages are bound to the SOAP 1.2 protocol.

The aim of this specification is to provide functions that are comparable with the binding for SOAP 1.1.

This specification is published as a formal submission request by the World Wide Web Consortium (W3C):

- World Wide Web Consortium (W3C)

The WSDL 1.1 Binding Extension for SOAP 1.2 specification is described at:

- http://www.w3.org/Submission/wsdl11soap12/

Related concepts:

"Web services external standards" on page 6696

Related reference:

"What is WSDL?" on page 1615
WSDL is an XML notation for describing a web service. A WSDL definition tells a client how to compose a web service request and describes the interface that is provided by the web service provider.

XML-Binary Optimised Packaging (XOP)

XML-binary Optimized Packaging (XOP) is one of a related pair of specifications that define how to efficiently serialize XML Infosets that have certain types of content.

XOP defines how to efficiently serialize XML Infosets that have certain types of content by:

- Packaging the XML in some format. This is called the XOP package. The specification mentions MIME Multipart/Related but does not limit it to this format.
- Re-encoding all or part of base64binary content to reduce its size.
- Placing the base64binary content elsewhere in the package and replacing the encoded content with XML that references it.

XOP is used as an implementation of the MTOM specification, which defines the optimization of SOAP messages. Because these two specifications are so closely linked, they are normally referred to as MTOM/XOP.

The specification is published by the World Wide Web Consortium (W3C) as a W3C Recommendation XML-binary Optimized Packaging (XOP):

- World Wide Web Consortium (W3C)
- XML-binary Optimized Packaging (XOP)

Related concepts:

"Web services external standards" on page 6696
WebSphere Message Broker support for Web services conforms to a number of industry standards and specifications.

"SOAP MTOM" on page 6697
SOAP Message Transmission Optimization Mechanism (MTOM) is one of a related pair of specifications that define conceptually how to optimize the transmission and format of a SOAP message.

"SOAP Binding for MTOM 1.0"
SOAP 1.1 Binding for MTOM 1.0 is a specification that describes how to use the SOAP Message Transmission Optimization Mechanism (MTOM) and XML-binary Optimized Packaging (XOP) specifications with SOAP 1.1.

SOAP Binding for MTOM 1.0

SOAP 1.1 Binding for MTOM 1.0 is a specification that describes how to use the SOAP Message Transmission Optimization Mechanism (MTOM) and XML-binary Optimized Packaging (XOP) specifications with SOAP 1.1.

This specification defines the minimum changes required to enable MTOM and XOP to be used interoperably with SOAP 1.1 and to reuse the SOAP 1.2 MTOM/XOP implementation.

The SOAP 1.1 Binding for MTOM 1.0 specification is published as a formal submission by the World Wide Web Consortium (W3C):

- World Wide Web Consortium (W3C)

The SOAP 1.1 Binding for MTOM 1.0 specification is described at:

- http://www.w3.org/Submission/soap11mtom10/

Related concepts:

"Web services external standards" on page 6696
WebSphere Message Broker support for Web services conforms to a number of industry standards and specifications.

"SOAP MTOM" on page 6697

"XML-Binary Optimised Packaging (XOP)" on page 6702
XML-binary Optimized Packaging (XOP) is one of a related pair of specifications that define how to efficiently serialize XML Infosets that have certain types of content.

"What is SOAP?" on page 1604
SOAP is an XML message format used in Web service interactions. SOAP messages are typically sent over HTTP or JMS, but other transport protocols can be used. The use of SOAP in a specific Web service is described by a WSDL definition.

Web Services Security: SOAP Message Security

Web Services Security (WSS): SOAP Message Security is a set of enhancements to SOAP messaging that provides message integrity and confidentiality. WSS: SOAP Message Security is extensible, and can accommodate a variety of security models and encryption technologies.

WSS: SOAP Message Security provides three main mechanisms that can be used independently or together:

- The ability to send security tokens as part of a message, and for associating the security tokens with message content
- The ability to protect the contents of a message from unauthorized and undetected modification (message integrity)
- The ability to protect the contents of a message from unauthorized disclosure (message confidentiality).

WSS: SOAP Message Security can be used in conjunction with other Web service extensions and application-specific protocols to satisfy a variety of security requirements.

The specification is published by the Organization for the Advancement of Structures Standards (OASIS). The specification is called Web Services Security: SOAP Message Security 1.0 (WS-Security 2004).

- Organization for the Advancement of Structured Information Standards (OASIS)
- Web Services Security: SOAP Message Security 1.0 (WS-Security 2004)

Web Services Security: SOAP Message Security 1.0 (WS-Security 2004)

XML Encryption Syntax and Processing

XML Encryption Syntax and Processing specifies a process for encrypting data and representing the result in XML. The data can be arbitrary data (including an XML document), an XML element, or XML element content. The result of encrypting data is an XML Encryption element that contains or references the cipher data.

XML Encryption Syntax and Processing is a recommendation of the World Wide Web Consortium (W3C):

- World Wide Web Consortium (W3C)

The XML Encryption Syntax and Processing recommendation is published at:

- XML Encryption Syntax and Processing

Related concepts:

"Web services external standards" on page 6696
WebSphere Message Broker support for Web services conforms to a number of industry standards and specifications.

XML-Signature Syntax and Processing

XML-Signature Syntax and Processing specifies the processing rules and syntax for XML digital signatures.

XML digital signatures provide integrity, message authentication, and signer authentication services for data of any type, whether located in the XML that includes the signature or elsewhere.

The recommendation for XML-Signature Syntax and Processing is published by the World Wide Web Consortium (W3C):

- World Wide Web Consortium (W3C)

The XML-Signature Syntax and Processing recommendation is published at:

- XML-Signature Syntax and Processing

Related concepts:

"Web services external standards" on page 6696
WebSphere Message Broker support for Web services conforms to a number of industry standards and specifications.

WebSphere Message Broker compliance with Web services standards

WebSphere Message Broker complies with the supported Web services standards and specifications, in that you can generate and deploy Web services that are compliant.

However, WebSphere Message Broker does not enforce this compliance. For example, for support of the WS-I Basic Profile 1.1 specification, you can apply additional qualities of service to your Web service that might break the interoperability outlined in this Profile.

The topics in this section describe how WebSphere Message Broker complies with Web services standards.

- "How WebSphere Message Broker complies with Web Service Security specifications" on page 6705

Related concepts:

"Web services external standards" on page 6696
WebSphere Message Broker support for Web services conforms to a number of industry standards and specifications.

How WebSphere Message Broker complies with Web Service Security specifications:

WebSphere Message Broker conditionally complies with Web Services Security: SOAP Message Security and related specifications by supporting the following aspects.

Compliance with Web Services Security: SOAP Message Security

Security header

The `<wsse:Security>` header provides a mechanism, in the form of a SOAP actor or role, for attaching security-related information that is targeted at a specific recipient. The recipient can be the ultimate recipient of the message or an intermediary. The following attributes are supported in WebSphere Message Broker:

- S11:actor (for an intermediary)
- S11:mustUnderstand
- S12:role (for an intermediary)
- S12:mustUnderstand

Security tokens

The following security tokens are supported in the security header:

- Username and password
- Binary security tokens:
  - X.509 certificate
  - Kerberos ticket
  - LTPA certificate
- SAML assertion

Token references

A security token conveys a set of claims. Sometimes these claims are elsewhere and need to be accessed by the receiving application. The `<wsse:SecurityTokenReference>` element provides an extensible mechanism for referencing security tokens. The following mechanisms are supported:

- Direct reference
- Key identifier
- Key name
- Embedded reference

Signature algorithms

This specification builds on XML Signature and therefore has the same algorithm requirements as those specified in the XML Signature specification. WebSphere Message Broker supports the signature algorithms as shown in the following table.

Algorithm type	Algorithm	URI
Digest	SHA1	`http://www.w3.org/2000/09/xmldsig#sha1`

Algorithm type	Algorithm	URI
Signature	DSA with SHA1 (validation only)	`http://www.w3.org/2000/09/xmldsig#dsa-sha1`
Signature	RSA with SHA1	`http://www.w3.org/2000/09/xmldsig#rsa-sha1`
Canonicalization	Exclusive XML canonicalization (without comments)	`http://www.w3.org/2001/10/xml-exc-c14n#`

Signature signed parts

WebSphere Message Broker allows the following SOAP elements to be signed:

- The SOAP message body
- The identity token (a type of security token) that is used as an asserted identity

Encryption algorithms

The data encryption algorithms that are supported are shown in the following table.

Algorithm	URI
Triple Data Encryption Standard algorithm (Triple DES)	`http://www.w3.org/2001/04/xmlenc#tripledes-cbc`
Advanced Encryption Standard (AES) algorithm with a key length of 128 bits	`http://www.w3.org/2001/04/xmlenc#aes128-cbc`
Advanced Encryption Standard (AES) algorithm with a key length of 192 bits	`http://www.w3.org/2001/04/xmlenc#aes192-cbc`
Advanced Encryption Standard (AES) algorithm with a key length of 256 bits	`http://www.w3.org/2001/04/xmlenc#aes256-cbc`

The key encryption algorithm that is supported is shown in the following table.

Algorithm	URI
Key transport (public key cryptography) RSA Version 1.5	`http://www.w3.org/2001/04/xmlenc#rsa-1_5`

Encryption message parts

WebSphere Message Broker allows the following SOAP elements to be encrypted:

- The SOAP body

Timestamp

The `<wsu:Timestamp>` element provides a mechanism for expressing the creation and expiration times of the security semantics in a message. WebSphere Message Broker tolerates the use of timestamps within the Web services security header on inbound SOAP messages.

Error handling

WebSphere Message Broker generates SOAP fault messages using the standard list of response codes listed in the specification.

Compliance with Web Services Security: Username Token Profile 1.1

The following aspects of this specification are supported:

Password types
Text

Token references
Direct reference

Compliance with Web Services Security: X.509 Certificate Token Profile 1.1

The following aspects of this specification are supported:

Token types

- X.509 Version 3: Single certificate.
- X.509 Version 3: X509PKIPathv1 without certificate revocation lists (CRL).
- X.509 Version 3: PKCS7 with or without CRLs. The IBM Software Development Kit (SDK) supports both. The Sun Java Development Kit (JDK) supports PKCS7 without CRL only.

For more information, refer to Web Services Security X.509 Certificate Token Profile.

Token references

- Key identifier - subject key identifier
- Direct reference
- Custom reference - issuer name and serial number

Compliance with Web Services Security: SAML Token Profile

SAML passthru support is provided, which enables interoperability with WS-Security SAML profiles, without performing subject confirmation processing. This means that it does not provide validation of the trust relationship between the SAML subject and message content signatures.

The token is passed through for processing by the message flow security manager, which passes the token to a WS-Trust STS for processing.

Compliance with Web Services Security: Kerberos Token Profile

The following aspects of this specification are supported:

Token types

- Kerberos GSS v5 AP_REQ
- Kerberos v5 AP_REQ

Aspects that are not supported

The following items are not supported in WebSphere Message Broker:

- Validation of Timestamps for freshness.
- Nonces.
- Web services security for SOAP attachments.
- XrML token profile.
- Web Services Interoperability (WS-I) Basic Security Profile.
- XML enveloping digital signature.
- XML enveloping digital encryption.

- The following transport algorithms for digital signatures:
  - XSLT: `http://www.w3.org/TR/1999/REC-xslt-19991116`.
  - SOAP Message Normalization. For more information, refer to http://www.w3.org/TR/2003/NOTE-soap12-n11n-20031008.
- The Diffie-Hellman key agreement algorithm for encryption. For more information, refer to Diffie-Hellman Key Values.
- The following canonicalization algorithm for encryption, which is optional in the XML encryption specification:
  - Canonical XML with or without comments
  - Exclusive XML canonicalization with or without comments
- The digest password type in the Username Token Version 1.0 Profile specification.

Testing and debugging applications

Use the reference information in this section to accomplish the testing and debugging tasks that address your business needs.

- "Test Client"
- "Message flow debugger" on page 6718

Test Client

Use the Test Client to test message flow applications.

You can send test messages to message flows that use any of the input nodes specified in "Test Client overview" on page 3144.

The following topics provide reference information to help you to use the Test Client effectively:

- "Test Client **Events** tab" on page 6709
- "Enqueue" on page 6712
- "Dequeue" on page 6712
- "Test Client Configuration tab" on page 6713
- "Test Client preferences" on page 6716
- "Deployment Location wizard" on page 6716
- "JMS events in the Test Client" on page 6717

Test Client Events tab

You can use the **Events** tab in the Test Client to edit the properties and content of your test messages. You also view test events in the **Events** tab when you run the test.

Purpose

Use the **Events** tab to edit and send the test messages, and to monitor the results of the test.

Message Flow Test Events

The **Message Flow Test Events** section of the **Events** tab displays the status and history of the test execution:

Invoke Message Flow
The Invoke Message Flow event starts the selected message flow. The message flow selection is defined by the selected message flow input node. Invoke Message Flow can also be the start of a new test execution with an empty test message. You can enter the message content and start the execution.

Starting
The Starting event indicates the beginning of the test execution.

Sending Message
The Sending Message event indicates that the message is being sent.

Enqueue
The Enqueue event indicates that the current message has been queued on an existing WebSphere MQ queue. Put a message to the specified queue manager, queue, port, and host name as defined in the Detailed Properties section. For more information, see “Enqueue” on page 6712.

Dequeue
The Dequeue event indicates that the current message has been dequeued from an existing WebSphere MQ queue. Click **Get Message** from the specified queue manager, queue, port and host name as defined in the Detailed Properties section. For more information, see “Dequeue” on page 6712.

Monitor
The Monitor event indicates the message was received on an output node monitor.

Stopped
The Stopped event indicates that the test execution has been stopped. The test execution can be stopped either by the Test Client or by the user.

Exception
The Exception event indicates when errors are encountered during the test. A message is displayed in the Exception message box on the right of the page and the message flow execution errors are logged in the Windows Event Viewer application log. To view the Windows Event Viewer application log, click **Event Viewer**.

Exception Trace
An Exception Trace event occurs when errors are encountered during test and Trace has been selected. Trace details are displayed in the Exception Trace panel on the right of the page.

Events tab actions

The following actions can be initiated on the **Events** tab, by right-clicking in **Message Flow Test Events**:

Re-run
Reruns the current message. To clone and rerun a previously started test message, right-click the message flow and click **Re-run**.

Duplicate
Duplicates the current message. To duplicate a previously started test message, right-click the message flow and click **Duplicate**.

Invoke
Restarts the current message. To restart a previously started test message, right-click the message flow and click **Invoke**.

Buttons on the Events tab

Several buttons are provided on the upper right of the **Events** tab:

Invoke
Starts a new Invoke Message Flow event where you can enter a request message and start the test execution.

Enqueue
Puts the message to the specified queue manager, queue, port, and host name as defined in the Detailed Properties section on the right of the page.

Dequeue
Gets the message from the specified queue manager, queue, port, and host name as defined in the Detailed Properties section on the right of the page.

Saved Messages
Displays the Data Pool editor in which you can select values that you have used in a previous test session. You can use the Data Pool editor to save or retrieve values for use during tests. When you use the Data Pool editor to save or retrieve values, the values are saved to, or retrieved from, a global data pool in your workspace. By selecting **Saved Messages**, you ensure that you are always working with the same set of values regardless of how many Test Client instances or test configurations you are using in your tests.

Stop Stops the current test.

Show Event Viewer
Displays the Event Viewer if the operating system is Windows.

Show Console
The Message Broker Runtime Console view opens. This view shows more details of the test run.

Detailed Properties

The Detailed Properties section varies according to the different events that you have selected in the Message Flow Test Events pane. The Detailed Properties section displays details of the current event type. The default details are:

- **Message Flow**. The name of the message flow that is being tested.
- **Input node**. The input node to which the test message is being sent.

Message

The Message section either displays the test message or the output message from a test event. If you are creating a new test message, you can select either the XML Structure editor or the Source editor to edit the test message. The XML Structure editor is available only if the input node that is selected on the message flow is expecting an XML message, and an existing message definition is associated with the message flow.

Header

Select the header to use for your test message if your message flow uses a WebSphere MQ or JMS input node.

SOAP operation

Select the SOAP operation to use for your test message if your message flow uses a SOAP input node.

Viewer

Select the appropriate editor to view or edit your test message or output message from the following editors:

XML Structure editor

Use the XML Structure editor to view and edit an XML test message derived from an associated message definition. You can change the content of the message by editing the entries in the Values column. Right-click to display a menu with options to change the content of the XML structure, including adding and removing elements. To view the generated source code, click **Show Generated Source**. Click **Saved messages** to display a list of saved error messages.

Source editor

Use the Source editor to compose and send test messages if you want to import a test message, or if the test message is not in XML format. To import a test message from a file, click **Import Source**.

Source tab

Edit the test message as plain text using the **Source** tab.

XML Source tab

Edit the test message in an XML editor using the **XML Source** tab.

Hexadecimal (read only) tab

View the test message in hexadecimal format by using the **Hexadecimal (Read Only)** tab.

Related tasks:

"Test Client" on page 6708
Use the Test Client to test message flow applications.

"Test Client Configuration tab" on page 6713
Configure your test environment in the **Configuration** tab in the Test Client.

Enqueue:

Enqueue is the term that is used to describe the process of putting a message on to a WebSphere MQ queue.

The following properties are entered on the Events page:

Host The name of the host computer.

Port The number of the port that is used.

Queue Manager
The name of WebSphere MQ Queue manager.

Queue
The name of the queue on the Queue manager.

Related reference:

"WebSphere MQ resources for the broker" on page 585
Each broker depends on a number of WebSphere MQ resources: some are required, others are optional, and depend on your environment and requirements. Some of these resources are created for you, but others you must define for yourself.

"Test Client **Events** tab" on page 6709
You can use the **Events** tab in the Test Client to edit the properties and content of your test messages. You also view test events in the **Events** tab when you run the test.

"Dequeue"
Dequeue is the term that is used to describe the process of removing a message from a WebSphere MQ queue.

Dequeue:

Dequeue is the term that is used to describe the process of removing a message from a WebSphere MQ queue.

The following properties are entered on the Events page:

Host The name of the host computer.

Port The number of the port that is used.

Queue Manager
The name of WebSphere MQ Queue manager.

Queue
The name of the queue on the Queue manager.

Related reference:

"WebSphere MQ resources for the broker" on page 585
Each broker depends on a number of WebSphere MQ resources: some are required, others are optional, and depend on your environment and requirements. Some of these resources are created for you, but others you must define for yourself.

"Enqueue"
Enqueue is the term that is used to describe the process of putting a message on to a WebSphere MQ queue.

"Test Client **Events** tab" on page 6709
You can use the **Events** tab in the Test Client to edit the properties and content of your test messages. You also view test events in the **Events** tab when you run the test.

Test Client Configuration tab

Configure your test environment in the **Configuration** tab in the Test Client.

Purpose

You can use the Test Client **Configuration** tab to alter the settings that are used when you test your message flow.

You can set the following settings in the **Configuration** tab:
- Message Flows
- Deployment
- MQ Settings
- JMS Settings
- MQ Message Headers
- JMS Message Headers

MQ settings apply to invoke, adding to queue, and removing from queue events; all other settings apply to invoke events only.

Select the relevant options in the left pane to display the properties in the right pane of the **Configuration** tab. The following sections describe the properties on the **Configuration** tab.

Message Flows

Add or remove Message Flows to be tested
In this section of the **Configuration** tab, the message flow that you have selected to test is listed. You can add more message flows to the test configuration so that you can test multiple message flows at the same time; for example, if you have an output message from one message flow that triggers another message flow, or if you are using subflows. Click **Add** to add message flows to your test configuration. Click **Remove** to remove message flows from the configuration.

Deployment

I will deploy the specified Broker Archive manually
You can select this option to prevent the Test Client from deploying the message flow before you send a message to test the message flow. Specify the broker archive (`.bar`) file that you want to deploy manually in the **Specify Broker Archive file** property on the **Deployment** section of the **Configuration** tab. Deploy the broker archive file to the execution group that is specified in the Deployment Location section.

Always rebuild and deploy a Broker Archive automatically
The Test Client always builds and deploys the file irrespective of whether there is a change to the broker archive file or its dependents, including message flows.

You can use this option to force the Test Client to deploy when the Test Client cannot detect changes in the message flow.

Only rebuild and deploy Broker Archive when changes occur
The Test Client rebuilds and deploys the broker archive file only when there is a change in the content of the message flow. This action is the default option.

Override configurable properties when rebuilding Broker Archive file
You can define the configurable properties in the Broker Archive editor.

Use this option to specify whether the user-defined value is overridden when the Test Client rebuilds the broker archive file.

Click **Change** to select a deployment location, see the "Deployment Location wizard" on page 6716.

MQ Settings

Stop when first MQ message is received
Use this option if you want the Test Client to stop receiving events when the first WebSphere MQ Output queue contains a message.

Add one or more conditions. This option is ignored if no MQ queues are being monitored.

The Test Client monitors MQ queues that are defined in the MQOutput nodes in the message flows that are being tested. If you check the option, it instructs the Test Client to stop testing when the message reaches any of the WebSphere MQ queues that are being monitored.

Select Purge or Browse option
Use this option to either purge a message from the queue or to browse the messages on the output queue.

Queue manager connection parameters
Enter the character set ID to use for connection to your queue manager.

JMS Settings

Stop when first JMS message is received
Use this option to stop the Test Client receiving events when the first JMS Output destination contains a message.

Specify JMS Client JARs
Use this option to add and remove JAR files that are used to create JMS connections.

Select **Use preference settings** to configure preference settings. This option is a global setting that can be applied to every Test Client in the same workbench.

WMQ Message Headers

WMQ Message Headers
Use this option to build multiple MQMD header definitions. When you send a message to a message flow that contains an MQInput node, you have the option to select an MQMD with suitable values for your test. Click **Add** to enter additional MQMD headers. Each new header is listed under 'MQ Message Headers' in the left navigator column. Each MQMD definition name must be unique within the Test Client configuration file.

MQ Message Header "Default Header"
This options specifies the default MQ Message Header definition. You can edit the values in this definition for your test configuration, or create a new WebSphere MQ Message Header definition.

If you select **MQ Message Headers** or **JMS Message Headers**, a **Duplicate** context menu is displayed. This context menu gives you the option to create a new message header based upon one that already exists.

If you select **Include RFH V2 header** in the right hand pane you can specify values in a different folder that are applicable to the MQRFH2 header.

If you select **Include MCD folder**, the MCD folder properties are included in the MQRFH2 header.

If you select **Include JMS folder**, the JMS folder properties are included in the MQRFH2 header.

If you select **Include USR folder**, any additional properties you add are included in the MQRFH2 header.

Note that if you have selected **Include JMS folder**, the MCD folder is included automatically. Furthermore, changing the **Message type** results in a change to the **Message domain** in the MCD folder.

When a message containing the MQRFH2 header is received, the header is parsed and the results appear in the **Detailed Properties** pane of the Test Client. To display all the properties of the MQRFH2 header, expand the **Header** tab.

For further information on how the MQRFH2 values work, see "MQRFH2 header" on page 6397

JMS Message Headers

JMS Message Headers

Use this option to enter multiple JMS Message Headers. Click **Add** to enter additional headers. Each new header is listed under 'JMS Headers' in the left navigator column.

Select each JMS Message Header to view and change the settings.

JMS Header

Enter the values for your JMS configuration in the JMS Header page.

Related concepts:

You can configure the settings in the Test Client to control how your tests are run.

Related reference:

"Test Client" on page 6708
Use the Test Client to test message flow applications.

"Test Client **Events** tab" on page 6709
You can use the **Events** tab in the Test Client to edit the properties and content of your test messages. You also view test events in the **Events** tab when you run the test.

"Deployment Location wizard" on page 6716
Use the Deployment Location wizard to set the execution group to which the test message flow is deployed. You can also use the wizard to create a broker, a connection to a remote broker, and a new execution group.

"MQRFH2 header" on page 6397
The MQRFH2 header is used to pass messages to and from a message broker that belongs to WebSphere Message Broker.

Test Client preferences

You can set test settings for the local test environment that are used by the Websphere Message Broker Test Client.

You can configure the settings for the test in the Deployment Location wizard, or on the Test Client preferences. If you configure the settings on the Test Client preferences, these settings are applied to all tests. You can access the Test Client preferences by using the following instructions:

1. Click **Window** > **Preference**. The Preferences dialog is displayed.
2. Expand the item for Broker Development on the left and click Message Broker Test Client.

Use the following fields to define the settings for the local test engine:

Seconds to wait for deployment completion
The amount of time in seconds to allow for deployment. The default value is 20.

Seconds to wait after Test Client complete the deployment
The amount of time in seconds to wait after the Test Client completes deployment. The default value is 0.

Seconds to wait on launching the debugger for tracing purposes
The amount of time in seconds to wait before launching the debugger. The default value is 20.

Show information dialog before disconnecting the debugger
Select this option to display a dialog when you use the Test Client in Run mode if the flow debugger is already connected.

Seconds to wait for test client to stop
The amount of time in seconds to wait before ending the test. When the number of seconds has elapsed, monitoring of output nodes is stopped, and a Timeout event and a Stop event are displayed in the Test Client. The default value is 120.

Also select the required options:

Create queues of input and output nodes for message flows when host name is localhost
Use this option to create queues for the local host.

Add or modify (but not clear) what has already been deployed on the execution group Use this option to add or change, but not delete, what has previously been deployed on the current execution group.

Related reference:

"Deployment Location wizard"
Use the Deployment Location wizard to set the execution group to which the test message flow is deployed. You can also use the wizard to create a broker, a connection to a remote broker, and a new execution group.

Deployment Location wizard

Use the Deployment Location wizard to set the execution group to which the test message flow is deployed. You can also use the wizard to create a broker, a connection to a remote broker, and a new execution group.

The Deployment Location wizard is displayed when you click **Send Message** on the **Events** tab of the Test Client the first time that you run a test.

You can run the Test Client in one of the following modes:

- Run mode: test events are produced when the test message has been sent successfully from the message flow, or when an error occurs. Although you can also use the debugger, and the Test Client execution halts at the breakpoints, the Test Client does not receive and record message node-level trace information. When you use the Test Client in this mode, you are given the option to disconnect the flow debugger if it is already running. To use the Test Client in Run mode, ensure that **Trace and Debug** is not selected on the Deployment location wizard.
- Trace and debug mode: test trace events are produced when the test message leaves each node so that you can see the path that the message takes through the message flow. The results are stored in the broker. If you save the message flow test file, you can view the results at a later time. The flow debugger is launched in this mode, if it is not already connected. The test message stops at any breakpoints that you have configured in the message flow. You must configure a Java Debug port to run the test in the trace and debug mode.

If you use the Test Client in trace and debug mode, you can select the option **Stop at the beginning of the flow during debug**. This option suspends the test at the beginning of the message flow by setting a breakpoint on every connection after the selected input node. When you use the Test Client in the trace and debug mode, you can use the flow debugger in the Debug perspective.

You can also use the Deployment Location wizard to specify settings for the test. For more information about the test settings, see "Test Client preferences" on page 6716.

After you run a test for the first time, you can access the settings for the deployment location by clicking **Change** in the **Deployment** section of the **Configuration** tab.

JMS events in the Test Client

Use the information in this topic to help you to understand JMS events in the Test Client.

When you test a message flow that contains JMS nodes, you might see some of the following events in the Message Broker Test Events section of the Test Client.

JMS Information event

The event details are displayed in the following properties.

Property name	Description
Initial Context Factory	The initial context factory that is used for JNDI look up
Location JNDI binding	The JNDI URL that is used for JNDI look up
Connection Factory	The JNDI name of the Connection Factory
Message Properties	The properties of the JMS message
Message Header	The header of the JMS message

The message content is displayed in the XML Structure or Source view.

JMS Response event

The event details are displayed in the following properties.

Property name	Description
Initial Context Factory	The initial context factory that is used for JNDI look up
Location JNDI binding	The JNDI URL that is used for JNDI look up
Connection Factory	The JNDI name of the Connection Factory
Message Properties	The properties of the JMS message
Message Header	The header of the JMS message

The message content is displayed in the XML Structure or Source view.

JMS Exception event

The event details are displayed in the following properties.

Property name	Description
Initial Context Factory	The initial context factory that is used for JNDI look up
Location JNDI binding	The JNDI URL that is used for JNDI lookup
Connection Factory	The JNDI name of the Connection Factory

The detailed trace message is displayed as well as the Exception trace details.

Use the tasks described in this section of the documentation to manage and work with the flow debugger.

Flow debugger shortcuts

You can use function keys and shortcut keys to complete actions in the flow debugger views and windows.

Shortcut keys are shown as a pair that you press together, followed by a subsequent key, for example `Shift-F10, C` means hold the Shift key down and press F10, then release both and press key C.

The following tables describe the main shortcuts that are available in the debug session:

- "Debug view"
- "Breakpoints view"
- "Flow Breakpoint Properties dialog" on page 6720
- "Variables view" on page 6720

To see a complete list of all the shortcuts that are available, press `Shift-F10` and release; the contextual menu is displayed.

Debug view:

Key combination	Function
Shift-F10, C	Run to completion
Shift-F10, E	Disconnect
F5 or Shift-F10, I	Step into
F8 or Shift-F10, M	Resume
Shift-F10, N	Terminate All
F6 or Shift-F10, O	Step over
Shift-F10, T	Terminate
F7 or Shift-F10, U	Step return
Shift-F10, V	Terminate and Remove

Breakpoints view:

Key combination	Function
Shift-F10, A	Select All
Shift-F10, B	Add breakpoint
Shift-F10, D	Disable the selected breakpoints
Shift-F10, E	Enable the selected breakpoints
Shift-F10, L	Remove all breakpoints
Shift-F10, O	Remove the selected breakpoints

Flow Breakpoint Properties dialog:

Key combination	Function
E	Enable the breakpoint
Alt-R, <space>	Restrict the breakpoint to the selected flow instances

Variables view:

Key combination	Function
Shift-F10, A	Select All
Shift-F10, C	Change the value of the selected flow variable
Shift-F10, V	Copy variables

Use the **mqsireportflowstats** command to display the current options for accounting and statistics that have been set using the **mqsichangeflowstats** command.

Message flow accounting and statistics details

You can collect message flow, thread, node, and terminal statistics for message flows.

Message flow statistics

One record is created for each message flow in an execution group. Each record contains the following details:

- Message flow name and UUID
- Execution group name and UUID
- Broker name and UUID
- Start and end times for data collection
- Type of data collected (snapshot or archive)
- Processor and elapsed time spent processing messages
- Processor and elapsed time spent waiting for input
- Number of messages processed
- Minimum, maximum, and average message sizes
- Number of threads available and maximum assigned at any time
- Number of messages committed and backed out
- Accounting origin

Thread statistics

One record is created for each thread assigned to the message flow. Each record contains the following details:

- Thread number (this has no significance and is for identification only)
- Processor and elapsed time spent processing messages
- Processor and elapsed time spent waiting for input
- Number of messages processed
- Minimum, maximum, and average message sizes

Node statistics

One record is created for each node in the message flow. Each record contains the following details:

- Node name
- Node type (for example MQInput)
- Processor time spent processing messages
- Elapsed time spent processing messages
- Number of times that the node is invoked
- Number of messages processed
- Minimum, maximum, and average message sizes. When the node type is FileInput, the message size is reported as 0 because the size is not known at the time that the message is propagated.

Terminal statistics

One record is created for each terminal on a node. Each record contains the following details:

- Terminal name
- Terminal type (input or output)
- Number of times that a message is propagated to this terminal

For further details about specific output formats, see the following topics:

- "User trace entries for message flow accounting and statistics data" on page 6730
- "XML publication for message flow accounting and statistics data" on page 6726

Message flow accounting and statistics data is the information that can be collected by a broker to record performance and operating details of message flow execution.

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

"Monitoring message flow performance" on page 3279
You can configure your message flow to collect statistics about the operation and behavior of your message flows. Use this information to assess the performance of your message flows.

Chapter 9, "Developing message flow applications," on page 1019
Develop message flows to process your business messages and data.

Related reference:

"**mqsichangeflowstats** command" on page 3744
Use the **mqsichangeflowstats** command to control the accumulation of statistics about message flow operation.

Use the **mqsireportflowstats** command to display the current options for accounting and statistics that have been set using the **mqsichangeflowstats** command.

"Example message flow accounting and statistics data" on page 6739
You can view message flow accounting and statistic data in an XML publication or user trace entries. To view z/OS SMF records, use a utility program that processes SMF records.

XML publication for message flow accounting and statistics data:

Certain information is written to the XML publication for message flow accounting and statistics data.

The data is created in the folder `WMQIStatisticsAccounting`, which contains subfolders that provide more detailed information. All folders are present in the publication even if you set current data collection parameters to specify that the relevant data is not collected.

Snapshot data is used for performance analysis, and is published as retained and not persistent. Archive data is used for accounting where an audit trail might be required, and is published as retained and persistent. All publications are global and can be collected by a subscriber that is registered anywhere in the network. They can also be collected by more than one subscriber.

One XML publication is generated for each message flow that is producing data for the time period that you choose. For example, if MessageFlowA and MessageFlowB are both producing archive data over a period of 60 minutes, both MessageFlowA and MessageFlowB produce an XML publication every 60 minutes.

If you are concerned about the safe delivery of these messages (for example, for charging purposes), use a secure delivery mechanism such as WebSphere MQ.

The folders and subfolders in the XML publication have the following identifiers:
- WMQIStatisticsAccounting
- MessageFlow
- Threads
- ThreadStatistics
- Nodes
- NodesStatistics
- TerminalStatistics

The tables provided here describe the contents of each of these folders.

The following table describes the general accounting and statistics information, created in folder WMQIStatisticsAccounting.

Field	Data type	Details
RecordType	Character	Type of output, one of: • Archive • Snapshot
RecordCode	Character	Reason for output, one of: • MajorInterval • Snapshot • Shutdown • ReDeploy • StatsSettingsModified

The following table describes the message flow statistics information, created in folder MessageFlow.

Field	Data type	Details
BrokerLabel	Character (maximum 32)	Broker name
BrokerUUID	Character (maximum 32)	Broker universal unique identifier
ExecutionGroupName	Character (maximum 32)	Execution group name
ExecutionGroupUUID	Character (maximum 32)	Execution group universal unique identifier
MessageFlowName	Character (maximum 32)	Message flow name
StartDate	Character	Interval start date (YYYY-MM-DD)
StartTime	Character	Interval start time (HH:MM:SS:NNNNNN)
EndDate	Character	Interval end date (YYYY-MM-DD)
EndTime	Character	Interval end time (HH:MM:SS:NNNNNN)
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
MaximumElapsedTime	Numeric	Maximum elapsed time that is spent processing an input message (microseconds)
MinimumElapsedTime	Numeric	Minimum elapsed time that is spent processing an input message (microseconds)
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)
MaximumCPUTime	Numeric	Maximum processor time that is spent processing an input message (microseconds)
MinimumCPUTime	Numeric	Minimum processor time that is spent processing an input message (microseconds)

Field	Data type	Details
CPUTimeWaitingForInputMessage	Numeric	Total processor time spent waiting for input messages (microseconds)
ElapsedTimeWaitingForInputMessage	Numeric	Total elapsed time that is spent waiting for input messages (microseconds)
TotalInputMessages	Numeric	Total number of messages processed TotalInputMessages records only those messages that are propagated from input node terminals.
TotalSizeOfInputMessages	Numeric	Total size of input messages (bytes)
MaximumSizeOfInputMessages	Numeric	Maximum input message size (bytes)
MinimumSizeOfInputMessages	Numeric	Minimum message input size (bytes)
NumberOfThreadsInPool	Numeric	Number of threads in pool
TimesMaximumNumberofThreadsReached	Numeric	Number of times the maximum number of threads is reached
TotalNumberOfMQErrors	Numeric	Number of MQGET errors (MQInput node) or web services errors (HTTPInput node) For example, a conversion error occurs when the message is got from the queue.
TotalNumberOfMessagesWithErrors	Numeric	Number of messages that contain errors These errors include exceptions that are thrown downstream of the input node, and errors that are detected by the input node after it successfully retrieves the message from the queue, but before it propagates it to the output terminal (for example, a format error). TotalNumberOfMessagesWithErrors can include messages that are not included in TotalInputMessages.
TotalNumberOfErrorsProcessingMessages	Numeric	Number of errors when processing a message
TotalNumberOfTimeOutsWaitingForRepliesToAggregateMessages	Numeric	Number of timeouts when processing a message (AggregateReply node only)
TotalNumberOfCommits	Numeric	Number of transaction commits
TotalNumberOfBackouts	Numeric	Number of transaction backouts
AccountingOrigin	Character (maximum 32)	Accounting origin

The following table describes the thread statistics information, created in folder `Threads`.

Field	Data type	Details
Number	Numeric	Number of thread statistics subfolders in Threads folder

The following table describes the thread statistics information for each individual thread, created in folder ThreadStatistics, a subfolder of Threads.

Field	Data type	Details
Number	Numeric	Relative thread number in pool
TotalNumberOfInputMessages	Numeric	Total number of messages that are processed by a thread
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)
CPUTimeWaitingForInputMessage	Numeric	Total processor time spent waiting for input messages (microseconds)
ElapsedTimeWaitingForInputMessage	Numeric	Total elapsed time that is spent waiting for input messages (microseconds)
TotalSizeOfInputMessages	Numeric	Total size of input messages (bytes)
MaximumSizeOfInputMessages	Numeric	Maximum size of input messages (bytes)
MinimumSizeOfInputMessages	Numeric	Minimum size of input messages (bytes)

The following table describes the node statistics information, created in folder Nodes.

Field	Data type	Details
Number	Numeric	Number of node statistics subfolders in Nodes folder

The following table describes the node statistics information for each individual node, created in folder NodesStatistics, a subfolder of Nodes.

Field	Data type	Details
Label	Character	Name of node (Label)
Type	Character	Type of node
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
MaximumElapsedTime	Numeric	Maximum elapsed time spent processing input messages (microseconds)
MinimumElapsedTime	Numeric	Minimum elapsed time spent processing input messages (microseconds)
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)
MaximumCPUTime	Numeric	Maximum processor time spent processing input messages (microseconds)
MinimumCPUTime	Numeric	Minimum processor time spent processing input messages (microseconds)
CountOfInvocations	Numeric	Total number of messages that are processed by this node
NumberOfInputTerminals	Numeric	Number of input terminals
NumberOfOutputTerminals	Numeric	Number of output terminals

The following table describes the terminal statistics information, created in folder TerminalStatistics.

Field	Data type	Details
Label	Character	Name of terminal
Type	Character	Type of terminal, one of: • Input • Output
CountOfInvocations	Numeric	Total number of invocations

User trace entries for message flow accounting and statistics data:

Certain information is written to the user trace log for message flow accounting and statistics data.

The data records are identified by the following message numbers:
- BIP2380I
- BIP2381I
- BIP2382I
- BIP2383I

The inserts for each message are described in the following tables.

This table describes the inserts in message BIP2380I. One message is written for the message flow.

Field	Data type	Details
ProcessID	Numeric	Process ID

Field	Data type	Details
Key	Numeric	Key that is used to associate related accounting and statistics BIP messages
Type	Character	Type of output, one of: • Archive • Snapshot
Reason	Character	Reason for output, one of: • MajorInterval • Snapshot • Shutdown • ReDeploy • StatsSettingsModified
BrokerLabel	Character (maximum 32)	Broker name
BrokerUUID	Character (maximum 32)	Broker universal unique identifier
ExecutionGroupName	Character (maximum 32)	Execution group name
ExecutionGroupUUID	Character (maximum 32)	Execution group universal unique identifier
MessageFlowName	Character (maximum 32)	Message flow name
StartDate	Character	Interval start date (YYYY-MM-DD)
StartTime	Character	Interval start time (HH:MM:SS:NNNNNN)
EndDate	Character	Interval end date (YYYY-MM-DD)
EndTime	Character	Interval end time (HH:MM:SS:NNNNNN)
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
MaximumElapsedTime	Numeric	Maximum elapsed time that is spent processing an input message (microseconds)
MinimumElapsedTime	Numeric	Minimum elapsed time that is spent processing an input message (microseconds)
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)
MaximumCPUTime	Numeric	Maximum processor time that is spent processing an input message (microseconds)
MinimumCPUTime	Numeric	Minimum processor time that is spent processing an input message (microseconds)
CPUTimeWaitingForInputMessage	Numeric	Total processor time spent waiting for input messages (microseconds)

Field	Data type	Details
ElapsedTimeWaitingForInputMessage	Numeric	Total elapsed time that is spent waiting for input messages (microseconds)
TotalInputMessages	Numeric	Total number of messages processed TotalInputMessages records only those messages that are propagated from input node terminals.
TotalSizeOfInputMessages	Numeric	Total size of input messages (bytes)
MaximumSizeOfInputMessages	Numeric	Maximum input message size (bytes)
MinimumSizeOfInputMessages	Numeric	Minimum input message size (bytes)
NumberOfThreadsInPool	Numeric	Number of threads in pool
TimesMaximumNumberofThreadsReached	Numeric	Number of times the maximum number of threads is reached
TotalNumberOfMQErrors	Numeric	Number of MQGET errors (MQInput node) or web services errors (HTTPInput node) For example, a conversion error occurs when the message is got from the queue.
TotalNumberOfMessagesWithErrors	Numeric	Number of messages that contain errors These errors include exceptions that are thrown downstream of the input node, and errors that are detected by the input node after it successfully retrieves the message from the queue (for example, a format error). TotalNumberOfMessagesWithErrors can include messages that are not included in TotalInputMessages.
TotalNumberOfErrorsProcessingMessages	Numeric	Number of errors while processing a message
TotalNumberOfTimeOutsWaitingForRepliesToAggregateMessages	Numeric	Number of timeouts while processing a message (AggregateReply node only)
TotalNumberOfCommits	Numeric	Number of transaction commits
TotalNumberOfBackouts	Numeric	Number of transaction backouts
AccountingOrigin	Character (maximum 32)	Accounting origin

The following table describes the inserts in message BIP2381I. One message is written for each thread.

Field	Data type	Details
ProcessID	Numeric	Process ID
Key	Numeric	Key that is used to associate related accounting and statistics BIP messages

Field	Data type	Details
Number	Numeric	Relative thread number in pool
TotalNumberOfInputMessages	Numeric	Total number of messages that are processed by a thread
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
TotalCUPTime	Numeric	Total processor time spent processing input messages (microseconds)
CPUTimeWaitingForInputMessage	Numeric	Total processor time spent waiting for input messages (microseconds)
ElapsedTimeWaitingForInputMessage	Numeric	Total elapsed time that is spent waiting for input messages (microseconds)
TotalSizeOfInputMessages	Numeric	Total size of input messages (bytes)
MaximumSizeOfInputMessages	Numeric	Maximum size of input messages (bytes)
MinimumSizeOfInputMessages	Numeric	Minimum size of input messages (bytes)

The following table describes the inserts in message BIP2382I. One message is written for each node.

Field	Data type	Details
ProcessID	Numeric	Process ID
Key	Numeric	Key that is used to associate related accounting and statistics BIP messages
Label	Character	Name of node (Label)
Type	Character	Type of node
TotalElapsedTime	Numeric	Total elapsed time spent processing input messages (microseconds)
MaximumElapsedTime	Numeric	Maximum elapsed time spent processing input messages (microseconds)
MinimumElapsedTime	Numeric	Minimum elapsed time spent processing input messages (microseconds)
TotalCPUTime	Numeric	Total processor time spent processing input messages (microseconds)
MaximumCPUTime	Numeric	Maximum processor time spent processing input messages (microseconds)
MinimumCPUTime	Numeric	Minimum processor time spent processing input messages (microseconds)
CountOfInvocations	Numeric	Total number of messages that are processed by this node
NumberOfInputTerminals	Numeric	Number of input terminals
NumberOfOutputTerminals	Numeric	Number of output terminals

The following table describes the inserts in message BIP2383I. One message is written for each terminal on each node.

Field	Data type	Details
ProcessID	Numeric	Process ID

Field	Data type	Details
Key	Numeric	Key that is used to associate related accounting and statistics BIP messages
Label	Character	Name of terminal
Type	Character	Type of terminal, one of: • Input • Output
CountOfInvocations	Numeric	Total number of invocations

z/OS SMF records for message flow accounting and statistics data:

Certain information is written to z/OS SMF records for message flow accounting and statistics data.

The data records are type 117 records with the following identifiers:
- BipSMFDate
- BipSMFRecordHdr
- BipSMFTriplet
- BipSMFMessageFlow
- BipSMFThread
- BipSMFNode
- BipSMFTerminal

The following tables describe the contents of each of these records.

The following table describes the contents of the BipSMFDate record.

Field	Data type	Details
YYYY	signed short int	2 byte year
MM	char	1 byte month
DD	char	1 byte day

The following table describes the contents of the BipSMFRecordHdr record.

Field	Data type	Details
SM117LEN	unsigned short int	SMF record length
SM117SEG	unsigned short int	System reserved
SM117FLG	char	System indicator
SM117RTY	char	Record type 117 (x'75')
SM117TME	unsigned int	Time when SMF moved the record (time since midnight in hundredths of a second)
SM117DTE	unsigned int	Date when SMF moved the record in packed decimal form 0cyydddF where: c is 0 (19xx) or 1 (20xx) yy is the current year (0-99) ddd is the current day (1-366) F is the sign
SM117SID	unsigned int	System ID
SM117SSI	unsigned int	Subsystem ID
SM117STY	unsigned short int	Record subtype, one of : • 1 (only message flow or threads data is being collected) • 2 (node data is being collected)[1]
SM117TCT	unsigned int	Count of triplets
SM117SRT	unsigned char	Record type, one of: • Archive • Snapshot
SM117SRC	unsigned char	Record code, one of: • 00 = None • 01 = Major Interval • 02 = Snapshot • 03 = Shutdown • 04 = Redeploy • 05 = Stats Settings Modified
SM117RSQ	unsigned short int	Sequence number of the record when multiple records are written for a collection interval.
SM117NOR	unsigned short int	Total number of related records in a collection interval.

Note:

1. When only nodes data is being collected, a single subtype 2 record is written. If nodes and terminals data is being collected, multiple subtype 2 records are written.

The following table describes the contents of the BipSMFTriplet record.

Field	Data type	Details
TRPLTOSE	signed int	Offset of record from start of SMF record

Field	Data type	Details
TRPLTDLE	signed short int	Length of data type
TRPLTNDR	signed short int	Number of data types in SMF record

The following table describes the contents of the BipSMFMessageFlow record.

Field	Data type	Details
IMFLID	short int	Control block hex ID (BipSMFMessageFlow_ID)
IMFLLEN	short int	Length of control block
IMFLEYE	char[4]	Eyecatcher (IMFL)
IMFLVER	int	Version number (BipSMFRecordVersion)
IMFLBKNM	char[32]	Broker name
IMFLBKID	char[36]	Broker universal unique identifier
IMFLEXNM	char[32]	Execution group name
IMFLEXID	char[36]	Execution group universal unique identifier
IMFLMFNM	char[32]	Message flow name
IMFLSTDT	BipSMFDate	Interval start date
IMFLSTTM	unsigned int	Interval start time (format as for SM117TME)
IMFLENDT	BipSMFDate	Interval end date
IMFLENTM	unsigned int	Interval end time (format as for SM117TME)
IMFLTPTM	long long int	Total elapsed time spent processing input messages (8 bytes binary, microseconds)
IMFLMXTM	long long int	Maximum elapsed time spent processing an input message (8 bytes binary, microseconds)
IMFLMNTM	long long int	Minimum elapsed time spent processing an input message (8 bytes binary, microseconds)
IMFLTPCP	long long int	Total processor time spent processing input messages (8 bytes binary, microseconds)
IMFLMXCP	long long int	Maximum processor time spent processing an input message (8 bytes binary, microseconds)
IMFLMNCP	long long int	Minimum processor time spent processing an input message (8 bytes binary, microseconds)
IMFLWTCP	long long int	Total processor time spent waiting for input messages (8 bytes binary, microseconds)
IMFLWTIN	long long int	Total elapsed time spent waiting for input messages (8 bytes binary, microseconds)
IMFLTPMG	unsigned int	Total number of messages processed
IMFLTSMG	long long int	Total size of input messages (bytes)
IMFLMXMG	long long int	Maximum input message size (bytes)
IMFLMNMG	long long int	Minimum input message size (bytes)
IMFLTHDP	unsigned int	Number of threads in pool
IMFLTHDM	unsigned int	Number of times the maximum number of threads is reached
IMFLERMQ[1]	unsigned int	Number of MQGET errors (MQInput node) or Web services errors (HTTPInput node)

Field	Data type	Details
IMFLERMG[2]	unsigned int	Number of messages that contain errors
IMFLERPR	unsigned int	Number of errors processing a message
IMFLTMOU	unsigned int	Number of timeouts processing a message (AggregateReply node only)
IMFLCMIT	unsigned int	Number of transaction commits
IMFLBKOU	unsigned int	Number of transaction backouts
IMFLACCT	char[32]	Accounting origin

Notes:
1. For example, a conversion error occurs when the message is got from the queue.
2. These include exceptions that are thrown downstream of the input node, and errors detected by the input node after it has successfully retrieved the message from the queue (for example, a format error).

The following table describes the contents of the BipSMFThread record.

Field	Data type	Details
ITHDID	short int	Control block hex ID (BipSMFThread_ID)
ITHDLEN	short int	Length of control block
ITHDEYE	char[4]	Eyecatcher (ITHD)
ITHDVER	int	Version number (BipSMFRecordVersion)
ITHDNBR	unsigned int	Relative thread number in pool
ITHDTPMG	unsigned int	Total number of messages processed by thread
ITHDTPTM	long long int	Total elapsed time spent processing input messages (8 bytes binary, microseconds)
ITHDTPCP	long long int	Total processor time spent processing input messages (8 bytes binary, microseconds)
ITHDWTCP	long long int	Total processor time spent waiting for input messages (8 bytes binary, microseconds)
ITHDWTIN	long long int	Total elapsed time spent waiting for input messages (8 bytes binary, microseconds)
ITHDTSMG	long long int	Total size of input messages (bytes)
ITHDMXMG	long long int	Maximum size of input messages (bytes)
ITHDMNMG	long long int	Minimum size of input messages (bytes)

The following table describes the contents of the BipSMFNode record.

Field	Data type	Details
INODID	short int	Control block hex ID (BipSMFNode_ID)
INODLEN	short int	Length of control block
INODEYE	char[4]	Eyecatcher (INOD)
INODVER	int	Version number (BipSMFRecordVersion)
INODNDNM	char[32]	Name of node (Label)
INODTYPE	char[32]	Type of node
INODTPTM	long long int	Total elapsed time spent processing input messages (8 bytes binary, microseconds)

Field	Data type	Details
INODMXTM	long long int	Maximum elapsed time spent processing input messages (8 bytes binary, microseconds)
INODMNTM	long long int	Minimum elapsed time spent processing input messages (8 bytes binary, microseconds)
INODTPCP	long long int	Total processor time spent processing input messages (8 bytes binary, microseconds)
INODMXCP	long long int	Maximum processor time spent processing input messages (8 bytes binary, microseconds)
INODMNCP	long long int	Minimum processor time spent processing input messages (8 bytes binary, microseconds)
INODTPMG	unsigned int	Total number of messages processed by this node
INODNITL	unsigned int	Number of input terminals
INODNOTL	unsigned int	Number of output terminals

The following table describes the contents of the BipSMFTerminal record.

Field	Data type	Details
ITRMID	short int	Control block hex ID (BipSMFTerminal_ID)
ITRMLEN	short int	Length of control block
ITRMEYE	char[4]	Eyecatcher (ITRM)
ITRMVER	int	Version number (BipSMFRecordVersion)
ITRMTLNM	char[32]	Name of terminal
ITRMTYPE	char[8]	Type of terminal, one of: • Input • Output
ITRMTINV	unsigned int	Total number of invocations

You can collect message flow, thread, node, and terminal statistics for message flows.

Example message flow accounting and statistics data

You can view message flow accounting and statistic data in an XML publication or user trace entries. To view z/OS SMF records, use a utility program that processes SMF records.

The following topics give example output in two formats:
- XML publication
- User trace entries

An example is not provided for z/OS SMF records, because these contain hexadecimal data and are not easily viewed in that form. To view SMF records, use any available utility program that processes SMF records.

Develop message flows to process your business messages and data.

Related reference:

"Message flow accounting and statistics output formats" on page 6725
The message flow accounting and statistics data can be written in three formats.

"**mqsichangeflowstats** command" on page 3744
Use the **mqsichangeflowstats** command to control the accumulation of statistics about message flow operation.

"**mqsireportflowstats** command" on page 3929
Use the **mqsireportflowstats** command to display the current options for accounting and statistics that have been set using the **mqsichangeflowstats** command.

Example of an XML publication for message flow accounting and statistics:

This example shows an XML publication that contains message flow accounting and statistics data.

The following example shows what is generated for a snapshot report. The content of this publication message shows that the message flow is called *XMLflow*, and that it is running in an execution group named *default* on broker *MQ02BRK*. The message flow contains the following nodes:
- An MQInput node called *INQueue3*
- An MQOutput node called *OUTQueue*
- An MQOutput node called *FAILQueue*

The MQInput node's Out terminal is connected to the OUTQueue node. The MQInput node's Failure terminal is connected to the FAILQueue node.

During the interval for which statistics have been collected, this message flow processed no messages.

A publication that is generated for this data always includes the appropriate folders, even if there is no current data.

The following command has been issued to achieve these results:

```
mqsichangeflowstats MQ02BRK -s -c active -e default -f XMLFlow -n advanced -t basic -b basic -o xml
```

Blank lines have been added between folders to improve readability.

The broker takes information about statistics and accounting from the operating system. On some operating systems, such as Windows, UNIX, and Linux, rounding can occur because the system calls that are used to determine the processor times are not sufficiently granular. This rounding might affect the accuracy of the data.

The following example is the subscription message. The <psc> and <mcd> elements are part of the RFH header.

```
<psc>
  <Command>Publish</Command>
  <PubOpt>RetainPub</PubOpt>
  <Topic>$SYS/Broker/MQ02BRK/StatisticsAccounting/SnapShot/default/XMLflow
  </Topic>
</psc>

<mcd>
  <Msd>xml</Msd>
</mcd>
```

The following example is the publication that the broker generates:

```
<WMQIStatisticsAccounting RecordType="SnapShot" RecordCode="Snapshot">

Develop message flows to process your business messages and data.

Related reference:

"Message flow accounting and statistics output formats" on page 6725
The message flow accounting and statistics data can be written in three formats.

Example of user trace entries for message flow accounting and statistics:

This example shows a user trace that contains message flow accounting and statistics data.

The following example shows what is generated for a snapshot report. The messages that are written to the trace show that the message flow is called

myExampleFlow, and that it is running in an execution group named *default* on broker *MQ01BRK*. The message flow contains the following nodes:
- An MQInput node called *inNode*
- A Compute node called *First1*
- An MQOutput node called *outNode*

The nodes are connected together (Out terminal to In terminal for each connection).

During the interval for which statistics have been collected, this message flow processed 150 input messages.

The records show that two threads are assigned to this message flow. One thread is assigned when the message flow is deployed (the default number); an additional thread (thread 0) listens on the input queue. The listening thread starts additional threads to process input messages that are dependent on the number of instances that you have configured for the message flow, and on the rate of arrival of the input messages on the input queue.

The following command has been issued to achieve these results:

```
mqsichangeflowstats MQ01BRK -s -c active -e default -f myExampleFlow -n advanced -t basic -b basic
```

The trace entries have been retrieved with the **mqsireadlog** command and formatted using the **mqsiformatlog** command. The output from **mqsiformatlog** is shown in the following example. Line breaks have been added to aid readability.

The broker takes information about statistics and accounting from the operating system. On some operating systems, such as Windows, UNIX, and Linux, rounding can occur because the system calls that are used to determine the processor times are not sufficiently granular. This rounding might affect the accuracy of the data.

Metrics for accounting and statistics data in the WebSphere Message Broker Explorer

You can filter the metrics displayed for accounting and statistics data in the Broker Statistics and Broker Statistics Graph views in the WebSphere Message Broker Explorer.

Broker statistics

The metrics that you can select in the Broker Statistics Graph view for a broker are:

- Total number of input messages
- Total elapsed time
- Total processor time spent processing messages
- Processor time waiting for input message
- Elapsed time waiting for input message
- Total size of input messages
- Maximum size of input messages
- Minimum size of input messages

Execution group statistics

The metrics that you can select in the Broker Statistics Graph view for an execution group are:

- Total elapsed time
- Maximum elapsed time
- Minimum elapsed time
- Total processor time
- Maximum processor time
- Minimum processor time
- Processor time waiting for input message
- Elapsed time waiting for input message
- Total input messages
- Total size of input messages
- Maximum size of input messages
- Minimum size of input messages

- Number of threads in pool
- Times maximum number of threads reached
- Total number of WebSphere MQ errors
- Total number of messages with errors
- Total number of errors processing messages
- Total number of time-outs waiting for replies to aggregate messages
- Total number of commits
- Total number of messages backed out

Message flow statistics

The metrics that you can select in the Broker Statistics Graph view for a message flow are:

- Total elapsed time
- Maximum elapsed time
- Minimum elapsed time
- Total processor time
- Maximum processor time
- Minimum processor time
- Count of invocations
- Number of input terminals
- Number of output terminals

You can select the metrics for the snapshot accounting and statistics data that are displayed in the Broker Statistics and Broker Statistics Graph views in the WebSphere Message Broker Explorer.

Resource statistics data

Learn about the measurements for which data is returned when you activate resource statistics collection.

Statistics information is collected for the following resource types:

- CICS
- CORBA
- File
- File Transfer Protocol
- FTEAgent
- IBM Sterling Connect:Direct

- Java Virtual Machine (JVM)
- JDBC connection pools
- ODBC
- Outbound sockets
- Parsers
- Security
- SOAP
- TCPIP Client Nodes
- TCPIP Server Nodes

You can view these statistics in the WebSphere Message Broker Explorer, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

The information collected, which is different for each type, is shown in the following tables.

Related concepts:

Use the **mqsireportresourcestats** command to display current statistics gathering options for resources in the broker.

Example of an XML publication for resource statistics

This example message shows an XML publication that contains resource statistics data.

A single XML publication includes all the statistics information that is reported for the resource types listed in "Resource statistics data" on page 6745. The publication message starts with information that identifies the broker and the execution group to which the statistics apply.

For information about subscribing to these publication messages, see "Subscribing to statistics reports" on page 3317.

The following message is an example that shows three sections, one for each of three different resource types, and the values that are returned for each type. The output lines in this example have been split to improve readability.

```

All times are reported in local time, and the timezone used is reported by the timezone attribute in the standard TZ Area/Location format. The date is in the format yyyy-MM-dd, and time is in the format HH:mm:ss, independent of locale and timezone.

The collectionStartDate and collectionStartTime specify when resource statistics collection started, typically when the execution group was last started.

The endDate and endTime specify when the statistics data in the current message was gathered. The startDate and startTime is when the previous set of data was reported.

Resource statistics data: CICS

Learn about the data that is returned for the CICS resource type when you activate resource statistics collection.

You can view these statistics in the WebSphere Message Broker Explorer, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

A CICSRequest node calls CICS Transaction Server for z/OS programs. Use these resource statistics to review how many successful and unsuccessful calls the node is making to CICS, how many unsuccessful requests are related to security issues such as authentication failures, and how often connection attempts fail.

A statistics summary is returned for the whole execution group, followed by a breakdown for each named CICS Transaction Server for z/OS region.

The following table describes the measurements that are returned for each CICS region. Each row of statistics represents a CICS region, which is identified either by a configurable service, or by the CICSRequest node `CICS server` URL.

- In this example, the configurable service is identified by *myCICSConnectionService*, and the broker is identified by APPLID*BRKApp* and qualifier *BRKQual*:

  myCICSConnectionService.BRKApp.BRKQual

- In this example, the CICSRequest node `CICS server` URL is identified by *tcp://mycicsregion.com:12345*:

  tcp://mycicsregion.com:12345

Measurements	Description
RequestSuccess	The number of requests to CICS that are successful.
RequestFailures	The total number of requests to CICS that fail. The value that is returned by this measurement does not include connection failures. Connection failure values are returned by the `ConnectionAttemptFailures` measurement.
RequestSecurityFailures	The number of failed requests to CICS that were caused by security issues, such as authentication failures.
ConnectionAttemptFailures	The number of connection attempts that fail.

Resource statistics data: CORBA

Learn about the data that is returned for the CORBA resource type when you activate resource statistics collection.

You can view these statistics in the WebSphere Message Broker Explorer, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

A CORBARequest node calls a CORBA server. Use these resource statistics to review how many calls the node is making to the CORBA server, and how many of those calls are successful or result in CORBA exceptions. A statistics summary is returned for the whole execution group.

The following table describes the measurements that are returned for each CORBA node. The measurements apply to the number of calls since the execution group started.

Measurements	Description
OutboundInvocations	The total number of calls made to a CORBA server.
OutboundSuccessfulInvocations	The number of calls to the CORBA server that are successful.
OutboundCorbaExceptions	The number of calls to the CORBA server that result in CORBA exceptions.

Resource statistics data: File

Learn about the data that is returned for the file resource type when you activate resource statistics collection.

You can view these statistics in the WebSphere Message Broker Explorer, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

A summary is displayed for the local file system of any file actions done by any type of file node. It does not have any other entries; there is only one local file system. Remote file systems are reported in FTEAgent and FTP resource statistics.

Measurements	Description
FilesRead	The number of files successfully read by any file node
RecordsRead	The number of records read by either a file input node, FTE input node, or a file read node
BytesRead	The total number of bytes read by either a file input node, FTE input node, or a file read node
FilesCreated	The number of files successfully created by a file output node
RecordsWritten	The number of records written to files by a file output node or FTE output node
BytesWritten	The total number of bytes written by a file output node or FTE output node

Resource statistics data: File Transfer Protocol

Learn about the data that is returned for the File Transfer Protocol resource type when you activate resource statistics collection.

You can view these statistics in the WebSphere Message Broker Explorer, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

A summary is displayed of file transfers that occur in the execution and a list for each server used.

Measurements	Description
Protocol	The protocol used: either FTP or SFTP
FTPGets	The number of transfers from a remote server to the file system of the broker
BytesReceived	The number of bytes transferred from a remote server to the file system of the broker
FTPPuts	The number of transfers from the file system of the broker to a remote server
BytesSent	The number of bytes transferred from the file system of the broker to a remote server **Note:** The FTPPuts counter can increase in two cases: either when a new file is transferred, or when an append is made to an existing file.

Resource statistics data: FTEAgent

Learn about the data that is returned for the FTEAgent resource type when you activate resource statistics collection.

You can view these statistics in the WebSphere Message Broker Explorer, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

The FTE agent is an embedded FTE component that allows WebSphere Message Broker to send and receive files by using WebSphere MQ File Transfer Edition. A one-to-one mapping exists between an execution group and its FTE agent. Therefore, the resource manager statistics provide an accurate picture of the WebSphere MQ File Transfer Edition activity of that execution group.

The following table describes the measurements that are returned for the agent.

Measurements	Description
inboundTransfers	The number of transfers received by the agent.
outboundTransfers	The number of transfers sent by the agent.
inboundBytes	The number of bytes received by the agent.
outboundBytes	The number of bytes sent by the agent.

Resource statistics data: IBM Sterling Connect:Direct

Learn about the data that is returned for the CDServer resource type when you activate resource statistics collection.

You can view these statistics in the WebSphere Message Broker Explorer, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

Statistics are available for all Connect:Direct server activity, together with one line for each configurable service used.

The following table describes the measurements that are returned.

Measurements	Description
connectionDetails	The host name and port for the Connect:Direct server that is being connected to, in the format `<hostname>:port`. For the summary line, this property is set to an empty string.
inboundTransfers	The number of transfers received by the Connect:Direct server selected for processing in a message flow.
inboundBytes	Total number of bytes received in transfers, selected from Connect:Direct server.
nohitTransfers	The number of transfers received by the Connect:Direct server not selected for processing in a message flow. Reasons for not processing a transfer include: • The WebSphere Message Broker system has no access to the transferred file. • A deployed CDInput node has a filter that matches the transferred file. This number gives the total for the whole broker and not just this execution group.
outboundTransfers	The number of transfers sent to the Connect:Direct server.
outboundBytes	Total number of bytes contained in transfers sent to the Connect:Direct server.

Resource statistics data: Java Virtual Machine (JVM)

Learn about the data that is returned for the JVM resource type when you activate resource statistics collection.

You can view these statistics in the WebSphere Message Broker Explorer, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

Each execution group starts its own Java Virtual Machine (JVM), which provides support for all Java activities in that execution group. Some Java activity is present in the execution group even if you have not yet deployed or started message flows in that group. Use these resource statistics to review how much memory is in use by the JVM, and how often garbage collection might be occurring in the execution group.

Statistics are collected for the following JVM resources:
- Heap memory
- Non-heap memory
- Garbage collection

A summary is also provided, which adds the values in the three groups.

The special value `-1` is returned for measurements that are undefined or are not set.

The following table describes the measurements that are returned for each of the listed resources. The garbage collection measurements are cumulative, and continue to increase until you stop statistics collection.

Measurements	Resource	Description
InitialMemoryInMB	• Heap memory • Non-heap memory	The initial amount of memory that the JVM requests from the operating system for memory management during startup. Its value might be undefined.

Measurements	Resource	Description
UsedMemoryinMB	• Heap memory • Non-heap memory	The amount of memory that is currently in use.
CommittedMemoryInMB	• Heap memory • Non-heap memory	The amount of memory that is allocated to the JVM by the operating system.
MaxMemoryInMB	• Heap memory • Non-heap memory	The maximum amount of memory that can be used for memory management. Its value might be undefined.
CumulativeGCTimeInSeconds	Garbage collection	The accumulated garbage collection elapsed time in seconds for this instance of the JVM. Its value might be undefined.
CumulativeNumberOfGCCollections	Garbage collection	The total number of garbage collections that have occurred for this instance of the JVM. Its value might be undefined.

Resource statistics data: JDBC connection pools

Learn about the data that is returned for the JDBC connection pools resource type when you activate resource statistics collection.

You can view these statistics in the WebSphere Message Broker Explorer, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

A statistics summary is returned for each JDBC provider defined in the broker configurable service that is switched to use connection pools. The following examples are named JDBC data sources:

- DB2
- Oracle
- Microsoft SQLServer

The following table describes the measurements that are returned for each JDBC Provider configurable service.

Measurements	Description
NameOfJDBCProvider	The name of the JDBCProviders configurable service that is using connection pooling. If there are no connection pools started, this defaults to `none`.
MaxSizeOfPool	The maximum size of the connection pool.
ActualSizeOfPool	A snapshot of the number of connections currently in the pool when the statistics were reported.
CumulativeRequests	A count of the number of requests received by the connection pool during this accounting period.
CumulativeDelayedRequests	The number of times a request for a connection could not be satisfied immediately, because the number of allocated connections reached the maximum pool size and no connections are currently available.
MaxDelayInMilliseconds	The maximum time a caller waited for a connection to be allocated, in milliseconds.
CumulativeTimedOutRequests	A count of the number of requests for connections that could not be satisfied within 15 seconds.

Resource statistics data: ODBC

Learn about the data that is returned for the ODBC resource type when you activate resource statistics collection.

You can view these statistics in the WebSphere Message Broker Explorer, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

Statistics are reported for each ODBC DSN that was accessed since the execution group started. XA connections are distinguished from non-XA connections from the same DSN. Each resource is named either *DSN* or *DSN* (XA). This information is published on topic `$SYS/Broker/brokerName/ResourceStatistics/executionGroupLabel`.

Measurements	Description
ExecuteSuccess	The total number of times any statement was run against this DSN.
ExecuteFailure	The total number of times any statement failed against this DSN.
ActiveConnections	The number of connections currently open to this DSN.
ClosedConnections	The number of connections to this DSN that were ever open, but are now closed. This figure includes connections closed due to an error, forced closed by the DBMS or closed by broker because it was no longer required (for example, thread idle for 60 seconds).
ConnectionErrors	The number of times a connection to this DSN was detected to have a connection error (which would have caused the error to be closed and therefore also contributed to the closed connections measurement).

Resource statistics data: Outbound sockets

Learn about the data that is returned for the sockets resource type when you activate resource statistics collection.

You can view these statistics in the WebSphere Message Broker Explorer, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

Outbound sockets are used by the execution group when a message is sent out through a SOAP, SCA, or HTTP request node. SOAP and SCA nodes always use keepalive sockets; therefore outbound sockets are reused for many requests. HTTPRequest nodes use keepalive sockets only if you set the property Enable HTTP/1.1 keep-alive. Use these resource statistics to review whether you are reusing outbound sockets, and to see the size and volume of message data that is flowing through those sockets.

A statistics summary is returned, followed by an entry for each outbound socket endpoint, which is defined by its URL. Examples of endpoints are `localhost:7080` and `www.soaphub.org:80`.

The following table describes the measurements that are returned for each endpoint that was accessed since the execution group was last restarted.

Measurements	Description
TotalSockets	The number of outbound sockets that have been opened since the last execution group restart.
TotalMessages	The number of requests for a socket; for example, from a SOAPRequest node.
TotalDataSent_KB	The number of bytes sent, in kilobytes (KB).
TotalDataReceived_KB	The number of bytes received, in kilobytes (KB).
SentMessageSize_0-1KB SentMessageSize_1KB-10KB SentMessageSize_10KB-100KB SentMessageSize_100KB-1MB SentMessageSize_1MB-10MB SentMessageSize_Over10MB	The number of messages sent in each size range. For example, a message of 999 bytes is counted in SentMessageSize_0-1KB; a message of 1000 bytes is counted in SentMessageSize_1KB-10KB.
ReceivedMessageSize_0-1KB ReceivedMessageSize_1KB-10KB ReceivedMessageSize_10KB-100KB ReceivedMessageSize_100KB-1MB ReceivedMessageSize_1MB-10MB ReceivedMessageSize_Over10MB	The number of messages received in each size range.

Resource statistics data: Parsers

Learn about the data that is returned for the parsers resource type when you activate resource statistics collection.

You can view these statistics in the WebSphere Message Broker Explorer, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

All message flows in an execution group create parsers to parse and write input and output messages. Use the Parsers statistics to see how much resource is being used by the message trees and bit streams that these parsers own.

A statistics summary is returned, followed by an entry for accumulation by parser type for each message flow. The rows are named in the style *<Message Flow>.<Parser>*. A row is shown for every parser type used by that message flow. Additional instances are included in the accumulated statistics for each message flow.

The following table describes the statistics that are returned for each message flow parser since the execution group was last restarted.

Measurements	Description
Threads	The number of message flow threads that contributed to the statistics for a message flows parser type accumulation.
ApproxMemKB	The approximate amount of user data-related memory used for the named message flow parser type. It is not possible to calculate the exact amount of memory used by a parser.
MaxReadKB	Shows the largest bit stream parsed by the parser type for the named message flow.

Measurements	Description
MaxWrittenKB	Shows the largest bit stream written by the parser type for the named message flow.
Fields	Shows the number of message fields associated with the named message flow parser type. These fields are retained by the parser and are used for constructing the message trees.
Reads	The number of successful parses that were completed by the named message flow parser type.
FailedReads	The number of failed parses that occurred for the named message flow parser type.
Writes	The number of successful writes that were completed by the named message flow parser type.
FailedWrites	The number of failed writes that occurred for the named message flow parser type.

Resource statistics data: Security

Learn about the data that is returned for the security resource type when you activate resource statistics collection.

You can view these statistics in the WebSphere Message Broker Explorer, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

When a message flow is configured with a security profile, requests are typically made to a security provider or security token server (STS) to process and approve authentication, mapping, or authorization. Use the security resource statistics to review the number of requests that are made, how many of those requests are successful, and how many are being serviced from the security cache.

A statistics summary is returned for the whole execution group, followed by a breakdown for each named security provider. Examples of named security providers are WS-Trust v1.3 STS and LDAP.

The following table describes the measurements that are returned for each provider.

Measurements	Description
TotalOperations	The number of security operations (authentication, mapping, or authorization) since collection started. A security profile with both authentication and authorization counts as two operations.
TotalSuccessfulOperations	The number of security operations (authentication, mapping, or authorization) that were approved.
TotalOperationsServicedByCache	The number of security operations (authentication, mapping, or authorization) that were serviced from the security cache (without accessing the STS directly).
TotalCacheEntries	The total number of security operation result entries in the security cache. A security operation is defined in the security profile as authentication, mapping, or authorization. A cache entry might include a returned security token.

Resource statistics data: SOAP

Learn about the data that is returned for the SOAPInbound resource type when you activate resource statistics collection.

You can view these statistics in the WebSphere Message Broker Explorer, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

The SOAPInput and SOAPReply nodes send and receive SOAP messages. Use the SOAPInput resource statistics to review how many inbound messages the SOAPInput node is receiving, how many replies the SOAPReply node is sending, and how many of those calls are successful or result in SOAP Faults, on a per-operation basis. Statistics for the SOAP nodes are collected with both HTTP and JMS transport. You can review the name of the applied policy set if one is defined. A statistics summary is returned for the whole execution group.

The following table describes the measurements that are returned for the SOAPInput and SOAPReply nodes. These statistics do not include messages which timed out.

Measurements	Description
Name	This measurement takes one of the following values: • "Summary" • *Flow*.*Node*.*Operation* • [Undeployed].*Flow*.*Node*.*Operation* where *Flow* is the name of your message flow, *Node* is the node name, and *Operation* is the name of the operation.
InboundMessagesTotal	The total number of SOAP messages received from the client. This measurement is equal to the sum of `InboundMessagesMadeFlow` and `InboundMessagesFaultedBeforeFlow`.
RepliesSentTotal	The total number of SOAP replies sent back to the client. This measurement is equal to the sum of `SuccessfulRepliesSent` and `FaultRepliesSent`.
InboundMessagesMadeFlow	The number of messages that made the flow without faulting.
InboundMessagesFaultedBeforeFlow	The number of messages that faulted before reaching the flow. This measurement includes input messages that are sent down the Failure terminal.
SuccessfulRepliesSent	The number of successful replies, without SOAP Fault, sent to the client.
FaultRepliesSent	The number of SOAP Fault replies sent to client. These faults can be user-defined faults or broker exceptions.
PolicySetApplied	The name of the policy set if one was defined.

Resource statistics data: TCPIP Client Nodes

Learn about the data that is returned for the TCPIP Client Nodes resource type when you activate resource statistics collection.

You can view these statistics in the WebSphere Message Broker Explorer, or you can write a program that subscribes to a publication (single XML message) that returns this data. For an example of the publication message, see Example XML output.

Use these statistics to get a view of the level of activity and health of TCP/IP nodes in an execution group. You can see how many connection managers are active and reporting statistics, and the following details from each:

Measurements	Description
OpenConnections	The current number of open connections
ClosedConnections	The total number of connections that were closed since the last execution group restart
MessagesReceived	The total number of messages received (by TCPIPClientInput or TCPIPClientReceive nodes)
MessagesSent	The total number of messages sent (by TCPIPClientOutput nodes)
BytesSent	The total amount of data sent (by TCPIPClientOutput nodes), excluding SSL wrappers.
BytesReceived	The total amount of data received (by TCPIPClientInput or TCPIPClientReceive nodes), excluding SSL wrappers.
FailedConnections	The total number of attempted connections that failed since the last execution group restarts.

Measurements	Description
OpenConnections	The current number of open connections
ClosedConnections	The total number of connections that were closed since the last execution group restart
MessagesReceived	The total number of messages received (by TCPIPServerInput or TCPIPServerReceive nodes)
MessagesSent	The total number of messages sent (by TCPIPServerOutput nodes)
BytesSent	The total amount of data sent (by TCPIPServerOutput nodes), excluding SSL wrappers.
BytesReceived	The total amount of data received (by TCPIPServerInput or TCPIPServerReceive nodes), excluding SSL wrappers.
FailedSSLConnections	The total number of attempted inbound SSL connections from external clients that failed or were refused since the last execution group restart.

Monitoring profile

To customize events after a message flow has been deployed, but without redeploying the flow, use a monitoring profile configurable service. By using this service, you can apply a monitoring profile to one or more message flows.

A monitoring profile is an XML document that specifies the event sources in a message flow that will emit events, and the properties of those events. The monitoring profile XML must conform to XML schema file `MonitoringProfile.xsd`.

Outline monitoring profile

Here is an outline monitoring profile that contains a single event source to illustrate the structure:

```
<p:monitoringProfile
xmlns:p="http://www.ibm.com/xmlns/prod/websphere/messagebroker/6.1.0.3/monitoring/profile" p:version="2.0">
    <p:eventSource p:enabled="true" p:eventSourceAddress="SOAPInput.transaction.Start">
        <p:eventPointDataQuery>
            <p:eventIdentity>
                <p:eventName p:literal="" p:queryText=""/>
            </p:eventIdentity>
            <p:eventCorrelation>
                <p:localTransactionId p:queryText="" p:sourceOfId="automatic"/>
                <p:parentTransactionId p:queryText="" p:sourceOfId="automatic"/>
                <p:globalTransactionId p:queryText="" p:sourceOfId="automatic"/>
            </p:eventCorrelation>
           <p:eventFilter p:queryText="true()"/>           <p:eventUOW p:unitOfWork="messageFlow" />        </p:eventPointDataQuery>
        <p:applicationDataQuery>
            <p:simpleContent p:dataType="boolean" p:name="" p:targetNamespace="">
                <p:valueQuery p:queryText=""/>
            </p:simpleContent>
            <p:complexContent p:name="" targetNamespace="">
                <p:payloadQuery p:queryText=""/>
            </p:complexContent>
        </p:applicationDataQuery>
        <p:bitstreamDataQuery p:bitstreamContent="all" p:encoding="base64Binary"/>
    </p:eventSource>
</p:monitoringProfile>
```

The root element is `p:monitoringProfile`. It contains one or more `p:eventSource` elements, each of which specifies an event source and defines its properties. Each `p:eventSource` element contains:

- A `p:eventPointDataQuery` element that provides key information about the event.
- Optional: A `p:applicationDataQuery` element if the event payload will include data fields extracted from a message.
- Optional: A `p:bitstreamDataQuery` element if the event payload will include bitstream data from a message.

Creating a monitoring profile

To help you create monitoring profiles, the following sample contains an outline monitoring profile XML file and the monitoring profile XML schema file (`MonitoringProfile.xsd`):

- WebSphere Business Monitor

Validate your monitoring profiles against the XML schema to ensure that they are correct.

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Tip: If you have a deployed message flow that has monitoring properties configured using the Message Flow editor, you can use the **mqsireportflowmonitoring** command to create the equivalent monitoring profile XML file for the message flow. You can use this profile as a starting point for creating other monitoring profiles.

The following steps describe how to create a monitoring profile XML. Follow these steps for each `p:eventSource` element.

1. Specify the `p:eventSource/@p:eventSourceAddress` attribute.

   This is a string that uniquely identifies the event source in the message flow. It must follow the fixed format for transaction events and terminal events, as shown in the following table:

Event type	Event source address
Transaction Start event	*nodelabel*.transaction.Start
Transaction End event	*nodelabel*.transaction.End
Transaction Rollback event	*nodelabel*.transaction.Rollback
Terminal event	*nodelabel*.terminal.<Terminal>

   Note: *nodelabel* is the label of the node as known by the broker runtime components. If the node is in a subflow the label reflects this. For example, flow A contains an instance of flow B as a subflow labeled `myB`; flow B contains an instance of a Compute node labeled `myCompute`. The *nodelabel* for the Compute node is `myB.myCompute`.

   In the emitted event, the address string of the event source is set in the `wmb:eventData/@wmb:eventSourceAddress` attribute.

2. Optional: Specify the name by which events from this event source will be known, in the `p:eventPointDataQuery/p:eventIdentity/p:eventName` element.
   - If the event name is a fixed string, complete the `p:eventName/@p:literal` attribute
   - If the event name is to be extracted from a field in the message, complete the `p:eventName/@p:queryText` attribute by specifying an XPath query.

   In the emitted event, the event name is set in the `wmb:eventPointData/wmb:eventIdentity/@wmb:eventName` attribute.

   If `p:eventName` element is not supplied, `@wmb:eventName` in the emitted event defaults to `@p:eventSourceAddress`.

3. Optional: Complete the `p:eventPointDataQuery/p:eventFilter/@p:queryText` attribute by specifying an XPath expression to control whether the event is emitted. The expression must evaluate to true (the event is emitted), or false (the event is not emitted). The expression can reference fields in the message tree, or elsewhere in the message assembly. If an event does not contain an eventFilter element, the event is always emitted.

   Using this facility, you can tailor event emissions to your business requirements, by filtering out events that do not match a set of rules. This can reduce the number of events emitted, and reduce the workload on your monitoring application.

4. Optional: Complete the p:applicationDataQuery element, if the event is to contain selected data fields extracted from the message. You can extract one or more fields from the message data and include it with the event. The fields can be simple or complex.
   - For each simple data field, complete a p:simpleContent element:
     - Complete the p:simpleContent/p:valueQuery/@p:queryText attribute by specifying an XPath query.
     - Complete the p:simpleContent/@p:name, @p:namespace and @p:dataType attributes. The @p:dataType value must be one of boolean, date, dateTime, decimal, duration, integer, string or time.
   - For each complex data field, complete a p:complexContent element:
     - Complete the p:complexContent/p:payloadQuery/@p:queryText attribute by specifying an XPath query.
     - Complete the p:complexContent/@p:name and @p:namespace attributes.

   This facility is commonly used for communicating significant business data in a business event. If the event contains the input bit stream, this facility can also be used to extract key fields, allowing another application to provide an audit trail or to resubmit failed messages.

   In the emitted event, the extracted data is set in the wmb:applicationData/wmb:simpleContent and wmb:applicationData/wmb:complexContent elements.
5. Optional: Complete the p:bitstreamDataQuery element, if the event is to capture message bitstream data:
   - Complete the @p:bitstreamContent attribute. The attribute value must be one of headers, body, or all.
   - Complete the @p:encoding attribute. The attribute value must be one of CDATA, base64Binary or hexBinary.

   In the emitted event, the extracted bitstream data is set in the wmb:bitstreamData/wmb:bitstream element.
6. Optional: Complete the p:eventPointDataQuery/p:eventCorrelation element. For information about correlation, see "Correlation and monitoring events" on page 6778.

   Every emitted monitoring event can contain up to three correlation attributes. If no correlation information is specified in the monitoring profile, no correlation attributes will be used.

   a. Optional: Complete the p:localTransactionId element.
      - If you want to reuse the local correlator from the Environment tree, set the p:localTransactionId/@p:sourceOfId attribute to automatic. If no local correlator exists yet, a new unique value will be generated and saved in the Environment tree.
      - If you want to use a value contained in a location in the message, set the p:localTransactionId/@p:sourceOfId attribute to query, then complete the p:localTransactionId/@p:queryText attribute by specifying an XPath query. Ensure that the specified location contains a correlator value unique to this invocation of the message flow. The value is saved in the Environment tree.

   b. Optional: Complete the p:parentTransactionId element.
      - If you want to reuse the parent correlator from the Environment tree, set the p:parentTransactionId/@p:sourceOfId attribute to automatic. If no parent correlator exists yet, no parent correlator will be used.
      - If you want to use a value contained in a location in the message, set the p:parentTransactionId/@p:sourceOfId attribute to query, then complete

the p:parentTransactionId/@p:queryText attribute by specifying an XPath query. Ensure that the specified location contains a suitable value for the parent correlator. The value is saved in the Environment tree.

c. Optional: Complete the p:globalTransactionId element.
   - If you want to reuse the global correlator from the Environment tree, set the p:globalTransactionId/@p:sourceOfId attribute to automatic. If no global correlator exists yet, no global correlator will be used.
   - If you want to use a value contained in a location in the message, set the p:globalTransactionId/@p:sourceOfId attribute to query, then complete the p:globalTransactionId/@p:queryText attribute by specifying an XPath query. Ensure that the specified location contains a suitable value for the global correlator. The value is saved in the Environment tree.

7. Complete the p:eventPointDataQuery/p:eventUOW element. This determines whether the emission of monitoring events by a message flow is coordinated with the message flow transaction, or is in an independent unit of work, or is not in a unit of work.

   Set the p:eventUOW/@p:unitOfWork attribute to one of the following values:

   messageFlow
   The event, and all other events with this setting, are emitted only if the message flow commits its unit of work successfully.

   If the transaction start event is specified to be included in the message flow unit of work, but the message processing fails and this unit of work is not published, the transaction start event will be included in an independent unit of work. This ensures that your monitoring application receives a pair of events (start and rollback), rather than receiving a rollback event in isolation.

   independent
   The event is emitted in a second unit of work, independent of the main unit of work. The event, and all other events with this setting are emitted whether or not the main unit of work commits successfully.

   An independent transaction can be started only if the main transaction has been either committed or rolled back. If the **Commit count** property of the flow is greater than one, ("Configurable message flow properties" on page 4020), or the **Commit by message group** property is set ("Receiving messages in a WebSphere MQ message group" on page 1554), the events targeted for the independent transaction are instead emitted out of sync point, and a message is output stating that this has been done.

   none The event is emitted out of sync point (not in any unit of work.) The event is emitted when the message passes through the event source, and is available for reading immediately.

   Not all these options are available on all event types. The allowed values are shown in the following table:

Event Type	Allowed values
transaction.Start	messageFlow independent none
transaction.End	messageFlow none

Event Type	Allowed values
transaction.Rollback	independent none
terminal	messageFlow independent none

If you do not include the `eventUOW` element for an event source, transactionality for all events issued from that source, except transaction.rollback events, defaults to `messageFlow`. Transactionality for transaction.rollback events defaults to `independent`.

XPath queries and XML namespaces

If an XPath query contains a component that has an XML namespace, the XPath contains a namespace prefix for the namespace. For example, the following XPath refers to components in two different namespaces:

```
<p:localTransactionId p:sourceOfId="query" p:queryText="$Body/soapenv:Header/wsa:messageID" />
```

For the broker to resolve the namespace prefix, the namespace URL must also be provided. Supply a prefix mapping element for each namespace:

```
<p:localTransactionId p:sourceOfId="query" p:queryText="$Body/soapenv:Header/wsa:messageID">
  <p:prefixMapping p:prefix="soapenv" p:URI="http://www.w3.org/2003/05/soap-envelope" />
  <p:prefixMapping p:prefix="wsa" p:URI="http://www.w3.org/2005/08/addressing" />
</p:localTransactionId>
```

Monitoring profile examples

The following XML documents conform to the monitoring profile schema

Monitoring profile 1: Two event sources, each supplying an event name

```
<p:monitoringProfile
xmlns:p="http://www.ibm.com/xmlns/prod/websphere/messagebroker/6.1.0.3/monitoring/profile" p:version="2.0">
 <p:eventSource p:eventSourceAddress="SOAPInput.transaction.Start">
  <p:eventPointDataQuery>
    <p:eventIdentity>
      <p:eventName p:literal="SOAP start event"/>
    </p:eventIdentity>
  </p:eventPointDataQuery>
 </p:eventSource>
 <p:eventSource p:eventSourceAddress="SOAPInput.transaction.End">
  <p:eventPointDataQuery>
    <p:eventIdentity>
      <p:eventName p:literal="SOAP end event"/>
    </p:eventIdentity>
  </p:eventPointDataQuery>
 </p:eventSource>
</p:monitoringProfile>
```

Monitoring profile 2: Supply an alternative local correlator

```
<p:monitoringProfile
xmlns:p="http://www.ibm.com/xmlns/prod/websphere/messagebroker/6.1.0.3/monitoring/profile" p:version="2.0">
 <p:eventSource p:eventSourceAddress="SOAPInput.transaction.Start">
  <p:eventPointDataQuery>
    <p:eventCorrelation>
      <p:localTransactionId p:queryText="$Body/soapenv:Header/wsa:messageID" p:sourceOfId="query">
        <p:prefixMapping p:prefix="soapenv" p:URI="http://www.w3.org/2003/05/soap-envelope"/>
        <p:prefixMapping p:prefix="wsa" p:URI="http://www.w3.org/2005/08/addressing"/>
      </p:localTransactionId>
    </p:eventCorrelation>
  </p:eventPointDataQuery>
 </p:eventSource>
</p:monitoringProfile>
```

Monitoring profile 3: Include two simple fields from the message

```
<p:monitoringProfile
xmlns:p="http://www.ibm.com/xmlns/prod/websphere/messagebroker/6.1.0.3/monitoring/profile" p:version="2.0">
 <p:eventSource p:eventSourceAddress="MQInput.terminal.out">
  <p:applicationDataQuery>
    <p:simpleContent p:dataType="integer" p:name="InvoiceNumber">
      <p:valueQuery p:queryText="$Body/invoice/invoiceNo"/>
    </p:simpleContent>
    <p:simpleContent p:dataType="string" p:name="BatchID">
      <p:valueQuery p:queryText="$Body/batch/batchNo"/>
    </p:simpleContent>
  </p:applicationDataQuery>
 </p:eventSource>
</p:monitoringProfile>
```

Monitoring profile 4: Include the bitstream, encoded as CDATA

By default, bitstreams are encoded in base64Binary format. The following monitoring profile changes the encoding to CDATA.

```
<p:monitoringProfile
xmlns:p="http://www.ibm.com/xmlns/prod/websphere/messagebroker/6.1.0.3/monitoring/profile" p:version="2.0">
 <p:eventSource p:eventSourceAddress="MQInput.terminal.out">
    <p:bitstreamDataQuery p:bitstreamContent="body" p:encoding="CDATA"/>
 </p:eventSource>
</p:monitoringProfile>
```

CDATA encoding is not suitable for all types of data. Use CDATA only when `@p:bitstreamContent="body"`. Do not use CDATA if your message bitstreams might contain characters that are not allowed in XML (see http://www.w3.org/TR/2006/REC-xml-20060816/#charsets).

You can configure your message flow to emit event messages that can be used to support transaction monitoring and auditing, and business process monitoring.

"Configuring monitoring event sources using monitoring properties" on page 3327
In the Message flow Editor, use the Monitoring tab on the properties of a node to add one or more monitoring events.

"Configuring monitoring event sources using a monitoring profile" on page 762
You can create a monitoring profile and use the **mqsichangeflowmonitoring** command to configure your message flows to emit monitoring events.

"Activating monitoring" on page 3334
Use the **mqsichangeflowmonitoring** command to activate monitoring after you have configured monitoring event sources.

"Enabling and disabling event sources" on page 3336
When events have been configured for a message flow and deployed to the broker, you can enable and disable individual events. You can do this from the command line, without having to redeploy the message flow, or you can do this from the Message Flow Editor, in which case you must redeploy.

"Reporting monitoring settings" on page 3343
Use the **mqsireportflowmonitoring** command to report monitoring settings for a flow.

Related reference:

"The monitoring event"
You can configure WebSphere Message Broker to emit a monitoring event (an XML document) when something interesting happens. Events are typically emitted to support transaction monitoring, transaction auditing, and business process monitoring. The event XML conforms to the monitoring event schema `WMBEvent.xsd`.

Related information:

"Correlation and monitoring events" on page 6778
A monitoring application uses correlation attributes to identify events that belong to the same business transaction.

The monitoring event

You can configure WebSphere Message Broker to emit a monitoring event (an XML document) when something interesting happens. Events are typically emitted to support transaction monitoring, transaction auditing, and business process monitoring. The event XML conforms to the monitoring event schema `WMBEvent.xsd`.

You can find the `WMBEvent.xsd` schema file in the WBMonitorEventsProject folder of the WebSphere Business Monitor sample when you import it to your workspace. The `WMBEvent.xsd` file is also available in the default message catalog. To access the schema from the WebSphere Message Broker Toolkit, click **File** > **New** > **Message Definition File From** > **IBM supplied message** > **Message Broker Monitoring Event**.

Each event contains the following information:

- Source of the event
- Name of the event
- Creation time and sequence number
- Correlation ID for events emitted by the same transaction or unit of work
- Details of the message flow

Tip: A terminal emits an event only if the message passes through that terminal. In particular, the output terminal of an output node emits events only if it is connected.

A monitoring event can also contain the following items:

- Application data extracted from the message.
- Part or all of the message bit stream.

  The bit stream cannot be included in monitoring events if one of the following nodes created the message:
  - FileInput, if the message domain is MRM or XMLNSC
  - TCPIPClientInput, if the message domain is MRM or XMLNSC
  - TCPIPServerInput, if the message domain is MRM or XMLNSC
  - SOAPInput, SOAPAsyncResponse
  - Any of the following Adapter input nodes:
    - PeopleSoftInput
    - SiebelInput
    - JDEdwardsInput
    - TwineballInput

Note: The bit stream can be included if a SAPInput node created the message.

The bit stream cannot be included in monitoring events if the message is a response from one of the following nodes:

– SOAPRequest

– Any of the Adapter request nodes:

  - SAPRequest
  - PeopleSoftRequest
  - SiebelRequest
  - JDEdwardsRequest
  - TwineballRequest

A warning is logged to user trace if an event source is configured to include the bit stream, but it cannot be included. You might be able to extract some or all of the data in the message as Event Payload; be aware that large event messages might affect performance.

Use either the monitoring properties of a message flow or a monitoring profile configurable service to configure the following items:

- Where an event is emitted from
- The content of the event

Sequence number

To enable software that processes events, such as WebSphere Business Monitor, to sequence them correctly, both an ISO 8601 time stamp and a counter attribute are produced. The counter attribute is in the EventSequence element of the monitoring event. This counter starts at 1 for the first event produced by the processing of a message (normally the transaction.Start event) and is incremented for each subsequent event produced. It is reset to 1 at the start of the next message. The creation time and counter are always produced on all monitoring events. The software processing the events can choose which field, or a combination of the two, to use to sequence the events.

If a message is processed successfully, the monitoring events generated have a contiguous, incrementing set of counter values, starting at 1 and assigned at the time when the event is created. If a message fails and is rolled back, there might be gaps in the counter sequence. The missing values are those used for events that were produced as part of the message flow unit of work that was rolled back.

Monitoring events can be included in the main unit of work of a message flow, an independent unit of work, or outside of a unit of work. Consequently, if a message flow fails the sequence numbers are not guaranteed to be contiguous. For example consider the following scenario:

- Sequence 1: the transaction start event.
- Sequence 2, 3, 4: events in the message flow unit of work.
- Sequence 5: the independent unit of work.
- Sequence 6: an event outside of a unit of work.
- Sequence 7: an event in the message flow unit of work.
- Sequence 8: an event outside of a unit of work.
- The flow then fails and is rolled back.
- Sequence 9: the transaction rollback event in the independent unit of work.

Only sequence numbers 1, 5, 6, 8 and 9 are sent to the monitoring application.

Example event

```
<?xml version="1.0" encoding="UTF-8"?>
<wmb:event xmlns:wmb=http://www.ibm.com/xmlns/prod/websphere/messagebroker/6.1.0/monitoring/event>
   <wmb:eventPointData>
     <wmb:eventData wmb:eventSourceAddress="MQInput1.terminal.in"
                    wmb:eventSchemaVersion="6.1.0.3" wmb:productVersion="7000">
       <wmb:eventIdentity wmb:eventName="MQInput event"/>
       <wmb:eventSequence wmb:creationTime="2001-12-31T12:00:00+01:00" wmb:counter='2'/>
       <wmb:eventCorrelation wmb:localTransactionId="123"
                             wmb:parentTransactionId="456"
                             wmb:globalTransactionId="789"/>
     </wmb:eventData>
     <wmb:messageFlowData>
       <wmb:broker wmb:UUID="d53122ae-1c01-0000-0080-b1b02528c6bf"
                   wmb:name="myBroker"/>
       <wmb:executionGroup wmb:UUID="d43122ae-1c01-0000-0080-b1b02528c6bf"
                           wmb:name="default"/>
       <wmb:messageFlow wmb:UUID="e6d224ae-1c01-0000-0080-9100cd1a61f7"

   </wmb:bitstreamData>
</wmb:event>
```

Default content of monitoring events

When an event is emitted, the fields in the event are created using the information provided by the monitoring properties of the message flow, or a monitoring profile configurable service if one has been applied to the message flow. Any event field that is not explicitly specified is given a default value as shown in the table.

Field in event	Default Value
eventData/@wmb:eventSourceAddress	No default; you must provide this information.
eventData/@wmb:eventSchemaVersion	6.1.0.3
eventData/@wmb:productVersion	7000
eventData/eventIdentity/ @wmb:eventName	The default is derived from @eventSourceAddress
eventData/eventSequence/@counter	The counter is set to 1 for first event emitted and increased by 1 for each subsequent event.
eventData/eventSequence/@creationTime	The date and time when the event was created.

Field in event	Default Value
eventData/eventCorrelation/ @localTransactionId	A generated unique identifier.
eventData/eventCorrelation/ @parentTransactionId	No default. Unless you set this value, an empty string is used.
eventData/eventCorrelation/ @globalTransactionId	No default. Unless you set this value, an empty string is used.
messageFlowData/broker/@name	The name of the broker.
messageFlowData/broker/@UUID	The UUID of the broker.
messageFlowData/executionGroup/ @name	The name of the execution group.
messageFlowData/executionGroup/ @UUID	The UUID of the execution group.
messageFlowData/messageFlow/@name	The name of the message flow.
messageFlowData/messageFlow/@UUID	The UUID of the message flow.
messageFlowData/messageFlow/ @uniqueFlowName	A string composed of the names of the broker, execution group, and flow in the form: *brokerName.executionGroupName.flowName*
messageFlowData/messageFlow/ @threadId	The thread ID of the message flow. The format depends on the platform.
messageFlowData/node/@nodeLabel	The label of the node that emitted the event.
messageFlowData/node/@nodeType	The type of the node that emitted the event.
messageFlowData/node/@nodeDetail	Optional information about the node. **MQInput** The name of the queue. **Other nodes** Omitted.
applicationData	No default; omitted if not provided.
bitstreamData	No default; omitted if not provided.

XPath queries that end in a wildcard

If an XPath query ends in a wildcard, each element node or attribute node appears in a separate complexContent or simpleContent folder in the emitted event.

Related concepts:

"Monitoring profile" on page 6768
To customize events after a message flow has been deployed, but without redeploying the flow, use a monitoring profile configurable service. By using this service, you can apply a monitoring profile to one or more message flows.

Correlation and monitoring events

A monitoring application uses correlation attributes to identify events that belong to the same business transaction.

A business transaction can be any of the following scenarios:

- A single invocation of a message flow.
- Multiple invocations of the same message flow from a parent application. The parent application might be another message flow.
- Multiple invocations of various message flows from a parent application. The parent application might be another message flow.

Three correlation attributes are available for you to use in your events: *local correlator*, *parent correlator* and *global correlator*. The exact usage of the correlation attributes varies depending on the requirements. For example, a parent application can pass its transaction identifier to the child message flow (perhaps in a header) so that the child message flow can report it in the event as a parent correlator.

Every emitted monitoring event can contain a local correlator, a parent correlator, and a global correlator. Correlation information is placed in the following attributes of the event:

```
wmb:eventPointData/wmb:eventCorrelation/@wmb:localTransactionId
wmb:eventPointData/wmb:eventCorrelation/@wmb:parentTransactionId
wmb:eventPointData/wmb:eventCorrelation/@wmb:globalTransactionId
```

You can specify correlation information when you configure the event.

If you do not specify any correlation information when you configure your events, no correlation attributes will be used.

If you do specify correlation information, you must configure the correlation attributes to be used, and where they will read their value from. Typically you

need to specify correlation information only for the first event source in the message flow; by default all later event sources retrieve the same value from the Environment tree.

The exact steps for specifying correlation information depend on whether you are using monitoring properties or a monitoring profile to configure your events, but the principle is the same for both techniques:

Local correlator

If you want to reuse the local correlator from the Environment tree, specify `Automatic`. If no local correlator exists yet, a new unique value will be generated and saved in the Environment tree.

If you want to use a value contained in a location in the message, specify the location of the correlator by supplying an XPath into the message tree. Ensure that the specified location contains a correlator value unique to this invocation of the message flow. The extracted value is saved in the Environment tree as the local correlator.

Parent correlator

If you want to reuse the parent correlator from the Environment tree, specify `Automatic`. If no parent correlator exists yet, no parent correlator will be used.

If you want to use a value contained in a location in the message, specify the location of the correlator by supplying an XPath into the message tree. Ensure that the specified location contains a suitable value for the parent correlator. The extracted value is saved in the Environment tree as the parent correlator.

Global correlator

If you want to reuse the global correlator from the Environment tree, specify `Automatic`. If no global correlator exists yet, no global correlator will be used.

If you want to use a value contained in a location in the message, specify the location of the correlator by supplying an XPath into the message tree. Ensure that the specified location contains a suitable value for the global correlator. The extracted value is saved in the Environment tree as the global correlator.

When a correlator value has been set, it is saved in the Environment tree. Later event sources can reuse the saved value by specifying `Automatic`. There is no need to use the same XPath in all the event sources in your message flow, and doing so might adversely affect performance.

The locations in the Environment tree used to save correlator values for use by later events are:

```
Environment.Monitoring.EventCorrelation.localTransactionId
Environment.Monitoring.EventCorrelation.parentTransactionId
Environment.Monitoring.EventCorrelation.globalTransactionId
```

The following message tree locations often contain a value that can be used as a correlator:

```
$Root/MQMD/MsgId
$Root/MQMD/CorrelId
$Root/JMSTransport/Transport_Folders/Header_Values/JMSMessageID
$Root/JMSTransport/Transport_Folders/Header_Values/JMSCorrelationID
$LocalEnvironment/Destination/HTTP/RequestIdentifier
$LocalEnvironment/Wildcard/WildcardMatch
```

Tip: If the three available correlators are not sufficient, you can configure the event to extract other correlation fields from the message and place them in the `wmb:applicationData/wmb:simpleContent` section of the event.

Tip: The Collector node and the AggregateControl node do not preserve the Environment tree for later nodes in the message flow. If you want to use the same correlator value later in the flow, ensure that the correlator value is available in the message tree, and that the first event source after the Collector or AggregateControl node specifies the location of the correlator by supplying an XPath into the message tree.

Scenarios

Scenario 1: In this scenario, all three correlators are used to monitor data that starts in an external process. Several message flows then transform the data.

- The `globalTransactionID` field contains an identifier from the message header or payload. This identifier correlates events from the external process and WebSphere Message Broker.
- The `parentTransactionID` correlates events in WebSphere Message Broker from different message flows.
- The `localTransactionID` correlates events from the same message flow.

Scenario 2: In this scenario, the `parentTransactionID` field is used to correlate request and reply messages between two message flows:

- The Request flow sends a **`purchaseOrder`** request to an external application for processing.
- The Reply flow receives a confirmation reply from the external application when the **`purchaseOrder`** has been processed.

You need to correlate the request and replies belonging to the same purchase order. You can do this by setting the `parentTransactionID` to a field in the **`purchaseOrder`**, such as a **`purchaseOrderID`**, which is available in both the request and reply.

Use the **mqsichangeflowmonitoring** command to enable monitoring of message flows.

Example XPath expressions for event filtering

Use numeric, string, or Boolean expressions when configuring an event source, to determine whether the event is emitted.

When you configure an event source, using either monitoring properties or a monitoring profile, you use an XPath expression to determine whether the event is emitted.

- If the event is always required, use `true()`.
- If the event is required only in certain circumstances, use an expression of the form

  xpath-query relational-operator value

Comparing numeric values

To emit an event only when the value is greater than 10 000, for example, enter an expression such as this:

```
$Body/StockTrade[1]/Details[1]/Value[1] > 10000
```

The [1] suffixes in the query specify that the first occurrence of the element within its parent is required. If these suffixes are not specified, the XPath engine searches the message for other occurrences of each element. This search might adversely affect performance.

Comparing string values

To emit an event only when the company is "Stock Co" for example:

```
$Body/StockTrade[1]/Details[1]/Company[1] = 'Stock Co'
```

Comparing Boolean values

Consider the example of a shares transfer approval. The approval flag in the message tree is a Boolean value. You cannot simply specify the element name, because this always returns true if the element exists. Instead, you query the value of the element, and compare the value to the string 'true' to yield the actual true or false result. The XPath query is:

```
$Body/StockTrade[1]/Shares[1]/Transfer[1]/Approved[1] = 'true'
```

XPath queries that return a nodeset, such as `$Body/StockTrade[1]/Details[1]`, are always evaluated as false, because they cannot be converted to a Boolean value.

You can create a monitoring profile and use the **mqsichangeflowmonitoring** command to configure your message flows to emit monitoring events.

XPath expressions that are not suitable for the export monitoring information option

Some XPath expressions produce a warning on the Monitoring tab.

The following expressions are not suitable for the export monitoring information option used to create a monitor model in WebSphere Business Monitor Version 7, and produce a warning. If you export monitoring information for any of the following listed expressions, an event part is not generated for that XPath expression, and a warning message is written to the *flowProjectName*_batchgen.report.txt file.

$Body

WebSphere Message Broker Toolkit

The WebSphere Message Broker Toolkit provides your application development environment on Windows and Linux on x86.

Within the WebSphere Message Broker Toolkit, you can access resources through several perspectives, and create and modify them using the supplied editors:

- Perspectives
- Editors
- Resource types

For information about how to use the keyboard in the WebSphere Message Broker Toolkit, see "WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit keyboard shortcuts" on page 6828.

When you create resources in the WebSphere Message Broker Toolkit, or import resources into the WebSphere Message Broker Toolkit, be aware of the file system limit of 256 characters that is imposed by the Windows file system. This limit can cause restrictions in path specifications to resources (for example, message flow projects), and might cause access problems if the combination of path and resource name exceeds this limit. Keep installation locations and resource names short to avoid problems associated with this restriction.

Resource editors do not automatically reflect the changes that you make in one window in additional windows that you have opened to view the same resource. Close and reopen additional windows each time you update a resource in an editor session.

A minimum display resolution of at least 1024 x 768 is required for some dialogs; for example, the Preferences dialog.

You can configure various settings in the workbench to suit your requirements and your working environment.

Perspectives in the WebSphere Message Broker Toolkit

The following links provide a description of each of the perspectives in the WebSphere Message Broker Toolkit:

- "Broker Application Development perspective" on page 6784
- "Debug perspective" on page 6789
- "Plug-in Development perspective" on page 6792

Related concepts:

"WebSphere Message Broker Toolkit perspectives" on page 34
A perspective is a group of views and editors that shows various aspects of the resources in the WebSphere Message Broker Toolkit.

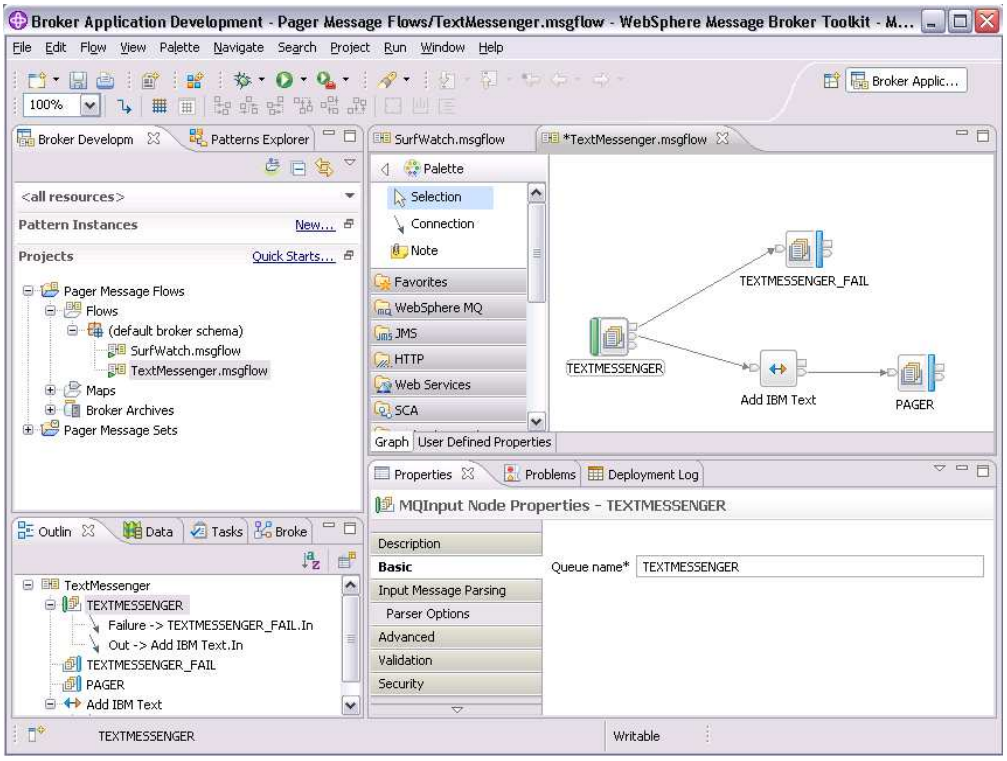
Broker Application Development perspective

The Broker Application Development perspective is the default perspective that is displayed when you start the WebSphere Message Broker Toolkit.

Typically, you complete the following tasks in this perspective:

- Developing message flows and message sets.
- Enqueuing and dequeuing test and production messages, which is useful when you are debugging message flows.
- Creating user-defined nodes and user-defined node projects.

The following figure shows the Broker Application Development perspective of the WebSphere Message Broker Toolkit. The `TextMessenger.msgflow` file in the Broker Development view is open in the Message Flow editor.



The Broker Application Development perspective provides several views to navigate, browse, and update your resources.

Broker Development view:
Use the Broker Development view to navigate and browse your resources, and to select resources for editing. You can also use this view to access the Quick Start wizards, which help you create the basic resources that are required for a broker application.

The Broker Development view contains the following sections:

- <all resources> (a working set selection list)
- Pattern Instances
- Projects

When the Broker Development view contains projects in the Projects section, to display the list of Quick Starts, click **Quick Starts**.

When the Broker Development view does not contain projects in the Projects section, the Quick Starts list is displayed in the Projects section.

The following Quick Starts links are shown:

Quick Starts

Start building your message flow application with one of the following tasks.

Start from scratch

Start from WSDL and/or XSD files

Start from existing message set

Start from adapter connection

Start from SCA Import or Export

Start from patterns

Start from samples

The Projects section of the Broker Development view displays a hierarchical view of the following message flow and message set resource files:

- Pattern instance projects
- User-defined nodes
- Message flow projects
- Message flows
- ESQL files
- Mappings files
- Flow test files
- Broker archive files
- Message set projects
- Message sets
- Message definition files
- Java projects
- Data Design projects

When you create resources, they are grouped by file type in logical categories within the hierarchy, and placed in virtual folders. These virtual folders are described in "Resources" on page 36.

Other folders and files that are created for the message flow project or message set project are placed directly under the project folders.

You can hide the categories (virtual folders) by clicking **Hide Categories**  on the Broker Development view toolbar. You can use the **Hide Categories** menu item or button to toggle between category mode and non-category mode.

You can also toggle between showing and hiding broker schema (in a message flow project) and namespaces (in a message set project), by selecting **Hide Namespaces** from the view menu (shown by a down arrow) in the Broker Development view toolbar. By default, broker schema and namespaces are shown. This option is available only in category mode.

You can toggle between showing and hiding file extensions for files that are under virtual folders, broker schema (or namespaces) and `messageSet.mset`. To toggle between hiding and showing the file extensions, select **Hide Categorized File Extensions** from view menu (shown by the down arrow) in the Broker Development view toolbar. By default, file extensions are shown. Other files and folders that are directly under the project are not affected by this option.

By default, the hierarchy view contains the resource files for all of your projects. However, you can limit the number of resources that are displayed in the Broker Development view by organizing and displaying them in *working sets*. A working set is a logical collection of projects, which makes it easier to manage and work with your application projects. When you create a pattern instance project by using the Patterns Explorer view, the pattern instance project is placed into a working set of the same name. For more information about working sets, see "Working sets" on page 42.

You use specialized editors to open and edit all the resources in the Broker Development view, except project files.

Editor view:
Double-click a resource in the Broker Development view to open the associated editor in the Editor view.

The WebSphere Message Broker Toolkit shows the Message Flow editor by default for working with the content of message flow files.

The WebSphere Message Broker Toolkit provides the following specialized editors by default for working with the content of message flow and message set files:

ESQL editor
For viewing and updating the ESQL statements that are associated with Compute, Database, and Filter nodes.

Message Category editor
For creating, viewing, and updating message categories that you define within the MRM domain.

Message Definition editor
For creating, viewing, and updating messages that you define within the MRM domain.

Message Flow editor
For creating, viewing, and updating message flows, and the nodes and user-defined nodes that define them.

Message Mapping editor
For defining transformations between data sources and targets, without the requirement for programming in XPath, XSLT, XQuery, Java, or ESQL.

Message Set editor
For creating, viewing, and updating message sets that you define within the MRM domain.

Outline view:
The Outline view provides a summary of the content of the resource that is currently open in the Editor view.

Click the **Overview Mode** icon  to switch to the Overview view, which provides a useful summary for large, complex message flows because it shows a small-scale version of the flow. Click the **Overview Mode** icon again to return to the Outline view.

Brokers view:
Use the Brokers view to create and work with brokers in the WebSphere Message Broker Toolkit. Brokers that are created on the local system are automatically displayed in the Brokers view. Remote brokers can be added to the Brokers view. When you open or switch to the Brokers view, the WebSphere Message Broker Toolkit attempts to connect to brokers on the local system and to any remote brokers that have been defined; see “Brokers view” on page 6796.

Properties view:
The Properties view displays the properties for the node that is selected in the Editor view. The Properties are grouped and displayed on tabs, which are listed on the left of the Properties view.

Problems view:
The Problems view displays any messages (information and error) that are associated with the resource that is currently open in the Editor view. For example, if you save a message flow that has an error (such as a mandatory property not set), you can check the content of the Problems view to determine any corrections that you must make. When you double-click a Problems view entry, the appropriate editor opens the resource that contains an error, and positions the cursor at the point of the error (where possible).

Deployment Log view:
The Deployment Log view shows the result of deploying brokers that are in the WebSphere Message Broker Toolkit; see “Deployment Log view” on page 6797.

Data Project Explorer view:
The Data Project Explorer view displays Data design and Data development projects. You can use the Data Project explorer to work with these projects and other data objects.

Data Source Explorer view:
The Data Source Explorer view displays database connections. You can use the Data Source Explorer view to create database connections.

Patterns Explorer view:
The Patterns Explorer view displays patterns that you can use in the WebSphere Message Broker Toolkit. You can use the Patterns Explorer view to configure and apply patterns for use in your environment. Select a pattern in the Patterns Explorer view to see more information about the pattern; see “Choosing a pattern” on page 1313.

Tasks view:
The Tasks view displays outstanding tasks to be completed. You can create tasks within the Tasks view by selecting **Add Task**. For example, if you would like to record reminders to follow up on something later, add it to the Tasks view. When you add a task, you have the option of associating it with a resource so that you can use the Tasks view to quickly open that resource for editing.

Broker Application Development perspective toolbar:

You can add icons to the toolbar for the actions that you might want to complete in the perspective. To add icons to the toolbar, complete the following steps.

1. Click **Window** > **Customize Perspective**. The Customize Perspective dialog box is displayed.
2. Click the **Command Groups Availability** tab. This tab displays the available command groups and their corresponding menu bar details and toolbar details.
3. Click a command group name to display its toolbar details. The available command groups and toolbar details for the icons that you might want to use in the perspective are shown in the **Available command groups** table.
4. Select the command groups that you want to add, and click **OK**. The toolbar displays the icons from the selected command groups.

Available command groups	Toolbar details: icon	Toolbar details: label and action
ESQL Actions		Generate a New Message Flow ESQL File
Mapping Actions		Create a Message Map File
Message Creation		Create a New Message Set
		Create a New Message Definition File
		Create a New Message Category File
Message Flow Element Creation		Create a New Message Flow Project
		Create a New Broker Schema
		Create a New Message Flow
Message Set		Generate a Web Service Definition File
		Generate HTML Documentation for a Message Set
		Generate an XML Schema from a Message Definition File

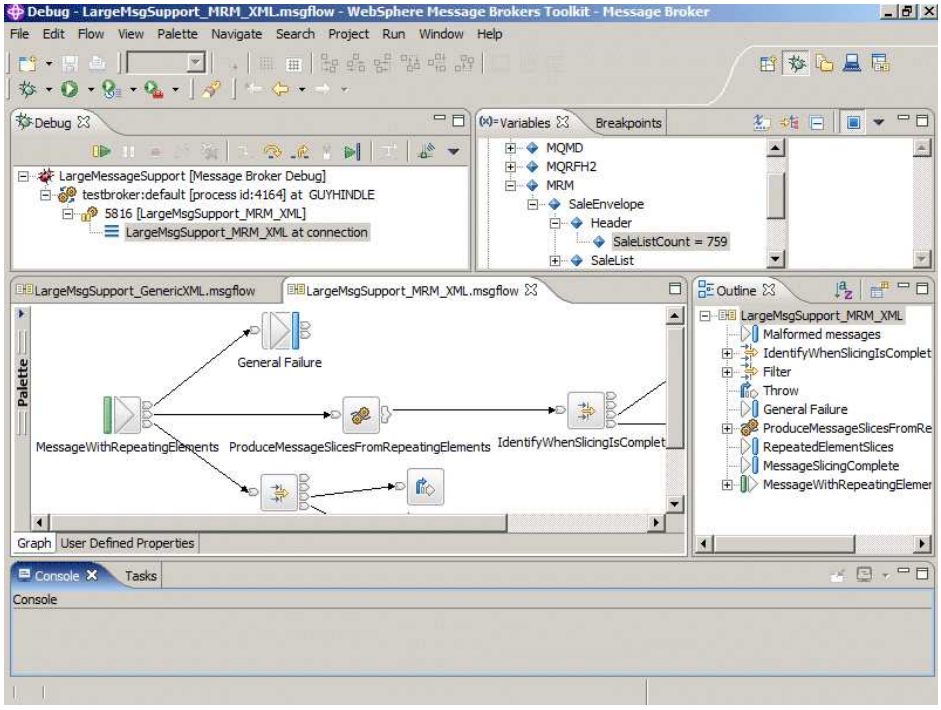
"Editors in the WebSphere Message Broker Toolkit" on page 6793

"Plug-in Development perspective" on page 6792
You can use the Plug-in Development perspective to create user-defined node projects and user-defined nodes in the WebSphere Message Broker Toolkit, however, the preferred option is to use the Broker Application Development perspective.

Debug perspective

The Debug perspective is where you test and debug a graphical representation of your message flows using the message flow debugger.

The following figure shows the Debug perspective of the WebSphere Message Broker Toolkit. In the figure, the LargeMsgSupport_MRM_XML message flow is being debugged.



Debug perspective views: The Debug perspective contains the following views:

Debug view

Displays the deployed message flow types for a selected host to help you manage flow debugging. Toolbar buttons are provided for controlling the execution of the flow. You can start, stop, and resume a flow, step into, and out of a subflow, and step into the source code.

When you attach the flow debugger to the flow runtime engine, the Debug view displays the names of the following flow-related entities:

- The host computer and the flow runtime engine that it is running. This is shown as a concatenation of the names of the following entities, delimited by colons.
  - The host computer
  - The broker
  - The execution group
  - The flow engine

  The entry is identified by the flow runtime engine symbol. For example:

  -  `TestPC01:WMQIV5BR:TestExecution:DataFlowEngine`
- The flows that are deployed in the flow runtime engine, identified by the flow symbol, for example:

  -  `TestFlow`
- When a breakpoint is reached, the flow instances that have been created for each flow, identified by the following symbol, for example:

  -  `3068` (Paused)

In the Debug view, you can perform the following debugging tasks:
- Query a flow runtime engine for currently deployed flows
- Detach a flow runtime engine from the flow debugger
- Resume flow execution

- Run to termination
- Step over a node
- Step into or out of a subflow
- Step over, into, or out of, source code

Breakpoints view

Lists the breakpoints that have been set on connections in your message flow. In this view you can add, disable, enable or remove breakpoints. You can also restrict a breakpoint to one or more specific instances of a message flow using the Properties view.

The Breakpoints view and the Variables view share the same pane. Click one of the tabs to select the view that you want.

The Breakpoints view displays the breakpoints that are set in all instances of a selected flow. Each breakpoint is identified by one of two symbols (as also used in the Message Flow editor) as follows:

-  breakpoint enabled
-  breakpoint disabled

In the Breakpoints view, you can perform the following debugging tasks:

- Remove breakpoints
- Disable or enable breakpoints
- Restrict breakpoints to one or more instances of a flow

Variables view

When a message flow is interrupted by a breakpoint, you can view the message content to check whether the message flow is executing as expected, and to make any changes required.

The Variables view and the Breakpoints view share the same pane. Click one of the tabs to select the view that you want.

The Variables view displays the messages that are currently traveling through the flow. Use the view to examine or change the content of a message in a flow during debugging.

Message Flow editor view

The Message Flow editor graphically displays and debugs flows. In this view you can add breakpoints to the connections of a message flow.

The Message Flow editor also displays any breakpoints that are set in the flow. Each breakpoint is identified by a symbol as follows:

-  breakpoint enabled.
-  breakpoint disabled.
-  flow paused at breakpoint.

Also the editor displays the following symbol above a node:

-  flow paused at a node containing ESQL code or Java code that the flow debugger can step into

In the Broker Application Development perspective, the Message Flow editor is used to create, graphically display, and edit flows. For details of

the other uses of this editor, see the description in "Message Flow editor" on page 6810 and the tasks in "Defining message flow content" on page 1488.

Related concepts:

The Broker Application Development perspective is the default perspective that is displayed when you start the WebSphere Message Broker Toolkit.

Editors in the WebSphere Message Broker Toolkit

More information about each of the editors provided by WebSphere Message Broker Toolkit can be found in the following topics:

Related concepts:

"Editors" on page 35
An editor is a component of the WebSphere Message Broker Toolkit. Editors are typically used to edit or browse resources, which are the files, folders, and projects that exist in the workbench.

Related tasks:

"Changing ESQL editor settings" on page 2409
When you open an ESQL file in the editor view, you can tailor the editor appearance by changing editor settings.

Related reference:

"Editor preferences and localized settings"
If you want to share the files that are associated with message flow and message set development, you must ensure that the files and the content of these files are compatible and can be shared by users working on different systems and in different locales.

Editor preferences and localized settings

If you want to share the files that are associated with message flow and message set development, you must ensure that the files and the content of these files are compatible and can be shared by users working on different systems and in different locales.

You can share the following files:

- Message flow definition files (`.msgflow`)
- ESQL files (`.esql`)
- Mappings files (`.msgmap`)
- Message set files (`.mset`)
- Message files (`.mxsd` and `.xsd`)
- Message category files (`.category`)

Restrict the names of these files to a specific set that all your users can understand, for example the characters in the US English code page (a to z, A to Z, 0 to 9, plus special characters underscore and hyphen). This is not a restriction, nor is it enforced, but the users must be able to use each others resources without confusion or error.

The contents of all files listed above, with the exception of ESQL files, are stored in UTF-8, and are therefore common, regardless of individual user settings.

The contents of the ESQL files, which users can edit directly, are governed by the editor preference settings that you specify in the workbench:

1. Click **Window** > **Preferences**.
2. Expand the Workbench item on the left. Click **Editors**. Within "Text file encoding", select the code page that you want content to be stored in:
   a. If you select Default, this represents the default code page for the locale in which you are currently working.
   b. If you select Other, you can choose one from the list of available code pages.

If you expect users to share ESQL files, by using either shared drives across a LAN, or a shared repository such as CVS, you must ensure that all users set the editor preference to be the same value. This allows each user to work in their current locale, but be able to access and work with files created by any other user. For example, select UTF-8 to ensure consistent ESQL file content that is accessible by all users regardless of current locale.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Message modeling" on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

"Publish/Subscribe" on page 2215
Publish/subscribe is a style of messaging application in which the providers of information (publishers) are decoupled from the consumers of that information (subscribers).

Broker Archive editor

Use the Broker Archive editor to create and manage broker archive (BAR) files.

The Broker Archive editor is available in both the WebSphere Message Broker Toolkit and the WebSphere Message Broker Explorer. Using this editor, you can add, edit, build, and remove deployable resources to a BAR file. You can also use command-line tools to create BAR files.

Broker Archive editor views:
The Broker Archive editor includes these views:

Prepare view

The Prepare view displays the options for creating a new broker archive file. The Prepare view is available only in the WebSphere Message Broker Toolkit. Use the Prepare view to add and build deployable resources to the BAR file. All available resources in the current workspace (including Java, XML and XSL/XSLT files, message flows, message sets, and adapters) are included with each build type. Resources that are identified but that do not match resources in the workspace are highlighted.

You can select the items that you want to include in the broker archive, and use the build options to perform the following tasks:

- Select items to add or remove from the broker archive
- Include source files
- Override the properties of configurable items

The Build options are:

- **Include source files** to include source files
- **Remove contents of Broker Archive before building** to remove all existing contents of the broker archive file before building the new broker archive file
- **Override configurable properties values** to override the existing configurable property values. Check this option to override any value set by the flow compiler, that is, the values from the message flow. If you do not check this option the properties in the `broker.xml` file are used when compiling a message flow.

Manage and Configure view

The Manage and Configure view displays the message flows, message sets, and other files that are currently in the BAR file. Use the icons to add, edit, and remove files from the BAR file. When you select a message flow in the list, its properties, including configurable properties, are displayed in the Properties view. You can also expand the message flows to display the nodes in the message flow. When you select a node the associated configurable properties are displayed in the Properties view. To edit a property, replace the current value with a new value.

You can filter the content in the Manage and Configure view, by selecting one of the available options from the Filter by list:

- Built resources
- Built resources with source
- Configurable properties

To display resources with specific names, type a filter string in the Filter by field. For example, to display all resources that contain SWIFT in the name, type SWIFT into the Filter by field.

User Log view

The User view displays the build information for the broker archive user log. Use the User Log view to review or clear the details in the user log of the BAR file.

Service Log view

The Service view displays system information for the current build in the broker archive Service log. Use the Service Log view to review or clear the details in the service log of the BAR file.

Broker Archive editor toolbar:

The icons on the toolbar in the Manage and Configure page, and their actions are shown in the following table.

Icon	Label	Action
	**Build**	Builds a broker archive file, making any changes that have been specified
	**Remove**	Removes message flows, message sets, or other items from this archive
	**Edit**	Edits selected message flows, message sets, or other items in this archive
	**Add**	Adds message flows, message sets, or other items to this archive

Related concepts:

"Broker archive" on page 3216
The unit of deployment to the broker is the *broker archive* or *BAR* file.

"Version and keyword information for deployable objects" on page 1443
Use the Broker Archive editor to view the version and keyword information of deployable objects.

Related tasks:

Chapter 11, "Packaging and deploying," on page 3209
Package resources that you create in the WebSphere Message Broker Toolkit, such as message flows, and deploy them to execution groups on brokers.

Related reference:

"**mqsireadbar** command" on page 3697
Use the **mqsireadbar** command to read a deployable BAR file and identify its defined keywords.

"Broker Application Development perspective" on page 6784
The Broker Application Development perspective is the default perspective that is displayed when you start the WebSphere Message Broker Toolkit.

Brokers view

Use the Brokers view to create and work with brokers in the WebSphere Message Broker Toolkit.

By default, the Brokers view is displayed at the bottom of the Broker Application Development perspective in the WebSphere Message Broker Toolkit. If the Brokers view is not displayed, you can show it by clicking **Window** > **Show View** > **Other** > **Broker Runtime** > **Brokers**.

Brokers that are created on the local system are automatically displayed in the Brokers view. You can add remote brokers to the Brokers view. When you open or switch to the Brokers view, the WebSphere Message Broker Toolkit attempts to connect to brokers on the local system, and any remote brokers that have been defined. Warnings and errors might be displayed if the WebSphere Message Broker Toolkit cannot connect to brokers, for example, if the broker is stopped, or the queue manager listener is not running.

Right-click the Brokers folder in the Brokers view to display the following options:

- **New Local Broker**
- **Connect to a Remote Broker**

If you specify a keystore or truststore in the remote connection information, you are prompted to enter a password for the keystore or truststore when you connect to the remote broker.

- **Connect to a Remote Broker Using *.broker File**
- **Refresh**

Related tasks:

Chapter 6, "Configuring brokers for development environments," on page 563
Set up application development environments on Linux on x86 or Windows to create, test, and deploy message flows and associated resources.

Chapter 8, "Administering brokers and broker resources," on page 899
Administering brokers and associated broker resources includes the tasks that you perform frequently to activate and manage those resources. Choose the method you prefer to administer your brokers and associated resources.

"Connecting to a remote broker" on page 902
To administer your brokers by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer, you must connect to the broker.

"Deploying resources" on page 3234
Deploy message flow applications to execution groups by sending a broker archive (BAR) file to a broker, which unpacks and stores the contents ready for when your message flows are started.

"Attaching the flow debugger to an execution group for debugging" on page 3160
Before you can debug your message flow, you must attach the flow debugger to the execution group where your flow is deployed, then start a debugging session.

Related reference:

"WebSphere Message Broker Toolkit" on page 6783
The WebSphere Message Broker Toolkit provides your application development environment on Windows and Linux on x86.

Deployment Log view

The Deployment Log view shows the result of deployment actions on brokers in the WebSphere Message Broker Toolkit.

The Deployment Log view is displayed at the bottom of the Broker Application Development perspective in the WebSphere Message Broker Toolkit. If the Deployment Log view is not displayed, you can show it by clicking **Window** > **Show View** > **Other** > **Broker Runtime** > **Deployment Log**.

Right-clicking in the Deployment Log view displays a menu with the following item:

- **Clean Log**

  Clears all log entries from the Deployment Log view, but does not delete the log entries from the administration log.

  Messages are automatically cleared after 72 hours.

Columns in the Deployment Log view:
Details

The Details column displays the message number, the name of the broker that the deployment message has come from, and the detail of the deployment message.

Timestamp

The Timestamp column displays the date and time for each of the deployment messages from the broker.

Related tasks:

"Viewing Administration log information" on page 1007
You can view Administration log information by using either the WebSphere Message Broker Explorer, or the CMP API.

"Saving Administration log information" on page 1008
Save the Administration log information that is written to the Administration Log view in the WebSphere Message Broker Explorer.

"Clearing Administration log information" on page 1009
Clear Administration log information to reduce the size of the log by using either the WebSphere Message Broker Explorer or the CMP API.

Related reference:

"Administration Log view" on page 6840
The Administration Log view shows administration requests and their results, changes made to objects, and the result of deployment actions on brokers. The Administration Log view can also describe configuration changes that have been automatically applied as a result of moving the broker from one version to another; for example, after applying maintenance.

ESQL editor

The ESQL editor is the default editor provided by the Broker Application Development perspective for editing ESQL (`.esql`) files.

The editor is launched in the editor area when you select the menu item **Open ESQL** for a Compute, Database, or Filter node, or when you double-click an ESQL file in the Broker Development view.

ESQL editor views:
The ESQL editor has the following views:

Broker Development view
The Broker Development view shows all the resources in your workspace, that is all message set resources and all message flow resources, including ESQL files.

Editor view
The editor view shows the contents of the resource that is currently open. It also shows tabs for each of the resource that you have open so that you can quickly switch between them.

Outline view
The Outline view displays any schemas, defined constants, modules, and routines that you have referenced in this ESQL file.

Problems view
The problems view displays the warning and error messages that are generated by the editor's validation when you save the ESQL file. If you double-click an error, the editor indicates where it is located by moving the cursor to the corresponding ESQL code.

ESQL editor functions:
The ESQL editor provides:

- A context sensitive Content Assist. You can invoke Content Assist from the Edit menu or, on some systems, by pressing Ctrl+Space if that has not been assigned to another function.

  Content Assist helps you construct references to the content of the Properties folder. When you use the ESQL editor with predefined messages, it also helps you construct field references.

  When you use the ESQL editor with the database schema definitions, Content Assist helps you construct schema, table, and column references. You can also use the ESQL editor to call user-defined maps.

  When you create functions and procedures within the ESQL file, the names that you define must not start with the characters IBM_ (IBM underscore).

  Note: To get Content Assist to work, you must set up a project reference from the project containing the ESQL or mappings to the project containing the message set. For information about setting up a project reference, see "Project references" on page 44.
- Automatic code formatting.

Right-click in the editor view to access the following additional functions:

- **Undo** and **Revert File**: To undo a change that you have made to the ESQL file, click **Undo**. If you want to undo all the changes since the last time you saved, you can reinstate them by clicking **Revert File**.
- **Cut**, **Copy**, and **Paste**: Standard editor functions.
- **Shift Right** and **Shift Left**: Standard editor functions.
- **Save**: Save your changes.
- **Comment** and **Uncomment**: Click **Comment** to change a line of ESQL code into a comment. Click **Uncomment** to change a comment into a line of ESQL code.
- **Format**. This function formats all selected lines of code (unless only partially selected, when they are ignored), or, if no lines are selected, formats the entire file (correcting alignments and indentation).
- **Organize Schema Paths** and **Add Schema Path**: These functions assist you with broker schema management.

  Click **Organize Schema Paths**, and a broker schema that contain procedures or function called by the ESQL file is automatically added to the PATH statement (if you have not already added it). This function scans the ESQL file for instances of procedures or function residing in schemas not already fully qualified in the file.

  Click **Add Schema Path** when you code a call to a procedure or function residing in a different broker schema to paths you have included on the PATH statement, and this schema is added to the PATH statement. Ensure that the cursor is on the name of the procedure you are calling.

ESQL editor preferences:
You can modify settings that affect the way the ESQL code is handled:

- Editor Settings (how code is displayed in the editor view):
  - Text font
  - Displayed tab width (default 4)
  - Background and foreground colors (for comments, statements, and so on)
- Validation Settings (what level of validation is performed when you save the file):

  Validation detects four potential problems:

Unresolved identifiers
The validator attempts to resolve all identifiers that you have referenced (for example, a message field).

Message references mismatch message definition
If a message definition exists (messages in the MRM domain only), the validator checks that the use of the reference is consistent with its definition (for example, the action against a numeric field is a valid numeric action).

Database references mismatch database schema
The validator checks that the use of the reference is consistent with the database schema (for example, the action against a numeric field is a valid numeric action).

Use of deprecated keywords
The validator checks if you have used keywords that have been deprecated in this release.

For each of these situations, select one of the following validation settings:

Ignore No validation is performed.

Warning
The validator writes warning messages to the Problems view for each potential problem that it detects. Warning is the default setting.

Error The validator writes error messages to the Problems view for each potential problem that it detects.

Validation does not check that you have specified names in the case in which you declared them. The names of modules, functions, and procedures are not case sensitive; all other names (schemas, constants, variables, and labels) are case sensitive. Check that the names that you use match the declarations for those names, because the broker handles these names in a case sensitive way, and generates a runtime error if they do not match.

For details of how to change these preferences, see "Changing ESQL preferences" on page 2408.

ESQL editor toolbar:
The ESQL editor does not provide additional icons and actions on the toolbar.

Related concepts:

"Project references" on page 44
When a projects refers to other projects in the workspace, this is called a *project reference*. When one project references another, the files in the referenced project are available for use by the referring project. For example to configure certain nodes, to create libraries of reusable message flows, and to enable Content Assist in the ESQL editor.

Related tasks:

"Developing ESQL" on page 2370
Customize processing implemented by the Compute, Database, DatabaseInput, and Filter nodes in your message flows by coding ESQL.

"Changing ESQL preferences" on page 2408
You can modify the way in which ESQL is displayed in the editor and validated by the editor:

Related reference:

"ESQL statements" on page 5067
You can use ESQL statements to manipulate message trees, update databases, or

interact with nodes.

"Calling ESQL functions" on page 5168
Most ESQL functions belong to a schema called SQL and this is particularly useful if you have functions with the same name.

"Broker Application Development perspective" on page 6784
The Broker Application Development perspective is the default perspective that is displayed when you start the WebSphere Message Broker Toolkit.

"Editor preferences and localized settings" on page 6793
If you want to share the files that are associated with message flow and message set development, you must ensure that the files and the content of these files are compatible and can be shared by users working on different systems and in different locales.

Impact Analysis view

The Impact Analysis view shows information about selected resources, which changes have been marked as complete, and previous results. You can also use this view to copy results to the clipboard.

The Impact Analysis dialog box

When you have run impact analysis, you see a list of affected resources in the Impact Analysis dialog box.

- At the top is a one-line description of the operation.
- The middle table shows the primary impacts, and therefore the actions that must be performed to make this change.
- The bottom table shows secondary impacts (other objects in the workspace that are affected by this change.) Some secondary impacts might not be shown; for more information, see "Impact analysis: reference" on page 4174.

For both tables, you can reorder columns by dragging the column heading to a new location, and sort information in each column by clicking the column heading. No changes are made to the objects listed, and you cannot use this window to change any of the objects.

You can click **Copy Analysis to Clipboard** to paste the results of the analysis into an external application.

- If the application supports tables, the information is pasted as a table. Applications that support tables include Lotus Symphony® spreadsheets, Microsoft Word, and Microsoft Excel.
- If the application does not support tables, the information is pasted as text.

To switch easily between the impact analysis results and file editors, click **Show in view** to view the results in the Impact Analysis view.

The Impact Analysis view

After you have run impact analysis, the Impact Analysis view is displayed at the bottom of the Broker Application Development perspective in the WebSphere Message Broker Toolkit.

The left pane lists the affected resources and the right pane provides some tips to guide you. If you select one of the resources in the left pane, more information is provided in the right pane.

Resources that you have not selected are in bold. After you have viewed an item in the list, it is no longer bold.

When you have made a change in the appropriate file editor, you can mark the item in the results view as complete by clicking **Mark as complete** (represented on the toolbar by a check mark). The completed item in the list is crossed out.

You can view previous impact analysis results by clicking the arrow to the right of the show history icon.

Message Category editor

The Message Category editor is the default editor provided by the Broker Application Development perspective for working with message category (`.category`) files in a message set.

The editor is launched in the editor area when you open an existing message category file using the Broker Development view, or when you create a new message category file by using the New Message Category File wizard.

Message Category editor views:
The Message Category editor has the following views:

Broker Development view
: The Broker Development view shows a hierarchical view of all the resources that are currently in your workspace. By expanding the folder for a message set project, you can see the resources, including the message category file or files, that this message set project contains.

Editor view

You edit the properties of message category in the editor area of the Message Category editor, which has a single tab, the **Properties** tab. This tab provides:

- The Properties Hierarchy, which shows the hierarchy for a message category file and the messages that have been added to it.
- The Details view, which when you select a message category file, shows the properties of the message category, or of an individual message in the category, depending on what you have selected in the Properties Hierarchy.

There are tabs across the top of the editor area containing the file name for each file that you have open, so that you can quickly switch between them.

Problems view

Each time you save a change within a message set project, the content is validated to ensure that the message model follows certain rules. All informational, warning or error messages relating to the validation appear in this view.

Properties Hierarchy functions:

Right-click in the Properties Hierarchy to display the following menu items:

- **Add Messages** (available at the **Message Category** level only) adds a new message to a message category file.
- **Undo** and **Redo** allow you to undo and redo changes to message category files. These two menu items apply to adding new messages, and also to changes that you make in the Details view. To undo a change that you have made to a message category file but not yet saved, click **Undo**. If you undo a change, you can reinstate it by clicking **Redo**.
- **Delete** (available at the individual **Message** level only) deletes the selected message from the message category file.

Details view functions:

In the Details view, use the **Message Category Kind** field to specify whether the message category will be used to generate WSDL (Web Services Description Language) files.

If the **Message Category Kind** is WSDL, you must provide definitions in the **Role Name** and **Role Type** fields for each message that you add to the message category file. These two fields appear when you select a message in the Properties Hierarchy.

Create all required documentation for a message set in the **Documentation** field. Right-click in this field to display a menu of standard text editing menu items that apply specifically to this field. You can undo changes, cut, copy, paste, and delete text, and select all the text in the field.

Related concepts:

"Message categories" on page 1200
Message category files have the suffix `.category`. These files are optional. You can have many message category files in a message set.

Related tasks:

"Working with a message category file" on page 2923
This topic area lists the tasks that are involved when working with a message category file.

"Generating a WSDL definition from a message set" on page 2968
To ensure the highest interoperability of your Web services, use the document style of WSDL whenever possible. If rpc style WSDL is necessary, use literal encoding.

Related reference:

"Broker Application Development perspective" on page 6784
The Broker Application Development perspective is the default perspective that is displayed when you start the WebSphere Message Broker Toolkit.

"Message category properties" on page 5413
A message category provides a way of grouping your messages.

Message Definition editor

The Message Definition editor is the default editor provided by the Broker Application Development perspective for editing message definition (`.mxsd`) files.

The editor is launched in the editor area when you open an existing message definition file using the Broker Development view, or when you create a new message definition file by using the New Message Definition File wizard.

You use the Message Definition editor to:

- Edit message definitions created by importing data structures using the XML Schema, DTD, C or COBOL importers. The message definition file that the import process creates is automatically populated with the imported content, which you can then edit as required.
- Populate empty message definition files with message model objects by creating the elements, attributes, groups, types and messages needed to represent your message formats. The message model that you create can consist of both logical and physical information, if appropriate physical formats exist in the message set.

Message Definition editor views:

The Message Definition editor has the following views:

Broker Development view

The Broker Development view shows a hierarchical view of all the resources that are currently in your workspace. By expanding the folder for a message set project, you can see the resources, including message definition file or files, that this message set project contains.

Outline view

You use the Outline view to select message set objects to display in the editor area. When you open a message definition file, the Outline view shows a hierarchical view of the messages, types, groups and elements and attributes that the selected message definition contains.

Editor view

You edit the properties of message set objects in the editor area, which displays the message definition information for the object that you have currently selected in the Outline view. There are tabs across the top of the editor area for each file that you have open, so that you can quickly switch between them.

In the editor area, you can make any of the following types of change:

- Edit the logical structure of a message.
- Create and edit the physical structure and properties of a message.
- Create message definitions.

- Create common constructs within a message set for use with other message definition files.

The Message Definition editor comprises an Overview editor and a Properties editor. You switch between them by clicking the two tabs in the lower left of the editor area. You can change the order in which the tabs are displayed by changing the message set preferences.

Problems view

Each time you save a change within a message set project, the content is validated to ensure that the message model follows certain rules. All informational, warning or error messages relating to the validation appear in this view. Double-click a message to display the properties of the relevant object in the editor area. The location of this object is highlighted at the appropriate levels in the Broker Development view and the Outline view.

Message Definition editor functions:

For information on the functions that the Message Definition editor provides, refer to the following topics:

Message Definition editor: Outline view:

When you open a message definition file, the hierarchy for the selected file appears in the Outline view. Use the Outline view to select objects whose details you want to view and edit in the Message Definition editor area.

Global actions:
The toolbar icons in the Outline view provide a number of global actions that apply to all levels of the displayed hierarchy. The icons in the toolbar and their actions are shown in the following table.

Icon	Label	Action
	**Find Element**	Finds the specified message definition construct.
	**Sort global constructs alphabetically**	If selected, global constructs are sorted alphabetically. If not selected, global constructs are displayed in the order that you create them.
	**Collapse All**	Collapses all the levels that are currently displayed in the Outline view.

You can also select these global actions from the toolbar menu that appears when you click the icon.

Common editing and navigation actions:

The Outline view provides the following common actions, which are also available in the Overview editor. Right-click in the Outline view or Overview editor to display the menu items.

- **Copy** and **Paste** provide standard editing functions.
- **Undo** and **Redo** allow you to undo and then redo changes that you have made. To undo a change, click **Undo**. If you undo a change, you can reinstate it, if you want to, by clicking **Redo**.
- **Go To Declaration** takes you to the appropriate point in the hierarchy (global group from a group reference, global attribute from an attribute reference, global element from an element reference, global element from a message) either in the same or in a different message definition file.
- **Go to Type Definition** takes you to the appropriate point in the hierarchy.
- **Go to Properties** switches to the Properties view in the editor.
- **Rename** allows you to rename the selected message set object.
- **Delete** deletes the selected message set object.
- **Save** saves the current message set definition file.

Options for adding message model objects:

The Outline view provides options for adding the message model objects shown in the following list. These options are also available in the Overview editor.

- Messages

  Message

  Message From Global Element

  Message From Global Type

- Types
  - Complex Type
  - Simple Type Restriction
  - Simple Type List
  - Simple Type Union
- Groups
  - Group
  - Attribute Group
- Elements and Attributes
  - Global Element
  - Global Attribute

Right-click the appropriate level of the displayed hierarchy to display in more detail what can be added at the selected level.

The Message Definition editor is the default editor provided by the Broker Application Development perspective for editing message definition (`.mxsd`) files.

"Message Definition editor: Overview editor"
The Overview editor displays the contents of the message set object that you select in the Outline view, and you can view and change this object's most common properties.

"Message Definition editor: Properties editor" on page 6808

Message Definition editor: Overview editor:

The Overview editor displays the contents of the message set object that you select in the Outline view, and you can view and change this object's most common properties.

The Overview editor appears when you click the Overview tab in the editor area. Use the navigation buttons and links on the toolbar to move back and forth between different objects. In the Overview editor you can make the following types of change:

- Edit the displayed values of any of the following objects:

- Structure
- Type
- Min Occurs
- Max Occurs

  To edit any of these values, click the appropriate field in the Overview editor. Depending on the type of field, this either displays a list from which you can choose, or it enables the field for direct editing.

- Add message model objects as in the Outline view.

  To add a new message model object, right-click **Structure**, then click the appropriate item from the displayed menu.

  For example, the menu for **Messages** provides **Add Message**, **Add Message From Global Element**, or **Add Message From Global Type**.

Related concepts:

"Message definition files" on page 1171
A *message definition file* contains the messages, elements, types, and groups which make up a message model within a message set.

The Message Definition editor is the default editor provided by the Broker Application Development perspective for editing message definition (`.mxsd`) files.

"Message Definition editor: Outline view" on page 6806
When you open a message definition file, the hierarchy for the selected file appears in the Outline view. Use the Outline view to select objects whose details you want to view and edit in the Message Definition editor area.

"Message Definition editor: Properties editor"

"Message set editor" on page 6819
The Message set editor is the default editor provided by the Broker Application Development perspective for editing message set (`messageSet.mset`) files.

Message Definition editor: Properties editor:

The Properties editor allows you to change the properties for the selected message set object. The information that appears depends on what is currently selected in the Outline view and Overview editor. The Properties editor appears when you click the Properties tab in the editor area. The navigation buttons and links on the toolbar allow you to move back and forth between different objects. The Properties editor comprises the Properties Hierarchy and Details view.

Properties Hierarchy functions:

When you select a object in the Outline view, the Properties Hierarchy shows the following hierarchy for the message definition file that is currently open in the Message Definition editor:

- Logical properties
- Physical properties
- Documentation

Right-click in the Properties Hierarchy to display a number of menu items. The displayed menu items depend on which level of the hierarchy you select:

- **Undo** and **Redo** are available for all levels in the Properties Hierarchy and apply to changes that you make in the Details view for the currently selected object. To undo a change that you have made to a file but not yet saved, click **Undo**. If you undo a change, you can reinstate it by clicking **Redo**.
- **Add Include** and **Add Import** are available when the top level of the message definition (`.mxsd`) file's hierarchy is displayed in the **Outline** view. They allow you to link message definition files together.
- **Apply default physical format settings** is available for **Physical formats** only and applies the default wire format settings for the selected object.

If you add a new physical format in the message set (`messageSet.mset`) file, this new format is added under **Physical Properties** in the Properties Hierarchy. When you click **Physical Properties**, a link to the Message Set editor appears in the Details view.

Details view functions:

The Details view shows the properties for the object that is currently selected in the Properties Hierarchy. You can save any changes to the properties as you make them.

You create any required documentation for a message set in the **Documentation** field. This field appears when you select an object under **Documentation** in the Properties Hierarchy. Right-click in this field to display a menu of standard text editing menu items that apply specifically to this field and allow you to undo changes, cut, copy, paste and delete text, and select all the text in the field.

"Message set editor" on page 6819
The Message set editor is the default editor provided by the Broker Application Development perspective for editing message set (`messageSet.mset`) files.

Message Flow editor

The Message Flow editor is the default editor provided by the Broker Application Development perspective for defining a graphical representation of a message flow in the WebSphere Message Broker Toolkit, and for setting properties for individual message flow nodes.

Open a message flow file (`.msgflow`) in the Broker Development view to launch the appropriate editor in the Editor view. The Editor view is where you select built-in and user-defined nodes, and the connections between them, to define a message flow.

Message Flow editor views:
The Message Flow editor has the following views:

Broker Development view

The Broker Development view shows all the resources in your workspace; that is, all message set resources, and all message flow resources.

Editor view

The editor view shows the contents of the resource that is currently open. It also shows tabs for each of the resources that you have open so that you can quickly switch between them.

When the resource that is open is a message flow, two tabs are displayed, called **Graph** and **User Defined Properties**.

When you select **Graph**, the editor view contains a graphical display of the message flow.

The Palette contains all the available nodes that you can include in the message flow. By default, the palette appears on the left side of the editor view. You can move it to the right side of the editor view by clicking the palette while it is in collapsed mode, and dragging the bar to the right of the editor view.

When you select the **User Defined Properties** tab, a User Defined Properties editor is opened that allows you to change the User Defined Properties of the message flow. The User Defined Properties editor consists of a User Property Hierarchy view and a Details view.

The User Property Hierarchy view displays three icons, **`Add Property Group`**, **`Add Property`**, and **`Delete`** that you can use to update the property hierarchy. When you add a property, a Details view is opened. In the Details view you can define the property Type and Default Value.

Outline view

The Outline view enables you to navigate to a particular node in a message flow, and edit its properties.

Palette view

The Palette view lists the available nodes that you can select and include in the message flow. For more information about the palette and how to customize the layout and settings, see “Message flow node palette” on page 1027.

Overview view

The Overview view provides a useful summary for large, complex message flows because it shows a small-scale version of the flow. Click the tab to show or hide the outline view.

Problems view

This view displays the warning and error messages that are generated by the editor's validation when you save the message flow file. If you double-click an error, the editor indicates where it is located (for example, if you have not set a mandatory property in a node, it opens the Properties view for that node).

Message Flow editor toolbar:
The icons in the toolbar and their actions are shown in the following table.

Icon	Label	Action
	**Manhattan**	Displays all node connections as a series of horizontal and vertical lines
	**Show grid**	Displays a grid of horizontal and vertical dotted lines in the background of the editor area.
	**Grid properties**	Defines the horizontal and vertical spacing of the grid markers, and the gap between the borders of the editor area and the start of the grid markers.
	**Align left**	Lines up the left edge of the currently selected nodes. Enabled only when more than one node is selected.
	**Align center**	Lines up the horizontal center point (between left and right) of the currently selected nodes. Enabled only when more than one node is selected.
	**Align right**	Lines up the right edge of all the currently selected nodes. Enabled only when more than one node is selected.
	**Align top**	Lines up the top edge of the currently selected nodes. Enabled only when more than one node is selected.

Icon	Label	Action
	**Align middle**	Lines up the vertical center point (between top and bottom) of the currently selected nodes. Enabled only when more than one node is selected.
	**Align bottom**	Lines up the bottom edge of the currently selected nodes. Enabled only when more than one node is selected.
	**Show distribute box**	Displays a rectangular box around the currently selected nodes.
	**Distribute horizontally**	Aligns the currently selected nodes with the nearest right or left edge within the distribute box.
	**Distribute vertically**	Aligns the currently selected nodes with the nearest top or bottom edge within the distribute box.

Use the advice given here to help you to resolve common problems that can arise when developing message flows.

Related reference:

"Broker Application Development perspective" on page 6784
The Broker Application Development perspective is the default perspective that is displayed when you start the WebSphere Message Broker Toolkit.

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

"User-defined nodes" on page 6415
You can define your own nodes to use in WebSphere Message Broker message flows.

Message Flow editor hover-feedback:

In the Message Flow editor, you can display node and connection metadata by holding the mouse pointer over a node or subflow in a message flow. To view metadata information for a node, subflow, or connection:

1. Switch to the Broker Application Development perspective.
2. Open a message flow.
3. In the Message Flow editor, hold the mouse pointer over a node, a subflow, or a node connection in the open message flow by placing the mouse over the element.

A custom tooltip is displayed below the element.

- To turn the pop-up window into a scrollable window, press **F2**.
- To hide the pop-up window, either press Esc or move the mouse away from the node.

Node and subflow feedback

When you hold the mouse pointer over a node or subflow in the Message Flow editor, the pop-up window contains the following metadata information:

- The first line of text contains the node type and the display name of the node instance. This line appears as **bold text**.
- The line below the node type and display name contains the node's short description.
- The final line contains the node's long description.

If the node or subflow has no short or long description associated with it, only the first line of text is displayed.

If the task list contains errors or warnings that are associated with the node or subflow, the error or warning information is displayed instead of the metadata information.

Connection feedback

When you hold the mouse pointer over a connection in the Message Flow editor, hover-help is displayed, containing the names of the output and input terminals that are connected.

Message Flow editor menus:

All the actions that you can perform in the Editor view of the Message Flow editor are also available from a series of drop-down menus in WebSphere Message Broker. When the Message Flow editor is open, the following menus appear in the Workbench:

Menu	Keyboard shortcut
Flow	Alt + O
View	Alt + V
Palette	Alt + L
Run	Alt + R

The Navigate menu also contains actions specific to the Message Flow editor.

Flow menu

The flow menu contains all the actions that address editing of the flow model. Actions are statically positioned on the menu, and are enabled or disabled when nodes or connections are selected in the editor.

The following actions are available:

Menu item	Keyboard shortcut
Create Connection	C
Add subflow...	A
Rename...	N
Locate Subflow...	L
Promote Property	P
Properties...	R

View menu

The View menu contains all actions specific to the visual presentation of the flow model.

Menu item	Keyboard shortcut
Zoom In	I
Zoom Out	O
Manhattan Layout	M
Show Grid	G
Snap to Grid	G
Grid Properties...	P
Align	A
Distribute	D
Layout	L
Rotate	R

Palette menu

The Palette menu contains all actions specific to the Message Flow editor Palette.

Menu item	Keyboard shortcut
Add Node to Canvas	N
Customize	T
Settings...	S
Revert Palette to Defaults	T

Run menu

The Run menu contains the flow debug actions.

Menu item	Keyboard shortcut
Add Breakpoint	A
Remove Breakpoint	E
Add Breakpoints After Node	A
Add Breakpoints Before Node	B

Navigate menu

The Navigate menu contains the following actions specific to the Message Flow editor:

Menu item	Keyboard shortcut
Open Subflow	O
Open Source	S

You can navigate all interfaces in the WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit by using the keyboard.

Adding a node by using the keyboard:

You can use the keyboard to perform tasks in the Message Flow editor, such as adding a node to the canvas.

Before you begin

Before you start:
- Ensure that you have created or opened a message flow. For more information, see "Creating a message flow" on page 1431 or "Opening an existing message flow" on page 1433.
- Read the concept topic, "Message flow nodes" on page 1024.

Procedure
1. Open the message flow to which you want to add a node.
2. Open the Palette view or the Palette bar.
3. Select a node in the Palette view or Palette bar by using the up and down arrows to highlight the node that you want to add to the canvas.
4. Add the node to the canvas by using one of the following methods:
   - Press **Alt + L**, then press **N**.
   - Press **Shift + F10** to open the pop-up menu for the Palette, and press **N**.

   The node that you selected in the Palette bar or Palette view is placed on the canvas in the Editor view.

   When you add a node to the canvas, the editor automatically assigns a name to the node, but the name is highlighted and you can change it by entering a name of your choice. If you do not change the default name at this time, you can change it later by following the instructions in "Renaming a message flow node" on page 1502. The default name is set to the type of node for the first instance. For example, if you add an MQInput node to the canvas, it is given the name MQInput. If you add a second MQInput node, the default name is MQInput1; the third is MQInput2, and so on.

Results

You can move the node that you have placed on the canvas by using the keyboard controls described in "WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit keyboard shortcuts" on page 6828.

Related concepts:

"Message flow node palette" on page 1027

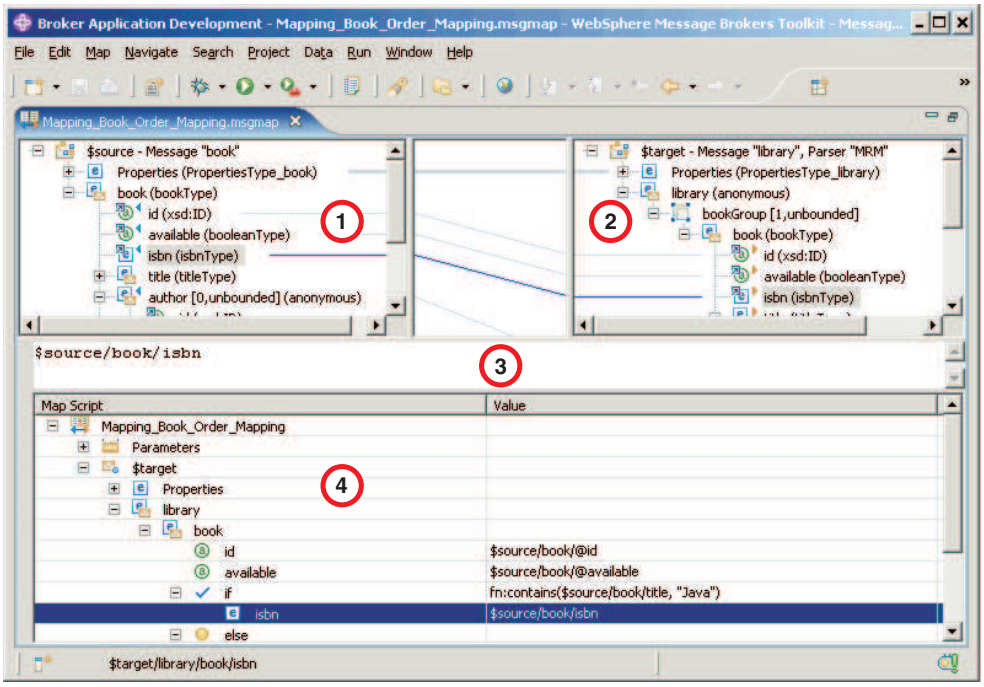
Message Mapping editor

You use the Message Mapping editor to create and edit message mappings.

You can use the Message Mapping editor to set values for:

- The message destination
- Message headers
- Message content

Here is an example of the Message Mapping editor. There are separate panes for working with sources, targets and expressions, as well as a spreadsheet view.



1. **Source pane:** displays a source message or database table
2. **Target pane:** displays a target message
3. **Edit pane:** displays the expression to be used to derive the target element value

4. **Spreadsheet pane:** displays a summary of the mappings in spreadsheet columns (each target field and its value)

Use the Message Mapping editor to perform various mapping tasks.

Wizards and dialog boxes are provided for tasks such as adding mappable elements, working with ESQL, and working with submaps. Mappings that are created with the Message Mapping editor are automatically validated and compiled, ready for adding to a broker archive (BAR) file, and subsequent deployment to WebSphere Message Broker.

Message Node editor

The Message Node editor is the default editor provided by the Plug-in Development perspective for defining the content of user-defined nodes.

The editor is launched in the editor area of the perspective when a new message flow node file (`.msgnode`) is created.

Message Node editor views

The Message Node editor has two tabs:

Terminals
: This tab is for adding, renaming, or deleting input and output terminals for the new node.

Properties
: This tab is for adding properties and property groups to the node, and defining property type.

Related concepts:

"User-defined extensions overview" on page 2971
A user-defined extension is an optional component that you design and create to extend the functionality of WebSphere Message Broker.

Related reference:

"Plug-in Development perspective" on page 6792
You can use the Plug-in Development perspective to create user-defined node projects and user-defined nodes in the WebSphere Message Broker Toolkit, however, the preferred option is to use the Broker Application Development perspective.

"Plug-in Development projects and files" on page 6825

Message set editor

The Message set editor is the default editor provided by the Broker Application Development perspective for editing message set (`messageSet.mset`) files.

The editor is launched in the editor area when you open an existing message set file using the Broker Development view, or when you create a new message set file using the New Message Set File wizard.

Message set editor views:

The Message set editor has the following views:

Broker Development view
The Broker Development view shows a hierarchical view of all the resources that are currently in your workspace. By expanding the folder for a message set project, you can see the resources, including the message set file, that this message set project contains.

Editor view
You edit the properties of message set in the editor area of the Message set editor, which has a single tab, the **Properties** tab. This tab provides:

- The Properties Hierarchy, which provides a hierarchy with four basic categories: **Message Set**, **XML Wire Formats**, **Custom Wire Formats**, and **Tagged/Delimited String Formats**.
- The Details view, which displays the properties relating to the currently selected level in the Properties Hierarchy.

  You select the **Default message domain** you require from the read-only drop down list. When you select the domain from the drop down list, the corresponding **Supported message domains** check box is greyed out and you cannot select it.

  You can add other domains by selecting the appropriate check boxes in **Supported message domains**.

There are tabs across the top of the editor area containing the file name for each file that you have open; this enables you to quickly switch between the open files.

Problems view
Each time that you save a change within a message set project, the content is validated to ensure that the message model follows certain rules. All informational, warning, or error, messages that relate to the validation appear in the this view.

Properties Hierarchy functions:
Right-click in the Properties Hierarchy to display the menu items available for the level of the hierarchy that you have currently selected:

- **Undo** and **Redo** are available for all levels in the Properties Hierarchy and apply to changes that you make in the Details view. To undo a change that you have made to a message set file, but have not yet saved, click **Undo**. If you undo a change, you can reinstate it by clicking **Redo**.

- If **XML Wire Formats**, **Custom Wire Formats**, or **Tagged/Delimited String Formats** are selected, menu items are available for adding physical format layers to a message set file. These are **Add XML Wire Format**, **Add Custom Wire Format**, and **Add Tagged/Delimited String Format**, respectively.
- If an existing physical format is selected, the following menu items are available for the selected physical format layer:
  - **Apply default physical format settings** applies the default physical format settings to the selected physical format layer.
  - **Rename** renames the selected physical format layer for the message set file. Click **Finish** on the displayed window to confirm the change of name.
  - **Delete** deletes the selected physical format layer from the message set file. Click **Finish** on the displayed window to confirm the deletion.

Details view functions:
You use the Details view to define and edit global properties for the message set, and to create and edit properties for the physical format layers that you have added to the message set.

You create any required documentation for a message set in the **Documentation** field. Right-click in this field to display a menu of standard text editing menu items that apply specifically to this field and that allow you to undo changes, cut, copy, paste and delete text, and select all the text in the field.

Related concepts:

"Message sets overview" on page 1162
A message set is a container for grouping messages and associated message resources (elements, types, groups).

Related tasks:

The Broker Application Development perspective is the default perspective that is displayed when you start the WebSphere Message Broker Toolkit.

"Message set preferences" on page 5366
Preferences for message sets.

"Message set properties" on page 5371
Message sets have properties that you can set to define their characteristics and the way in which they are processed.

WSDL editor

Use the WSDL editor to browse and edit a WSDL file.

The WSDL editor is launched in the editor area of the Broker Application Development perspective when you either double-click a WSDL file, or right-click a WSDL file and select **Open With**; the WSDL editor is the default editor.

The Design view provides a graphical way to browse and edit your WSDL file.

Each type of top level WSDL object is shown within a tabular view, for example, **service**, **binding**, and **port type**.

The service, binding, and port type objects are linked and a line is displayed to denote a reference, or association, between these objects.

The WSDL editor has three panes called General, Documentation, and Extensions. You can toggle between each pane.

WSDL editor panes:
General pane

The name of the top-level WSDL object you select is displayed at the top of the pane. All WSDL objects have a `Name` field that you can edit.

The top-level WSDL object you select defines the layout of the General pane and the number of rows in the table represents the structure of the object.

Some objects have an additional box that you can select, for example, **Binding**. In this case, clicking **Generate Binding Content** starts the Binding wizard.

Documentation pane

The Documentation pane allows you to add notes.

Extensions pane

You can add an extension to the top-level object you have selected.

Click **Add** to display the `Add Extension Components` window. You can then select from an extension category, a component, or both.

To add an extension category, select the category and click **Add** on the `Add Extension Components` window. On the window that is displayed, enter a name and select a schema. Click **Add** on this second window to add the category.

To add a component, select the component and click **OK** on the `Add Extension Components` window.

- "Pattern instance projects" on page 6827

Related concepts:

"Resources" on page 36
The projects, folders, and files that you work with in the WebSphere Message Broker Toolkit workspace are called *resources*. By default, these resources are stored with their metadata in the workspace directory in your local file system. The workspace directory is created the first time that you start the WebSphere Message Broker Toolkit.

"WebSphere Message Broker Toolkit" on page 31
The WebSphere Message Broker Toolkit is an integrated development environment and graphical user interface based on the Eclipse platform.

Related reference:

"Rules for naming workspace objects" on page 6827

Message flow projects and files

You develop message flows in the Broker Application Development perspective. Message flow resources are maintained within message flow projects. A message flow project compiles to one or more deployable flows.

Message flow projects contain the following resource files:

.msgflow files
: A message flow file is a graphical representation of a message flow, containing message nodes and connections. It also contains property values and overrides to define, implement and control the behavior of the message flow nodes. The New Message Flow Wizard automatically creates this file.

  Default editor: Message Flow editor

.esql file
: (Optional) ESQL modules containing compute, filter, and database ESQL functions and procedures. If none of the message flows defined in the project include any nodes that require ESQL, you do not need to create an ESQL file.

  Default editor: ESQL editor

.msgmap file
: (Optional) Mapping transformation descriptions for messages and databases. If none of the message flows defined in the project include any nodes that require mappings, you do not need to create a mapping file.

  Default editor: Message Mapping editor

You can define more than one message flow, each in a separate `.msgflow` file, in the same message project.

Related concepts:

"WebSphere Message Broker Toolkit" on page 31
The WebSphere Message Broker Toolkit is an integrated development environment and graphical user interface based on the Eclipse platform.

"Resources" on page 36
The projects, folders, and files that you work with in the WebSphere Message Broker Toolkit workspace are called *resources*. By default, these resources are stored with their metadata in the workspace directory in your local file system. The workspace directory is created the first time that you start the WebSphere Message

Broker Toolkit.

Related tasks:

"Creating a message flow" on page 1431
Create a message flow to specify how to process messages in the broker. You can create one or more message flows and deploy them to one or more brokers.

Related reference:

"Rules for naming workspace objects" on page 6827

"Message Flow editor" on page 6810
The Message Flow editor is the default editor provided by the Broker Application Development perspective for defining a graphical representation of a message flow in the WebSphere Message Broker Toolkit, and for setting properties for individual message flow nodes.

Message set projects and files

A message set project contains all the resources associated with exactly one message set. A message set is a logical grouping of messages and the objects (elements, types and groups) that comprise them. It contains the following resources, which you create and maintain in the Broker Application Development perspective.

messageSet.mset file
: A message set file contains those message model properties that are common across all the content of the message set. It also contains the physical format definitions for the message set. A message set project must contain exactly one message set file.

  Default editor: "Message set editor" on page 6819

.mxsd files
: A message definition file contains, in XML Schema form, the logical model and associated physical model for one or more messages. Each message set requires at least one message definition file to describe its properties, and you can have as many as you want within the same message set. One message definition file can, if required, reference XML Schema objects in another message definition file.

  You can create a message definition file in a message set by importing any of the following data structures:

  - XML Schemas
  - XML DTD
  - C header files
  - COBOL copybooks

  Importing any of these data structures automatically creates the message definition file and its content for you. Alternatively, you can create a blank message definition file and add the message definitions yourself.

  Default editor: "Message Definition editor" on page 6804

  Previous versions of the message set model
  The message definition contains the same application data that, previously, was stored in the following separate files:

  - Message set (MRProject) that contains wire formats and their default properties
  - Messages (MRMessage) that provides a unique name for a message and specifies its element
  - Elements (MRElement) that defines a node in the message tree

- Types (MRType) that specify the structure of elements
- Declaration Qualifiers (MRDeclaration Qualifier) that specify constraints applied to elements in the message model

.category files

A message category file provides you with another way of grouping related messages, for example for documentation generation, or for convenience purposes such as specifying the messages that define a complete request/reply transaction. You can also use a message category file to assist in generating a Web Services Description Language (WSDL) document. Message category files are optional, and you can have as many as you want within the same message set.

Default editor: "Message Category editor" on page 6802

Once you have created and populated a message set, you can use it to generate your message model in several different representations for use by your applications:

- A message dictionary for deployment to the WebSphere Message Broker.
- A W3C XML Schema for use by an application that is building or processing XML messages.
- A Web Services Description Language (WSDL) document that specifies the interface for a Web Service.
- An HTML document for use by business analysts and developers.

Data Design projects and files

A Data Design project contains resources relating to databases.

Data Design projects can contain the following resource files:

.dbm files
: A database definition file contains information about a connection to a database. The New Database Definition File wizard automatically creates this file. The name of the database definition file is the name of the database that the file connects to.

  Default editor: Physical Data Model editor

You can define more than one database definition in the same Data Design project, but each must be for a separate database.

Related concepts:

Use the New Database Definition File wizard to add database definitions to the WebSphere Message Broker Toolkit.

Plug-in Development projects and files

A plug-in project can contain any WebSphere Message Broker Toolkit-developed plug-in resource. In WebSphere Message Broker, it is used for user-defined message nodes.

User-defined Message Nodes:
Plug-in development projects used to create Message Nodes contain these resources:

.msgnode file
: Contains the definition of the node.

palette.xmi file
: Lists the user-defined nodes in the project and the Message Editor palette group in which they are shown.

.html file
: Contains the help files for the node.

.java file
Java source code for Property Editors and Compilers.

plugin.xml file
The plug-in manifest file that adds the node to the WebSphere Message Broker installation

.properties file
National Language properties - contains the translations for Properties and Terminals

.gif file
Icon - contains the image to associate with the node

Java projects and files

Developing Java projects using a .java file

You develop Java projects using the Java perspective WebSphere Message Broker Toolkit.

You can add any valid Java code to a JavaCompute node, making full use of the Java user-defined node API to process an incoming message. You can use the Java editing facilities of the Eclipse platform to develop your Java code.

If you have selected a user-defined message node, you have access to various resources that include the .java file; this file includes Java source code for Property Editors and Compilers.

You can also call Java methods directly from the Mapping node.

Related tasks:

"Managing Java Files" on page 2629
The Java code that you provide to modify or customize the behavior of a JavaCompute node is stored in a Java project. WebSphere Message Broker uses the Eclipse Java perspective for developing and administering Java files.

"Calling a Java method" on page 2310
To call an existing Java method from a mapping node, select the method from the

Call Existing Java Method wizard, or enter an XPath expression in the Edit pane.

Related reference:

"JavaCompute node" on page 4514
Use the JavaCompute node to work with messages by using the Java language.

Pattern instance projects

A pattern instance project contains project references to all the other projects in the workspace that relate to a specific pattern instance.

Pattern instance projects are shown in the Broker Development view by default when a pattern instance is generated. You can view all the generated resources that relate to a pattern instance by selecting the pattern instance from the working set selection list in the Broker Development view.

Related concepts:

"WebSphere Message Broker Toolkit" on page 31
The WebSphere Message Broker Toolkit is an integrated development environment and graphical user interface based on the Eclipse platform.

"Resources" on page 36
The projects, folders, and files that you work with in the WebSphere Message Broker Toolkit workspace are called *resources*. By default, these resources are stored with their metadata in the workspace directory in your local file system. The workspace directory is created the first time that you start the WebSphere Message Broker Toolkit.

"Using patterns" on page 1312
Use patterns that are supplied with the WebSphere Message Broker Toolkit to create resources that are used to solve a specific business problem.

Related tasks:

"Working with patterns in the Broker Development view" on page 1314
Using the Broker Development view to create patterns.

Rules for naming workspace objects

You can uniquely identify and locate a workspace resource using a namespace and a name. An organization uses its own name to form a namespace, and all resource names within that namespace are safe from clashes with those of another organization. The combination of a user specified namespace and name is often called the "fully qualified name". The unnamed namespace (name space="") is supported.

Note, that you must not include an exclamation mark (!) in the workspace name.

WebSphere Message Broker defines an application symbol space using project references. No fully qualified names can be duplicated across the application symbol space. A Tasks List error is displayed if duplicate or ambiguous names are detected within an application symbol space.

Related concepts:

"WebSphere Message Broker Toolkit" on page 31
The WebSphere Message Broker Toolkit is an integrated development environment and graphical user interface based on the Eclipse platform.

"Resources" on page 36
The projects, folders, and files that you work with in the WebSphere Message Broker Toolkit workspace are called *resources*. By default, these resources are stored with their metadata in the workspace directory in your local file system. The workspace directory is created the first time that you start the WebSphere Message

Broker Toolkit.

"Project references" on page 44
When a projects refers to other projects in the workspace, this is called a *project reference*. When one project references another, the files in the referenced project are available for use by the referring project. For example to configure certain nodes, to create libraries of reusable message flows, and to enable Content Assist in the ESQL editor.

WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit keyboard shortcuts

You can navigate all interfaces in the WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit by using the keyboard.

The following table shows the general shortcut keys that are provided in the WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit.

Keyboard shortcut	Result
Left, right, up, and down arrow keys	Move in the direction shown on the key.
Tab	Move the focus forward through the workbench.
Shift+Tab	Move the focus backward through the workbench.
Esc	Cancel the action.
Enter	Commit the action.
Spacebar	Select the object that currently has the focus.
Shift+F10	Open a pop-up menu.
Ctrl+F6	Open the Editors window. (Continue to hold down Ctrl to keep the window open. Use the up and down arrow keys to select a file. Release Ctrl. Press Enter.)
Ctrl+F7	Move between panes.

When you use the keyboard to navigate the toolbar of the Broker Development view, use the Tab key to access the first icon on the toolbar, then use the arrow keys to access other icons. For example, use the Tab key to access the **Hide Categories** icon, then use the right arrow key to access the **Collapse All** icon.

Message Flow editor keyboard shortcuts

The following table shows keyboard shortcuts that are specific to the Message Flow editor:

Keyboard shortcut	Result when the Selection tool is active	Result when the Connection tool is active
Left, right, up, and down arrow keys	Select a node on the palette or on the canvas. Use with Shift, or Ctrl+Spacebar, to select multiple nodes.	Select a terminal on a node.

Keyboard shortcut	Result when the Selection tool is active	Result when the Connection tool is active
slash (/) and backslash (\)	Press slash (/) to cycle forwards, or press backslash (\) to cycle backwards through the connections of the selected node. Use with Shift, or Ctrl+Spacebar, to select multiple connections.	
decimal key (.) and Shift+decimal key (.)	Press the decimal key (.) to cycle forwards, or press Shift and the decimal key (.) to cycle backwards through the move handles, or the resize handles, of the currently selected object on the canvas. When a node is selected, use this shortcut to activate the move handles, then use the arrow keys to move the node. Press Enter to confirm the move. When a connection is selected, use this shortcut to activate its resize handles, then use the arrow keys to create bend points in the connection. Press Enter to confirm the move.	
Esc		Typically, pressing Esc cancels the previous action. When there is no previous action to cancel, and the Connection tool is selected, pressing Esc activates the Selection tool.

The following examples show how to use the Message Flow editor keyboard shortcuts.

Adding nodes from the palette to the canvas:

1. If the palette is already open, go straight to step 2. If the palette is not already open, follow these steps to open the palette:
   a. Open the Editors window.
   b. Select the file that you want to use.
   c. Press Tab until the focus moves to the palette arrow.
   d. Press Enter, or Spacebar, to give focus to the palette.
2. Press Tab to give focus to the palette arrow.
3. Press Tab once to give focus to the drawers within the palette. (Note: There are no visual highlights to indicate the focus.)
4. Use the up and down arrow keys to highlight the drawer required. Press Enter.
5. Use the up and down arrow keys to highlight the node required.
6. Press Alt+L to open the palette menu, and select **Add Node to Canvas**. Press Enter. The node is now on the canvas.

Moving nodes on the canvas:

1. Press Tab to give focus to the palette arrow. (It does not matter whether the palette is open or closed.)
2. Press Tab two times. The focus is now on the canvas. (Note: There are no visual highlights to indicate the focus.)
3. Select a node on the canvas.

4. Press the decimal key (.) to select one of the move handles around the node.
5. Use the left, right, up, and down arrow keys to move the node to a new location.
6. Press Enter to confirm the move.

Connecting nodes:

1. Press Tab to give focus to the palette arrow. (It does not matter whether the palette is open or closed.)
2. Press Tab two times; the focus is now on the canvas. (Note: There are no visual highlights to indicate the focus.)
3. Select the node on the canvas from which you want to create a connection.
4. Press Shift+F10 to open a pop-up menu.
5. Use the arrow keys to select **Create Connection**. Press Enter. The Terminal Selection window opens.
6. Press Tab until the focus is in the **Select Terminal** field. Use the arrow keys to select a source (output) terminal.
7. Press Tab to select **OK**, press Enter to confirm your selection.
8. Use the arrow keys to select the input terminal of the target node. Press Enter to confirm the connection.

Selecting a node connection:

1. Press Tab to give focus to the palette arrow. (It does not matter whether the palette is open or closed.)
2. Press Tab two times. The focus is now on the canvas. (Note: There are no visual highlights to indicate the focus.)
3. Use the arrow keys to select a node that has a connection you want to select.
4. Use the slash (/) and backslash (\) keys to cycle through the connections.

Creating a bend point:

1. Select a node connection.
2. Press the decimal key (.) until the midpoint of the connection is selected.
3. Use the arrow keys to move the midpoint to a new location, and press Enter to confirm the move.

Reconnecting an existing connection to a new terminal:

1. Select a node connection.
2. Press the decimal key (.) until the end of the connection that you want to modify is selected.
3. Use the arrow keys to select a new source (input) terminal, and press Enter to confirm your selection.

Related concepts:

"Message flow node palette" on page 1027
The palette in the Message Flow editor contains all the built-in nodes, which are organized into categories, or drawers. A drawer is a container for a list of icons, such as the **Favorites** drawer.

Accessibility features help users who have a physical disability, such as restricted mobility or limited vision, to use information technology products successfully.

Workbench User Guide - Keyboard shortcuts for the Workbench, Java development tools, and the debugger

What's new if you are migrating from Version 6.0

Find out about new features in WebSphere Message Broker if you are migrating from Version 6.0.

See the following topics for high level information about new features in Version 6.1:

- "Web services"
- "Security" on page 6832
- "WebSphere Adapter nodes" on page 6833
- "File nodes" on page 6834
- "Other new nodes" on page 6835
- "Usability" on page 6836
- "Performance" on page 6837

Web services

Find out about the significant enhancements to Web services support including integrated support for WebSphere Service Registry and Repository, Web services security, and SOAP nodes.

SOAP nodes

- Full support for Web Services Provider and Consumer scenarios with 5 SOAP nodes:
  - Provider nodes:
    - "SOAPInput node" on page 4795
    - "SOAPReply node" on page 4819
  - Consumer nodes:
    - "SOAPRequest node" on page 4828
    - "SOAPAsyncRequest node" on page 4750
    - "SOAPAsyncResponse node" on page 4777
  - These nodes can be combined to provide a Web service intermediary.
- Processing of SOAP payload and headers are simplified by the following SOAP nodes:
  - "SOAPEnvelope node" on page 4786
  - "SOAPExtract node" on page 4790

Single SOAP domain for all Web Services message formats

- A SOAP parser and SOAP tree format.
- Supported message formats are SOAP 1.1, SOAP 1.2, SOAP with Attachments (SwA), and MTOM
- HTTP and HTTPS transports are supported.

Improved WSDL Integration

- Simplified import and generation of WSDL.
- Improved WSDL editor.
- WSDL is now an integral part of a message set.
- WSDL from a message set can be used directly in the creation and configuration of message flows, including support for drag-and-drop operations.

Web services extensions

- Support for WS-Addressing Endpoint References and Message addressing properties.
- Support for WS-Security authentication, encryption, and signing:
  - Authentication using username and password.
  - Authentication using X509 certificates.
  - Comprehensive encryption and signing algorithms.
  - Configuration using Policy Sets.

WebSphere Service Registry and Repository

- General concepts:
  - WebSphere Service Registry and Repository contains a variety of entities such as WSDL and XSD, together with their relationships and associated user properties.
  - Governance can be achieved by using the WebSphere Service Registry and Repository to determine Message Broker processing.
- Runtime interactions:
  - Message flows can use, access, and select specific WebSphere Service Registry and Repository entities.
  - Nodes to support retrieval of entities and services:
    - "EndpointLookup node" on page 4407
    - "RegistryLookup node" on page 4646

Related tasks:

"Processing Web service messages" on page 1601
Use WebSphere Message Broker nodes and services to connect to other Web services providers and consumers.

Security

WebSphere Message Broker provides enterprise-wide identity, authentication and authorization with Tivoli and LDAP. Click on the links to get more information about security in WebSphere Message Broker.

Security model

- WebSphere Message Broker now has a powerful runtime security model:
  - Supporting cross domains security processing.
  - Identity, Authentication and Authorization are native capabilities.
- Support for major policy decision points technologies including Tivoli and LDAP.

Identity

- A rich identity context can be defined including properties for source and mapped identities:
  - Type
  - Token
  - Password
  - Issued by
- MQ, HTTP, JMS, and SOAP transports can all provide identity information.
- Identity attributes can be set on input and output nodes.
- Identity information is also present in the Message Tree.

Security profiles

- You can configure different security profiles to differentiate between the security requirements for your different message flows and nodes.
- The security profile contains information on:
  - Authentication type and configuration.
  - Mapping type and configuration.
  - Authorization type and configuration.

Related concepts:

"Security overview" on page 351
When you are designing a WebSphere Message Broker application it is important to consider the security measures that are needed to protect the information in the system.

"Message flow security overview" on page 383
WebSphere Message Broker provides a security manager, which enables you to control access to individual messages in a message flow, using the identity of the message.

WebSphere Adapter nodes

You can connect to Enterprise Information Systems using the integrated WebSphere Adapter nodes. Highlights of the WebSphere Adapter nodes are provided in this topic. Click on the links to get more information about the WebSphere Adapter nodes.

Support for Enterprise Information Systems

- Inbound and outbound support is provided for the following Enterprise Information Systems (EIS):
  - SAP
  - Siebel
  - PeopleSoft
- Enterprise Metadata Discovery (EMD) is used for key data structure discovery and accelerated message set generation.
- The use of the native message broker tree provides high performance access to the EIS using WebSphere Adapters.
- TwineBall input and request nodes provided as sample nodes with their own EIS for learning about how the WebSphere Adapter nodes work.

SAP Adapter nodes

- Integrated SAP Adapter nodes enable you to interact with SAP applications:
  - "SAPInput node" on page 4676
  - "SAPRequest node" on page 4685

Siebel Adapter nodes

- Integrated Siebel Adapter nodes enable you to interact with Siebel applications:
  - "SiebelInput node" on page 4740
  - "SiebelRequest node" on page 4745

PeopleSoft Adapter nodes

- Integrated PeopleSoft Adapter nodes enable you to interact with PeopleSoft applications:
  - "PeopleSoftInput node" on page 4630
  - "PeopleSoftRequest node" on page 4635

TwineBall Adapter nodes

- Educational TwineBall Adapter nodes included to help you learn how the WebSphere Adapter nodes work:
  - "TwineballInput node" on page 4951
  - "TwineballRequest node" on page 4955

Related concepts:

"WebSphere Adapters nodes" on page 1914
A WebSphere Adapters node is a message flow node that is used to communicate with Enterprise Information Systems (EIS), such as SAP, Siebel, JD Edwards, and PeopleSoft.

Related reference:

"WebSphere Adapters properties" on page 4024
Reference information about the properties that you set for WebSphere Adapters nodes.

File nodes

You can access, process, and produce very large files with the file input and output nodes.

Built-in support for File processing

- Two nodes support inbound and outbound file processing:
  - "FileInput node" on page 4415
  - "FileOutput node" on page 4430

Large file handling

- Very large files can be processed without using excessive storage.

Record detection

- Comprehensive support for record detection:
  - Simple record detection: LF, CRLF, Fixed Length, and user-defined.
  - Parser: Use an existing message definition to identify record boundaries.
- Advanced record detection techniques enable simplified processing of large, repeating content files.

FTP support

- Configure FTP server properties on the FileInput and FileOutput nodes

Other new nodes

Find out about other new nodes in Version 6.1.

For information about new nodes in Version 7.0, see "What's new in Version 7.0?" on page 7.

Collector node

- Use the Collector node for complex condition processing.
- Coordinate messages from one or more sources.
- Wait for multiple input conditions and process when all satisfied.
- Messages matching the configured conditions are grouped into message collections for processing.
- Configurable conditions include:
  - Number of messages received.
  - Messages received in a set period of time.
  - Messages that match the contents of a correlation path.
  - Contents of messages that match a correlation pattern.

DatabaseRetrieve node

- Use the DatabaseRetrieve node to ensure that information in a message is up to date.
- Look up information from a database row using a message key, for example an account number, and store it in a message.
- Configure the value for the message key using XPath or ESQL syntax.

DatabaseRoute node

- Use the DatabaseRoute node to pass through or route messages using information from a database.
- Look up information from a database row using a message key, for example an account number, and store it in a message.
- Route the message for further processing based on these XPath values.
- Messages can be routed to multiple destinations if they are matched.

EmailOutput node

- Use the EmailOutput node to send an email message to one or more recipients from a message flow.
- This node builds and sends the email message to an SMTP server that you specify.
- Several options are available to generate the email message:
  - Configure an email with a statically-defined subject and text to a statically-defined list of recipients.
  - Configure a statically-defined email as a MIME message, with an attachment derived from the message tree.
  - Create a dynamic email message where the SMTP server, list of recipients, subject, text, and multiple attachments are determined at run time.
  - Pass a MIME message to the EmailOutput node by using the MIME parser to write the MIME message to a bit stream.

Route node	• Use the Route node to direct messages that meet certain criteria down different paths of a message flow. • XPath filter expressions are used to control processing. • Add extra output terminals to the node to route matching expressions down a selected processing path.

Related reference:

Use the Route node to direct messages that meet certain criteria down different paths of a message flow.

Usability

Find out about usability enhancements to help make developing applications and testing applications easier and faster. Click on the links to get more information about usability enhancements in WebSphere Message Broker.

Message Broker Toolkit improvements	• Quick Start wizards. • Simplified and improved application development wizards and editors. • Enhanced graphical mapping. • Simplified menus. • Display projects in working sets. • Categories for nodes on the node palette. • Enhancements to message flow debugging. • Enhancements to message broker archive editor. • Drag WSDL on to the message flow canvas to speed up development.
Improved test support in the Message Broker Toolkit	• Create a test configuration to rapidly test message flows. • Template test messages are generated if you are using a message set. • Monitor test execution events. • Test configurations can be saved for reuse and analysis. • Review and save test execution traces.

Samples

- Additional samples demonstrating functionality.
- Categories for Technology samples:
  - File processing
  - Message formats
  - Control and routing
  - Message transformation
  - Security
  - Transports and connectivity
  - Web services

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Help view

- See context-sensitive help and related topics links by using the Help view, even when you are using a wizard or dialog box.
- Search the documentation and access fully indexed help topics by using the Help view.

Related concepts:

"Quick Start wizards overview" on page 1409
You can use a Quick Start wizard to set up the basic resources that are required to develop a message flow application. The wizard sets up and gives names to containers for the resources that you need when you develop a message flow.

"Testing message flows by using the Test Client" on page 3144
You can test message flows in a safe environment before they are used on a production system by using the Test Client.

"Samples" on page 98
The WebSphere Message Broker Toolkit provides samples that show the features that are available in WebSphere Message Broker, and how to use them. This topic provides links to the information about the individual samples.

Related tasks:

"Creating a working set" on page 575
Create a working set to limit the number of resources that are displayed in the Broker Development view.

"Creating an application by using the Configure New Web Service Usage wizard" on page 1417
Use these instructions to generate a message flow by using the Configure New Web Service Usage wizard.

Related reference:

"Broker Archive editor" on page 6794
Use the Broker Archive editor to create and manage broker archive (BAR) files.

Performance

Find out about continued performance improvements in WebSphere Message Broker.

Parser Performance	• Significant XML message performance improvement. • XML validation performance improvement. • Opaque parsing for named XML elements to further improve performance. • Industry and existing message formats benefit from binary and string parser improvements. – Supporting cross domains security processing. – Identity, Authentication and Authorization are native capabilities. • Support for major policy decision points technologies including Tivoli and LDAP.
XSLT Performance	• XSLT engine now directly accesses message tree leading to major performance gains.
Storage Performance	• Compacted runtime storage leads to a significant reduction in the runtime storage usage.

WebSphere Message Broker Explorer views

The WebSphere Message Broker Explorer can be used to manage and administer your brokers and deployed resources.

The WebSphere Message Broker Explorer is an extension of the WebSphere MQ Explorer.

Typically, you carry out the following tasks in the WebSphere Message Broker Explorer:

- Setting up your brokers, including:
  - Creating brokers
  - Connecting to brokers
  - Removing brokers
- Adding and removing execution groups
- Editing and deploying broker archive (BAR) files
- Viewing the results of deployment and other broker activity in the Administration log
- Viewing and editing broker properties
- Viewing and editing security profiles and policy sets
- Viewing and editing configurable properties
- Viewing message flow accounting and statistics data

The WebSphere Message Broker Explorer provides several views that you can use to browse and update your broker resources.

If you cannot see the Brokers folder and Broker Archive Files folder in your MQ Explorer session, you have not installed the broker-specific plug-ins that are provided by WebSphere Message Broker Explorer. Close your WebSphere MQ Explorer session, follow the instructions to install the WebSphere Message Broker Explorer, then start the WebSphere MQ Explorer again.

Navigator view

The Navigator view shows folders that contain all the WebSphere MQ and broker resources that are currently available for you to administer from the WebSphere Message Broker Explorer. Right-click the WebSphere MQ folder to configure settings that affect the whole of WebSphere MQ on your system, and to perform other administration tasks.

The icons shown in the Navigator view indicate the status of the WebSphere MQ and broker objects.

Right-click the Brokers folder to create brokers and view existing broker resources. Right-click brokers, execution groups, and other broker objects to perform configuration and administration tasks.

Right-click the Broker Archive Files folder to view and deploy broker archive files to your brokers.

When you click a WebSphere MQ or broker object in the Navigator view, properties associated with the object are shown in the Content view.

Content view

The Content view shows properties associated with a selected object in the Navigator view. The properties that are shown depend on the associated object that has been selected. With some objects, you can double-click properties shown in the Content view to see more information, and to edit the properties.

Broker Statistics and Broker Statistics Graph views

Use the Broker Statistics and Broker Statistics Graph views in the WebSphere Message Broker Explorer to view snapshot accounting and statistics data as the broker produces it. For more information about viewing broker accounting and statistics data, see “Viewing message flow accounting and statistics data” on page 3300.

Policy Sets and Policy Set Bindings editor

Use the Policy Sets and Policy Set Bindings editor for editing, saving, importing, and exporting a policy set or binding. You can define all the WS-Security policies for a single node, or a set of nodes. The policy set can be associated by the administrator with either a message flow or a node. To access the Policy Sets and Policy Set Bindings editor, right-click the broker and click **Properties**. Select the **Security** tab and click **Policy Sets**. For more information about the Policy Sets and Policy Set Bindings editor, see “Policy Sets and Policy Set Bindings editor” on page 6841.

Security Profiles editor

Use the Security Profiles editor to specify whether identity propagation, authentication, authorization, and mapping are performed on the identity of messages in the message flow, and if so, which external security provider is used. For more information about Security Profiles, see “Security profiles” on page 387.

DataPower Security wizard

Use the DataPower Security wizard in the WebSphere Message Broker Explorer to configure an external DataPower appliance to handle the WS-Security Policy for your HTTP, HTTPS input, and SOAP nodes in your message flow. For more information about the DataPower Security wizard, see “Configuring DataPower security settings” on page 639.

Administration Log view

The Administration Log view shows administration log information for the broker selected in the Navigator view. The messages in the Administration log show the results from deployment or other actions you have performed on the broker. Double-click individual messages to read the full content of the messages in the Administration Log view.

You can save the messages from the Administration log, or permanently remove the administration log information messages.

For more information about the Administration Log view, see "Administration Log view."

Related reference:

"Administration Log view"
The Administration Log view shows administration requests and their results, changes made to objects, and the result of deployment actions on brokers. The Administration Log view can also describe configuration changes that have been automatically applied as a result of moving the broker from one version to another; for example, after applying maintenance.

"Broker Application Development perspective" on page 6784
The Broker Application Development perspective is the default perspective that is displayed when you start the WebSphere Message Broker Toolkit.

Administration Log view

The Administration Log view shows administration requests and their results, changes made to objects, and the result of deployment actions on brokers. The Administration Log view can also describe configuration changes that have been automatically applied as a result of moving the broker from one version to another; for example, after applying maintenance.

The Administration Log view is displayed at the bottom of the WebSphere Message Broker Explorer, and at the bottom of the Broker Application Development perspective in the WebSphere Message Broker Toolkit. If the Administration Log view is not displayed, you can show it by clicking **Window** > **Show View** > **Administration Log**.

To view messages from a broker, the broker must be started, and you must be connected to it. Click the broker in the Navigator view, to view deployment and other messages in the Administration log.

Right-clicking in the Administration Log view displays the following menu items:

- **Clear Administration Log**

  Clears all log entries from the Administration Log view and deletes the log entries from the broker. You cannot retrieve a message that has been cleared.

  Messages are automatically cleared when the broker starts.
- **Save Log As**

  Saves the messages to a filename and path of your choice. **Save Log As** does not remove messages from the Administration Log view or the broker.

Columns in the Administration Log view

Message

The Message column displays the message number.

Source

The Source column displays the reason the message was produced. Examples of sources are: Administration Request, Administration Result, and Change Notification.

Timestamp

The Timestamp column displays the date and time for each of the deployment messages from the broker.

Message detail

The Message detail column displays the detail of the deployment message. To view the full message, double-click the row containing the message. The message is displayed in a new window.

Related tasks:

"Viewing Administration log information" on page 1007
You can view Administration log information by using either the WebSphere Message Broker Explorer, or the CMP API.

"Saving Administration log information" on page 1008
Save the Administration log information that is written to the Administration Log view in the WebSphere Message Broker Explorer.

"Clearing Administration log information" on page 1009
Clear Administration log information to reduce the size of the log by using either the WebSphere Message Broker Explorer or the CMP API.

Policy Sets and Policy Set Bindings editor

The Policy Sets and Policy Set Bindings editor is the default editor for editing, saving, importing, and exporting a policy set or binding. You can define all the WS-Security policies for a single node, or a set of nodes. The policy set can be associated by the administrator with either a message flow or a node.

Launching the editor

You must connect the WebSphere Message Broker Explorer to a broker before you can edit policy sets and bindings.

To launch the Policy Sets and Policy Set Bindings editor, take the following steps:

1. Open the WebSphere Message Broker Explorer.
2. Right-click the broker with which you want to work, and click **Properties**.
3. Select the Security tab, and click **Policy Sets**.

The Policy Sets and Policy Set Bindings editor includes the following panels:

"Policy Sets and Policy Set Bindings editor: main panel" on page 6852

"Policy Sets and Policy Set Bindings editor: Authentication tokens panel" on page 6843

"Policy Sets and Policy Set Bindings editor: Message Level Protection panel" on page 6845

"Policy Sets and Policy Set Bindings editor: Message Part Protection panel" on page 6849

Policy set bindings

The administrator associates a policy set binding with a policy set when the policy set binding is added. Information about the binding is then displayed on the main panel of the policy set binding. You cannot change the policy set to which a binding is associated. You can delete the policy set binding independently of the policy set. However, deleting a policy set also deletes the associated policy set binding.

The Policy Set Bindings editor includes the following panels:

"Policy Sets and Policy Set Bindings editor: Authentication and Protection Tokens panel" on page 6854

"Policy Sets and Policy Set Bindings editor: Key Information panel" on page 6858

"Policy Sets and Policy Set Bindings editor: Kerberos settings panel" on page 6860

"Policy Sets and Policy Set Bindings editor: Message Part Policies panel" on page 6856

"Policy Sets and Policy Set Bindings editor: Message Expiration panel" on page 6862

"Policy Sets and Policy Set Bindings editor: Advanced panel" on page 6863

Related concepts:

"Policy sets" on page 774
Policy sets and bindings define and configure your WS-Security requirements, supported by WebSphere Message Broker, for the SOAPInput, SOAPReply, SOAPRequest, SOAPAsyncRequest, and SOAPAsyncResponse nodes.

Related tasks:

"Viewing and setting keystore and truststore runtime properties at broker level" on page 780
Configure the message broker to refer to a keystore, a truststore, or both, before deploying any message flows that require policy set or bindings for signature, encryption, or X.509 Authentication.

"Implementing WS-Security" on page 769
Configure authentication, XML encryption, XML signature, and message expiration by using the Policy Sets and Policy Set Bindings editor.

"Associating policy sets and bindings with message flows and nodes" on page 785
Use the Broker Archive editor to associate policy sets and bindings with message flows and nodes, so that they are available to the broker at run time.

Policy Sets and Policy Set Bindings editor: Authentication tokens panel

Use this panel, which is in the Policy Sets section of the editor, to create Username, X.509, SAML, and LTPA authentication tokens.

You can further configure X.509 tokens in the bindings panels, at which time they can be associated to key information.

Request and Response is always the same in any server/client relationship. A message from a client to the server is a request, and the message back from the server to the client is the response.

Fields

Table 292. Username authentication tokens

Field name	Description and valid options
Token name	Enter a user-defined name for the token policy. When you add a new row, this field defaults to `default_request`. You can select and change this value.
SOAP Message	One of the following values: • `Request`: a message from the client to the server. • `Response`: a message from the server to the client. When you add a new row, this field defaults to `Request`. You can select and change this value.
WS-Security Version	One of the following values: • `1.0` • `1.1` When you add a new row, this field defaults to `1.0`. You can select and change this value.

Table 293. X.509 authentication tokens

Field name	Description and valid options
Token name	Enter a user-defined name for the token policy. When you add a new row, this field defaults to `default_request`. You can select and change this value.
SOAP Message	One of the following values: • `Request`: a message from the client to the server. • `Response`: a message from the server to the client. When you add a new row, this field defaults to `Request`. You can select and change this value.

Table 293. X.509 authentication tokens (continued)

Field name	Description and valid options
WS-Security Version	One of the following values: • `1.0` • `1.1` When you add a new row, this field defaults to `1.0`. You can select and change this value.
Token Type	One of the following values: • X.509 Version 3 • X.509 PKCS7 • X.509 PKI Path Version 1 When you add a new row, this field defaults to `X.509 Version 3`. You can select and change this value.

Table 294. Other authentication tokens

Field name	Description and valid options
Token name	Enter a user-defined name for the token policy. When you add a new row, this field defaults to `default_request`. You can select and change this value.
Token Type	One of the following values: • SAML V1.1 pass-through • SAML V2.0 pass-through • LTPA V2 pass-through

Use this panel, which is in the Policy Set Bindings section of the editor, to further

configure any message part protection tokens defined in the associated policy set.

"Policy Sets and Policy Set Bindings editor: Key Information panel" on page 6858
Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any message level protection tokens that are defined in the associated policy set.

"Policy Sets and Policy Set Bindings editor: Kerberos settings panel" on page 6860
Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any Kerberos tokens that are defined in the associated policy set.

"Policy Sets and Policy Set Bindings editor: Message Expiration panel" on page 6862
Use this panel, which is in the Policy Set Bindings section of the editor, to define settings for message expiration. When message expiration is enabled, the message expires after the specified time interval.

"Policy Sets and Policy Set Bindings editor: Advanced panel" on page 6863
Use this panel, which is in the Policy Set Bindings section of the editor, to configure the **mustUnderstand** attribute in the security header of the consumer message. By default this check box is selected. If you unselect the check box, you can omit the **mustUnderstand=1** attribute from the security header. This attribute applies to consumer binding only.

Policy Sets and Policy Set Bindings editor: Message Level Protection panel

Use this panel, which is in the Policy Sets section of the editor, to apply signatures and encryption to the whole message, whether inbound or outbound.

Field	Description and valid options
Message level protection	Select this check box to specify that message level protection (using digital signatures or encryption) is required. If this check box is selected the other fields on this panel are available, and you can use the associated panels to define signature and encryption policies. This field is cleared by default.
Require signature confirmation	Select this check box to require signature confirmation.
Include timestamp in security header	Select this check box to include a time stamp in the header. You can specify where the time stamp is placed in the header by using **Security header layout**.
Security header layout	Specify rules for the layout of the security header: **Strict - declarations must precede use** The declarations in the header must precede the use. This is the default value. **Lax - order of contents can vary** The order of contents in the header can vary. **Lax but timestamp required first in header** The timestamp must be first in the header but the order of the remaining elements can vary. **Lax but timestamp required last in header** The timestamp must be last in the header but the order of the remaining elements can vary.

Tokens

Use this panel to define symmetric and asymmetric tokens to be used for signature and encryption.

Associate the asymmetric tokens that you define here with parts of the message that require signature and encryption. The tokens are also associated with private keys or X.509 Public Key Certificates (PKCs), which are part of public/private key pairs. Define one token for each distinct private key and PKC. The administrator can create any number of asymmetric X.509 tokens.

Associate the symmetric tokens that you define here with parts of the message that require signature and encryption. Only symmetric Kerberos tokens are supported. The administrator can create any number of Kerberos tokens.

You can edit this panel only if the **Message level protection** check box is selected on the Message Level Protection panel.

Field Name	Description and valid options
Token Name	Enter a name for the token.
Token Type	Either: **Initiator** The initiator of the request and response conversation, who owns the public/private pair of keys for which this token refers. **Recipient** The recipient of the request and response conversation, who owns the public/private pair of keys for which this token refers. When you add a new row, this field defaults to `Initiator`. You can change this value.

WS-Security Version	Either:
	`1.0`
	`1.1`
	When you add a new row, this field defaults to `1.0`. You can change this value.

Token Type (Asymmetric)	Any of: X.509 Version 3 X.509 PKCS7 X.509 PKI Path Version 1 When you add a new row, this field defaults to `X.509 Version 3`. You can change this value.
Token Type (Symmetric)	Any of: GSS_Kerberos5_AP_REQ Kerberos5_AP_REQ When you add a new row, this field defaults to `GSS_Kerberos5_AP_REQ`. You can change this value.

Algorithms

Use this panel to set the supported cryptographic and canonicalization algorithms. Algorithms are used to reconcile XML differences.

You can edit this panel only if **Message level protection** is selected on the Message Level Protection panel.

Field Name	Description and valid options
Algorithm suite	Select the algorithm that is required for performing cryptographic operations with symmetric or asymmetric key-based security tokens. All of the algorithm values in this field specify an algorithm suite. Algorithm suites and the values they each represent are detailed in the Web Services Security Policy Language (WS-SecurityPolicy) July 2005 Version 1.1 specification. The default algorithm is `Basic128Rsa15`. Basic256 Basic192 Basic128 TripleDes Basic256Rsa15 Basic192Rsa15 Basic128Rsa15 TripleDesRsa15 Basic256Sha256 Basic192Sha256 Basic128Sha256 TripleDesSha256 Basic256Sha256Rsa15 Basic192Sha256Rsa15 Basic128Sha256Rsa15 TripleDesSha256Rsa15
Canonicalization algorithm	Select the type of canonicalization. The following supported canonicalization algorithms are available in this list: Exclusive canonicalization Inclusive canonicalization The default value is `Exclusive canonicalization`.
Use security token reference transformation	Select this check box to specify that the security token reference is transformed. The default state is cleared.

This table defines values for the components of each algorithm suite.

Algorithm suite	Digest	Encryption	Symmetric Key Wrap	Asymmetric Key Wrap	Encryption key derivation	Signature key derivation	Minimum symmetric key length
Basic256	Sha1	Aes256	KwAes256	KwRsaOaep	PSha1L256	PSha1L192	256
Basic192	Sha1	Aes192	KwAes192	KwRsaOaep	PSha1L192	PSha1L192	192

By default this check box is selected. If you unselect the check box, you can omit the **mustUnderstand=1** attribute from the security header. This attribute

applies to consumer binding only.

Policy Sets and Policy Set Bindings editor: Message Part Protection panel

Use this panel, which is in the Policy Sets section of the editor, to define the parts of a message that encryption and signature apply to. Encrypted parts are used to protect message confidentiality. Signature parts are used for message integrity.

Create a row in this table for each part of the message that is to be encrypted or signed.

Field	Description and valid options
Name	Enter a user-defined name for the part. You can replicate the name to group several parts together; previously defined names are given as options.

Security type	Either:
	`Encryption`
	`Signature`

SOAP Message	Either: `Request`: a message from the client to the server. `Response`: a message from the server to the client.
Message Body	Determines that the whole message body is to be either encrypted or signed. If the whole message body is not to be encrypted or signed, further configuration is needed in one of the subsequent panels: Aliases, Qname, or Xpath.

Aliases

Use this panel to refer to an alias identified in a SOAPInput, SOAPRequest, or SOAPAsyncRequest node. The message flow with which this policy set will be associated in the Broker Archive editor must contain one of these nodes with an alias defined.

When developing a message flow containing one of these nodes, the developer might decide to identify a part of the message for which encryption or signature applies. This identification is done in the WS Extension properties panel of the node, by defining an XPath expression that refers to the part of the message and an associated alias name. The administrator then refers to that alias name by using this panel, and sets the correct security type for the alias on the corresponding Message Part Protection panel.

You can edit the Aliases panel only if **Message level protection** is selected on the Message Level Protection panel, and a part has been added in the Message Part Protection panel.

Field	Description and valid options
Name	Select a name from the list. All names created in the corresponding Message Part Protection panel are displayed.
Alias	Enter the alias value defined on the SOAP node property panel.

Qname

Use this panel to define namespaces, and optional elements within those namespaces, within the SOAP message header for which encryption or signature applies.

Namespaces are used primarily when WS-Addressing headers exist. If no local part name is specified to refer to specific elements, all elements in the SOAP message header for the specified namespace apply.

To use the QName selection method, the SOAP header elements must be the immediate children of the SOAP header. You cannot select header elements that are subelements of other elements in the SOAP header that is using QName. To select such elements, you must use an XPath expression.

You can edit the Qname panel only if **Message level protection** is selected on the Message Level Protection panel, and a part has been added in the Message Part Protection panel.

Field	Description and valid options
Name	Select a name from the list. All names created in the corresponding Message Part Protection panel are displayed.
Local part	An optional local part name within the namespace. In the following example, `securitybinding` is the namespace; within that namespace, `securityOutboundBindingConfig` and `securityInboundBindingConfig` are local parts. `<securitybinding:securityBindings xmlns:securitybinding="http://www.example.com/xmlns/ws-securitybinding"> <securitybinding:securityBinding name="application"> <securitybinding:securityOutboundBindingConfig/> <securitybinding:securityInboundBindingConfig> <securitybinding:encryptionInfo name="con_myMPPToken"> <securitybinding:keyEncryptionKeyInfo reference="con_myToken_encmyMPPToken_keyinfo"/> <securitybinding:encryptionPartReference reference="request:myMPPToken"/> </securitybinding:encryptionInfo> <securitybinding:keyInfo classname="com.ibm.ws.wssecurity.wssapi.CommonContentConsumer" name="con_auth_keyinfo" type="STRREF">`
NameSpace	The namespace of the SOAP message headers for which encryption and signature apply.

Xpath

Use this panel to define an XPath expression that refers to an element in the message to which encryption or signature applies.

Use this panel as an alternative, or in addition to, specifying XPath expressions and aliases directly on the nodes.

You cannot edit the first table in the Xpath panel, which shows five different prefix and namespaces values (based on the SOAP 1.1 specification). The second table allows the administrator to paste a fully qualified XPath expression directly into the XPath column, or select one from the list:

```
Envelope, Header, Security, Timestamp
Envelope, Header, Security
Envelope, Header, Security, Signature
```

Selecting one of the preceding options, causes the appropriate XPath expression to be created for both SOAP 1.1 (`http://schemas.xmlsoap.org/soap/envelope/`) and

SOAP 1.2 (`http://www.w3.org/2003/05/soap-envelope/`). For example, selecting `Envelope, Header, Security, Timestamp` results in the following XPath expressions being added to the policy set:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
    and local-name()='Envelope']
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
    and local-name()='Header']
/*[namespace-uri()=
    'http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-
    secext-1.0.xsd' and local-name()='Security']
/*[namespace-uri()=
    'http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-
    utility-1.0.xsd' and local-name()='Timestamp']

/*[namespace-uri()='http://www.w3.org/2003/05/soap-envelope'
    and local-name()='Envelope']
/*[namespace-uri()='http://www.w3.org/2003/05/soap-envelope'
    and local-name()='Header']
/*[namespace-uri()=
    'http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-
    secext-1.0.xsd' and local-name()='Security']
/*[namespace-uri()=
    'http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-
    utility-1.0.xsd' and local-name()='Timestamp']
```

Line breaks have been added to enhance readability; in the Toolkit each expression is pasted on a single line. The preceding expressions show the format of the fully qualified XPath expression syntax required by the broker. If you paste your own XPath expressions into the XPath column, ensure that they adhere to this syntax. When you paste your own XPath expressions, the prefix and namespace table is unavailable for substitution of values, and only a single expression is added to the policy set, instead of both a SOAP 1.1 and SOAP 1.2 variant.

You can edit the Xpath panel only if **Message level protection** is selected on the Message Level Protection panel, and a part has been added in the Message Part Protection panel.

Field	Description and valid options
Name	Select a name from the list. All names created in the corresponding Message Part Protection panel are displayed.
XPath	A user-defined value that the administrator assigns to an element in the SOAP message for encryption or signing.

Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any message part protection tokens defined in the associated policy set.

"Policy Sets and Policy Set Bindings editor: Key Information panel" on page 6858
Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any message level protection tokens that are defined in the associated policy set.

"Policy Sets and Policy Set Bindings editor: Kerberos settings panel" on page 6860
Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any Kerberos tokens that are defined in the associated policy set.

"Policy Sets and Policy Set Bindings editor: Message Expiration panel" on page 6862
Use this panel, which is in the Policy Set Bindings section of the editor, to define settings for message expiration. When message expiration is enabled, the message expires after the specified time interval.

"Policy Sets and Policy Set Bindings editor: Advanced panel" on page 6863
Use this panel, which is in the Policy Set Bindings section of the editor, to configure the **mustUnderstand** attribute in the security header of the consumer message. By default this check box is selected. If you unselect the check box, you can omit the **mustUnderstand=1** attribute from the security header. This attribute applies to consumer binding only.

Policy Sets and Policy Set Bindings editor: main panel

Use this panel, which is in the Policy Sets section of the editor, to associate a policy set binding with a policy set, and to specify whether the binding is a consumer or provider binding.

A policy set binding must always be associated with a policy set. When adding a policy set binding, the administrator must select, on the main panel, the policy set with which it is associated. Changing the associated policy set on the main panel removes any previous configuration for the policy set binding.

The administrator must also select whether the policy set binding is to be a `Consumer` or `Provider` binding.

Consumer

A consumer policy set binding can apply only to the following nodes:

SOAPRequest

SOAPAsyncRequest

SOAPAsyncResponse

Provider

A provider policy set binding can apply only to the following nodes:

SOAPInput

SOAPReply

If your message flow incorporates both sets of nodes, create two policy set bindings, one for the consumer nodes and the other for the provider nodes.

Associate both policy set bindings with the message flows in the BAR file editor. A policy set binding can be deleted independently of the policy set, but a policy set cannot be deleted when it has an associated policy set binding.

Use the `Compatibility Mode` option to control the internal name-spacing of the bindings schema. When `Compatibility Mode` is selected, the policy set and bindings are limited to supporting Username and X.509 tokens only. When you create policy set bindings, `Compatibility Mode` is selected automatically based on the version of the selected broker. It is also selected by default for policy set bindings that were created with previous versions of WebSphere Message Broker. If the policy set and bindings include new token types such as Kerberos, SAML pass-through, or LTPA pass-through, you must deselect the `Compatibility Mode` option. If you select `Compatibility Mode` on an existing policy set binding that includes new token types (such as Kerberos, SAML pass-through, or LTPA pass-through) a warning is displayed and these keys are ignored when the data is saved.

You can also use the panel to rename the policy set binding.

Fields

Field	Description and valid options
Name	Enter a user-defined name for the binding.
Associated Policy Set	Select the policy set with which this binding is to be associated.

This Policy Set Binding configuration will be used with:	Select the appropriate choice:
	`Consumer`
	`Provider`

Compatibility mode	When selected, this option enables Username and X.509 tokens only. Deselect this option to enable new token types such as Kerberos, SAML pass-through, or LTPA pass-through.

Use this panel, which is in the Policy Sets section of the editor, to define the parts of a message that encryption and signature apply to. Encrypted parts are used to protect message confidentiality. Signature parts are used for message integrity.

"Policy Sets and Policy Set Bindings editor: Authentication and Protection Tokens panel"
Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any X.509 authentication tokens defined in the associated policy set.

"Policy Sets and Policy Set Bindings editor: Message Part Policies panel" on page 6856
Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any message part protection tokens defined in the associated policy set.

"Policy Sets and Policy Set Bindings editor: Key Information panel" on page 6858
Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any message level protection tokens that are defined in the associated policy set.

"Policy Sets and Policy Set Bindings editor: Kerberos settings panel" on page 6860
Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any Kerberos tokens that are defined in the associated policy set.

"Policy Sets and Policy Set Bindings editor: Message Expiration panel" on page 6862
Use this panel, which is in the Policy Set Bindings section of the editor, to define settings for message expiration. When message expiration is enabled, the message expires after the specified time interval.

"Policy Sets and Policy Set Bindings editor: Advanced panel" on page 6863
Use this panel, which is in the Policy Set Bindings section of the editor, to configure the **mustUnderstand** attribute in the security header of the consumer message. By default this check box is selected. If you unselect the check box, you can omit the **mustUnderstand=1** attribute from the security header. This attribute applies to consumer binding only.

Policy Sets and Policy Set Bindings editor: Authentication and Protection Tokens panel

Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any X.509 authentication tokens defined in the associated policy set.

Fields

The table is prefilled, based on the following criteria

- Whether any X.509 authentication tokens exist in the associated policy set.
- Whether the SOAP message type of the authentication token is request or response.
- Whether this policy set binding is defined as being a consumer or provider.

Each authentication token identified as requiring further information is added to the table. An authentication token can require one of two types of additional information:

- Key information in the form of a key name and key alias, for lookup in the broker keystore.
- Verification information, which can be either `TrustAny` or `TrustStore`.

This table shows the different combinations of configuration for authentication tokens and whether key information or verification information is required:

Authentication X.509 tokens					
Policy set configuration	**Policy set bindings configuration**	**SOAP message**	**Key information**	**Key password**	**Verification information**
request	provider	inbound	N/A	N/A	required
response	provider	outbound	required	required	N/A
request	consumer	outbound	required	required	N/A
response	consumer	inbound	N/A	N/A	required

Where N/A is displayed in a field, no information is required. Where an authentication token is displayed, enter information in all fields that do not display N/A, so that the policy set binding can be generated correctly in accordance with the associated policy set.

Configure the broker to refer to a keystore and truststore. You might also need to configure passwords for these stores, and specific key passwords. See "Viewing and setting keystore and truststore runtime properties at broker level" on page 780 for further information.

Field name	Description and valid options
Authentication Token Name	Displays the names of all authentication X.509 tokens that require further configuration. The token name is displayed after either `request:` or `response:`, depending on the configuration of the token in the associated policy set.
Key name	The distinguished name (DN) that uniquely identifies the key in the keystore defined by the broker. For example `"CN=CommonName, O=Organisation, C=Country"`
Key Alias	The key alias of the key in the keystore defined by the broker. The broker also uses the key alias to look up the keystore password associated with this key. You define this in the broker using the **mqsisetdbparms** command.
Certificates	Either: **TrustAny** With no security profile set, all certificates are trusted. With a security profile set, the certificate is passed to the security provider defined by the security profile for it to establish trust. See "Setting up message flow security" on page 431. **TrustStore** Certificates are checked against the public key certificates in the truststore defined by the broker.

Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any Kerberos tokens that are defined in the associated policy set.

"Policy Sets and Policy Set Bindings editor: Message Expiration panel" on page 6862
Use this panel, which is in the Policy Set Bindings section of the editor, to define settings for message expiration. When message expiration is enabled, the message expires after the specified time interval.

"Policy Sets and Policy Set Bindings editor: Advanced panel" on page 6863
Use this panel, which is in the Policy Set Bindings section of the editor, to configure the **mustUnderstand** attribute in the security header of the consumer message. By default this check box is selected. If you unselect the check box, you can omit the **mustUnderstand=1** attribute from the security header. This attribute applies to consumer binding only.

Policy Sets and Policy Set Bindings editor: Message Part Policies panel

Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any message part protection tokens defined in the associated policy set.

The panel has two tables: the first table is for tokens that are used to encrypt message parts. The second table is for tokens used to sign message parts.

The tables are prefilled, based on the following criteria:

- Whether any message level protection tokens exist in the associated policy set.
- Whether the type of the message level protection token is initiator or recipient.
- Whether any message part protection tokens exist, and whether they define the message body, alias, Qname or XPath.
- Whether the SOAP message type of the message part protection token is request or response.
- Whether this policy set binding is defined as being a consumer or provider.

Each message part protection token that is added to one of the tables requires additional settings in either the Key information panel or the Kerberos Settings panel.

If you are using X.509 certificates, you must configure the Message Broker runtime environment to refer to a keystore and truststore. You might also need to configure passwords for these stores, and specific key passwords. See "Viewing and setting keystore and truststore runtime properties at broker level" on page 780 for further information.

If you are using Kerberos tickets, you must provide client credentials for accessing the Kerberos Key Distribution Center (KDC). You can provide these credentials either through a *Username and password* token type in the message tree properties folder, or by using the **mqsisetdbparms** command. For more information, see "Implementing WS-Security" on page 769.

Fields

Column Name	Description and valid options
Encryption Protection and Signature Protection	Displays the names of any Message Part Protection tokens that require further configuration. The token name is displayed after either `request:` or `response:`, depending on the configuration of the token in the associated policy set.

Timestamp	Either:
	`Yes`
	`No`

Nonce	Either:
	`Yes`
	`No`

Encryption	Either:
	`Data`
	`Key`

Token	Click this column to see a list of all message level protection tokens. Select the token that is to be associated with the message part protection token.
Token Type	Click this column to see a list of all token types. Token types can be specified for outbound policies and optionally for inbound policies. Select the appropriate token type from the list. Valid options are `STRREF`, `KEYID`, `EMB`, `KEYNAME`, and `X509ISSUER`.
Order	Defines the order that response message part policies should be processed in. N/A is displayed where this column is not required for certain combinations of tokens.

"Policy Sets and Policy Set Bindings editor: Message Expiration panel" on page 6862
Use this panel, which is in the Policy Set Bindings section of the editor, to define settings for message expiration. When message expiration is enabled, the message expires after the specified time interval.

"Policy Sets and Policy Set Bindings editor: Advanced panel" on page 6863
Use this panel, which is in the Policy Set Bindings section of the editor, to configure the **mustUnderstand** attribute in the security header of the consumer message. By default this check box is selected. If you unselect the check box, you can omit the **mustUnderstand=1** attribute from the security header. This attribute applies to consumer binding only.

"**mqsisetdbparms** command" on page 3954
Use the **mqsisetdbparms** command to associate a specific user ID and password (or SSH identity file) with one or more resources that are accessed by the broker.

Policy Sets and Policy Set Bindings editor: Key Information panel

Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any message level protection tokens that are defined in the associated policy set.

The table is prefilled based on the selections made in the message part policy panel. Different combinations of message level protection tokens and message part protection tokens require one or more of the following types of additional information:

- Key information in the form of a key name and key alias, for lookup in the broker keystore.
- Verification information, which can be either `trustany` or `truststore`.

Where a message level protection token is displayed, enter the required level of information so that the policy set binding can be generated correctly in accordance with the associated policy set.

Configure the broker to refer to a keystore and truststore. You might also need to configure passwords for these stores, and specific key passwords. See "Viewing and setting keystore and truststore runtime properties at broker level" on page 780 for further information.

Fields

Field name	Description and valid options
Token	Displays the names of any message level protection tokens that require further configuration. The token name is displayed after either `request:` or `response:`, depending on the configuration of the token in the associated policy set.
Key Name	The distinguished name (DN) that uniquely identifies the key in the keystore that is defined in the broker using the **mqsichangeproperties** command. For example `"CN=CommonName, O=Organisation, C=Country"`. When you require message level protection on the inbound signature token and the key is not known in advance, enter `Any` or leave blank.
Key Alias	The key alias of the key in the keystore defined by the broker. When you require message level protection on the inbound signature token and the key is not known in advance, enter `Any` or leave blank. You define the broker keystores using the **mqsisetdbparms** and **mqsichangeproperties** commands.
Trust	Either: **`TrustAny`** With no security profile set, all certificates are trusted. With a security profile set, the certificate is passed to the security provider defined by the security profile for it to establish trust. See "Setting up message flow security" on page 431. **`TrustStore`** Check against the public key certificates in the truststore defined by the broker.

Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any Kerberos tokens that are defined in the associated policy set.

"Policy Sets and Policy Set Bindings editor: Advanced panel" on page 6863
Use this panel, which is in the Policy Set Bindings section of the editor, to configure the **mustUnderstand** attribute in the security header of the consumer message. By default this check box is selected. If you unselect the check box, you can omit the **mustUnderstand=1** attribute from the security header. This attribute applies to consumer binding only.

Policy Sets and Policy Set Bindings editor: Kerberos settings panel

Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any Kerberos tokens that are defined in the associated policy set.

This panel is enabled only if the `Compatibility Mode` option in the Policy Sets and Policy Set Bindings editor: Main panel is deselected.

The table is pre-filled based on the Kerberos tokens in the associated policy. Symmetric tokens configured in the policy require additional information for consumer bindings only.

Fields

Field name	Description and valid options
Token	Displays the names of any Kerberos tokens that require further configuration.
Target Service Realm	The Kerberos target service realm. The default is a blank string, which results in the Kerberos default being used; other realms can be specified by changing this value.

Field name	Description and valid options
Target Service Name	The Kerberos target service name. The default is a blank string, which results in the default from the WSDL being used; other names can be specified by changing this value.
Target Service Host	The Kerberos target service host. The default is a blank string, which results in the Kerberos default being used; other hosts can be specified by changing this value. This option is not applicable to service providers.
Require Derived Keys	Specify derived keys. Valid values are *True* or *False*. The default is *True*.
Derived Key Token Namespace	The namespace to use for derived keys. The default value is *WS-SecureConversation 1.3*.
Key Size	The key size for derived keys. The default is *16*.
Acquire New Tokens	Specifies whether a new ticket must be acquired from the Key Distribution Center (KDC) for each request. Valid values are *True* or *False*. The default is *True*. This option is not applicable to service providers.

"Policy Sets and Policy Set Bindings editor: Advanced panel"
Use this panel, which is in the Policy Set Bindings section of the editor, to configure the **mustUnderstand** attribute in the security header of the consumer message. By default this check box is selected. If you unselect the check box, you can omit the **mustUnderstand=1** attribute from the security header. This attribute applies to consumer binding only.

Policy Sets and Policy Set Bindings editor: Advanced panel

Use this panel, which is in the Policy Set Bindings section of the editor, to configure the **mustUnderstand** attribute in the security header of the consumer message. By default this check box is selected. If you unselect the check box, you can omit the **mustUnderstand=1** attribute from the security header. This attribute applies to consumer binding only.

Fields

Field Name	Description and valid options
Include mustUnderstand attribute in security header	If you select this option, the **mustUnderstand** attribute of security header is created with the value 1. Otherwise, the security header is created with the value 0.
Check timestamp of response message	If you select this option, the **ws-security timestamp** response of the message is checked. If you unselect this option, the broker does not look for a timestamp in the response message. This option is valid when you are using a consumer binding and you have enabled the option **Include timestamp in security header** of the policy set Message Level Protection panel.

Troubleshooting

Use the reference information in this section to help you diagnose errors in WebSphere Message Broker.

Select the appropriate topic from the following list to diagnose problems and errors in WebSphere Message Broker:

- "Logs"
- "Trace" on page 6871
- "Trace logging from a user-defined C extension" on page 6693
- "Dumps" on page 6877
- "Abend files" on page 6880
- "WebSphere Message Broker event reports" on page 6883
- "WebSphere MQ facilities" on page 6890
- "Database facilities" on page 6891
- "Other sources of diagnostic information on z/OS" on page 6891
- "Solutions to similar problems" on page 6892
- "Resolving problems when installing" on page 3517
- "Resolving problems when uninstalling" on page 3525

Logs

If an error is reported by a WebSphere Message Broker component, start your investigations into its causes by looking at the product and systems logs to which information is written during component operation.

The information that is recorded in a log typically consists of a time stamp, which indicates when the error occurred, and a brief description of the error, which can be expanded to provide more details of the error. In some situations, a general error is written and is followed by a group of more specific errors that provide details about the general error.

When an error occurs, check STDOUT, STDERR, and the local error log first. These logs record information about major activities within the system. All components of WebSphere Message Broker provide diagnostic information whenever error or warning conditions affect broker operation. These conditions include:

- Unsuccessful attempts to write a message to a WebSphere MQ output queue
- Errors interacting with databases
- The inability to parse an input message

Additional logs that are specific to WebSphere Message Broker are written to record runtime errors, internal errors that are produced by the operating system or your code, or errors related to the work that you are doing in a particular perspective, all of which you can view using the WebSphere Message Broker Toolkit.

Data is written to the following logs:

- "Standard system logs" on page 6866
- "Local error logs" on page 6867
- "WebSphere Message Broker logs" on page 6867
- "WebSphere MQ logs" on page 6869
- "Database logs" on page 6870

You can view Administration log information by using either the WebSphere Message Broker Explorer, or the CMP API.

"Windows: Viewing the local error log" on page 3527
The Windows Event Viewer is where WebSphere Message Broker writes records to the local system. Use Windows system facilities to view this log.

"Linux and UNIX systems: Configuring the syslog daemon" on page 3529
On Linux and UNIX systems, all WebSphere Message Broker messages (other than messages that are generated by the command-line utilities) are sent to the syslog subsystem.

"z/OS: Viewing broker job logs" on page 3530
On z/OS, the broker writes messages to the appropriate z/OS system log and job logs. These messages might include information, warning, error, and severe messages to indicate various situations and events.

Related reference:

"Administration Log view" on page 6840
The Administration Log view shows administration requests and their results, changes made to objects, and the result of deployment actions on brokers. The Administration Log view can also describe configuration changes that have been automatically applied as a result of moving the broker from one version to another; for example, after applying maintenance.

Standard system logs

The broker writes information, warning, and error messages to standard output (STDOUT) and standard error (STDERR). The broker records this information for the execution group and for the broker admin agent (bipbroker process).

On some operating systems, the two standard logs are written to separate files, but the system might provide an option for the data to be recorded to a single merged file. On other systems, the two targets are defined to a single, and you might have the option to separate them. Check the documentation that is provided with your operating system for more details about STDOUT and STDERR.

Brokers write records to both STDOUT and STDERR. Always check the contents of the file or files when an error occurs.

Because the records are written whenever components are active, check occasionally that the location of the file or files has sufficient space, or trim the file contents on a regular basis.

The default location of STDOUT and STDERR depends on the operating system:

Operating system	Location of STDOUT and STDERR for broker admin agent	Location of STDOUT and STDERR for execution group
Linux UNIX Linux and UNIX systems	`/var/mqsi/components/`*`broker_name`*	`/var/mqsi/components/`*`broker_name`*`/`*`execution_group_uuid`*
Windows Windows systems	A single file, *`workpath`*`\components\`*`broker_name`*`\console.txt`, contains both STDOUT and STDERR data, generated by the admin agent, where *workpath* is the working directory defined for the broker.	A single file, *`workpath`*`\components\`*`broker_name`*`\`*`execution_group_uuid`*`\console.txt`, contains both STDOUT and STDERR data, where *workpath* is the working directory defined for the broker.
z/OS z/OS systems	The job log for the broker control address space.	The job log for the execution group address spaces.

The sample `BIPCRBK` file that is shipped with WebSphere Message Broker is included here for your reference.

Local error logs

WebSphere Message Broker components use the local error log (also known as the system log) to record information about major activities within the system. When an error occurs, check the local error log first.

Windows On Windows, the local error log is the Windows Event log (Application view).

UNIX On UNIX and Linux systems, the local error log is the *syslog*. Where syslog messages are sent depends on how you configure your UNIX or Linux system.

z/OS On z/OS, the local error log is the operator console.

Entries in the local error log that are generated by WebSphere Message Broker are identified in the following way:

- Windows On Windows: by events from the source `WebSphere Broker v****` and a message number in the form `nnnn`, where `****` is the current four-digit product version number.
- UNIX On UNIX: by a message number in the form `BIPnnnn`.
- z/OS On z/OS: by a started task ID, and a message number in the form `BIPnnnn`.

When a broker encounters an error, more than one message can be written to the local error log. Typically these messages start with a general message (for example, `Could not process a message`), and further messages give more details about the cause of the error (for example, `An error was detected while processing the following SQL statement`).

Windows On Windows, the event log can fill up; ensure that you have a log size that is sufficient, or that you have enabled circular logging.

Related concepts:

"z/OS: Viewing broker job logs" on page 3530
On z/OS, the broker writes messages to the appropriate z/OS system log and job logs. These messages might include information, warning, error, and severe messages to indicate various situations and events.

WebSphere Message Broker logs

WebSphere Message Broker writes information to a number of product-specific logs to report the results of actions that you take.

The following logs are used for reporting errors and events:

- "Eclipse error log"
- "Broker Administration log or Deployment log"
- "The Problems or Alerts view"
- "TDS log"

Eclipse error log:
The Eclipse error log captures internal errors from Eclipse and the code associated with your user-defined extensions. Check this log at run time for exceptions that you might have caused during development. When errors are triggered, they are added to the Error Log view of the Plug-in Development perspective, and you can double-click each one to examine details. Entries are sorted in reverse chronological order; that is, most recent first. You can open the Properties view to see entry details. You can also clear the view when you have fixed all the errors, although you cannot clear individual errors.

Some errors might be hierarchical; that is, a general entry for a complex problem might be followed by a number of child entries that list the individual problems in detail.

The same information that is shown in the Error Log view is stored in the `.log` file in the workspace directory. The default location for the workspace directory depends on your environment:

- Linux Linux on x86: *user_home_dir*/IBM/wmbt70/workspace/
- Windows Windows XP and Windows Server 2003: C:\Documents and Settings*user_ID*\IBM\wmbt70\workspace\
- Windows Windows 7, Windows Vista and Windows Server 2008: C:\Users*user_ID*\IBM\wmbt70\workspace\

The Eclipse error log shows errors that are generated only by the user ID that is working with that particular WebSphere Message Broker Toolkit session.

Broker Administration log or Deployment log:
Broker Administration log information is written to the Administration log. This log is stored and managed by the broker. The Administration log and displays messages about events that occur within the broker, such as the results of a deployment, or a change to broker properties. The messages can be information, errors, or warnings. You view the messages in the Administration Log view in the WebSphere Message Broker Explorer, and the Deployment log in the WebSphere Message Broker Toolkit.

The Problems or Alerts view:
Either the Problems or the Alerts view is displayed, depending on the perspective being used at the time.

- In the Broker Application Development perspective the Problems view shows information messages, warnings, and errors for message flow applications and associated resources, such as message flows, message sets, ESQL, Java, and mapping.

TDS log:
When you use the Tagged/Delimited String (TDS) physical format messages, you must conform to a number of rules that apply to the setting of values of properties. These rules are checked at deploy time, and, if an inconsistency is found, error

message BIP1836 is displayed in the WebSphere Message Broker Toolkit. Details of the error are written to the `TDS.log` file in the *install_dir*`/log` directory.

For more information about the rules for TDS physical format properties, see "TDS message model integrity" on page 6295.

Related concepts:

The Windows Event Viewer is where WebSphere Message Broker writes records to the local system. Use Windows system facilities to view this log.

Related reference:

"Local error logs" on page 6867
WebSphere Message Broker components use the local error log (also known as the system log) to record information about major activities within the system. When an error occurs, check the local error log first.

"WebSphere MQ logs"
WebSphere MQ messages are written to the local error log in the same way as WebSphere Message Broker messages.

"Database logs" on page 6870
Databases write severe error and warning conditions to the local error log (syslog). Typically, databases also write errors to a database log file, such as the `db2diag.log` file on DB2.

WebSphere MQ logs

WebSphere MQ messages are written to the local error log in the same way as WebSphere Message Broker messages.

WebSphere MQ messages start with the prefix AMQ followed by a number between 4000 and 9999. The number specifies from which part of WebSphere MQ the message originates:

4000 to 4999
: Windows user interface messages

5000 to 5999
: Installable services messages

6000 to 6999
: Common services messages

7000 to 7999
: WebSphere MQ product messages

8000 to 8999
: WebSphere MQ administration messages

9000 to 9999
: Remote messages

For a full explanation of each message, see the WebSphere MQ Library web page.

"Local error logs" on page 6867
WebSphere Message Broker components use the local error log (also known as the system log) to record information about major activities within the system. When an error occurs, check the local error log first.

"WebSphere MQ facilities" on page 6890
WebSphere Message Broker components depend on WebSphere MQ resources in many ways. You can therefore gain valuable information from the WebSphere MQ logs and events.

Database logs

Databases write severe error and warning conditions to the local error log (syslog). Typically, databases also write errors to a database log file, such as the `db2diag.log` file on DB2.

You can open the `db2diag.log` file in a text editor.

The following example shows a typical entry from the `db2diag.log` file:

```
Jun 18 15:02:53 bluj DB2[46827]: DB2(db2inst1.000(1))oper_system_services sqlobeep(2)
 reports:(3)
Jun 18 15:02:53 (4) bluj (5) DB2[46827(6)]: extra symptom string provided:(7) RIDS/sqlesysc_
Jun 18 15:02:53 bluj DB2[46827]:     data: (8)  54686973  20697320  616e2065  78616d70
Jun 18 15:02:53 bluj DB2[46827]:     data:   6c65206f  66206c6f  67676564  20646174
Jun 18 15:02:53 bluj DB2[46827]:     data:   61
Jun 18 15:02:53 bluj DB2[46827]: 2 piece(s) of dump data provided... to file(9) /u/db2inst1/
Jun 18 15:02:53 bluj DB2[46827]:         1. 'DUMP EXAMPLE #1' has been dumped (10)
Jun 18 15:02:53 bluj DB2[46827]:         2. 'DUMP EXAMPLE #2' has been dumped
```

The bold numbers in the example show various items in the log file:

(1) The instance name and node number

(2) The reporting component and function

(3) The probe ID and error and alert numbers

(4) A time stamp for when the event occurred

(5) The host name

(6) The process ID of the reporting process. Use the **ps** command to view

information about the process ID of the reporting process. For example, enter the following command to get information about the reporting process:

```
ps -fu 46827
```

(7) A symptom string that contains additional information about where and why the problem occurred

(8) A hexadecimal dump of data that includes return codes and other information that can be interpreted by your IBM Support Center

(9) Information about additional dump files. Larger structures and other binary data might be dumped to additional files. The name of the file is identified in the syslog file

(10) An entry to identify a piece of dump data

The database products used by WebSphere Message Broker also record information that might be useful if you have any problems with their access.

Trace

If you cannot get enough information about a particular problem from the entries that are available in the various logs, the next troubleshooting method to consider is using trace. Trace provides more details about what is happening while code runs. The information produced from trace is sent to a specified trace record, so that you or IBM support personnel can analyze it to discover the cause of your problem.

Trace is inactive by default, and must be explicitly activated by a command, or by the WebSphere Message Broker Toolkit.

There are two main types of trace available in WebSphere Message Broker: user trace and service trace. Typically, you utilize user trace for debugging your applications; you can trace brokers, execution groups, and deployed message flows. With service trace, you can activate more comprehensive broker tracing, and start tracing for the WebSphere Message Broker Toolkit. You can also trace the execution of all the commands described in "Commands" on page 3672.

When you start user tracing, you cause additional processing for every activity in the component that you are tracing. Large quantities of data are generated by the components. Expect performance to be affected while trace is active. You can limit this additional processing by being selective about what you trace, and by restricting the time during which trace is active.

Use the **mqsichangetrace** command to set the tracing characteristics for a broker.

"**mqsiformatlog** command" on page 3880
Use the **mqsiformatlog** command to process the XML log created by **mqsireadlog**. The command retrieves and formats any messages that the XML log contains into a form suitable for the locale of the user who runs the command.

"**mqsireadlog** command" on page 3905
Use the **mqsireadlog** command to retrieve trace records for the specified component.

"**mqsireporttrace** command" on page 3947
Use the **mqsireporttrace** command to display the trace options currently in effect. Trace can be run only against a broker, or any of its resources.

User trace

User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

For more information about logs, see "Logs" on page 6864.

Typically, you use user trace for debugging your applications, as it can trace brokers, execution groups, and deployed message flows.

You can use the WebSphere Message Broker Toolkit to control most of the trace activity that you need. You can also use the WebSphere Message Broker Toolkit to start and stop tracing on remote systems.

When you activate user trace, you cause additional processing for every activity in the component that you are tracing. Large quantities of data are generated by the components. Expect to see some effect on performance while user trace is active. You can limit this additional processing by being selective about what you trace, and by restricting the time during which trace is active.

The user trace log files:
When trace is active for any component, information is recorded in binary form.

The location of the trace logs depends on your environment:

Windows **Windows**

If you set the work path by using the **-w** parameter of the **mqsicreatebroker** command, the location is `workpath\log`.

If you have not specified the broker work path, the default location is `%ALLUSERSPROFILE%\Application Data\IBM\MQSI\common\log` where `%ALLUSERSPROFILE%` is the environment variable that defines the system working directory. The default directory depends on the operating system:

- On Windows XP and Windows Server 2003: `C:\Documents and Settings\All Users\Application Data\IBM\MQSI\common\log`
- On Windows Vista and Windows Server 2008: `C:\ProgramData\IBM\MQSI\common\log`

The value might be different on your computer.

Linux UNIX **Linux and UNIX**

`/var/mqsi/common/log`

z/OS **z/OS**

`/component_filesystem/log`

The file names reflect the component and subcomponent for which the trace is active. For example, the broker name and unique execution group identifier form part of the file name when you are tracing activity within that execution group.

For example, if you have created a broker called `MB7BROKER`, you might see the following files in the log subdirectory:

```
MB7BROKER.682ec116-dc00-0000-0080-ce28a236e03d.userTrace.bin.1
MB7BROKER.682ec116-dc00-0000-0080-ce28a236e03d.userTrace.bin.2
```

You cannot view these files directly; use the commands that are provided to access the trace information and convert it to a viewable format. Use the **mqsireadlog** command to retrieve the trace log for the specified component. Issue the command on the computer on which the log was generated. You can specify the output to be directed to a file, which is independent of operating system, and can be transferred to other systems for browsing or formatting by using the **mqsiformatlog** command.

Using a Trace node:
If you include a Trace node in your message flows when you are developing and testing them, this option not only gives you the ability to trace messages and activity in the flow, but also allows you to specify an alternate target file for the trace contents to isolate the detail in which you are interested. For details of how to use and configure a Trace node, see the "Trace node" on page 4942 topic.

"**mqsireporttrace** command" on page 3947
Use the **mqsireporttrace** command to display the trace options currently in effect. Trace can be run only against a broker, or any of its resources.

Service trace

Service trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Event Log or to user trace. Service trace is inactive by default; you must activate it explicitly by using a command.

With service trace, you can activate more comprehensive broker tracing, and start tracing for the WebSphere Message Broker Toolkit. You can also trace the execution of all the commands described in "Commands" on page 3672, including the trace

commands themselves. Use the **mqsichangetrace** command to work with service trace; you cannot use the WebSphere Message Broker Toolkit.

Activate service trace only when you receive an error message that instructs you to, or when directed to do so by your IBM Support Center.

When you activate service trace, you cause additional processing for every activity in the component that you are tracing. Large quantities of data are generated by the components. Expect performance to be affected while service trace is active. You can limit this additional processing by being selective about what you trace, and by restricting the time during which trace is active.

The location of the trace logs depends on your environment:

Windows **Windows**

If you have set the work path by using the **-w** parameter of the **mqsicreatebroker** command, the location is `workpath\log`.

If you have not specified the broker work path, the default location is `%ALLUSERSPROFILE%\Application Data\IBM\MQSI\common\log` where `%ALLUSERSPROFILE%` is the environment variable that defines the system working directory. The default directory depends on the operating system:

- On Windows XP and Windows Server 2003: `C:\Documents and Settings\All Users\Application Data\IBM\MQSI\common\log`
- On Windows Vista and Windows Server 2008: `C:\ProgramData\IBM\MQSI\common\log`

The value might be different on your computer.

Linux UNIX **Linux and UNIX**

`/var/mqsi/common/log`

z/OS **z/OS**

`/component_filesystem/log`

The directory to which the service trace logs are written must be able to hold all the logs for that computer. You might want to place it on a separate file system, if allowed by your system operator.

Related concepts:

"Trace" on page 6871
If you cannot get enough information about a particular problem from the entries that are available in the various logs, the next troubleshooting method to consider is using trace. Trace provides more details about what is happening while code runs. The information produced from trace is sent to a specified trace record, so that you or IBM support personnel can analyze it to discover the cause of your problem.

"Logs" on page 6864
If an error is reported by a WebSphere Message Broker component, start your investigations into its causes by looking at the product and systems logs to which information is written during component operation.

Related tasks:

"Starting service trace" on page 3534
Service trace is used to get detailed information about your environment for use by your IBM Support Center.

"Checking service trace options" on page 3537
Use the **mqsireporttrace** command or the WebSphere Message Broker Explorer to

check what tracing options are currently active for your brokers.

"Changing service trace options" on page 3538
Use the **mqsichangetrace** command or the WebSphere Message Broker Explorer to change the service trace options that you have set.

"Retrieving service trace" on page 3542
Use the **mqsireadlog** command to access the trace information recorded by the service trace facilities.

"Stopping service trace" on page 3540
Use the **mqsichangetrace** command or the WebSphere Message Broker Explorer to stop an active service trace.

"Formatting trace" on page 3543
Use the **mqsiformatlog** command to format trace information.

"Interpreting trace" on page 3546
Use the information in a formatted trace file to identify unexpected behavior.

"Clearing old information from trace files" on page 3548
If the component that you are tracing has stopped, you can delete its trace files from the log subdirectory of the WebSphere Message Broker home directory.

Related reference:

"User trace" on page 6873
User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

"cciUserTrace" on page 6678
Use cciUserTrace to write a message from a message catalog (with inserts) to user trace. A message is also written to service trace, if service trace is active.

"cciServiceTrace" on page 6663
Writes a message to service trace, if service trace is active.

"Commands" on page 3672
All WebSphere Message Broker Toolkit and runtime commands that are provided on distributed systems are listed, grouped by function, with references to command details.

"**mqsichangetrace** command" on page 3822
Use the **mqsichangetrace** command to set the tracing characteristics for a broker.

"**mqsiformatlog** command" on page 3880
Use the **mqsiformatlog** command to process the XML log created by **mqsireadlog**. The command retrieves and formats any messages that the XML log contains into a form suitable for the locale of the user who runs the command.

"**mqsireadlog** command" on page 3905
Use the **mqsireadlog** command to retrieve trace records for the specified component.

"**mqsireporttrace** command" on page 3947
Use the **mqsireporttrace** command to display the trace options currently in effect. Trace can be run only against a broker, or any of its resources.

Dumps

Under exceptional circumstances, Windows MiniDumps, UNIX core dumps, or z/OS SVC or core dumps might be produced.

For example, if errors occur in the broker executable files, or in the infrastructure main program. The amount and complexity of data produced in these cases typically requires the assistance of your IBM Support Center, see “Contacting your IBM Support Center” on page 3563.

Dumps on Windows

Windows MiniDumps might be produced by broker processes in extreme cases. Windows MiniDumps are never produced during typical operation.

Windows MiniDumps are accompanied by a BIP2111 error message (a message broker internal error) that contains the path to the MiniDump file in your `workpath/errors` directory. MiniDump files have the extension `.dmp`. You can analyze these MiniDumps by using a suitable debugger; contact IBM for assistance.

Dumps on UNIX systems

UNIX core dumps are produced by broker processes in extreme cases. UNIX core dumps are never produced during typical operation.

A BIP2060 error message (the execution group stopped unexpectedly) might be produced. Look in the directory where the broker was started to find the core dump file. If this directory is not writable by the service ID, the core dumps are produced in the service user ID's home directory.

You can analyze these core dumps by using a suitable debugger; contact IBM for assistance.

Dumps on WebSphere Message Broker for z/OS

A broker produces an SVC dump that is written to a data set that is named by using the system defined naming convention.

The format of this data set name can be displayed by using the dump options command `/D dump`.

Typically, the name definition has the following format:

```
DUMP.&SYSNAME..&JOBNAME..D&DATE..T&LTIME..S&SEQ
```

and, for example, this format displays a resolved name of:

```
DUMP.MVS1.MQ83BRK.D080924.T171755.S00005
```

An SVC dump that is caused by z/OS or WebSphere Message Broker for z/OS is written to the system's dump directory, and can be formatted with IPCS. The name of the dump is listed on the z/OS syslog.

The following example shows the format of the output that you receive:

```
 IEA794I SVC DUMP HAS CAPTURED:
         DUMPID=006 REQUESTED BY JOB (MQ83BRK )
         DUMP TITLE=MQ83BRK ,ABN=S0C4-00000004,C=M7500.600.BRKR
 IEA611I COMPLETE DUMP ON DUMP.MVS1.MQ83BRK.D080924.T171851.S00006
         DUMPID=006 REQUESTED BY JOB (MQ83BRK )
         FOR ASID (00B8)
         INCIDENT TOKEN: PLEXS    MVS1     09/24/2008 16:19:11
         ID = MQ83BRK ,ABN=S0C4-00000004
```

Under some circumstances, SVC dumps are not produced. Typically, dumps are suppressed because of time or space problems, or security violations.

In addition, you can suppress SVC dumps that duplicate previous dumps by using z/OS dump analysis and elimination (DAE), for example, use the command **SET DAE=xx**. (DAE is a z/OS service that enables an installation to suppress SVC dumps and ABEND SYSDUMP dumps that are not required because they duplicate previously written dumps.)

The following example shows a message on the z/OS syslog, indicating whether duplicates of SYSMDUMPs are suppressed:

```
   IEA995I SYMPTOM DUMP OUTPUT 504

```

The *MVS Diagnosis: Tools and Service Aids* manual provides details about using z/OS dump analysis and elimination.

In extreme cases, you might instead receive a core dump, which is written to the started task user's directory. The maximum size of a core dump is defined through MAXCORESIZE in the BPXPRMxx parmlib member. The IBM supplied default is 4 MB. To ensure the completeness of a core dump of any WebSphere Message Broker for z/OS address space, change the value to 2 GB. The started task user's directory must then have at least this size.

To make use of these core dumps, copy them to a partitioned data set by using the **TSO/E OGET** command. Allocate the data set as a sequential data set with a logical record length (LRECL) of 4160 and a record format of FBS. Specify a primary allocation of at least 500 cylinders and a secondary allocation of at least 250 cylinders. The data set must be transferred in binary format. For example:

```
oget '/u/user_directory/coredump.pid' 'mvs_dataset_name.pid' bin
```

To ensure that all of the diagnostic information is collected in these extreme cases, specify the following dump options in SYS1.PARMLIB:

- `Member IEADMP* SDATA=(LSQA,TRT,CB,ENQ,DM,IO,ERR,SUM)`
- `Member IEADMR* SDATA=(NUC,SQA,LSQA,SWA,TRT,RGN,LPA,CSA,SUM,GRSQ)`

WebSphere Message Broker for z/OS abends

Abend code

2C1

Explanation

The WebSphere Message Broker for z/OS infrastructure encountered a severe internal error. The reason code helps the IBM Support Center to identify the source of the error. It has the format `X'ppmmnnnn'`, where `pp`

defines the part within the infrastructure where the error occurred, `mm` defines the specific location of the error, and `nnnn` defines a recursion index.

You can resolve the following reason codes but you must refer other codes to the IBM Support Center.

ABN=S2C1-0001xxxx Error opening a file system file
The file system component might be full or the broker user ID might not have the correct permissions to access files or directories in the file system component.

ABN=S2C1-0113xxxx Region size too small

Source
WebSphere Message Broker for z/OS

System Action
The system might issue a dump.

Programmer Response
None

System Programmer Response
Search the problem-reporting databases for a fix for the problem. If no fix exists, contact the IBM Support Center, providing the reason code and, if present, the dump.

Related tasks:

"Checking for dumps" on page 3559
If a dump occurs on your system, an error message is produced.

"Using the DUMP command on z/OS" on page 3560
Follow the steps in this task to use the DUMP command on z/OS.

"Contacting your IBM Support Center" on page 3563
If you cannot resolve problems that you find when you use WebSphere Message Broker, or if you are directed to do so by an error message generated by WebSphere Message Broker, you can request assistance from your IBM Support Center.

Related reference:

"Local error logs" on page 6867
WebSphere Message Broker components use the local error log (also known as the system log) to record information about major activities within the system. When an error occurs, check the local error log first.

"Abend files"
When a process does not end normally an abend file is generated.

Abend files

When a process does not end normally an abend file is generated.

When a process does not end normally, an abend entry is made in the syslog, or the Windows Event log. If there is more data to be written than is appropriate for the log, a new file is created to contain it, and the log entry tells you the file name. You need to send the file to your IBM Support Center for analysis.

Abend files are never generated during normal operation; always involve your IBM Support Center when they do occur.

The new file is called:

Windows **Windows**
`filename.abend`; if you have set the workpath using the **-w** parameter of the **mqsicreatebroker** command, the location is `workpath\common\errors`. If you have not specified the broker workpath, the workpath can be resolved by issuing the command **echo %MQSI_WORKPATH%** from the installation's Command Console. If it is not possible to write to this directory, the file is put in the `workpath\common\log` directory, but in either case the message in the Event Log tells you where to find it.

UNIX **UNIX**
filename`.abend` in the `/var/mqsi/common/errors` directory.

z/OS **z/OS**
filename`.abend` in the `/<component_HFS>/common/errors` directory.

where *filename* is a unique dynamically-allocated name, as given in the syslog or Event Log message.

The abend file might provide a stack for the failing thread; this might help you to identify problems in the plug-in code when an abend occurs here. In which case, for z/OS, this stack will be available in a CEEDUMP file in the same directory as the abend file by default.

Each abend file contains a header that includes the following sections:

- Product details (the broker product that is being used)
- Operating System
- Environment (including the installation path and the process ID that contains the failing thread)
- Deployment (including the component and, where applicable, the execution group name and UUIDs)
- Build Information (for IBM internal use)
- Failure Location (including the time of failure and, where applicable, the message flow name)

The content and organization of the abend file and its header are subject to change without notice.

Periodically clear any unwanted abend files from the errors or z/OS log directory. You can do this by moving the files to an archive, or by deleting them when they are no longer needed. This ensures that the workpath does not become full; in extreme conditions, your system performance can be degraded if significant space is being used up with old abend files.

Related tasks:

"Contacting your IBM Support Center" on page 3563
If you cannot resolve problems that you find when you use WebSphere Message Broker, or if you are directed to do so by an error message generated by WebSphere Message Broker, you can request assistance from your IBM Support Center.

Abend in a user-defined extension

Information that applies only when you have written your own C language user-defined extension.

If the broker on WebSphere Message Broker for z/OS abends, and you have a user-defined extension written in the C programming language, you can use the traceback to locate the source of the problem.

The traceback is placed into a CEEDUMP file, which resides in the `<component_HFS>/common/errors` directory.

Each traceback is preceded by the date, time, and unique identifier; for example, `CEEDUMP file - CEEDUMP.20080924.171754.84017230`

Consider the following example trace in the CEEDUMP file:

```
Traceback:

WebSphere Message Broker event reports

Event messages are published by a broker in response to certain conditions that occur while the broker is active.

Reports are raised in response to the following circumstances:

- "WebSphere Message Broker event reports: configuration changes" on page 6885
- "WebSphere Message Broker event reports: operational information" on page 6886

Further information about events is provided in the following topics:

- "WebSphere Message Broker event reports: general architecture" on page 6884
- "WebSphere Message Broker event reports: notification message schema" on page 6887

The events are published on a series of system-defined topics. The body of the message contains additional information in XML format. Every message is generated in code page 1208.

The following set of events can be reported:

Configuration changes

- An execution group has been created, changed, or deleted
- A message flow has been created, changed, or deleted

Operational information

- A broker has been started or stopped
- A message flow has been started or stopped

Related tasks:

"Creating a broker" on page 611
You can create brokers on every platform that is supported by WebSphere Message Broker. The broker runs as a 64-bit application on all platforms except Linux on x86 and Windows on x86.

WebSphere Message Broker event reports: general architecture

Brokers publish messages on reserved topics after significant events within the broker. By subscribing to these topics, a client can be informed when these events occur.

For each topic, the type of event and message body are explained. The body of these messages is in XML format.

An event publication can contain more than one entry if the topic is the same (for example, if several message flows are created in the same operation).

The general form of the system topics on which events are published is:

`$SYS/Broker/`*`broker_name`*`/`*`event_type`*`/...`

where:

broker_name
: is the name of the broker issuing or raising this event.

event_type
: is the type of the event and is one of:
  - Configuration
  - Neighbor
  - Subscription
  - Topic
  - Status
  - Expiry

This specification of topics helps clients to filter events, based on the broker from which the event originated and the type of event. The clients register subscriptions for these topics to receive the reports.

For specific events, additional information is included in the topic to help filter on the specific object that raised the event. The inclusion of the string `Broker` at the second level of the topic hierarchy allows for future extension to additional subsystems that publish system management events through the broker.

WebSphere Message Broker event reports: configuration changes

Configuration changes include changes to the operational configuration of a single broker or brokers (for example, the addition or removal of a message flow).

This information is described in "Changes to the local configuration of the broker."

Related tasks:

"Creating a broker" on page 611
You can create brokers on every platform that is supported by WebSphere Message Broker. The broker runs as a 64-bit application on all platforms except Linux on x86 and Windows on x86.

Changes to the local configuration of the broker:

An event is published to a system topic when an entity is created, changed, or deleted.

Notification of changes to the broker's configuration (create, change, or delete entities) is provided by publishing events on the following system topic:

`$SYS/Broker/`*`broker_name`*`/Configuration/ExecutionGroup/`*`exec_grp_name`*

where:

broker_name
: is the name of the broker issuing this message

exec_grp_name
: is the name of the execution group for which the configuration has changed

One such event is published for each configuration request message that is received and processed by an execution group within the broker and can thus contain information that reflects complex configuration changes to multiple entities within the broker.

The body of each publication is the part of the configuration request that causes the event to be triggered. If an execution group is renamed, subsequent publications that report the state of that execution group use the new name.

These events are published non-persistently as non-retained publications.

Only create, change, and delete actions on the message flow are reported.

Configuration change:
The following figure shows an example notification when a message flow is created. The number of attributes mentioned in the example can vary.

```
<Broker uuid="1234" label="Broker1" version="1">
 <ExecutionGroup uuid="2345">
  <Create>
   <MessageFlow uuid="3456" label="MessageFlow1">
    <!-- Create the Input and Output Nodes -->
    <ComIbmMqInputNode uuid="4567"
     queueName="InputQueue1" label="InputNode1" />
    <ComIbmMqOutputNode uuid="5678"
                    queueName="OutputQueue1"
                    label="OutputNode1"/>
    <ComIbmMqOutputNode uuid="6789"
     queueManagerName="QueueManager1"
     queueName="OutputQueue2"
                    label="OutputNode2"/>
    <!-- Create the filter -->
    <ComIbmFilterNode uuid="7890"
                      filterExpression="Company=IBM"
                      label="FilterNode1"/>
    <!-- Connect them together -->
    <Connection sourceNode="4567"
     sourceTerminal="out"
     targetNode="7890" targetTerminal="in"/>
    <Connection sourceNode="7890"
     sourceTerminal="true"
     targetNode="5678" targetTerminal="in"/>
    <Connection sourceNode="7890"
     sourceTerminal="false"
     targetNode="6789" targetTerminal="in"/>
   </MessageFlow>
  </Create>
 </ExecutionGroup>
</Broker>
```

Related tasks:

"Creating a broker" on page 611
You can create brokers on every platform that is supported by WebSphere Message Broker. The broker runs as a 64-bit application on all platforms except Linux on x86 and Windows on x86.

WebSphere Message Broker event reports: operational information

Changes to the processing state of a broker or an individual message flow publish events with predefined system topics.

The following system topics are used:

`$SYS/Broker/`*`broker_name`*`/Status`

`$SYS/Broker/`*`broker_name`*`/Status/ExecutionGroup/`*`exec_grp_name`*

where:

broker_name
is the name of the broker whose execution state has changed

exec_grp_name
is the name of the execution group that contains the message flow whose execution state has changed

The body of each publication is an XML message that gives additional information concerning the state change that caused the event to be triggered, specifically indicating whether the entity has been started or stopped.

For example, starting a message flow generates the following message:

```
<Broker uuid="1234" label="Broker1" version="1">
<ExecutionGroup uuid="5678">
  <Start>
   <MessageFlow uuid="7812"/>
  </Start>
 </ExecutionGroup>
</Broker>
```

Stopping a broker generates the following message body:

```
<Broker uuid="1234" label="Broker1" version="1">
 <StatusChange state="Stopped"/>
</Broker>
```

Currently, the only states that are notified for both brokers and message flows are Started and Stopped.

These events are nonpersistent, retained publications.

Related tasks:

"Creating a broker" on page 611
You can create brokers on every platform that is supported by WebSphere Message Broker. The broker runs as a 64-bit application on all platforms except Linux on x86 and Windows on x86.

WebSphere Message Broker event reports: notification message schema

The structure of all valid notification messages.

This example describes the structure of the messages only. It does not define about how many elements are in the messages or the order in which they appear. The rules for the number of elements are:

- One broker element
- Other elements: zero, one, or more

There are no rules for the order of notification messages.

In this example, `<...>` denotes an XML element, and `???` indicates where individual class names are allowed:

```
<Broker identifier label>
. <ExecutionGroup identifier>
. . <Create>
. . . <MessageFlow message_flow_identifier message_flow_attributes>
. . . . <???Node node_identifier node_attributes>
. . . . <Connection connection_identifier>
. . <Change>
. . . <MessageFlow message_flow_identifier message_flow_attributes>
. . <Delete>
. . . <AllMessageFlows>
. . . <MessageFlow message_flow_identifier>
. . <Start>
. . . <AllMessageFlows>
. . . <MessageFlow message_flow_identifier>
. . <Stop>
. . . <AllMessageFlows>
. . . <MessageFlow message_flow_identifier>
```

You can create brokers on every platform that is supported by WebSphere Message Broker. The broker runs as a 64-bit application on all platforms except Linux on x86 and Windows on x86.

WebSphere MQ facilities

WebSphere Message Broker components depend on WebSphere MQ resources in many ways. You can therefore gain valuable information from the WebSphere MQ logs and events.

WebSphere MQ logs

The WebSphere MQ product logs can be useful in diagnosing errors that occur in your broker network. For example, if the WebSphere Message Broker Toolkit cannot communicate with a broker, the channels that connect them might be wrongly configured, or experiencing network problems.

On distributed systems, operational messages in a user-readable format (such as `queue manager started`), are written to the error logs in the errors subdirectory of the queue manager directory.

FFST files

First Failure Support Technology (FFST) records are normally severe, unrecoverable errors, and indicate either a configuration problem with the system, or a WebSphere MQ internal error. FFST files are named `AMQnnnnn.mm.FDC`, where `nnnnn` is the ID of the process that is reporting the error, and mm is a sequence number.

On Windows, records are written to the *install_dir*`\errors` directory. Operational messages and FFST records are also written to the Event log.

On UNIX and Linux systems, records are written to the `/var/mqm/errors` directory. WebSphere MQ writes one line for each FFST containing the name of the FFST file to the syslog, but no operational messages.

WebSphere MQ events

WebSphere MQ provides information about errors, warnings, and other significant occurrences in queue managers in the form of instrumentation event messages.

You can activate event activity by using the MQSC or PCF interfaces in three areas:

- Queue manager events
- Performance events
- Channel events

When active, these event messages are sent to event queues that can be monitored or triggered. You might find it appropriate to activate WebSphere MQ events when you are investigating the performance, or unexpected behavior, of your broker network.

"Using logs" on page 3526
There are a variety of logs that you can use to help with problem determination and troubleshooting.

Related reference:

"Troubleshooting" on page 6864
Use the reference information in this section to help you diagnose errors in WebSphere Message Broker.

"WebSphere MQ logs" on page 6869
WebSphere MQ messages are written to the local error log in the same way as

WebSphere Message Broker messages.

Database facilities

The database products used by WebSphere Message Broker also record information that might be useful if you have any problems with their access.

Refer to the database product documentation for details of logs and other problem determination options.

Database logs

DB2 has a number of facilities that assist you with problem diagnosis and recovery. For example, there are the error logs, `db2diag.log` on distributed systems, and `db2alert.log` on z/OS, that contain error and alert information recorded by various components of the DB2 product. Refer to the *DB2 Troubleshooting Guide* for comprehensive information about what options are available, how to use them, and how to interpret the information provided.

Other database products have similar logs; consult your database administrator or database documentation for more information.

ODBC trace

You can trace ODBC activity; follow the instructions in "ODBC trace" on page 3551.

Trace information is sent to the location specified in the file referenced by the environment variable:

- ODBCINI for data sources using the DataDirect drivers, or
- ODBCSYSINI for data sources using WebSphere Message Broker Database Extender (IE02), or
- In the ODBC configuration on Windows

.

Related tasks:

"ODBC trace" on page 3551
You can use various methods to trace for ODBC activity, depending on the operating system that you are using.

Related reference:

"Database logs" on page 6870
Databases write severe error and warning conditions to the local error log (syslog). Typically, databases also write errors to a database log file, such as the `db2diag.log` file on DB2.

Other sources of diagnostic information on z/OS

Other files that you might find useful for problem determination.

Files from a broker

The broker puts files into the file system. If you do not know where the files are for the broker, look at the `MQSI_REGISTRY` value in the component profile (`BIPBPROF`) in the component dataset. This is set to a value like `/u/argo/VCP0BRK`. Be careful to access the file system on the correct system; if the file system is not shared, there could be the same directory on each MVS image. To be sure, log on to the system where the broker is running and access the file system. You can use the **`TSO ISHell`** command, or go into OMVS itself. Go to the directory specified and select the output directory. The `traceodbc` file should appear in this directory.

When submitting JCL from the component PDSE, output files are written to the ++HOME++ location. The following files should appear in this directory:

- ENVFILE
- bipprof
- ENVFILE.<*8 character execution group name*>
- bipprof.<*8 character execution group name*>

Files in the home directory

Other files are stored in the home directory of the user ID of the started task. The MVS command **D A, jobname** displays the user ID of the job. The directory of the user ID is typically /u/userid but you should check this with your system programmer, or issue the TSO command **LU userid OMVS**. If you are authorized, this command displays text including the HOME statement.

There might be several different sorts of files in the home directory, such as core dump files.

Problems accessing files in the file system

If you cannot access a file system file or directory, it might be that you do not have permission to do so. This could mean that you are not able to issue certain commands. You need to ask the owner of the file or directory to give you permission to use the file.

Related concepts:

"Trace" on page 6871
If you cannot get enough information about a particular problem from the entries that are available in the various logs, the next troubleshooting method to consider is using trace. Trace provides more details about what is happening while code runs. The information produced from trace is sent to a specified trace record, so that you or IBM support personnel can analyze it to discover the cause of your problem.

Solutions to similar problems

Various sources of information about problems with IBM licensed programs and their use.

Useful Web sites

Various Web sites are available on the Internet, not all managed by IBM, that you might find useful aids to problem determination. Here are some URLs that you might try:

- WebSphere Message Broker support web page
- WebSphere MQ Integrator newsgroup
- MQSeries.net

RETAIN

IBM keeps records of all known problems with its licensed programs on its software support database (RETAIN). IBM Support Center staff continually update this database as new problems that are found. They regularly search the database to see if problems that they are told about are already known.

If you have access to one of IBM's search tools, such as INFORMATION/ACCESS or INFORMATION/SYSTEM, you can look on the RETAIN database yourself. If not, you can contact the IBM Support Center to search for you.

You can search the database using a string of keywords to see if a similar problem exists.

You can use the keyword string (also called the symptom string) that appears in a dump or SYS1.LOGREC record to search the database, or you can build your own keyword string.

If the search is successful, you find a similar problem description and, usually, a fix. If the search is unsuccessful, use these keywords when contacting IBM for additional assistance, or when documenting a possible authorized program analysis report (APAR).

Related tasks:

"Making initial checks" on page 3347
Before you start problem determination in detail, consider whether there is an obvious cause of the problem, or an area of investigation that is likely to give useful results. This approach to diagnosis can often save a lot of work by highlighting a simple error, or by narrowing down the range of possibilities.

"Dealing with problems" on page 3363
Learn how to resolve some of the typical problems that can occur.

"Contacting your IBM Support Center" on page 3563
If you cannot resolve problems that you find when you use WebSphere Message Broker, or if you are directed to do so by an error message generated by WebSphere Message Broker, you can request assistance from your IBM Support Center.
