"X.509 certificate token capabilities for authorization" on page 801
The X.509 certificate token is not supported for authorization in any configuration or direction.

"X.509 certificate token capabilities for identity mapping" on page 802
For Web services, you can map an identity by using an X.509 certificate token.

"X.509 certificate token capabilities for extraction and propagation" on page 803
This topic describes broker Web services capability for extraction and propagation X.509 certificate token.

X.509 certificate token capabilities for authentication:

For Web services, you can complete authentication by using an X.509 certificate token.

The X.509 certificate token "Authentication" on page 768 of an incoming SOAP message is supported in the following configurations:

Capability

- Authenticate

Policy Enforcement Point (PEP) and direction

- In (provider)

  "SOAPInput node" on page 4795

  Configured with a policy set and binding defining the certificate "Authentication" on page 770.

  Optionally configured with a security profile defining an external Policy Decision Point (PDP); see the PDP section that follows.

Trust Store or PDP

- Broker Trust store; for details, see "Viewing and setting keystore and truststore runtime properties at broker level" on page 780.
- WS-Trust v1.3 STS

  Configured by using a WS-Trust v1.3 STS security profile specifying authentication; see "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 440.
- TFIM V6.1

Configured by using a TFIM security profile specifying authentication; for details, see “Creating a security profile for TFIM V6.1” on page 444.

Certificate authentication with an external LDAP PDP is not supported.

"X.509 certificate token capabilities for identity mapping"
For Web services, you can map an identity by using an X.509 certificate token.

"X.509 certificate token capabilities for extraction and propagation" on page 803
This topic describes broker Web services capability for extraction and propagation X.509 certificate token.

X.509 certificate token capabilities for identity mapping:

For Web services, you can map an identity by using an X.509 certificate token.

The broker supports "Identity mapping" on page 403 from an X.509 certificate token in an incoming SOAP message header to username tokens in the following configurations:

Capability

- Identity mapping

Policy Enforcement Point (PEP) and direction

- In (provider)

  "SOAPInput node" on page 4795

  Configured with a policy set and binding defining the certificate "Authentication" on page 770.

  Configured with a security profile defining an external Policy Decision Point (PDP); see the PDP section that follows.

Trust Store or PDP

- TFIM V6.1

  Configured by using a TFIM security profile specifying identity mapping; for details, see "Creating a security profile for TFIM V6.1" on page 444.

- WS-Trust v1.3 STS (TFIM V6.2)

  Configured by using a WS-Trust v1.3 STS security profile specifying identity mapping; for details, see "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 440.

Identity mapping is not supported with LDAP, or at outbound nodes.

Username tokens only can be propagated.

Related concepts:

For Web services, you can complete decryption by using an X.509 certificate token.

"X.509 certificate token capabilities for signing" on page 798
For Web services, you can use an X.509 certificate token for signing.

"X.509 certificate token capabilities for verifying" on page 799
For Web services, you can verify a signing by using an X.509 certificate token profile.

"X.509 certificate token capabilities for authentication" on page 800
For Web services, you can complete authentication by using an X.509 certificate token.

"X.509 certificate token capabilities for authorization" on page 801
The X.509 certificate token is not supported for authorization in any configuration or direction.

"X.509 certificate token capabilities for extraction and propagation"
This topic describes broker Web services capability for extraction and propagation X.509 certificate token.

X.509 certificate token capabilities for extraction and propagation:

This topic describes broker Web services capability for extraction and propagation X.509 certificate token.

The broker does not support propagation of an X.509 certificate.

The X.509 certificate token extraction is supported in the following configurations:

Capability

- Extraction

Policy Enforcement Point (PEP) and direction

- In (provider)

  "SOAPInput node" on page 4795

  Configured with a policy set and binding defining the X.509 certificate is present; see "Implementing WS-Security" on page 769.

  Configured with a security profile defining propagation; see the "Security profiles" on page 387.

Related concepts:

For Web services, you can verify a signing by using an X.509 certificate token profile.

"X.509 certificate token capabilities for authentication" on page 800
For Web services, you can complete authentication by using an X.509 certificate token.

"X.509 certificate token capabilities for authorization" on page 801
The X.509 certificate token is not supported for authorization in any configuration or direction.

"X.509 certificate token capabilities for identity mapping" on page 802
For Web services, you can map an identity by using an X.509 certificate token.

SAML token capabilities:

This topic describes WS-Security SAML token capabilities of the broker.

The broker provides SAML pass-through support, which means that the mechanisms for subject confirmation are not enforced. The SAML token is extracted and passed to an external security token service (STS) for validation. The STS to be used is specified on a security profile.

For information about using WS-Security SAML tokens, see the following topics:

- "SAML token capabilities for encryption, decryption, signing, and verifying"
- "SAML token capabilities for authentication and authorization" on page 806
- "SAML token capabilities for identity mapping" on page 807
- "SAML token capabilities for extraction and propagation" on page 808

Related concepts:

"WS-Security mechanisms" on page 768
The WS-Security specification provides three mechanisms for securing Web services at the message level: authentication, integrity, and confidentiality.

"Identity" on page 390
In WebSphere Message Broker, an identity is a security token that uniquely identifies an individual, or that provides a set of assertions that can be validated.

Related tasks:

"Setting up message flow security" on page 431
Set up security on a message flow to control access based on the identity of a message passing through the message flow.

"Broker component security" on page 497
You must consider several security aspects when you are setting up brokers running on Windows, Linux, or UNIX platforms.

SAML token capabilities for encryption, decryption, signing, and verifying:

The broker provides SAML pass-through support, which means that the encryption, decryption, signing, and verifying mechanisms for achieving SAML subject confirmation are not enforced by the broker.

Related concepts:

"WS-Security mechanisms" on page 768
The WS-Security specification provides three mechanisms for securing Web services at the message level: authentication, integrity, and confidentiality.

"SAML token capabilities" on page 804
This topic describes WS-Security SAML token capabilities of the broker.

"Identity" on page 390
In WebSphere Message Broker, an identity is a security token that uniquely identifies an individual, or that provides a set of assertions that can be validated.

Related reference:

"SAML token capabilities for authentication and authorization" on page 806
For Web services, you can complete authentication and authorization using a SAML token.

"SAML token capabilities for identity mapping" on page 807
This topic describes the broker Web services capability for identity mapping using a SAML token.

"SAML token capabilities for extraction and propagation" on page 808
This topic describes broker capability for extraction, propagation, or both using a SAML token in Web services.

SAML token capabilities for authentication and authorization:

For Web services, you can complete authentication and authorization using a SAML token.

The SAML token "Authentication" on page 768 and "Authorization" on page 401 are supported only in the following configuration:

Capability

- Authenticate
- Authorize

Policy Enforcement Point (PEP) and direction

- In (provider)

  "SOAPInput node" on page 4795

  Configured with a security policy set and binding that defines that a SAML pass-through 1.1 or SAML pass-through 2.0 token is present for authentication; see "Authentication" on page 770. The broker provides only SAML pass-through support, which means that the SAML token is extracted and passed to an external security token service (STS) for validation. The STS to be used is specified in a security profile. The STS processing can be used to implement authentication based on the SAML principal, and authorization based on SAML attributes.

  Configured with a security profile defining the Policy Decision Point (PDP); see the PDP section that follows.

Trust Store or PDP

- WS-Trust v1.3 STS

  Configured by using a WS-Trust v1.3 STS security profile specifying authentication, authorization or both; see "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 440.

Related concepts:

"WS-Security mechanisms" on page 768

This topic describes the broker Web services capability for identity mapping using a SAML token.

"SAML token capabilities for extraction and propagation" on page 808
This topic describes broker capability for extraction, propagation, or both using a SAML token in Web services.

SAML token capabilities for identity mapping:

This topic describes the broker Web services capability for identity mapping using a SAML token.

"Identity mapping" on page 403 from a SAML identity token to a mapped SAML identity token is supported only in the following configurations:

Capability

- Identity mapping

Policy Enforcement Point (PEP) and direction

- In (provider)

  "SOAPInput node" on page 4795

  Configured with a security policy set and bindings that specifies a SAML pass-though 1.1 or SAML pass-through 2.0 authentication token.

  Configured with a security profile defining the external Policy Decision Point (PDP); see the PDP section that follows.

Trust store or PDP

- WS-Trust v1.3 STS

  Configured by using a WS-Trust v1.3 STS security profile that specifies identity mapping; see "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 440.

Related concepts:

"WS-Security mechanisms" on page 768

For Web services, you can complete authentication and authorization using a SAML token.

"SAML token capabilities for extraction and propagation"
This topic describes broker capability for extraction, propagation, or both using a SAML token in Web services.

SAML token capabilities for extraction and propagation:

This topic describes broker capability for extraction, propagation, or both using a SAML token in Web services.

The extraction of a SAML token into the Properties folder source "Identity" on page 390 fields, is supported in the following configurations:

Capability

- Extraction

Policy Enforcement Point (PEP) and direction

- In (provider)

  "SOAPInput node" on page 4795

  Configured with a security policy set and bindings that specifies a SAML pass-though 1.1 or SAML pass-through 2.0 authentication token.

  Configured with a security profile that defines propagation; see "Creating a security profile" on page 433

The propagation of a SAML token into the SOAP WS-Security header, from the token present in either the mapped or the source identity fields in the properties folder, is supported in the following configuration. For more information, see "Identity" on page 390.

Capability

- Propagate

Policy Enforcement Point (PEP) and direction

- Out (consumer)

  "SOAPRequest node" on page 4828

  "SOAPAsyncRequest node" on page 4750

  Configured with a security profile that defines propagation. For more information, see "Security profiles" on page 387.

  Configured with a security policy set and bindings that specifies SAML pass-though 1.1 or SAML pass-through 2.0 authentication token.

The WS-Security specification provides three mechanisms for securing Web services at the message level: authentication, integrity, and confidentiality.

"Identity" on page 390
In WebSphere Message Broker, an identity is a security token that uniquely identifies an individual, or that provides a set of assertions that can be validated.

Related tasks:

"Setting up message flow security" on page 431
Set up security on a message flow to control access based on the identity of a message passing through the message flow.

"Broker component security" on page 497
You must consider several security aspects when you are setting up brokers running on Windows, Linux, or UNIX platforms.

LTPA token capabilities for encryption, decryption, signing, and verifying:

This topic describes broker Web services capability for encryption, decryption, signing, and verifying using LTPA tokens.

The LTPA token is not applicable, or supported, for the following in any configuration or direction:

- Encryption
- Decryption
- Signing
- Verifying

Related concepts:

"WS-Security mechanisms" on page 768

"LTPA token capabilities for extraction and propagation" on page 817
This topic describes broker capability for extraction, propagation, or both using an LTPA token in Web services.

LTPA token capabilities for authentication and authorization:

For Web services, you can complete authentication and authorization using an LTPA token.

The LTPA token "Authentication" on page 768 and "Authorization" on page 401 are supported only in the following configuration:

Capability

- Authenticate
- Authorize

Policy Enforcement Point (PEP) and direction

- In (provider)

  "SOAPInput node" on page 4795

  Configured with a security policy set and binding that defines that an LTPA token is present for authentication; see "Authentication" on page 770. The broker provides only LTPA pass-through support, which means that the LTPA token is extracted and passed to an external security token service (STS) for validation. The STS to be used is specified in a security profile. The STS processing can be used to implement authentication and authorization based on the LTPA principal and realm.

  Configured with a security profile defining the Policy Decision Point (PDP); see the PDP section that follows.

Trust Store or PDP

- WS-Trust v1.3 STS

  Configured by using a WS-Trust v1.3 STS security profile specifying authentication, authorization or both; see "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 440.

Related concepts:

"WS-Security mechanisms" on page 768
The WS-Security specification provides three mechanisms for securing Web services at the message level: authentication, integrity, and confidentiality.

"LTPA token capabilities" on page 813
This topic describes WS-Security LTPA token capabilities of the broker.

"Authorization" on page 401
Authorization is the process of verifying that an identity token has permission to access a message flow.

"Authentication and validation" on page 398
Authentication is the process of establishing the identity of a user or system and verifying that the identity is valid. Applying authentication to a SAML security token involves validating the assertions that it carries and confirming that it is being processed within its validity period.

"Identity" on page 390
In WebSphere Message Broker, an identity is a security token that uniquely identifies an individual, or that provides a set of assertions that can be validated.

LTPA token capabilities for extraction and propagation:

This topic describes broker capability for extraction, propagation, or both using an LTPA token in Web services.

The extraction of an LTPA token into the Properties folder source "Identity" on page 390 fields, is supported in the following configurations:

Capability

- Extraction

Policy Enforcement Point (PEP) and direction

- In (provider)

  "SOAPInput node" on page 4795

  Configured with a security policy set and bindings that specifies an LTPA pass-though authentication token.

  Configured with a security profile that defines propagation; see "Creating a security profile" on page 433

The propagation of an LTPA token into the SOAP WS-Security header, from the token present in either the mapped or the source identity fields in the properties folder, is supported in the following configuration. For more information, see "Identity" on page 390.

Capability

- Propagate

Policy Enforcement Point (PEP) and direction

- Out (consumer)

  "SOAPRequest node" on page 4828

  "SOAPAsyncRequest node" on page 4750

  Configured with a security profile that defines propagation. For more information, see "Security profiles" on page 387.

  Configured with a security policy set and bindings that specifies an LTPA pass-through authentication token.

Moving from WebSphere Message Broker on a distributed system to z/OS

Define resources for WebSphere Message Broker for z/OS and move your message flow applications.

About this task

Read the following topics for guidance on what action you might want to take in moving part of your operations to z/OS:

- "z/OS customization overview" on page 592
- "Customizing the z/OS environment" on page 591
- "Creating a broker on z/OS" on page 620
- "Administration in z/OS" on page 3979

After reviewing your requirements, re-create your broker on z/OS and deploy your message flows and execution groups to the broker on z/OS. If you have extended WebSphere Message Broker in a distributed environment with user-defined parsers or message processing nodes, port them to run under z/OS.

Also consider the following points:

- Floating point conversion: z/OS runs under z/OS floating point format, so floating point operations on z/OS run in a different range and accuracy from distributed systems.
- Administration commands are partially implemented as console commands and partially as JCL commands. Some commands provide both options.
- Event log messages: All address spaces have a JOBLOG where messages appear. In addition to this, all messages appear on the SYSLOG, with important operator messages being filtered to the console through MPF (Message Processing Facility).

For information about message flow transactionality, see "Message flow transactions" on page 1281.

Moving user applications

About this task

You can write your own applications to work with WebSphere Message Broker. If these applications use the common subset of functionality of all WebSphere Message Broker brokers, no migration is necessary. If you are using functionality that is available on some WebSphere Message Broker systems only, for example message segmentation and WebSphere MQ message groups, be aware that WebSphere Message Broker for z/OS does not provide support for this migration.

Related concepts:

"z/OS customization overview" on page 592
After you have used SMP/E to install WebSphere Message Broker for z/OS, the installed executable code is located inside the file system. JCL samples are located in the PDS `<hlq>.SBIPSAMP`, the JCL procedures are located in the PDS `<hlq>.SBIPPROC`, and load module for synchronizing statistics with SMF are located in the PDS `<hlq>.SBIPAUTH`.

Related tasks:

"Customizing the z/OS environment" on page 591
If you are planning to use a z/OS environment, consider whether to create your brokers on z/OS. You must also complete a number of tasks to configure your environment.

"Creating a broker on z/OS" on page 620
Create the broker component and the other resources on which it depends.

Related reference:

"Administration in z/OS" on page 3979
In the z/OS environment, commands are issued through the console and others in batch jobs.

Changing locales

You can change the locale for the system on which a runtime component is installed.

About this task

The way in which you change the locale depends on the operating system:

- "Changing your locale on Linux and UNIX systems" on page 820
- "Changing your locale on Windows" on page 822
- "Changing your locale on z/OS" on page 823

WebSphere Message Broker uses code page converters to support character sets from different environments. "Code page converters" on page 823 describes what a code page converter is, and how to generate new converters.

Related reference:

"Supported processors" on page 3583
WebSphere Message Broker is supported on multiple processors.

"Operating system requirements" on page 3590
WebSphere Message Broker is supported on multiple operating systems.

"Supported code pages" on page 4176
Application messages must conform to supported code pages.

"Locales" on page 3629
Message support is provided in a number of locales.

Changing your locale on Linux and UNIX systems

You can change your system locale on UNIX and Linux systems.

About this task

You can set environment variables to control the system locale. You can set these variables to be system-wide, or on a per-session basis:

LC_ALL Overrides all LC_* environment variables with the given value

LC_CTYPE
Character classification and case conversion

LC_COLLATE
Collation (sort) order

LC_TIME
Date and time formats

LC_NUMERIC
Non-monetary numeric formats

LC_MONETARY
Monetary formats

LC_MESSAGES
Formats of informative and diagnostic messages, and of interactive responses

LC_PAPER
Paper size

LC_NAME
Name formats

LC_ADDRESS
Address formats and location information

LC_TELEPHONE
Telephone number formats

LC_MEASUREMENT
Measurement units (Metric or Other)

LC_IDENTIFICATION
Metadata about the locale information

LANG The default value, which is used when either LC_ALL is not set, or an applicable value for LC_* is not set

NLSPATH
Delimited list of paths to search for message catalogs

TZ Time zone

LC_MESSAGES and NLSPATH are the most important variables to the broker. These variables define the language and location of response messages that the broker uses. The broker profile file, mqsiprofile, sets NLSPATH. Either you, or your system must set LC_MESSAGES. The value set in LC_MESSAGES must be a value that is installed on your machine and that the broker recognizes. LC_CTYPE is also important to the broker because it defines the character conversion that the broker performs when interacting with the local environment.

Before setting these variables, check that the language and code page are installed on your machine, and are supported by WebSphere Message Broker.

You can use the command **locale** to show your current locale. The command **locale -a** displays all the locales that are currently installed on the machine. Make sure that the locale you select for LANG and LC_ALL is in the list that is returned by the command **locale -a**. The values that locale uses and returns are case sensitive, therefore copy them exactly when assigning them to an environment variable.

For information on languages and code pages supported by WebSphere Message Broker, see "Locales" on page 3629 and "Supported code pages" on page 4176.

If you use common desktop environment (CDE), use this environment to set the locale instead of setting LANG and LC_ALL directly. The NLSPATH variable respects either method.

For example, to set WebSphere Message Broker to run in a UTF-8 environment set the following values in the profile:

```
LANG=en_US.utf-8
LC_ALL=en_US.utf-8
```

where en_US sets the language, and utf-8 sets the code page.

When you start a broker component, the locale of that component is inherited from the shell in which it is started. The broker component uses the LC_MESSAGES environment variable as the search path in the NLSPATH environment variable (LC_MESSAGES is set when variable LC_ALL is exported).

Messages are sent to the syslog in the code page set by this locale. If you have multiple brokers that write to this syslog, their messages are in the code page of the locale in which they were started, for example:

locale	syslog code page	ccsid
pt_BR	iso8859-1	819
pt_BR	ibm-850	850
pt_BR	utf-8	1208

Set the locale of the user ID that runs the syslog daemon to one that is compatible with the locales of all brokers that write to the syslog on that system, for example, utf-8. For compatibility, you can set the default locale. On Solaris, set the LANG and LC_ALL variables in /etc/default/init. On AIX and Linux, these variables are in /etc/environment. This task is not required on HP-UX.

For full-time zone support in the broker, set the TZ variable using Continent/City notation. For example set TZ to Europe/London to make London, England the time zone, or set it to America/New_York to make New York, America the time zone.

If you want to add a new locale, refer to the operating system documentation for information about how to complete that task. If the code page of the new locale is not supported by WebSphere Message Broker you must add it by "Generating a new code page converter" on page 824.

Related tasks:

"Generating a new code page converter" on page 824
Generate a code page converter to handle conversions of data that belongs to a code page that is not in the default set of code pages provided by WebSphere Message Broker.

"Supported code pages" on page 4176
Application messages must conform to supported code pages.

Changing your locale on Windows

Change your system locale on Windows to view objects and information in a different language or code page.

About this task

Brokers are started as services on Windows, and are therefore influenced by the system locale. The command-line functions are influenced by the locale that is set for the current user. WebSphere Message Broker on Windows has all locale information installed by default. However, you might have to install additional locale packages, if prompted to do so by the Windows operating system.

To change locale, use one of the following methods:

- Install a locale-specific operating system.
- Alter the system or user locale by selecting *Regional Settings* in the Control Panel.

Messages are sent to the Event Log in the code page set by the current locale.

You can use the **chcp** command to change the active console code page. Enter the command at a command prompt; if you enter **chcp** without a parameter, it displays the current setting. If you enter it with a code page, it changes the locale to that code page.

For example, to check the current code page setting:

```
C:\>chcp
Active code page: 437
```

The current page is displayed (437 represents US-ASCII). If you want to change the value to GB18030, enter:

```
C:\>chcp 54936
Active code page: 54936
```

Before you use a code page, search for `windows-`*`number`* where *`number`* is the active code page you want to use in the list of "Supported code pages" on page 4176. If the code page is not in the list, either use a code page that is in the list, or generate a new code page converter.

Related tasks:

"Generating a new code page converter" on page 824
Generate a code page converter to handle conversions of data that belongs to a code page that is not in the default set of code pages provided by WebSphere Message Broker.

WebSphere Message Broker is supported on multiple operating systems.

"Supported code pages" on page 4176
Application messages must conform to supported code pages.

Changing your locale on z/OS

You can change your system locale on z/OS. If you want to change your system locale on z/OS, set the `LANG`, `LC_ALL`, and `NLSPATH` variables.

About this task

See "Installation information - broker" on page 621 for further information.

The locale is set in the broker profile (`BIPBPROF`) and you must run `BIPGEN` to create the broker `ENVFILE` and any execution group specific ENVFILE.

You can use the UNIX System Services (USS) executable `locale` to show your current locale. The command `locale -a` displays all the locales currently installed on the computer. Refer to the operating system documentation for information about adding new locales. If you add a new locale after you have installed WebSphere Message Broker, install that locale's message catalogs from the original install media.

You can set WebSphere Message Broker to operate with a specific code page. Set the code page after a period in the LANG and LC_ALL variable. This example sets the locale to `En_us` and the code page to `IBM-1140` (EBCDIC En_us with euro):

```
LANG=En_us.IBM-1140
LC_ALL=En_us.IBM-1140
```

Make sure that the selected code page is one of the "Supported code pages" on page 4176. If the code page is not in the list, either use a code page that is in the list, or generate a new code page converter.

Related tasks:

Code page converters

Brokers complete string operations in Universal Character Set coded in 2 octets (UCS-2). If incoming strings are not encoded in UCS-2, they are converted to UCS-2 on arrival.

The broker uses international components for Unicode (ICU) code page converters to convert data. The Unicode Consortium has further information on Unicode.

A code page converter is a mapping from the byte sequence in one code page to a serialized representation of UCS-2, known as UCS Transformation Format 16 bit form (UTF-16). A code page converter allows the broker to create a UCS-2 representation of an incoming string.

When you handle UTF-16 data, CCSIDs 1200, 13488 and 17584 are treated differently to others. Traditionally, in ICU usage, the endian encoding of these CSSIDs was platform-specific, and WebSphere Message Broker uses an encoding parameter with these CSSIDs. You can specify the encoding parameter as MQENC_INTEGER_REVERSED to use these CCSIDs to explicitly produce little endian data.

Consider this example of the use of a code page converter. A message comes in on a queue from z/OS, with the WebSphere MQ CCSID field set to 1047 (LATIN-1 Open Systems without euro). The broker looks up ibm-1047 and uses the resulting converter to create a UCS-2 representation for internal use.

If you try to convert from a Unicode to a Non-Unicode character set, the following errors might occur:

- The target buffer is too small. This error causes a recoverable exception, which you can handle; alternatively, the message is rolled back.
- A code point in the source does not have an equivalent value in the target. At first, fallback mappings are attempted (for example, if you are converting to Japanese, a backslash (\) can be mapped to a yen (¥) if the conversion supplies it as a fallback mapping). If fallback mappings are not present, a recoverable exception is thrown. You can handle the exception, or the message is rolled back.

  The MRM parser substitutes invalid code points with substitution characters.

WebSphere Message Broker currently supports the code pages listed in “Supported code pages” on page 4176. If you need support for an additional code page, or if you require a different variant of a code page, you can extend the broker to support this code page.

Generating a new code page converter:

Generate a code page converter to handle conversions of data that belongs to a code page that is not in the default set of code pages provided by WebSphere Message Broker.

Before you begin

Before you start:

- Read “Code page converters” on page 823, which provides information about what a code page converter is, and about the code pages that WebSphere Message Broker supports.

About this task

To generate a new code page converter:

Procedure

1. Create or find a mapping data file with the file extension `.ucm` for the converter that you require. You can download `.ucm` files from the ICU Character set mapping files archive. These mapping data files are available and can be modified without restriction. An example mapping data file is `ibm-1284_P100-1996.ucm`. (ICU is an external open source project, not an IBM tool.)
2. Rename the `.ucm` to a file name with the format `ibm-`*`number`*`.ucm` where *number* is a number that you choose to identify the code page. Make sure that this number is not already used in one of the "Supported code pages" on page 4176. For example, you could rename `ibm-1284_P100-1996.ucm` to `ibm-1284.ucm`.
3. Go to ICU downloads and download the binary distribution for your system. An exact match is not important provided that the binary files are compatible. If you have problems building the converter, see the ICU user guide.
4. Extract the files from the binary distribution archive into a temporary directory.
5. Copy the library and binary files to a directory in the environment PATH and LIBPATH. (Alternatively, copy the library and binary files to directory that is not temporary and modify the environment PATH and LIBPATH to include this directory.)
6. One of the extracted files is `makeconv.exe`; use this makeconv tool to convert the mapping data file (`.ucm` files) into a binary converter file (`.cnv` file), by entering the following command:

   makeconv *mapping_file.ucm*

   where *mapping_file.ucm* is the mapping data file that you are using.

   The name of the binary converter file that **makeconv** produces is:

   mapping_file.cnv

   where *mapping_file.cnv* is the name of the mapping data file that was converted.

   To make the `.cnv` file for `ibm-1284.ucm`, use the following command:

   ```
   makeconv ibm-1284.ucm
   ```
7. Copy the file with the file extension `.cnv` for the code page that you need, into a directory that WebSphere Message Broker can access.

   The name and location of the file is of the form

   ibm-1284`.cnv`

   and is located in the *$ICU_DATA/icudt38<platform-suffix>* directory, where the *<platform-suffix>* is one of the following values:

   - l for little-endian ASCII platforms
   - b for big-endian ASCII platforms
   - e for EBCDIC platforms
8. Optional: If you do not want the new code page converter to be in the same location as other ICU data, you must associate the broker with the new directory where the converter is stored (the directory added must contain the full path, not including the icudt38x subdirectory):
   - To create a new broker that is associated with the converter, include the **-c** parameter on the **mqsicreatebroker** command.

- To alter an existing broker to recognize the converter, include the **-c** parameter on the **mqsichangebroker** command.
- To affect all the products and the broker command-line tools that are using ICU, add the *directory* to the **ICU_DATA** environment variable. If you have used either the **mqsicreatebroker** command or the **mqsichangebroker** command to specify the code page converter to be used, the broker ignores the **ICU_DATA** value.

Note: To ensure consistent behavior in all components, modify the **ICU_DATA** environment variable.

Create one or more brokers on one or more computers, and configure them on your test and production systems to process messages that contain your business data.

Configuring a WebSphere Message Broker to run in multi-instance mode

How you configure a WebSphere Message Broker to run in multi-instance mode.

Before you begin

Before you start:

Read the overview of multi-instance queue managers on WebSphere MQ; see “Multi-instance queue managers” on page 828. For further information on multi-instance queue managers see the WebSphere MQ information center.

About this task

The set of tasks describing how you configure a multi-instance broker on WebSphere Message Broker assumes the following:

- A network server is being configured to host the shared work path for the multi-instance broker and the shared directories for the multi-instance queue manager.
- The network server is shared between two client machines, each of which has a licensed copy of the WebSphere Message Broker and WebSphere MQ products installed.
- The platform for the illustration is assumed to be AIX, but the steps are true for all platforms supported by WebSphere Message Broker and WebSphere MQ except for z/OS.

  Multi-instance brokers and multi-instance queue managers are not supported on z/OS

There are three steps in configuring a WebSphere Message Broker to run in multi-instance mode:

Procedure

1. Create a Shared work path directory on an NFS or NAS server. On Windows there is the option to use a shared UNC path.
2. Create a WebSphere MQ multi-instance queue manager.
3. Create a Multi-instance broker

Related concepts:

Multi-instance queue managers

A multi-instance queue manager restarts automatically on a standby server.

Figure 1 shows a multi-instance configuration for QM1. WebSphere MQ is installed on two servers, one of which is a spare. One queue manager, QM1, has been created. One instance of QM1 is active, and is running on one server. The other instance of QM1 is running in standby on the other server, doing no active processing, but ready to take over from the active instance of QM1, if the active instance fails.

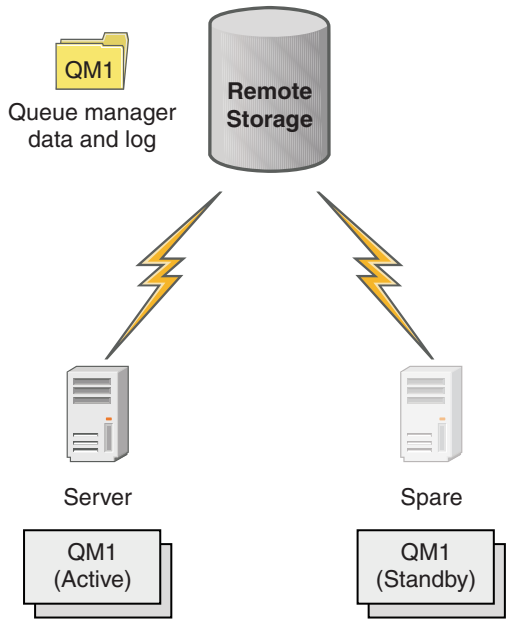

Figure 1. Multi-instance queue manager

When you intend to use a queue manager as a multi-instance queue manager, create a single queue manager on one of the servers using the WebSphere MQ **crtmqm** command, placing its queue manager data and logs in shared network storage. On the other server, rather than create the queue manager again, use the WebSphere MQ **addmqinf** command to create a reference to the queue manager data and logs on the network storage.

You can now run the queue manager from either of the servers. Each of the servers references the same queue manager data and logs; there is only one queue manager, and it is active on only one server at a time.

The queue manager can run either as a single instance queue manager, or as a multi-instance queue manager. In both cases only one instance of the queue manager is running, processing requests. The difference is that when running as a multi-instance queue manager, the server that is not running the active instance of the queue manager runs as a standby instance, ready to take over from the active instance automatically if the active server fails.

The only control you have over which instance becomes active first is the order in which you start the queue manager on the two servers. The first instance to acquire read/write locks to the queue manager data becomes the active instance.

You can swap the active instance to the other server, once it has started, by stopping the active instance using the switchover option to transfer control to the standby.

The active instance of QM1 has exclusive access to the shared queue manager data and logs folders when it is running. The standby instance of QM1 detects when the active instance has failed, and becomes the active instance. It takes over the QM1 data and logs in the state they were left by the active instance, and accepts reconnections from clients and channels.

The active instance might fail for various reasons that result in the standby taking over:

- Failure of the server hosting the active queue manager instance.
- Failure of connectivity between the server hosting the active queue manager instance and the file system.
- Unresponsiveness of queue manager processes, detected by WebSphere MQ, which then shuts down the queue manager.

You can add the queue manager configuration information to multiple servers, and choose any two servers to run as the active/standby pair.

A multi-instance queue manager is one part of a high availability solution. You need some additional components to build a useful high availability solution.

- Client and channel reconnection to transfer WebSphere MQ connections to the computer that takes over running the active queue manager instance.
- A high performance shared network file system that manages locks correctly and provides protection against media and file server failure.
- Resilient networks and power supplies to eliminate single points of failure in the basic infrastructure.
- Applications that tolerate failover. In particular you need to pay close attention to the behavior of transactional applications, and to applications that browse WebSphere MQ queues.
- Monitoring and management of the active and standby instances to ensure that they are running, and to restart active instances that have failed. Although multi-instance queue managers restart automatically, you need to be sure that your standby instances are running, ready to take over, and that failed instances are brought back online as new standby instances.

WebSphere MQ clients and channels reconnect automatically to the standby queue manager when it becomes active. Reconnection, and the other components in a high availability solution are discussed in related topics.

Creating the shared directories

How you create the shared directories that you need for your multi-instance WebSphere Message Broker.

Before you begin

Before you start:

Before you create the shared directory, read the documentation supplied with your NFS or NAS product used at your enterprise (or on Windows a shared UNC path). Note that, if you are intending to use an NFS server, this server must use NFSv4.

About this task

The following procedure gives a generalized set of instructions for a NFS shared path, because the specific instructions vary by product:

Procedure

1. Create an NFS Share on the server for the multi-instance WebSphere MQ queue manager.
2. Mount the NFS Share on both client nodes A and B, for the WebSphere MQ multi-instance queue manager, using a suitable location; for example, /Shared/Location/WMQ.
3. Ensure that the WMQ directories are owned by user and group mqm, and that the access permissions are set to rwx for user and group. For example **ls -al** displays:

   ```
   drwxrwxr-x mqm mqm 4096 Jun 14 14:38 WMQ
   ```

4. Create an NFS share on the server for the multi-instance broker.
5. Mount the NFS Share on both client nodes A and B, for the multi-instance broker, using a suitable location; for example, /Shared/Location/WMB.
6. Ensure that the WMB directories are owned by user and group mqbrkrs, and that the access permissions are set to rwx for user and group. For example **ls -al** displays:

   ```
   drwxrwxr-x mqbrkrs mqbrkrs 4096 Jun 14 14:39 WMB
   ```

7. If you are working on AIX you must turn off attribute caching so that you use the NFS server solely for multi-instance tasks.

   Use the following command, on both client nodes A and B, to turn off attribute caching for the example share locations used in the preceding instructions:

   ```
   nfs4cl setfsoptions /Shared/Location/WMQ noac
   nfs4cl setfsoptions /Shared/Location/WMB noac
   ```

   For further information, see AIX NFS commands

What to do next

Create a WebSphere MQ multi-instance queue manager.

Related tasks:

"Configuring a WebSphere Message Broker to run in multi-instance mode" on page 827
How you configure a WebSphere Message Broker to run in multi-instance mode.

How you create the multi-instance broker.

Creating the WebSphere MQ multi-instance queue manager

How you create the WebSphere MQ multi-instance queue manager that you need for your multi-instance WebSphere Message Broker.

Before you begin

Before you start:

Create the shared directories that you require for the multi-instance queue manager; see "Creating the shared directories" on page 829.

About this task

The following procedure gives an overview of how you create a multi-instance WebSphere MQ queue manager. See "Creating a multi-instance queue manager" on page 832 for more information.

Procedure

1. Create a multi-instance WebSphere MQ queue manager called `QM1` on client node `A`. You do this by using the following command:

   ```
   -crtmqm -md /SharedLocation/WMQ/data
                   -ld /SharedLocation/WMQ/logs QM1
   ```

   where:

   md Is the name of the directory used to hold data files for a queue manager.

   ld Is the name of the directory used to hold log files.

   Note that it is important that the name of the queue manager goes at the end of the syntax. See the WebSphere MQ documentation for further information on the **crtmqm** command.

2. Add the details of WebSphere MQ queue manager `QM1` onto client node `B`. You do this by using the following command:

   ```
   -addmqinf  -v Name=QM1 -v Directory=WMQ -v Prefix=/var/mqm
                       -v DataPath=/SharedLocation/WMQ/data/QM1
   ```

   where:

   Name Is the name of the queue manager.

   Directory
   Is the name of the queue manager data directory.

   Prefix Is the directory path *under* which this queue manager data directory is stored by default.

   Data Path
   Is the data path where the queue manager data files are placed. The value of `Directory` is not appended automatically to this path; you must provide the transformed queue manager name as part of `DataPath`.

   The parameters listed above are all required parameters on Windows and UNIX platforms, with the exception of `DataPath`, which is optional on UNIX platforms only.

   See the WebSphere MQ documentation for further information on the **addmqinf** command.

3. Start queue manager `QM1` on client node `A` in multi-instance mode. You do this by using the following command:

   ```
   strmqm -x QM1
   ```

   See the WebSphere MQ documentation for further information on the **strmqm** command.

4. Observe the queue manager running in active mode. You do this by using the following command:

   ```
   dspmq -x
   ```

   See the WebSphere MQ documentation for further information on the **dspmq** command.
5. Start queue manager QM1 on client node B. Observe the queue manager running in standby mode.
6. Ensure that queue manager QM1 works as follows when simulating a failover from node A to node B:
   a. Stop queue manager QM1 on client node A. You do this by using the following command:

      ```
      endmqm -s QM1
      ```

      Observe on client node B, queue manager QM1 running in active mode, and on client node A that queue manger QM1 is now stopped.
   b. Restart queue manager QM1 on client node A. You do this by using the following command:

      ```
      strmqm -x QM1
      ```

      Observe on client node A, queue manager QM1 running in standby mode, and on client node B, queue manager QM1 running in active mode.

What to do next

Create a multi-instance broker.

Related concepts:

"Creating a multi-instance queue manager"
Create a multi-instance queue manager by creating the queue manager on one server, and configuring WebSphere MQ on another server to use the shared queue manager data and logs.

Related tasks:

"Configuring a WebSphere Message Broker to run in multi-instance mode" on page 827
How you configure a WebSphere Message Broker to run in multi-instance mode.

"Creating the shared directories" on page 829
How you create the shared directories that you need for your multi-instance WebSphere Message Broker.

"Creating the multi-instance broker" on page 837
How you create the multi-instance broker.

Creating a multi-instance queue manager:

Create a multi-instance queue manager by creating the queue manager on one server, and configuring WebSphere MQ on another server to use the shared queue manager data and logs.

Most of the work of setting up a multi-instance queue manager involves setting up the network storage that holds the queue manager data and log files, and making the files available to other servers using network shares. These tasks need to be performed by someone with administrative authority, such as *root* on UNIX systems. Once the shares are set up, and a normal queue manager has been created using the shares for its queue manager data and logs, you only need to configure WebSphere MQ on the other servers. You do not create the queue manager again on the other servers.

File access control

You need to take care that the user and group `mqm` on all other servers have permission to access the shares.

On UNIX platforms, you need to make the `uid` and `gid` of `mqm` the same on all the systems. You might need to edit `/etc/passwd` on each system to set a common `uid` and `gid` for `mqm`, then reboot your UNIX systems.

On Microsoft Windows, you must install WebSphere MQ on a domain server, and create a user to own WebSphere MQ resources. The user must either be a member of domain group `mqm` or a member of another global domain group which is directly or indirectly a member of `mqm`. Make this user the owner of the shared queue manager and log files. The `sid` of the user who owns the queue manager and log files is then the same as the `sid` of the user that runs instances of the queue manager.

Configuration information

Configure as many queue manager instances as you need by modifying the WebSphere MQ configuration information about each server that has WebSphere MQ installed and is to run a queue manager instance. The commands, **dspmqinf** and **addmqinf** help you to configure the additional queue manager instances, or you can edit the `mqs.ini` file on UNIX servers directly. The topics, "Create a multi-instance queue manager on Linux" on page 834 and "Create a multi-instance queue manager on Windows Server" on page 836 are examples showing how to configure a multi-instance queue manager.

On UNIX systems, you can share a single `mqs.ini` file by placing it on the network share and setting the **AMQ_MQS_INI_LOCATION** environment variable to point to it.

On Microsoft Windows, WebSphere MQ has for a number of releases kept its configuration information in the Windows registry. In release level 7.0.1 (or later), some configuration information is moved from the registry into configuration files.

Multi-instance queue manager configuration is moved out of the registry into `qm.ini` and `qmstatus.ini` files, which are located in the queue manager data directory. The WebSphere MQ configuration information (`mqs.ini` on UNIX platforms) remains in the registry on Windows as does all the configuration information for existing queue managers and new queue managers that are configured to use the default data directory.

Restrictions

1. Configure multiple instances of the same queue manager only on servers having the same operating system, architecture (both machines having 32-bit or 64-bit word size, for example), and endian settings.
2. All WebSphere MQ installations must be at release level 7.0.1 (or later).
3. Typically active and standby installations are maintained at the same maintenance level. Consult the maintenance instructions for each upgrade to check if you must upgrade all installations together.
4. The network share that contains queue manager data and logs can only be shared between queue managers that are configured with the same WebSphere MQ user, group, and access control mechanism. For example, the network share set up on a Linux server could contain separate queue manager data and logs for AIX, Solaris, HP-UX, and Linux queue managers.

5. On UNIX systems, configure the shared file system on networked storage with a `hard`, interruptible, mount rather than a `soft` mount. A hard interruptible mount forces the queue manager to hang until it is interrupted by a system call. Soft mounts do not guarantee data consistency after a server crash.
6. On Microsoft Windows, the domain group `mqm` must have full access to shared WebSphere MQ log and data directories.
7. The shared log and data directories cannot be stored on a FAT, or an NFSv3 file system.
8. z/OS does not support multi-instance queue managers; use queue sharing groups.
9. Multi-instance queue managers are supported only on the platform on which they are created.

Related concepts:

How you create the shared directories that you need for your multi-instance WebSphere Message Broker.

Create a multi-instance queue manager on Linux:

An example shows how to set up a multi-instance queue manager on Linux. The setup is small to illustrate the concepts involved. The example is based on Linux Red Hat Enterprise 5. The steps differ on other UNIX platforms.

The example is set up on a 2 GHz notebook computer with 3 GB RAM running Windows XP Service Pack 2. Two VMware virtual machines run Linux Red Hat Enterprise 5 in 640 MB images. A WebSphere MQ client is installed on an additional 400 MB VMware image that runs Windows XP Service Pack 2 and runs the sample high availability applications. All the virtual machines are configured as part of a VMware host-only network for security reasons. Although it is generally recommended not to use an automatically generated IP address, it is acceptable to use one for a short demonstration, because the IP address is unlikely to change.

Example

Table 10. Illustrative multi-instance queue manager configuration on Linux

Server 1	Server 2
Log in as *root*	
Follow the instructions in WebSphere MQ Quick Beginnings for Linuxto install WebSphere MQ, create the mqm user and group, and define `/var/mqm`.	
Carry out the task, "Verifying shared file system locking" on page 837 to check the file system supports multi-instance queue managers.	

Table 10. Illustrative multi-instance queue manager configuration on Linux (continued)

Server 1	Server 2
Check what `uid` and `gid` `/etc/passwd` displays for mqm, for example, `mqm:x:501:100:MQ User:/var/mqm:/bin/bash`	Match the `uid` and `gid` for mqm in `/etc/passwd` and reboot if you have had to change the values.
Create log and data directories in a common folder, `/MQHA`, that is to be shared. For example, 1. **mkdir** */MQHA* 2. **mkdir** */MQHA/logs* 3. **mkdir** */MQHA/qmgrs*	Create the folder, `/MQHA`, to mount the shared file system. Keep the path the same as on server 1; for example: 1. **mkdir** */MQHA*
Ensure that the `MQHA` directories are owned by user and group mqm, and the access permissions are set to `rwx` for user and group; for example **ls -al** displays, `drwxrwxr–x mqm mqm 4096 Nov 27 14:38 MQDATA` 1. **chown -R** `mqm:mqm` */MQHA* 2. **chmod -R** `ug+rwx` */MQHA*	
Create the queue manager: **crtmqm -ld** */MQHA/logs* **-md** */MQHA/qmgrs* **-q** *QM1*	
Add(The `'*'` allows all machines that can reach this one mount /MQHA for read/write. Restrict access on a production machine.) `/MQHA` `*(rw,sync,no_wdelay,fsid=0)` to `/etc/exports`	
Start the NFS daemon: */etc/init.d/***nfs** `start`	
Discover the host name or IP address of server 1: **ifconfig**(Try the command **/sbin/ifconfig** if the simple **ifconfig** command does not work.)	Mount the exported file system `/MQHA`: **mount -hard -intr -t** `nfs4` *192.168.217.130:/ /MQHA*

Copy the queue manager configuration details from Server 1,
dspmqinf -o `command QM1`
 	
and copy the result to the clip board,
`addmqinf -s QueueManager`
`-v Name=QM1`
`-v Directory=QM1`
`-v Prefix=/var/mqm`
`-v DataPath=/MQHA/qmgrs/QM1`
	Paste the queue manager configuration command into Server 2,
	addmqinf -s `QueueManager`
	-v `Name=QM1`
	-v `Directory=QM1`
	-v `Prefix=/var/mqm`
	-v `DataPath=/MQHA/qmgrs/QM1`

Start the queue manager instances, in either order, with the **-x** parameter: **strmqm -x** `QM1`	

Related concepts:

Create a multi-instance queue manager on Windows Server:

An example shows how to set up an example multi-instance queue manager on Windows Server. The setup is small and simple, to demonstrate the concepts involved, rather than being production scale. The example is based on Windows Server 2003. The steps might differ on other versions of Windows Server.

Before you begin

On Windows, multi-instance queue managers must run on a domain controller. For this reason, and for this example, install two Windows servers, and configure them as domain controllers in the same domain.

The example was set up on a 2 GHz notebook computer with 3 GB RAM running Windows XP Service Pack 2. Two VMware virtual machines ran Windows Server 2003 Service Pack 2 in 500 MB images. A WebSphere MQ client was installed on an additional 400 MB VMware image that ran Windows XP Service Pack 2 to run the sample high availability applications. All the virtual machines were configured as part of a VMware host-only network for security reasons. Although it is recommended not to use automatically generated IP address, for a short demonstration it is satisfactory as the IP addresses ought not to change. As part of the configuration you need to update the TCP/IP properties of the virtual machines with the address of the domain server you have chosen to be the DNS server.

If you configure a queue manager to run as a service, you need to check that the user the service logs on as is a member of the local group `mqm`.

Example

Table 11. Illustrative multi-instance queue manager configuration on Windows Server 2003

Server 1	Server 2
Log in with user who is a member of the local group `mqm`.	

Create log and data directories in a folder on an NTFS drive, `c:\MQHA`, making sure that the owner is a member of `mqm`, and `mqm` has full-control authority to the folders.
`C:\MQHA\data`
`C:\MQHA\log`	

Create a share `MQHA` for `C:\MQHA`.	Connect to `\\`*`hostname`*`\MQHA`
Using WebSphere MQ Explorer, create a queue manager, `QM1`, overriding the default paths to the data and log folders and use UNC names to refer to the data and log folders. `\\`*`hostname`*`\MQHA\data` and `\\`*`hostname`*`\MQHA\log`.	
On a command-line run, **`dspmqinf -o`** `command QM1` and copy the result to the clip board, `addmqinf -s QueueManager` **`-v`** `Name=QM1` **`-v`** `Directory=QM1` **`-v`** `Prefix="C:\IBM\MQ\Data"` **`-v`** `DataPath="\\`*`hostname`*`\MQHA\data\QM1"`	Paste and run the command, **`addmqinf -s`** `QueueManager` **`-v`** `Name=QM1` **`-v`** `Directory=QM1` **`-v`** `Prefix="C:\IBM\MQ\Data"` **`-v`** `DataPath="\\`*`hostname`*`\MQHA\data\QM1"`
Using WebSphere MQ Explorer, start the manager instances with the **Permit a standby instance** check box selected.	

Related concepts:

Create a multi-instance queue manager by creating the queue manager on one server, and configuring WebSphere MQ on another server to use the shared queue manager data and logs.

"Create a multi-instance queue manager on Linux" on page 834
An example shows how to set up a multi-instance queue manager on Linux. The setup is small to illustrate the concepts involved. The example is based on Linux Red Hat Enterprise 5. The steps differ on other UNIX platforms.

Verifying shared file system locking:

Run the WebSphere MQ **amqmfsck** command to check obtaining and releasing file locks, and concurrent writing on UNIX systems.

Before you begin

Before you start:

You need a machine with networked storage, and two other machines connected to it that have WebSphere MQ installed. You need to have administrator (root) authority to configure the file system, and be a WebSphere MQ administrator to run **amqmfsck**.

About this task

Create the directory or directories on the networked storage that you are going to use to share queue manager data and logs. The directory owner needs to be a WebSphere MQ administrator, that is, a member of the `mqm` group on UNIX. The user who runs the tests must have WebSphere MQ administrator authority.

Use the example of exporting and mounting a file system in "Create a multi-instance queue manager on Linux" on page 834 to help you through configuring the file system. Different file systems require different configuration steps. Refer to the file system documentation.

Procedure

1. Export the shared directory on the networked storage system and start the NFS daemon.
2. Mount the exported directory on the two WebSphere MQ servers.
3. Run **amqmfsck**, without any options, on each system to check basic locking
4. Run **amqmfsck** on both WebSphere MQ systems simultaneously, using the **-c** option, to test writing to the directory concurrently.
5. Run **amqmfsck** on both WebSphere MQ systems at the same time, using the **-w** option, to test waiting for and releasing a lock on the directory concurrently.

Creating the multi-instance broker

How you create the multi-instance broker.

Before you begin

Before you start:

1. Create the WebSphere MQ multi-instance queue manager; see "Creating the WebSphere MQ multi-instance queue manager" on page 830.

2. Create the shared directories that you require for the multi-instance broker; see "Creating the shared directories" on page 829.

About this task

A multi-instance broker can be created by using the **mqsicreatebroker** command only. It is not possible to convert an existing broker to a multi-instance broker by using the **mqsichangebroker** command, nor is it possible to migrate a broker from a previous release to a Version 7.0 multi-instance broker.

Similarly, a broker instance can be created by using the **mqsiaddbrokerinstance** command only.

You can configure a multi-instance broker to start as a WebSphere MQ service.

The following procedure gives an overview of how you create a multi-instance broker:

Procedure

1. Create a multi-instance broker called MB1 on client node A. Do this by using the following command:

   ```
   mqsicreatebroker MB1 –q QM1 –e /SharedLocation/WMB
   ```

   On Windows 7 and Windows Server 2008 systems, to run the **mqsicreatebroker** command you must open a command console with elevated privileges. To open a command console with elevated privileges, use the **mqsicommandconsole** command. For more information, see "**mqsicommandconsole** command" on page 3830.

   Specify `-d defined` on the **mqsicreatebroker** command to start the multi-instance broker as a WebSphere MQ service.

   You must ensure that the SharedLocation exists, and that your user ID has access to the shared location before you run this command.

   See the "**mqsicreatebroker** command" on page 3831 for further information.
2. Add the details of broker MB1 onto client node B. Do this by using the following command:

   ```
   mqsiaddbrokerinstance MB1 –e /SharedLocation/WMB
   ```

   See "**mqsiaddbrokerinstance** command" on page 3715 for further information.

   Note that the preceding example is for a UNIX system.
3. Start broker MB1 on client node A. Do this by using the following command:

   ```
   mqsistart MB1
   ```

   Observe the broker becoming active. Note that this assumes that queue manager QM1 is active on client node A.
4. Start broker MB1 on client node B. Observe that broker MB1 is running in standby mode against the standby queue managerQM1. Do this by using the following command:

   ```
   mqsilist
   ```
5. Ensure that broker MB1 works as follows:
   a. Stop broker MB1 and queue manager QM1 on client node A. Observe on client node B that broker MB1 and queue manager QM1 change from standby to active mode.

b. Restart queue manager QM1 and broker MB1 on client node A. Observe on client node B that queue manager QM1 and broker MB1 return to standby mode.

Deleting a multi-instance broker

How you delete a multi-instance broker.

About this task

The order of deletion of a multi-instance message broker and its associated instances is important. You should take care to use the correct command for each step in the process.

Ideally, you should remove all of the broker instances using the **mqsiremovebrokerinstance** command before you attempt to remove the broker itself. This command removes all local references to the broker instance, but does not affect the shared configuration for the multi-instance broker on the shared work path (which was specified with the -e option on the **mqsicreatebroker** and **mqsiaddbrokerinstance** commands).

Note that the **mqsiremovebrokerinstance** command cannot be issued against a standby broker instance. Stop the active broker instance before you run this command.

Now, remove the multi-instance broker using the **mqsideletebroker** command. This process removes all references to the broker on both the local and shared work paths.

If you make a mistake, and unintentionally remove a broker instance, it can be re-created using the **mqsiaddbrokerinstance** command, providing that the **mqsideletebroker** command has not been used to delete the broker.

If the multi-instance broker has been removed using the **mqsideletebroker** command before removing any associated broker instances, it will not be possible to start the broker instances.

To recover from this situation, re-create the multi-instance broker using the **mqsicreatebroker** command with the -e option, specifying the original shared work path location.

The following procedure gives an overview of how you delete a multi-instance broker:

Procedure

1. Stop the multi-instance broker `MB1` on client node `A`.
2. Stop the multi-instance broker `MB1` on client node `B`.
3. Remove the broker instance `MB1` on client node `B`. Do this by using the following command:

   ```
   -mqsiremovebrokerinstance MB1
   ```

   See "**mqsiremovebrokerinstance** command" on page 3918 for further information.
4. Remove the broker `MB1` on client node `A`. Do this by using the following command:

   ```
   -mqsideletebroker MB1
   ```

   See "**mqsideletebroker** command" on page 3863 for further information.

   Note, that you must remove broker instances created by using the **mqsiaddbrokerinstance** command before you remove the main broker created using the **mqsicreatebroker** command.

"**mqsideletebroker** command" on page 3863
Use the **mqsideletebroker** command to delete a named broker. The command also deletes the queues on the associated queue manager (created when the broker was created). You can also specify that the queue manager is to be deleted.

"**mqsiremovebrokerinstance** command" on page 3918
Use the **mqsiremovebrokerinstance** command to remove a multi-instance broker from a server where WebSphere Message Broker has been installed.

Deleting a multi-instance queue manager

To delete a multi-instance queue manager completely, you need to use the WebSphere MQ **dltmqm** command to delete the queue manager, then remove instances from other servers using either the WebSphere MQ **rmvmqinf** or WebSphere MQ **dltmqm** commands.

Run the WebSphere MQ **dltmqm** command to delete a queue manager that has instances defined on other servers, on any server where that queue manager is defined. You do not need to run the WebSphere MQ **dltmqm** command on the same server that you created it on. Then run the WebSphere MQ **rmvmqinf** or WebSphere MQ **dltmqm** command on all the other servers which have a definition of the queue manager.

You can only delete a queue manager when it is stopped. At the time you delete it no instances are running, and the queue manager, strictly speaking, is neither a single or a multi-instance queue manager; it is simply a queue manager that has its queue manager data and logs on a remote share. When you delete a queue manager, its queue manager data and logs are deleted, and the queue manager stanza is removed from the `mqs.ini` file on the server on which you issued the WebSphere MQ **dltmqm** command. You need to have access to the network share containing the queue manager data and logs when you delete the queue manager. On Windows there is no `mqs.ini` file; instead, the queue manager stanza is removed from the registry.

On other UNIX platform servers where you have previously created instances of the queue manager there are also entries in the `mqs.ini` files on those servers. You need to visit each server in turn, and remove the queue manager stanza by running the WebSphere MQ command **rmvmqinf** *Queue manager stanza name*. On Windows, run the same command, and the queue manager stanza is removed from the registry.

On UNIX platforms, if you have placed a common `mqs.ini` file in network storage and referenced it from all the servers by setting the `AMQ_MQS_INI_LOCATION` environment variable on each server, you need to delete the queue manager from only one of its servers as there is only one `mqs.ini` file to update.

Example

First server

```
dltmqm QM1
```

Other servers where instances are defined

```
rmvmqinf QM1, or

dltmqm QM1
```

Listing a multi-instance broker

How you list a multi-instance broker.

Procedure

Use the **mqsilist** command to view multi-instance brokers. Do this by using the following command:

```
mqsilist
```

The output from the **mqsilist** command is of the following format:

```
BIP1284I: Broker 'BK1' on queue manager 'QM1' is running.
BIP1292I: The multi-instance Broker 'BKHA1' on multi-instance queue manager
 'QMHA1' has stopped.
BIP1294I   Broker 'BKHA2' is a multi-instance broker running in standby mode
 on multi-instance queue manager 'QMHA2'.
BIP1295I Broker 'BKHA3' is a multi-instance broker running in active mode on
 multi-instance queue manager 'QMHA3'
BIP8071I: Successful command completion.
```

Results

The preceding results show:

- A standard broker `BK1` running
- A multi-instance broker `BKHA1` stopped
- A multi-instance broker `BKHA2` started in Standby mode
- A multi-instance broker `BKHA3` running in Active mode.

Back up and restore a multi-instance broker

How you back up and restore a multi-instance broker.

Before you begin

Before you start:

To ensure that the backup is complete and correct, back up the broker when the broker is stopped, or when it is not processing a configuration change (such as a deployment or property change).

About this task

When you back up a multi-instance broker, you back up the registry and configuration from the shared work path of the broker and its associated instances.

Hence you perform the backup procedure described in this topic for the multi-instance broker only. There are no additional steps for backing up the associated instances of the broker.

When you restore a multi-instance broker, you re-create associated instances by using the **mqsiaddbrokerinstance** command.

Procedure

1. Back up a multi-instance broker in the standard way by using the **mqsibackupbroker** command. Do this by using the following command:

   ```
   mqsibackupbroker MB1 –d /BackupDirectory/WMB
   ```

   where:

   - `MB1` is the name of the broker.
   - `/BackupDirectory/WMB` is the directory in which the backup file is created.

   The command detects a multi-instance broker and backs up the registry and configuration from the shared work path of the broker.

   There are no additional backup steps for the associated instances of the broker.
2. Restore a multi-instance broker in the standard way by using the **mqsirestorebroker** command. Do this by using the following command:

   ```
   mqsirestorebroker MB1 –d /BackupDirectory/WMB -a 20091009.zip
   ```

   where:

   - `MB1` is the name of the broker.
   - `/BackupDirectory/WMB` is the directory in which the backup file is stored.
   - `20091009.zip` is the name of the backup (archive) file.

   The command detects a multi-instance broker and restores the registry and configuration to the shared work path of the broker.
3. Re-create associated instances of the multi-instance broker by using the **mqsiaddbrokerinstance** command. See the "**mqsiaddbrokerinstance** command" on page 3715 for further information.

Using a broker with an existing high availability manager

You can use WebSphere Message Broker Version 7.0 with an existing high availability manager, for example HACMP, HA/XD, VCS, or HP-UX Serviceguard.

About this task

With the introduction of multi-instance message brokers, configuring WebSphere Message Broker Version 7.0 with a high availability (HA) manager is much easier. Previously, support pack IC91 was provided to assist in configuring this requirement.

A number of scripts were provided, but most of these are no longer required because WebSphere Message Broker Version 7.0 has built in many of the functions as a result of the multi-instance work.

This topic summarizes how to complete the following tasks:

1. Create a broker.
2. Add a broker instance.
3. Start a broker.
4. Stop a broker.
5. Monitor a broker.
6. Delete a broker.

Procedure

1. To create a broker, mount the shared resource onto your primary node and use the following **mqsicreatebroker** command with the **-e** parameter to specify your shared resource location.

   ```
   mqsicreatebroker MyBroker -q MQ1 -e /MQHA/MyBroker/
   ```

   where:

   - `MyBroker` is the name of the broker.
   - `MQ1` is the name of the queue manager.
   - `/MQHA/MyBroker/` is the directory for your shared resource.

2. To add another broker instance, mount the shared resource onto your secondary nodes and use the following **mqsiaddbrokerinstance** command.

   ```
   mqsiaddbrokerinstance MyBroker –e /MQHA/MyBroker/
   ```

   where:

   - `MyBroker` is the name of the broker.
   - `/MQHA/MyBroker/` is the directory for your shared resource.

3. To start a broker, you can use one of the following script files:

   hamqsi_start_broker

   ```
   #!/bin/ksh
   # Module:
   #   hamqsi_start_broker
   #
   # Args:
   #   BROKER = name of broker to start
   #
   # Description:
   #   This script attempts to start the MQSI Broker
   #
   #   Runs as the userid which runs broker, and must have
   #   the user's environment (i.e. invoke from "su - $MQUSER ..")
   #

   BROKER=$1

   if [ -z "$BROKER" ]
   then
   ```

```
  echo "hamqsi_start_broker: ERROR! No Broker name supplied"
  echo "   Usage: hamqsi_start_broker <BROKER>"
  exit 1
fi

# Ensure that the broker is not already running. In this test
# we look for any broker-related processes, which might have
# been left around after a previous failure. Any that remain
# must now be terminated. This is a brutal means of mopping
# up broker processes.
# We stop the processes in the following order:
#   bipservice       - first so it cannot issue restarts
#   bipbroker        - next for same reason
#   biphttplistener
#   startDataFlowEngine
#   DataFlowEngine  - last
#
echo "hamqsi_start_broker: Ensure $BROKER not already running"
for process in bipservice bipbroker biphttplistener startDataFlowEngine DataFlowEngine
do
  # Output of kill redirected to /dev/null in case no processes
  ps -ef | grep "$process $BROKER" | grep -v grep | \
     awk '{print $2}'| xargs kill -9 > /dev/null 2>&1
done

# Start the Broker
echo "hamqsi_start_broker: Start Broker " $BROKER
mqsistart $BROKER > /dev/null 2>&1
if [ $? -ne "0" ]
then
  echo "hamqsi_start_broker: Bad result from mqsistart for $BROKER"
  exit 1
fi

# Check to see if the broker service has started. This loop
# uses a fixed online timeout of approx. 10 seconds.
TIMED_OUT=yes

  echo "hamqsi_start_broker: Broker service failed to start: " $BROKER
```

```
  exit 1
fi

exit 0
```

hamqsi_start_broker_as

```
#
#!/bin/ksh
# Module:
#   hamqsi_start_broker_as
#
# Args:
#   broker = broker name
#   qm     = name of broker queue manager
#   mquser = user account under which QM and Broker are run
#
# Description:
#   Starting an MQSI Broker requires the following services:
#   (1) The MQSeries Queue Manager which supports the Broker
#   (2) The MQSI Broker service
#   This script provides a single source to initiate the required
#   services in sequence.
#
#   Queue Manager:
#   This script uses the strmqm script supplied by MQSeries V7
#
#   Broker:
#   This script then invokes the hamqsi_start_broker script which
#   checks that the broker is fully stopped and then starts it.
#
#   The hamqsi_start_broker_as script should be run as root.

# Check running as root
if [ `id -u`  -ne 0 ]
then
  echo "Must be running as root"
  exit 1
fi

BROKER=$1
QM=$2
MQUSER=$3

# Check all parameters exist

if [ -z "$BROKER" ]
then
  echo "hamqsi_start_broker_as: ERROR! No Broker name supplied"
  echo "  Usage: hamqsi_start_broker_as <BROKER> <QM> <MQUSER>"

5. To monitor a broker, you can use the following script file that checks only for the existence of the main broker processes and provides a successful return code if they are found:

hamqsi_monitor_broker_as

```
#!/bin/ksh
# Module:
#   hamqsi_monitor_broker_as
#
# Args:
#   BROKER = name of broker in AppServer
#   QM     = name of queue manager in AppServer
#   MQUSER = userid under which queue manager and broker run
#
# Description:
#   This is the application monitor script used with HACMP/ES. It
#   needs to be invoked by a parameter-less wrapper script because
#   HACMP does not allow parameters to be passed to application
#   monitor scripts.
#
#   This hamqsi_monitor_broker_as script is run as root, and uses
#   su as needed to monitor the 3 components of the application server.
#
#   This script is tolerant of a queue manager that is still in
```

```
#   startup. If the queue manager is still starting this application
#   monitor script will exit with 0 - which indicates
#   to HACMP that there's nothing wrong. This is to allow for
#   startup time for the queue manager which might exceed the
#   Stabilisation Interval set for the Application Monitor in HACMP/ES.
#
#
# Exit codes:
#   0  => Broker & QM are all running OK or starting
#   >0 => One or more components are not responding.
#

# Check running as root
if [ `id -u`  -ne 0 ]
then
  echo "Must be running as root"
  exit 1
fi

BROKER=$1
QM=$2
MQUSER=$3

# Check the parameters

esac
```

If you require more information than that supplied by the preceding example, you can code your monitor to do the following actions:

- Subscribe to WebSphere Message Broker accounting and statistics, and analyze the results.
- Put a dummy message through the broker and analyze the results.

6. Before you delete the broker on the primary node, you must delete any brokers on the standby nodes. To delete a broker, use the **mqsiremovebrokerinstance** command on the secondary nodes, and the **mqsideletebroker** command on the primary node.

Results

For further information about configuring WebSphere MQ with a high availability manager, refer to the WebSphere MQ Version 7 Information Center online.

See the:

Using a broker with an existing Windows Cluster (Windows Server 2003 or 2008)

You can use WebSphere Message Broker Version 7.0 with the existing high availability manager for Windows Server 2003 (Microsoft Cluster Service - MSCS) or Windows Server 2008 (Failover Cluster Manager).

About this task

With the introduction of multi-instance brokers, configuring WebSphere Message Broker Version 7.0 with a high availability (HA) manager is much easier. Previously, support pack IC91 was provided to assist in configuring this requirement.

A number of scripts were provided in support pack IC91, but most of these scripts are no longer required because WebSphere Message Broker Version 7.0 has built-in many of the functions as a result of the multi-instance work.

This topic summarizes how to complete the following tasks:

1. Complete the prerequisite setup.
2. Configure a local group.
3. Create a broker.
4. Add broker instances to the additional nodes.
5. Add the broker service to the cluster configuration
6. Start and stop a broker.
7. Delete a broker.

Procedure

1. To complete the prerequisite setup, complete the following steps:
   a. Validate your MSCS configuration (on Windows Server 2003) or Failover Cluster Manager configuration (on Windows Server 2008).
   b. Complete all of the steps documented in 'Supporting the Microsoft Cluster Service' of the WebSphere MQ documentation to create a cluster configuration that contains the queue manager on which you want the broker to run.
   c. Note the `haregtyp.exe` command as a prerequisite for creating WebSphere MQ resources in the cluster.
2. To configure a local group, ensure that the domain user under which you want the broker to run exists in the local *mqbrkrs* group on all nodes on which you want the broker to run.
3. To create a broker, use the following **mqsicreatebroker** command on the node on which your cluster is currently running.

   ```
   mqsicreatebroker MyBroker -q MQ1 -e E:\Broker\Workspace
   ```

   where:
   - `MyBroker` is the name of the broker.
   - `MQ1` is the name of the queue manager.
   - `E:\Broker\Workspace` is the directory of a shared disk (nonquorum) in your cluster configuration.
4. To add this broker instance to the other nodes in your cluster, switch your cluster to each node in turn. When a node is active, use the following **mqsiaddbrokerinstance** command.

   ```
   mqsiaddbrokerinstance MyBroker –e E:\Broker\Workspace
   ```

   where:
   - `MyBroker` is the name of the broker.
   - `E:\Broker\Workspace` is the directory of a shared disk (nonquorum) in your cluster configuration.

5. To add a broker generic service resource to the cluster which contains the broker queue manager, complete the following steps:
   a. Select the IBM WebSphere Message Broker component `MyBroker` service when asked. All other settings can be left unchanged.
   b. Add a dependency on the WebSphere MQ resource, to ensure that the queue manager is started before the broker.
6. To start and stop the broker resource, use the MSCS configuration (on Windows Server 2003) or Failover Cluster Manager (on Windows Server 2008).
7. To delete a broker resource from the MSCS configuration (on Windows Server 2003) or Failover Cluster Manager (on Windows Server 2008), complete the following steps:
   a. Delete the broker generic service from the cluster configuration.
   b. Use the **mqsiremovebrokerinstance** command on all nodes but one, moving the cluster between nodes before running each command.
   c. On the final node, use the **mqsideletebroker** command to completely remove the broker configuration.

Results

HTTP proxy servlet overview

The HTTP proxy servlet is a Java servlet that you can use in an external web servlet container, such as IBM WebSphere Application Server or Apache Tomcat, to receive HTTP requests from web services client applications, to replace the support provided by the broker and execution group HTTP listeners.

By using the HTTP proxy servlet in an external web servlet container, you can support a larger number of concurrent HTTP sessions, high availability, load distribution, and access to the broker from multiple IP addresses and ports.You can use the servlet to replace either the broker-wide listener, or an embedded listener in a specific execution group.

The HTTP proxy servlet supports SSL (HTTPS) secure protocol when it is deployed in a properly configured web servlet container.

You cannot use the HTTP proxy servlet if you configure your broker environment to use multi-instance WebSphere MQ queue managers; the servlet cannot connect to the standby queue manager when it becomes active.

For a detailed description of the proxy servlet, its location in the runtime directory path, and its function, see: "HTTP proxy servlet; proxy servlet component" on page 865

Before you install and test the HTTP proxy servlet, ensure you understand the following concepts:

- "HTTP traffic handling in WebSphere Message Broker" on page 857

Before you can deploy the proxy servlet `web.xml` to the servlet container, you must configure it with the following initialization parameters for the broker environment that the servlet connects to.

HTTP traffic handling in WebSphere Message Broker

Before reading about HTTP traffic handling using the proxy servlet in an external Web container, ensure that you understand the basic structure of HTTP traffic handling in WebSphere Message Broker.

WebSphere Message Broker supports Web services requests over HTTP. Brokers have HTTP listeners that receive requests, which are propagated to message flows that contain the following nodes:

- HTTPInput
- HTTPReply
- SOAPInput
- SOAPReply

WebSphere Message Broker has two types of listeners:

- A listener that is started and managed by the broker, which you can use for messages for the HTTP nodes. This listener supports two ports, one for HTTP and one for HTTPS (HTTP over SSL) messages.
- A listener that is started and managed by an execution group (an embedded listener), which you can use for messages for the SOAP and HTTP nodes. This listener also supports two ports for HTTP and HTTPS messages.

HTTP traffic handling is based on node type:

- HTTP nodes: The default configuration for HTTP nodes is for the broker listener to handle HTTP messages through port `7080`. Connections are made into the broker HTTP listener, which places requests on the SYSTEM.BROKER.WS.INPUT queue, from which the HTTPInput nodes read the data. After the flow has reached an HTTPReply node, the reply data is placed on the SYSTEM.BROKER.WS.REPLY queue, where the data is read by the HTTP listener and sent back to the HTTP client.

  If you want HTTP nodes to handle HTTPS messages, you must update the broker configuration to define a second port for HTTPS, and set the property to enable HTTPS processing, by using the **mqsichangeproperties** command. You can also change the port or ports on which the listener is listening by using this command.

  Because WebSphere MQ queues are used to couple the HTTP listener to the message flows, requests received by the HTTP listener can be processed by any message flow in any execution group (provided that the Web address selector matches), and the reply can come back from any execution group.

  You can also use the embedded execution group listener to process HTTP and HTTPS messages. You can change the configuration and port numbers by using the **mqsichangeproperties** command.

Connections are made directly to the execution groups, and requests are passed to the HTTPInput nodes in that execution group. The HTTP data is passed to the HTTPInput node, processed in the flow, and sent back directly from the HTTPReply node.

Because the network connection is made to a particular execution group, the reply must be sent back from that execution group.

- SOAP nodes: Connections are made directly to the execution group listener, and requests are passed to the SOAPInput nodes in that execution group. The HTTP data is passed to the SOAPInput node, processed in the flow, and sent back directly from the SOAPReply node.

  Because the network connection is made to a particular execution group, the reply must be sent back from that execution group.

For more details about these listeners, see "Processing HTTP messages" on page 1579.

Before you install and test the HTTP proxy servlet, ensure that you understand the following concepts:

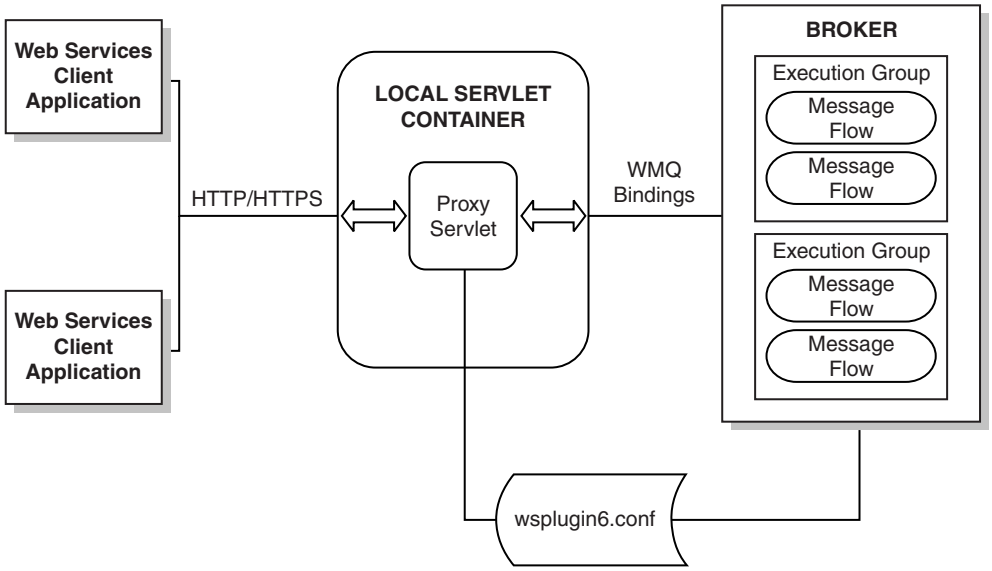
HTTP traffic handling by using the proxy servlet in an external web servlet container

Before you install and test the HTTP proxy servlet, ensure that you understand the structure of HTTP traffic handling by using the proxy servlet in an external web servlet container, such as IBM WebSphere Application Server or Apache Tomcat.

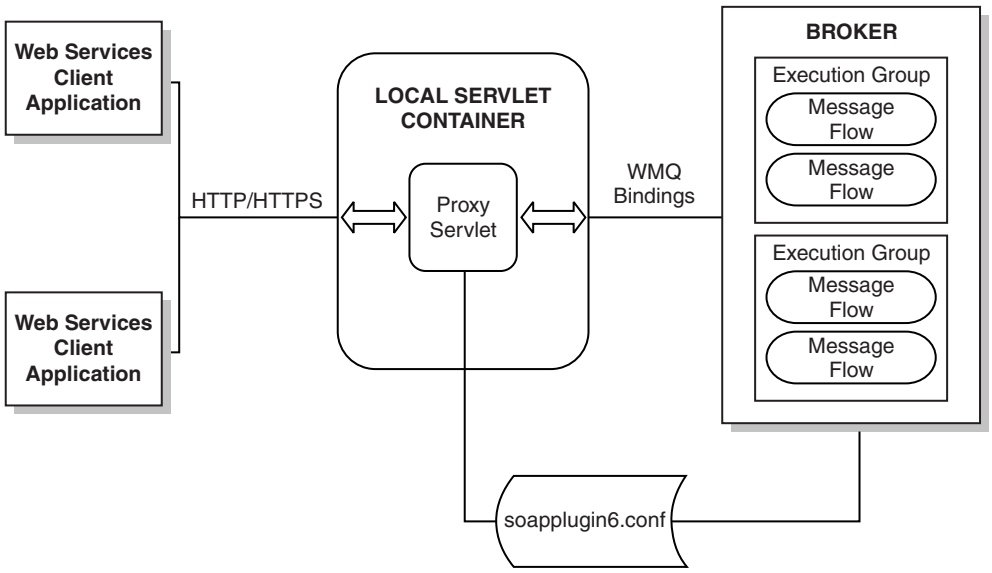
The proxy servlet is a Java servlet that produces the function of the broker HTTP listeners in an external web servlet container, such as WebSphere Application Server or Apache Tomcat. After the proxy servlet is deployed and running on the web servlet container, it uses the HTTP listener of the container to receive HTTP requests. If the web servlet container is configured to support SSL (HTTPS), web services requests are received by the message flows by using a secure communications protocol. For more information, see: "HTTP proxy servlet; proxy servlet component" on page 865

Components and configurations supported by the proxy servlet:

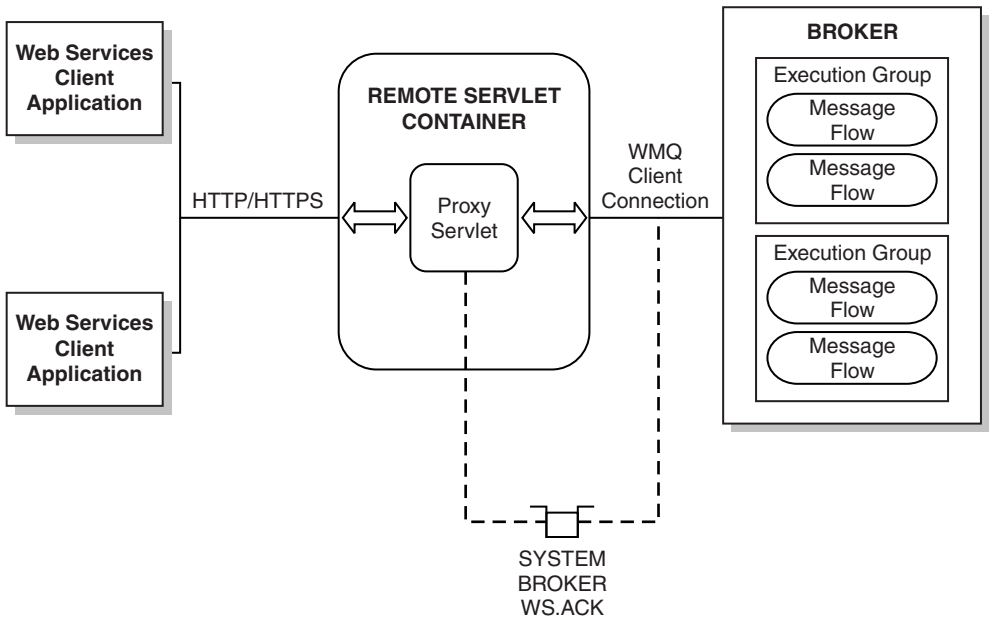
The following figures show the components and configurations that are supported by the proxy servlet, for descriptions of the components listed in these figures, see: "HTTP proxy servlet; descriptions of required components" on page 863



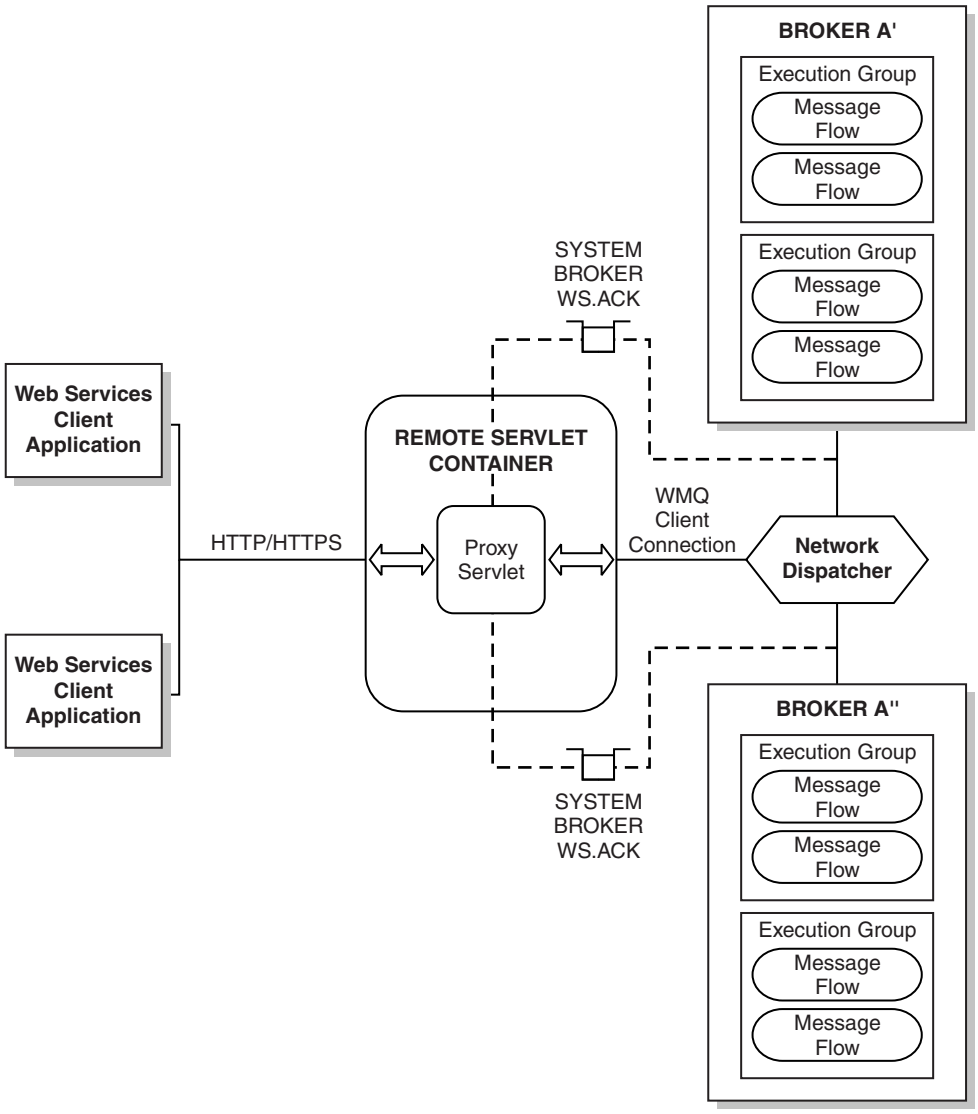
In the above figure the proxy servlet is running on the same server as the message broker. The proxy servlet connects to the broker queue manager by using bindings mode (local connection) and the servlet is configured to access only HTTP nodes and therefore has been configured to access the HTTP nodes configuration file `wsplugin6.conf`.



In the above figure the proxy servlet is running on the same server as the message broker. The proxy servlet connects to the broker queue manager by using bindings mode (local connection) and the servlet is configured to access only SOAP nodes and therefore has been configured to access the SOAP nodes configuration file `soapplugin6.conf`.



In the above figure the proxy servlet is running on a remote server to the message broker. The proxy servlet connects to the broker queue manager by using client mode (remote connection) and the servlet can be configured to access HTTP or SOAP nodes and the HTTP or SOAP node configuration is retrieved from the SYSTEM.BROKER.WS.ACK queue.



In the above figure the proxy servlet is configured to load balance WebSphere MQ connections across multiple message brokers. Network dispatchers or load balancers are required for this configuration to work.

When the proxy servlet is configured to connect to multiple brokers, the brokers must be identical clones of each other, which means that the same HTTP and SOAP flows are deployed with the same web addresses.

The proxy servlet sends the HTTP requests over the WebSphere MQ connections trying to distribute the load between the active broker connections.

Before you install and test the HTTP proxy servlet, ensure you understand the following concepts:

HTTP proxy servlet; message flows component:

The HTTP proxy servlet requires a number of components such as message flows, a proxy servlet, a servlet container, web addresses, the Broker component, and web services clients. Ensure that you are familiar with the message flows component.

Message flows execute the functions of transforming, logging, enriching, and routing messages. Message flows can use HTTP or SOAP input nodes to receive requests and HTTP or SOAP reply nodes to send responses. Each HTTP or SOAP input node has a web address configured in the node properties. The HTTP or SOAP input nodes only receive request messages addressed to the configured web address.

The proxy servlet is not aware of the execution groups that the message flows are deploying.

Before you install and test the HTTP proxy servlet, ensure you understand the following concepts:

"Testing the proxy servlet" on page 892
Test the proxy servlet with a message broker that receives HTTP requests and passes them to a message flow.

HTTP proxy servlet; proxy servlet component:

The HTTP proxy servlet requires a number of components such as message flows, a proxy servlet, a servlet container, web addresses, the Broker component, and web services clients. Ensure that you are familiar with the proxy servlet component.

A *Proxy servlet* is a Java Web Application Archive (WAR) file that is part of the runtime environment in WebSphere Message Broker Version 6.1 Fix Pack 3 (6.1.0.3) and above, and can be found in the following directory:

WMB61_runtime_install_path/tools. Where *WMB61_runtime_install_path* specifies the name of your runtime installation directory.

The proxy servlet is a Java servlet that receives HTTP requests. The proxy servlet matches the received web address with the web address that the HTTP or SOAP input nodes are monitoring, then passes the HTTPRequest to the correct HTTP or SOAP input node flow using WebSphere MQ.

The proxy servlet receives response messages from the HTTP or SOAP reply nodes and sends them back to the client applications over HTTP or HTTPS. The message broker has several internal WebSphere MQ queues, SYSTEM.BROKER.WS.* queues, that are used for the communication between the proxy servlet and the HTTP or SOAP input and reply nodes.

Each HTTP or SOAP input node monitors the arrival of requests associated to specific web addresses. The message broker has internal configuration files, and an internal WebSphere MQ queue SYSTEM.BROKER.WS.ACK, that contain the list of web addresses that are monitored by the different HTTP or SOAP input nodes in message flows deployed on any execution groups. The proxy servlet accesses the

internal file, or queue, to match the web addresses received in HTTP or HTTPS requests with the web addresses that the HTTP or SOAP input nodes that are waiting for.

The configuration files, or queue, have a unique correlation ID associated with each web address. The HTTP or SOAP input node uses this correlation ID to get the messages from the internal queue SYSTEM.BROKER.WS.INPUT, and the proxy servlet uses the same correlation ID to put the messages on this queue. This is the mechanism used to correlate the incoming HTTP or HTTPS requests and the HTTP or SOAP input nodes in the message flows.

The HTTP or SOAP input node copies the WebSphere MQ input message ID in the LocalEnvironment.Destination.HTTP.RequestIdentifier to be used by the HTTP or SOAP reply node for WebSphere MQ output message correlation ID. The proxy servlet does a selective GET by correlation ID to the reply queue SYSTEM.BROKER.WS.REPLY, and receives the response messages.

The proxy servlet accepts GET and POST HTTP or HTTPS requests.

Before you install and test the HTTP proxy servlet, ensure you understand the following concepts:

HTTP proxy servlet; servlet container component:

The HTTP proxy servlet requires a number of components such as message flows, a proxy servlet, a servlet container, web addresses, the Broker component, and web services clients. Ensure that you are familiar with the servlet container component.

A *Servlet container* is the runtime environment for servlets and Java Server Pages (JSP). WebSphere Application Server and Apache Tomcat are two examples of servlet containers (or web containers) that are available. The proxy servlet can be deployed in a local servlet container that is running on the same server as message broker or on a remote servlet container that is running on a remote server to message broker. The servlet container must allow the proxy servlet to configure and call the WebSphere MQ classes for Java.

The servlet container provides the SSL (HTTPS) listener support for web services applications. SSL must be configured and available in the container. The proxy servlet does not have to be configured for SSL but it enforces HTTP requests over SSL if the HTTP or SOAP input node is configured to use SSL.

Before you install and test the HTTP proxy servlet, ensure you understand the following concepts:

- "HTTP proxy servlet overview" on page 856

"Testing the proxy servlet" on page 892
Test the proxy servlet with a message broker that receives HTTP requests and passes them to a message flow.

HTTP proxy servlet; web addresses component:

The HTTP proxy servlet requires a number of components such as message flows, a proxy servlet, a servlet container, web addresses, the Broker component, and web services clients. Ensure that you are familiar with the web addresses component.

web addresses, or Universal Resource Locators (URLs), have an important role when HTTP or SSL (HTTPS) protocols are used. In WebSphere Message Broker, each HTTP or SOAP input node expects to receive requests from a specific web address, or web addresses when wildcard characters are used. The servlet container also uses the web address to locate the servlets that are going to process the HTTP or HTTPS requests received by the listener in the container.

The proxy servlet passes the requests from the servlet container to the broker and vice versa. web addresses have the dual function of locating servlets and locating HTTP or SOAP input nodes. This affects the format of the web addresses used for the broker.

A web address is made up of the following structure:

`<schema>://<hostname>:<port>/<url_path>`

web address structure definition:

- *<schema>*
- *<hostname>*
- *<port>*
- *<url_path>*

<schema> is HTTP or HTTPS.

<hostname> is the hostname, or IP address, of the server where the servlet container is running.

<port> is the port number that the servlet container is listening on.

<url_path> is a series of tokens separated by slashes /. These are used to indicate the location of the servlet and the location of the HTTP or SOAP input nodes.

Because the *<url_path>* is used for mapping two resources (instead of one with the broker internal listener) the format of the web address will change when the proxy servlet is used.

The broker structure of the *<url_path>* is:

/<url_path>=/<context_root>/<node_url_path>

Broker *<url_path>* structure definition:

- *<context_root>*
- *<node_url_path>*
- *<port>*
- *<url_path>*

<context_root> is the *<url_path>* allocated to the proxy servlet by the container when the servlet is installed and deployed.

<node_url_path> is the part of the web address path that is added to make the web address unique to a specific HTTP or SOAP input node.

The entire *<url_path>* has to be configured in the properties of the HTTPInput node.

In some web servlet containers, it is possible to configure the proxy servlet to receive all the HTTP or HTTPS requests arriving to the container (*<context_root>* = `"/*"`). In this case, the existing web addresses in the HTTP nodes do not have to change when the proxy servlet is implemented.

Before you install and test the HTTP proxy servlet, ensure you understand the following concepts:

- "HTTP proxy servlet overview" on page 856
- "HTTP traffic handling in WebSphere Message Broker" on page 857
- "HTTP traffic handling by using the proxy servlet in an external web servlet container" on page 859
- "HTTP proxy servlet; descriptions of required components" on page 863

When you have gained an understanding of the proxy servlet concept, read the following topics to help you install and test the HTTP proxy servlet:

- "Installing the proxy servlet" on page 872
- "Testing the proxy servlet" on page 892

Related concepts:

"HTTP proxy servlet overview" on page 856
The HTTP proxy servlet is a Java servlet that you can use in an external web servlet container, such as IBM WebSphere Application Server or Apache Tomcat, to receive HTTP requests from web services client applications, to replace the support provided by the broker and execution group HTTP listeners.

"HTTP traffic handling in WebSphere Message Broker" on page 857
Before reading about HTTP traffic handling using the proxy servlet in an external Web container, ensure that you understand the basic structure of HTTP traffic handling in WebSphere Message Broker.

"HTTP traffic handling by using the proxy servlet in an external web servlet container" on page 859
Before you install and test the HTTP proxy servlet, ensure that you understand the structure of HTTP traffic handling by using the proxy servlet in an external web servlet container, such as IBM WebSphere Application Server or Apache Tomcat.

"HTTP proxy servlet; descriptions of required components" on page 863
The HTTP proxy servlet requires a number of components such as message flows, a proxy servlet, a servlet container, web addresses, the Broker component, and web

services clients.

Related tasks:

"Testing the proxy servlet" on page 892
Test the proxy servlet with a message broker that receives HTTP requests and passes them to a message flow.

HTTP proxy servlet; Broker component:

The HTTP proxy servlet requires a number of components such as message flows, a proxy servlet, a servlet container, web addresses, the Broker component, and Web services clients. Ensure that you are familiar with the Broker component.

The Broker component is the runtime environment for the message flows. Message flows can receive requests over HTTP when there are HTTP or SOAP input nodes in the flow.

WebSphere Message Broker has two types of HTTP listener: broker-wide listeners and execution group (embedded listeners). For more information about the two types of listener, see "HTTP listeners" on page 1589.

Each listener has its unique TCP/IP port to listen for HTTP and HTTPS requests.

The proxy servlet implements the HTTP or HTTPS listener function in an external servlet container.

Before you install and test the HTTP proxy servlet, ensure that you understand the following concepts:

- "HTTP proxy servlet overview" on page 856
- "HTTP traffic handling in WebSphere Message Broker" on page 857
- "HTTP traffic handling by using the proxy servlet in an external web servlet container" on page 859
- "HTTP proxy servlet; descriptions of required components" on page 863

When you have gained an understanding of the proxy servlet concept, read the following topics to help you install and test the HTTP proxy servlet:

Installing the proxy servlet

The installation of the proxy servlet is made up of a number of tasks. Use this topic to complete each of the tasks to then move onto testing the proxy servlet.

Before you begin

Before you install the HTTP proxy servlet, ensure that you understand the following concepts:

- "HTTP traffic handling in WebSphere Message Broker" on page 857
- "HTTP traffic handling by using the proxy servlet in an external web servlet container" on page 859
- "HTTP proxy servlet; descriptions of required components" on page 863

About this task

The proxy servlet `proxyservlet.war` (WAR) file is part of the runtime environment in WebSphere Message Broker Version 6.1 Fix Pack 3 (6.1.0.3) and above, and can be found in the following directory:

WMB61_runtime_installation_path`/tools`. Where *WMB61_runtime_installation_path* specifies the name of your runtime installation directory.

Supported operating systems

The proxy servlet runs on any operating system that is supported by the servlet container. The documentation in this section describes the installation on Windows XP but the proxy servlet can be installed on other operating systems.

Prerequisites

The proxy servlet requires:

- WebSphere Message Broker Version 7.0, or later.
- A supported version of WebSphere MQ. For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.
- A servlet container and web server, such as WebSphere Application Server Version 6, or Apache Tomcat Version 6.

To install the proxy servlet:

Procedure

1. Install and customize a web servlet container, such as WebSphere Application Server or Apache Tomcat. For more information, see "Installing and customizing a web servlet container for the proxy servlet."
2. Configure the proxy servlet with the initialization parameters that are used by the proxy servlet. For more information, see "Configuring the proxy servlet" on page 876.
3. Enable the WebSphere MQ listener on each execution group where message flows with SOAP nodes are deployed so that the proxy servlet can access the SOAPInput and SOAPReply nodes. For more information, see "Enabling the WebSphere MQ listener for SOAP nodes for the proxy servlet to access" on page 889.
4. Deploy the proxy servlet in the web servlet container. For more information, see "Deploying the proxy servlet in the web servlet container" on page 891.

Results

You are now ready to test the proxy servlet. For information about how to complete this task, see "Testing the proxy servlet" on page 892.

Related concepts:

"Testing the proxy servlet" on page 892
Test the proxy servlet with a message broker that receives HTTP requests and passes them to a message flow.

Installing and customizing a web servlet container for the proxy servlet:

Download, install, and customize a web servlet container, such as WebSphere Application Server or Apache Tomcat, for the proxy servlet to use to receive HTTP requests from web services client applications.

Before you begin

Before you install the servlet container, you must have completed the following tasks:
- Installed WebSphere Message Broker.
- If you are planning to install Apache Tomcat V6 as your web servlet, you must have installed a Java SDK that is compatible with Apache Tomcat V6.

About this task

The documentation in this section is based on an Apache Tomcat Version 6 installation, however this procedure can be used to guide you through the installation of a different web servlet container because the procedures are similar. This information describes the Apache Tomcat V6 installation on Windows XP and assumes WebSphere Message Broker is installed and running on the same server.

Windows **Windows**

Procedure

1. Download Apache Tomcat V6 to your local directory from the Apache Tomcat 6 Downloads website at: Apache Tomcat 6 download page
2. Run the Apache Tomcat V6 installer.
   a. Accept the license agreement.
   b. Select the required Apache Tomcat components and features to install.
   c. Select the destination directory for the Apache Tomcat installation. For example, `C:\Tomcat6`.
   d. Enter an HTTP listener port. For example, 8181.
   e. Type an administrator user ID and password. For example, *admin*.
   f. Browse and select a path for the J2SE 5.0 Java Runtime Environment (JRE). For example, `C:\Program Files\IBM\Java50\jre`.
   g. Click **Install** to start the installation.
3. Restart Windows. Apache Tomcat is now running as a Windows Service.
4. Open a web browser, such as Internet Explorer, and enter web address http://localhost:8181. Apache Tomcats home page is displayed.
5. Find file `catalina.properties` in your local directory. For example, <*tomcat_installation_path*>`/conf`. Where <*tomcat_installation_path*> specifies the name of your Apache Tomcat installation directory.
6. Edit `catalina.properties` and change **`shared.loader=`** to **`shared.loader= ${catalina.home}/shared/lib,${catalina.home}/shared/lib/*.jar`**.
7. Create a directory called <*tomcat_installation_path*>`/shared/lib`.
8. Copy the required WebSphere MQ JAR files into the Apache Tomcat shared loader directory. The proxy servlet uses WebSphere MQ to communicate with WebSphere Message Broker. It requires the following JAR files to exist in the Apache Tomcat shared loader directory: `com.ibm.mq.jar` and `connector.jar`. From WebSphere MQ Version 7.0 onwards, you also require the following JAR files:
   - `com.ibm.mq.commonservices.jar`
   - `com.ibm.mq.headers.jar`
   - `com.ibm.mq.pcf.jar`
   - `com.ibm.mq.jmqi.jar`

Copy the JAR files from <*WebSphere_MQ_installation_path*>\Java\lib to <*tomcat_installation_path*>\shared\lib.

Results

You have downloaded, installed, and customized Apache Tomcat V6 ready for use by the proxy servlet.

You must now configure the proxy servlet, see:

- "Configuring the proxy servlet" on page 876

Related concepts:

Related reference:

"Proxy servlet configuration parameters" on page 878
Before you can deploy the proxy servlet `web.xml` to the servlet container, you must configure it with the following initialization parameters for the broker environment that the servlet connects to.

Configuring the proxy servlet:

Configure the proxy servlet with the initialization parameters that are used by the proxy servlet. These parameters need to be configured for the broker environment that the proxy servlet is connecting to before the proxy servlet can be deployed to the servlet container.

Before you begin

Before you configure the proxy servlet, you must complete the following task:
- "Installing and customizing a web servlet container for the proxy servlet" on page 873

About this task

The configuration of the proxy servlet is done by editing the Web Deployment Descriptor `web.xml` file that is packaged in the compressed `proxyservlet.war` (WAR) file. The WAR file can be found in the following directory:

<*WMB_runtime_install_path*>`/tools`.

You can either use the WebSphere Message Broker toolkit to edit the Web Deployment Descriptor `web.xml` file, or you can extract the `proxyservlet.war` file, find the `web.xml` file and edit it using an appropriate editor, such as Notepad. Both procedures are described in this section:

Procedure

1. To configure the Web Deployment Descriptor `web.xml` file by using the WebSphere Message Broker toolkit, start the toolkit, and switch to the J2EE perspective.
2. Click **File** > **Import**, expand the **Web** section, select **WAR file** in the list, and click **Next**.
3. Click **Browse** to find the WAR file in <*WMB_runtime_install_path*>`/tools`. Where <*WMB_runtime_install_path*> specifies the name of your runtime installation path. For example, in `C:\Program Files\IBM\MQSI\7.0\tools\proxyservlet.war`.
4. Set the name of the Web Project to `proxyservlet`.
5. Click **Finish**. The proxy servlet is now ready for configuring by using the J2EE perspective.
6. Expand **proxyservlet** in the Project Explorer view and double-click Deployment Descriptor to view the Web Deployment Descriptor.
7. Find the **Servlets and JSPs** section in the Web Deployment Descriptor, and click the servlet link called **WBIMBServlet** to display the servlet web address mappings and initialization parameters. The same parameters in the `web.xml` file can be configured through JNDI in WebSphere Application Server. This alternative method means that you set up at the application server side only once for any future deployment of the proxy servlet. This operation is possible because the JNDI configuration parameters take precedence over the initialization parameters in the `web.xml` file. For more information about

setting up the JNDI interface for the proxy servlet, see “Setting up the JNDI interface for the proxy servlet” on page 886

8. Click the Source tab, which is found at the bottom of the Web Deployment Descriptor view. You might need to click **>>** (Show List) to see the Source tab option. The source of the Web Deployment Descriptor `web.xml` displays the proxy servlet parameters.
9. Edit the proxy servlet parameters with initialization parameters specified at: “Proxy servlet configuration parameters” on page 878
10. When the configuration is complete, save the changes to the Deployment Descriptor `web.xml` file by pressing **Ctrl S**.
11. Export the configured proxy servlet ready for deployment to Tomcat. Click **File** > **Export**, expand the **Web** section, select **WAR file** in the list, and click **Next**.
12. Click **Browse**, specify a location for the configured WAR file, enter WAR file name `HTTPVSR1BKproxyserlet.war`, and click **Save**.
13. Enter the Web module name `proxyservlet`, and click **Finish**. You have now configured the proxy servlet by using the WebSphere Message Broker toolkit.

Results

To configure the Web Deployment Descriptor `web.xml` file directly, find and extract the `proxyservlet.war` file, find the `web.xml` file in the extracted contents, right-click the `web.xml` file, and select an appropriate editor, such as Notepad to edit the `web.xml` file with initialization parameters specified at: “Proxy servlet configuration parameters” on page 878.

You have now configured the proxy servlet with the initialization parameters.

In order that the proxy servlet can access the SOAPInput and SOAPReply nodes, you must now enable the WebSphere MQ listener on each execution group where message flows with SOAP nodes are deployed, see:

- “Enabling the WebSphere MQ listener for SOAP nodes for the proxy servlet to access” on page 889

Related concepts:

“HTTP proxy servlet overview” on page 856

"Testing the proxy servlet" on page 892
Test the proxy servlet with a message broker that receives HTTP requests and passes them to a message flow.

"Setting up the JNDI interface for the proxy servlet" on page 886
The JNDI interface for the proxy servlet requires a one time setup of the WebSphere Application Server full profile.

Proxy servlet configuration parameters:

Before you can deploy the proxy servlet `web.xml` to the servlet container, you must configure it with the following initialization parameters for the broker environment that the servlet connects to.

This topic contains the following sections:
- "General options"
- "Information options" on page 880
- "ReplyToQ and QMgr options" on page 880
- "SSL connection options" on page 880
- "MQ connection options" on page 881

General options:

Parameter name	Default value	Description
brokerName	* (auto-detect from config data for broker)	*broker name* or "*" Use this parameter to set the name used for error messages; the value is auto-detected if set to "*". Set a value if several brokers are being proxied, and a single name is required for error messages.

Parameter name	Default value	Description
forwardingNodes	http	*http*, *soap*, or *both* If you configure the servlet to replace the broker-wide listener, set this property to <*http*>. If you configure the servlet to replace the embedded execution group listener, set this property to <*soap*>. Use *both* with caution, because the merging of web address selectors might lead to unexpected results in conflicting cases; for example, if an HTTP node and a SOAP node both use `/fnerble` as a web address selector.
configFilePath	`/var/mqsi/components/MB7BROKER/config/wsplugin6.conf`	*full path to config file* If the proxied broker is local, set this parameter to the `wsplugin6.conf` file (for HTTP nodes) or the `soapplugin6.conf` (for SOAP nodes) for the broker. This file is used only when the parameter **useQueueManagerDataInsteadOfConfigFile** is set to blank. The configuration file can be used only when the proxy servlet is running on the same server as the broker, and it has access to the file. In Windows, the file is stored in `C:\`*`install_dir`*`\config\wsplugin.conf` or `C:\Documents and Settings\All Users\Application Data\IBM\MQSI\components\`*`broker_ name`*`\config\wsplugin6.conf`. On Linux and UNIX, the file is stored in `/var/mqsi/config/wsplugin.conf` or in `/var/mqsi/components/`*`broker_ name`*`/config/wsplugin6.conf`.
useFastpathBindingsConnection	false	*true* or *false* Causes the servlet to connect in fastpath mode, if using a local queue manager.
traceFileName		*full path to trace file* Specify the location and name of the trace file. If this parameter is not specified the trace is sent to stdout.
turnTraceOn	0	*0*, *1*, or *2* Set 0 for no trace, 1 for normal trace, or 2 for debug trace.

Information options:

Parameter name	Default value	Description
enableStatusPage (WebSphere Message Broker V6.1 FP 4 or later)	false	*true* or *false* Switches display of the status page. When true, the page is visible at `http://hostname:port/proxy_context/messagebroker/httpproxy/statuspage`
enableInfoHeaders (WebSphere Message Broker V6.1 FP 4 or later)	false	*true* or *false* Causes the servlet to add extra headers in the response. These headers are: X-WMB-Broker-Name X-WMB-QM-Name X-WMB-MQ-URL-CorrelId and contain details of the configuration used for that message.

ReplyToQ and QMgr options:

Parameter name	Default value	Description
useClusterMode	false	*true* or *false* Set to true if the servlet is required to put reply-to queue and queue manager information in the MQMD of sent messages to enable the broker to respond to the correct queue manager in a cluster.
clusterModeQueueManagerName	SOME_OTHER_ QUEUE_MANAGER	*queue manager name* Queue manager name for initial MQCONN and ReplyToQMgr.
clusterModeReplyToQ	OUR.REPLYTO.QUEUE	*reply queue name* Queue name on which to listen.

SSL connection options:

Parameter name	Default value	Description
useSecuredChannel	false	*true* or *false* Set the value of `useSecuredChannel` to `true` if SSL is configured on MQ Channel. If set to `true`, the servlet attempts to establish a secured connection to the MQ Channel by using the `keyStore`, `keyStorePassword`, `trustStore`, `trustStorePassword`, and `cipherSuite` parameter values.

Parameter name	Default value	Description
keyStore		*full path to the keystore file* The fully qualified path to the key store file, which is of type "JKS". For example, in Windows: `C:\\Program Files\\IBM\\MQSI\\ keystore.jks` On Linux and UNIX: `/var/mqsi/keystore.jks`
keyStorePassword	changeit	The password to the keystore file.
trustStore		*full path to the truststore file*The fully qualified path to the truststore file, which is of type "JKS". For example, on Windows: `C:\\Program Files\\IBM\\MQSI\\ truststore.jks` On Linux and UNIX: `/var/mqsi/truststore.jks`This field is mandatory if `useSecuredChannel` is set to `true`.
trustStorePassword	changeit	The password to the truststore file.
cipherSuite		The encryption type that is configured in the MQ Channel. For example: `SSL_RSA_WITH_NULL_MD5` This field is mandatory if `useSecuredChannel` is set to `true`.

MQ connection options:

Parameter name	Default value	Description
useClientMode	false	*true* or *false* Use WebSphere MQ client (true) or bindings connection (false). Normally, **useQueueManagerDataInsteadOfConfigFile** would also be set to the broker queue manager if this parameter is set to true.
clientModeHostname	localhost	*hostname or IP address* Hostname or IP for the Queue Manager.
clientModeChannelName	SYSTEM.DEF. SVRCONN	*WebSphere MQ SVRCONN channel name* The name of the WebSphere MQ SVRCONN to use.
clientModePortNumber	1414	*port number* WebSphere MQ listener port number.

Parameter name	Default value	Description
clientModeConnectRetryCount (WebSphere Message Broker V6.1 FP 4 or later)	1	*integer* Number of times to retry the WebSphere MQ connect call. Use this parameter in cases where a network dispatcher or load balancer is being used to distribute work to a set of queue managers and one fails. A new connect might fail the first time, but succeed the second time. The retry count must be set to a high number to provide the greatest chance of success.
useQueueManagerDataInsteadOfConfigFile		*queue manager name*, "*", or *blank* Queue manager name, '*' (remote proxy), or blank for none (local proxy). This option causes the servlet to read Web address data from a queue, and avoid the need for a config file to be accessible from the servlet.
sleepBeforeGet	0	*time in seconds* Sleep time in seconds. This value causes the servlet to wait before issuing an MQGET for a response message from the broker.
disconnectBeforeSleep	true	*true* or *false* To release WebSphere MQ handle while sleeping. Useful for keeping the number of simultaneous WebSphere MQ connections down.
reconnectActiveLinksAge (WebSphere Message Broker V6.1 FP 4 or later)	-1	*time in seconds*, 0, or -1 If set to a number greater than zero, this parameter causes WebSphere MQ connections to be disconnected and reconnected if they have been inactive, because of low traffic volumes, for more than the specified number of seconds. Setting this to -1 prevents this reconnection. Setting it to 0 causes all connections to be used once only. This parameter is of most use if the connection to WebSphere MQ goes through a firewall that closes connections after a period of inactivity. Setting this parameter to a value less than the firewall timeout might prevent clients from getting WebSphere MQ 2009 (connection broken) errors.

Parameter name	Default value	Description
testConnectionBeforeReuse (WebSphere Message Broker V6.1 FP 4 or later)	false	*true* or *false* If set to true, the servlet attempts an MQINQ before doing the MQPUT of the HTTP data message. All problems with a cached WebSphere MQ client connection are detected at that point, and a new connection is established for the MQPUT of the actual data (and MQGET of the response). This parameter causes significant extra network traffic, and must be used only if problems have been seen with dropped connections, which are usually seen as WebSphere MQ 2009 errors, indicating connection broken.
maximumConnectionAge (WebSphere Message Broker V6.1 FP 6 or later)	-1	*time in seconds*, 0, or -1 If set to a number greater than zero, this parameter causes WebSphere MQ connections to be disconnected and reconnected if they are older than the specified number of seconds. Setting this parameter to -1 prevents these reconnections; setting this parameter to 0 causes all connections to be used only once. This parameter is of most use, if the frequent changes to the WebSphere MQ connection parameters are expected due to redeploys of the WebSphere Message Broker flows and you require the *ProxyServlet* to reflect these changes within the specified number of seconds.

You can define one or more mappings that are supported by the proxy servlet. These mappings are used by the servlet container to filter Web address requests before executing the correct instance of the proxy servlet.

The mappings are the */node_url_path* paths described in "HTTP proxy servlet; web addresses component" on page 868 (*/url_path=/context_root/node_url_path*).

You can define a */node_url_path* equal to "/*" to accept Web address paths similar to this example: /HTTPMyBrkServletProxy/*your_value*.

Example configuration scenarios:

In each of the following scenarios, **forwardingNodes** must be set for the HTTP and SOAP nodes:

- Scenario 1: The Web servlet container is on the same server as WebSphere Message Broker:

  In this configuration example, you must set **useClientMode** and **useQueueManagerDataInsteadOfConfigFile** to false, and the **configFile**

parameter must point to a valid file. The servlet attempts to connect to the local queue manager for the broker after reading the queue manager name from the config file.

- Scenario 2: The Web servlet container is on a different server to WebSphere Message Broker with an WebSphere MQ client link to the broker queue manager:

  In this configuration example, you must set **useClientMode** to true, **useQueueManagerDataInsteadOfConfigFile** to "*", or the broker queue manager name, and **clientModeHostname**, **clientModeChannelName**, and **clientModePortNumber** to the correct values defined in this section. The servlet attempts to connect to the remote queue manager for the broker, reading the required node configuration data from the broker from the WebSphere MQ client connection.

  You can copy the config file from the broker server to the Web servlet container server, and then use **configFile**, after ensuring that **useQueueManagerDataInsteadOfConfigFile** is set to blank to force reading from the config file. However, you must copy the config file every time it is changed by the broker.

- Scenario 3: The Web container is on a different server to WebSphere Message Broker with its own queue manager and a WebSphere MQ channel link to the broker queue manager:

  This configuration example is similar to scenario 1 in that client mode is not used, but you must set **useClusterMode** to true, **clusterModeQueueManagerName** to the queue manager of the Web servlet container, and **clusterModeReplyToQ** to a queue that exists on that queue manager.

  The servlet tries to open the queue SYSTEM.BROKER.WS.INPUT on the specified queue manager by using the queue manager name from the config file. Therefore, you must set up channels and transmit queues beforehand, to ensure the messages arrive on the broker queue manager.

  You must copy the config files from the broker server in this scenario.

- Scenario 4: This scenario is the same as scenario 2, but uses a network load-balancer for distributing work for several brokers:

  The configuration can be the same as scenario 2, with the network load-balancer IP address taking the place of the broker server. In general, config files cannot be used, because there are several brokers behind one virtual IP address, and each one has a different config file. The servlet loads information on a per-connection basis, and uses the correct configuration information for each broker.

  Because failover is often one of the reasons for this configuration, the following extra options can be useful:

  Set **clientModeConnectRetryCount** to ensure that a single failed server does not cause intermittent errors, even if the load-balancer does simple round connection dispatching. Setting the parameter to a high enough value to attempt to connect to all the brokers prevents problems in these cases, and the servlet uses the first available broker.

  Use **reconnectActiveLinksAge** to avoid reusing old connections that might have been discarded by firewalls in between the servlet and the load-balancer (or the load-balancer and the brokers). Set this parameter to a value less than the firewall timeout, to ensure connections are used only when they are valid.

  Use **testConnectionBeforeReuse** as an alternative way to handle dropped WebSphere MQ links between the Web servlet container and broker queue managers. This option causes an MQINQ to be performed before attempting to put any data to the broker. If the MQINQ fails, a new connection is established,

and the data is sent over the new connection. Because configuration adds another operation to the MQPUT and MQGET, it results in a significant overhead for every message; use this option only if no alternative options are available.

To finish completing the proxy servlet configuration, see "Configuring the proxy servlet" on page 876.

"Testing the proxy servlet" on page 892
Test the proxy servlet with a message broker that receives HTTP requests and passes them to a message flow.

Setting up the JNDI interface for the proxy servlet:

The JNDI interface for the proxy servlet requires a one time setup of the WebSphere Application Server full profile.

About this task

The proxy servlet initialization parameters must be configured for the broker environment that the proxy servlet is connecting to each time the proxy servlet is deployed to the servlet container. It is now possible to configure the `web.xml` parameters only once through the JNDI in WebSphere Application Server, regardless of how many future deployments there might be of the proxy servlet. Because the JNDI configuration parameters take precedence over the initialization parameters in the `web.xml` file, using this method means that you need to set up at the application server side only once for any future deployments of the proxy servlet.

These setup tasks must all be completed in the WebSphere Application Server administrative console.

Creating a resource environment provider:
About this task

Configure a resource environment provider, which encapsulates the referenceables that convert resource environment entry data into resource objects. These resource objects can then be accessed by applications.

Procedure

1. Select **Resources** > **Resource Environment** > **Resource Environment Providers**. The Resource environment providers wizard opens.
2. Click **New**. The Configuration panel opens so that you can configure a new resource environment provider.
3. Type a name for the resource environment provider in the **Name** filed. For example, `MyResourceEnvironmentProvider`. It is recommended that you enter a meaningful description in the **Description** field, but it is not required. Click **OK** to continue and then save the changes.

Results

The new resource environment provider is listed in the wizard.

Creating a referenceable object:
About this task

Configure a new referenceable, which specifies the factory class that converts data in the Java Naming and Directory Interface (JNDI) name space into an object that represents your resource to WebSphere Application Server.

Procedure

1. Select **Resources** > **Resource Environment** > **Resource Environment Providers**. The Resource environment providers wizard opens.
2. From the Resource environment providers panel, select the provider that you created in the previous task: In this example, it is called *MyResourceEnvironmentProvider*.
3. Click **Referenceables**. The Referenceables panel opens.

4. Click **New**. The Configuration panel opens.
5. In the Configuration panel, type the following values:
   a. In the **Factory class name** field, type:
   `com.ibm.broker.httpproxy.MQResourceConnectionFactory`
   b. In the **Class name** field, type:
   `com.ibm.broker.httpproxy.MQResourceConnection`
6. Click **OK** and save the changes.

Creating resource environment entries:
About this task

Configure resource environment entries, which are objects that contain information about a resource, and represent it in the JNDI name space.

Procedure

1. Select **Resources** > **Resource Environment** > **Resource Environment Providers** > ***MyResourceEnvironmentProvider***. The Resource environment providers wizard opens at the configuration panel for your provider.
2. Click **Resource environment entries**. The Resource environment entries panel opens.
3. Click **New**. The Configuration panel opens.
4. In the Configuration panel, type your values. In this example, the values are:
   a. In the **Name** field, type for example: `MQResourceReference`
   b. In the **JNDI name** field, type for example: `proxyservlet/reference/MQResourceReference` . This JNDI name is used during application deployment resource mapping.
   c. In the **Referenceables** drop-down list, ensure that `com.ibm.broker.httpproxy.MQResourceConnectionFactory` is selected.
5. Click **OK** and save the changes.

Creating custom properties or define the parameters to be configured:
About this task

Specify custom properties that your enterprise information system (IES) requires for the resource providers and resource factories that you configure. For example, most database vendors require extra custom properties for data sources that access the database.

Procedure

1. Select **Resources** > **Resource Environment** > **Resource Environment Providers** > ***MyResourceEnvironmentProvider*** > **ResourceEnvironment Entries** > ***MQResourceReference***. where *MyResourceEnvironmentProvider* and *MQResourceReference* are your own specified values. The Resource environment providers wizard opens at the configuration panel for your entry.
2. Click **Custom properties**. The Configuration panel opens.
3. Click **New**.
4. In the Configuration panel, you must type your values for all the resources that are administered through the administrative console. For example: The message broker name, the configuration file path, the client mode channel name, and the client mode port number. For each resource, you must provide values for **Name**, **Value**, **Description**, and **Type**. The following example is for the message broker name

Option	Description
Name	This field refers to the value in the "<param-name> </param-name>" tag in the web.xml. For example: brokerName
Value	This field refers to the value in the "<param-value> </param-value>" tag in the web.xml. For example: RRB
Description	Optional. It is recommended that you provide a meaningful description.
Type	Specify the type. For example: java.lang.String

5. Click **OK** to save the configuration.
6. Click **New** to create a new configuration for the remaining resources.

Results

You have a list of configured resources that is similar to the following table, but with the values that you specified:

Table 12. .

Name	Value	Description	Required
brokerName	RRB	Message Broker Name	false
configFilePath	C:\\Documents and Settings\\All Users.WINDOWS\\Application Data\\IBM\\MQSI\\components\\RRB\\config\soapplugin6.conf	Configuration File Path	false
clientModeChannelName	SYSTEM.DEF.SVR.CONN	Client Mode Channel Name	false
clientModePortNumber	2028	Client Mode Port Number	false

The WebSphere Application Server wizard does not provide an option to specify the **Required** attribute and so the default value is set to false. This attribute can be ignored.

What to do next

After you complete these tasks, you must deploy the proxyservlet.war file. During the deployment, you must provide the JNDI reference name for the **Resource Environment** reference that is defined in the web.xml file. For example: proxyservlet/reference/MQResourceReference.

After the deployment, proxyservlet gives precedence to the values configures in the Resource Environment Entries. If there is an environment change, the values must be modified in the custom properties of the Resource Environment Entries. After you modify a value, restart the Proxyservlet application in WebSphere Application Server for the new values to take effect.

Test the proxy servlet with a message broker that receives HTTP requests and passes them to a message flow.

Enabling the WebSphere MQ listener for SOAP nodes for the proxy servlet to access:

Enable the WebSphere MQ listener on each execution group where message flows with SOAP nodes are deployed so that the proxy servlet can access the SOAPInput and SOAPReply nodes.

Before you begin

Before you start:

Before you enable the WebSphere MQ listener, you must have completed the following tasks:
- "Installing and customizing a web servlet container for the proxy servlet" on page 873
- "Configuring the proxy servlet" on page 876

If your message flow uses HTTPS, you must also set the proxy servlet, browser, application server, and broker to use HTTPS.

Procedure

1. Open a command window that is configured for your environment and enter the following command:

   ```
   mqsichangeproperties <broker_name> -e <execution_group_name> -o HTTPConnector
   -n enableMQListener -v true
   ```

   For example:

   ```
   mqsichangeproperties VSR1BK -e default -o HTTPConnector -n enableMQListener -v true
   ```

2. Stop and start the broker.
3. Enter the following command to verify the property value:

   ```
   mqsireportproperties <broker_name> -e <execution_group_name> -o HTTPConnector
   -n enableMQListener
   ```

   For example:

   ```
   mqsireportproperties VSR1BK -e default -o HTTPConnector –n enableMQListener
   ```

4. Repeat these steps for all execution groups where message flows with SOAP nodes are deployed.

Results

You have enabled the WebSphere MQ listener for all execution groups where message flows with SOAP nodes are deployed.

You are now ready to deploy the proxy servlet in the Web servlet container. For information about how to complete this task, see “Deploying the proxy servlet in the web servlet container” on page 891.

Related concepts:

Load and install the proxy servlet file in the web servlet container, such as

WebSphere Application Server or Apache Tomcat.

"Testing the proxy servlet" on page 892
Test the proxy servlet with a message broker that receives HTTP requests and passes them to a message flow.

Deploying the proxy servlet in the web servlet container:

Load and install the proxy servlet file in the web servlet container, such as WebSphere Application Server or Apache Tomcat.

Before you begin

The documentation in this section is based on deploying the proxy servlet in Apache Tomcat Version 6 on Windows XP and assumes WebSphere Message Broker is installed and running on the same server.

Before you deploy the proxy servlet in Apache Tomcat, you must complete the following tasks:

- "Installing and customizing a web servlet container for the proxy servlet" on page 873
- "Configuring the proxy servlet" on page 876
- "Enabling the WebSphere MQ listener for SOAP nodes for the proxy servlet to access" on page 889

Procedure

1. Open a web browser and enter web address http://localhost:8181 to open the Tomcat home page.
2. Click**Tomcat Manager** and enter the *admin* user ID and password.
3. Scroll down to the section **WAR file to deploy** and click **Browse** and search for the `HTTPVSR1BKproxyservlet.war` file.
4. Click **Deploy**. The <*context_root*> associated to the proxy servlet is the same as the WAR file name. It is possible to rename the `.war` file before deploying it to Tomcat to have a different <*context_root*>. See "HTTP proxy servlet; web addresses component" on page 868 for a description of the <*context_root*>.
5. Click **/HTTPVSR1BKproxyservlet** on the Applications view to test if the servlet is active. If the proxy servlet trace is enabled, the trace file shows that the servlet has received the request and rejected it.

Results

The proxy servlet is now ready to be tested with a message broker that receives HTTP (not HTTPS) requests and passes them to a message flow. For information about how to complete this task see:

- "Testing the proxy servlet" on page 892

"Testing the proxy servlet"
Test the proxy servlet with a message broker that receives HTTP requests and passes them to a message flow.

Testing the proxy servlet

Test the proxy servlet with a message broker that receives HTTP requests and passes them to a message flow.

Before you begin

To test the proxy servlet, use an existing web services client application or write your own SSL test client application using Java.

Before you test the proxy servlet, you must have completed the following tasks:
- "Installing and customizing a web servlet container for the proxy servlet" on page 873
- "Configuring the proxy servlet" on page 876
- "Enabling the WebSphere MQ listener for SOAP nodes for the proxy servlet to access" on page 889
- "Deploying the proxy servlet in the web servlet container" on page 891

Procedure

To test the proxy servlet, complete the following steps:

1. Install a client application that can send HTTP or SSL (HTTPS) requests. There are several options that can be used, such as:

- Nettool: An open source graphical utility available from the Internet at: Nettool downloads website. You can use this tool to send HTTP requests or to tunnel a request.
- OpenSSL: Another open source tool available from the Internet at: OpenSSL downloads website that can be used to send SSL (HTTPS) requests to the web servlet container.
- A broker message flow that has an HTTPRequest or SOAPRequest node can generate and send HTTP requests to an HTTP listener.
- A web browser using web pages or Java Server Pages (JSP) that can send HTTP POST requests. Most web browsers support HTTP and SSL (HTTPS).
- A client application that sends requests by using HTTP, or (SSL) HTTPS, or both.

2. Configure the proxy servlet to access the message broker in the `web.xml` file.
3. Configure a message flow with HTTP and SOAP input and reply nodes. The message flow receives the messages from the proxy servlet. If an HTTP and SOAP reply node is configured, responses are sent back to the proxy servlet.

Results

You have now finished testing the proxy servlet.

How you create the multi-instance broker.

Starting and stopping a WebSphere Message Broker as a WebSphere MQ service

Configuring a WebSphere Message Broker to start and stop as a WebSphere MQ service.

Before you begin

Before you start:

Ensure that you make the mqm user ID a member of the mqbrkrs group. On Windows, you must reboot your workstation for the change to take effect.

About this task

To configure a WebSphere Message Broker to run as a WebSphere MQ service, use one of the following options:

Procedure

- Create a broker to start as a WebSphere MQ service by using the **mqsicreatebroker** command with the **-d** parameter. For example,

```
mqsicreatebroker MyBroker –q MyQMGR –d defined
```

where

MyBroker
Is the name of the broker that you want to start and stop as a WebSphere MQ service.

MyQMGR
Is the name of the queue manager associated with the broker.

- Modify an existing broker to start as a WebSphere MQ service by using the **mqsichangebroker** command with the **-d** parameter. For example,

```
mqsichangebroker MyBroker –d defined
```

where

MyBroker
Is the name of the broker that you want to start and stop as a WebSphere MQ service.

Results

When you have configured a broker to start and stop as a WebSphere MQ service:

- The broker starts and stops automatically when its associated queue manager starts and stops. For a multi-instance broker, this action can occur during failover of the active queue manager.
- A multi-instance broker cannot be started in standby mode when its WebSphere MQ service is defined as active.
- You can stop the broker manually by using the **mqsistop** command, but the broker does not restart until the queue manager is stopped and started again.

  Alternatively, you can start the broker manually with the **mqsistart** command, which invokes the WebSphere MQ service to start the broker.
- On UNIX systems the broker environment is inherited from WebSphere MQ. Set any required environment variables (such as ODBCINI) by using a script in the `work_path/common/profiles` directory. See "Command environment: Linux and UNIX systems" on page 310 for more information.

Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

Modifying the WebSphere MQ service for a broker

How you modify the WebSphere MQ service for a broker.

About this task

To alter the status of a WebSphere Message Broker so that it runs as a WebSphere MQ service use the **mqsichangebroker** command.

Carry out the following procedure:

Procedure

1. Stop the broker and its associated queue manager. If it is a multi-instance broker, you must stop all broker instances, and the multi-instance queue manager, if you want the changes to take affect immediately after the queue manager restarts.
2. Use the **mqsichangebroker** command with the **–d defined** option to activate the WebSphere MQ service as follows:

   ```
   mqsichangebroker MyBroker –d defined
   ```

   where

   MyBroker
   Is the name of the broker that you want to modify.

   If the WebSphere MQ service did not previously exist, it is defined, and the service CONTROL attribute is set to QMGR.

   You should no longer start the broker with the **mqsistart** command. The broker starts and stops automatically when the queue manager starts and stops.

   You can stop the broker manually with the **mqsistop** command, but the broker will not restart until the queue manager is stopped and started again. For a multi-instance broker this can occur during failover of the active queue manager.
3. Use the **mqsichangebroker** command with the **–d undefined** option to remove the WebSphere MQ service as follows:

   ```
   mqsichangebroker MyBroker –d undefined
   ```

   where

   MyBroker
   Is the name of the broker that you want to modify.

   When a WebSphere MQ service is being removed, and the queue manager is stopped, the **mqsichangebroker** command needs to start the queue manager to perform the deletion of the service. The command then stops the queue manager. The following example shows a possible output:

   ```
   >mqsichangebroker BK3 -d undefined
   WebSphere MQ queue manager 'QM3' starting.
   5 log records accessed on queue manager 'QM3' during the log replay phase.
   Log replay for queue manager 'QM3' complete.
   Transaction manager state recovered for queue manager 'QM3'.
   WebSphere MQ queue manager 'QM3' started.
   Waiting for queue manager 'QM3' to end.
   Waiting for queue manager 'QM3' to end.
   WebSphere MQ queue manager 'QM3' ended.
   BIP8071I: Successful command completion.
   ```

   You can start the broker manually using the **mqsistart** command, which invokes the WebSphere MQ service to restart the broker.

Deleting the WebSphere MQ service for a broker

How you delete a WebSphere MQ service for a broker.

About this task

You can use either of the following methods to delete the WebSphere MQ service from a WebSphere Message Broker:

Procedure

1. Use the **mqsichangebroker** command with the **–d undefined** option, as described in step 3 on page 896 of "Modifying the WebSphere MQ service for a broker" on page 896 This reverts the broker to manual stop and start operation.
2. Use the **mqsideletebroker** command. Using this command also removes a previously configured WebSphere MQ service when the broker is removed.

Reporting and displaying the status of WebSphere Message Broker that runs as a WebSphere MQ service

How you report and display the status of a WebSphere Message Broker that runs as a WebSphere MQ service

Procedure

1. Use the **mqsireportbroker** command to show the property that displays the broker running as a WebSphere MQ service.

   The `StartAsMQService` property is set to **defined** if the broker is set to start as a WebSphere MQ service, otherwise this property is set to **undefined**.

   See the Windows, Linux, and UNIX systems version of the "**mqsireportbroker** command" on page 3919 for an example output from the command.
2. Use the **mqsilist** command to display the status of a broker that starts as a WebSphere MQ service. Message bip1297 is output when a broker is stopped, but will start as a WebSphere MQ service.

Chapter 8. Administering brokers and broker resources

Administering brokers and associated broker resources includes the tasks that you perform frequently to activate and manage those resources. Choose the method you prefer to administer your brokers and associated resources.

About this task

Administration of brokers includes the following tasks:

- "Managing brokers" on page 900
- "Managing execution groups" on page 935
- "Managing message flows" on page 950
- "Developing applications that use the Administration API" on page 956
- "Managing resources used by brokers" on page 1001
- "Administering Java applications" on page 1005
- "Accessing Administration log information" on page 1006
- "Changing the location of the work path" on page 1011
- "Backing up resources" on page 1013

These tasks can be performed by using one, or more, of the administrative techniques supported by WebSphere Message Broker:

- The WebSphere Message Broker Toolkit
- The WebSphere Message Broker Explorer
- The WebSphere Message Broker commands
- The Administration API for WebSphere Message Broker (also known as the CMP API)

For each task, the administrative techniques that you can use are identified.

Administration API for WebSphere Message Broker (CMP API)

Connecting to a local broker using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer

To administer a broker by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer, you must be connected to the broker.

Before you begin

Before you start:

- Create a broker

About this task

In the WebSphere Message Broker Toolkit, local brokers are automatically connected. You must manually connect to remote brokers. In the WebSphere Message Broker Explorer you can choose to disconnect from both local and remote brokers. You can also choose to automatically reconnect to a broker when you start the WebSphere Message Broker Explorer.

To connect to a broker in the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view, expand the Brokers folder.
2. Right-click the broker you want to connect to, and click **Connect**.

Results

You can now view properties and configure your broker by using the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.

Related concepts:

"WebSphere Message Broker Explorer" on page 57
The WebSphere Message Broker Explorer is a graphical user interface based on the Eclipse platform for administering your brokers.

Related tasks:

Chapter 8, "Administering brokers and broker resources," on page 899
Administering brokers and associated broker resources includes the tasks that you perform frequently to activate and manage those resources. Choose the method you prefer to administer your brokers and associated resources.

Connecting to a remote broker

To administer your brokers by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer, you must connect to the broker.

Before you begin

Before you start:

- Create a broker

Before you can connect to a remote broker, the broker and its queue manager must be running. You must also complete the following steps:

- Ensure that a command server is running on the queue manager.
- Ensure a server-connection channel has been defined on the broker queue manager. When you create a broker, a default SVRCONN channel, called `SYSTEM.BKR.CONFIG`, is created. This channel supports connections from one or more remote clients to the broker.
- Create a TCP/IP listener on the broker queue manager.
- Ensure that the listener is running.
- Create a group and a user ID on the computer where the broker is running by using the local system facilities; for example, the **Groupadd** command on Linux on x86. Add the user ID to the group.
- Run the **setmqaut** command on the broker queue manager to grant authority to the group:

  ```
  setmqaut -m queueManager -t qmgr -g group +connect
  ```

About this task

You can create a connection to a remote broker, or you can create a connection to a remote broker by using settings from a `.broker` file. Right-click the Brokers folder,

and click **Connect to a Remote Broker Using *.broker File**. Select the `.broker` file, and click **Open**. The connection to the remote broker is created in your workspace.

To create a connection to a remote broker:

Procedure

1. Open the WebSphere Message Broker Explorer, or open the Brokers view in the WebSphere Message Broker Toolkit.
2. To create a connection to a remote broker, right-click the Brokers folder, and click **Connect to a Remote Broker**.
3. In the Connect to a broker wizard, enter the following values:
   a. The value for the **Queue Manager name** that your remote broker is using.
   b. The **Host** name or IP address of the computer on which your broker is running.
   c. The TCP **Port** on which the WebSphere MQ queue manager is listening (the default is 1414). This property must be a valid positive number.
   d. Optional: The name of the server-connection channel in the **SVRCONN Channel Name** field. The channel has a default name of `SYSTEM.BKR.CONFIG`.

      You can create more than one server-connection channel and define a different SSL certificate on each channel to enforce; for example, users with `view` access on to one channel and users with `deploy` access on to a different channel.

      You can then create WebSphere MQ exits on each channel to provide additional authentication of the WebSphere MQ message sent to the broker.

      You must create the server-connection channel manually on the broker queue manager by using one of the following options:

      - The WebSphere MQ **`runmqsc`** command to create a channel with options `CHLTYPE(SVRCONN)` and `TRPTYPE(TCP)`.
      - The WebSphere MQ Explorer to create a server-connection channel with the transmission protocol set to TCP.

      For more information see your WebSphere MQ documentation.

      If you do not change the name, or attempt to delete it, the default name of `SYSTEM.BKR.CONFIG` is assumed. The name of the server-connection channel is changed only if you enter another name in place of `SYSTEM.BKR.CONFIG`.
   e. Optional: The **Class** of the Security Exit required to connect to the WebSphere MQ queue manager. This property must be a valid Java class name, but you can leave this field blank if it does not apply to your domain connection.
   f. Optional: The **JAR File Location** for the Security Exit required to connect to the WebSphere MQ queue manager. Click **Browse** to find the file location. If this field does not apply to your domain connection, you can leave it blank. If you enter a Security Exit **Class**, you must provide a **JAR File Location**.
   g. Optional: The **Cipher Suite**, **Distinguished Names**, **CRL Name List**, **Key Store**, and **Trust Store** parameters are required to enable SSL. For more information, see "Implementing SSL authentication" on page 504. The **Cipher Suite** field lists available cipher suites. Click **More** to configure Custom SSL Cipher Suites in the Broker Administration Preferences window. If a **Cipher Suite** is not specified, all of the other fields in the SSL section are unavailable.

If you specify a keystore or truststore when you define the connection information, you are prompted for the keystore or truststore when you connect to the remote broker.

4. Click **Finish** to connect to the remote broker.

Results

You can now view properties and configure your broker using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer.

Connecting to a remote broker on z/OS in the WebSphere Message Broker Explorer

To administer your brokers by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer, you must connect to the broker.

Before you begin

Before you start:

- Create a broker

About this task

To connect to a remote broker on z/OS:

Procedure

1. In the Navigator view, or Brokers view, right-click the Brokers folder, and click **Connect** > **Remote Broker**.
2. In the Connect to a broker wizard, enter the following values:
   a. The value for the **Queue Manager name** that your remote broker is using.

b. The **Host** name or IP address of the machine on which your broker is running.

c. The TCP **Port** on which the WebSphere MQ queue manager is listening (the default is 1414). This property must be a valid positive number.

d. Optional: The name of the server-connection channel in the **SVRCONN Channel Name** field. The channel has a default name of `SYSTEM.BKR.CONFIG`.

   You can create more than one server-connection channel and define a different SSL certificate on each channel to enforce; for example, users with `view` access on to one channel and users with `deploy` access on to a different channel.

   You can then create WebSphere MQ exits on each channel to provide additional authentication of the WebSphere MQ message sent to the broker.

   You must create the server-connection channel manually on the queue manager for the broker by using one of the following options:

   - The WebSphere MQ **runmqsc** command to create a channel with options `CHLTYPE(SVRCONN)` and `TRPTYPE(TCP)`.
   - The WebSphere MQ Explorer to create a server-connection channel with the transmission protocol set to TCP.

   For more information see your WebSphere MQ documentation.

   The default name of `SYSTEM.BKR.CONFIG` is assumed if you do not change the name, or attempt to delete it. The name of the server-connection channel is changed only if you enter another name in place of `SYSTEM.BKR.CONFIG`.

e. Optional: The **Class** of the Security Exit required to connect to the WebSphere MQ queue manager. This property must be a valid Java class name, but you can leave this field blank if it does not apply to your domain connection.

f. Optional: The **JAR File Location** for the Security Exit required to connect to the WebSphere MQ queue manager. Click **Browse** to find the file location. You can leave this field blank if it does not apply to your domain connection. You must provide a **JAR File Location** if you enter a Security Exit **Class**.

g. Optional: The **Cipher Suite**, **Distinguished Names**, **CRL Name List**, **Key Store**, and **Trust Store** parameters are required to enable SSL. For more information, see "Implementing SSL authentication" on page 504. The **Cipher Suite** field displays available cipher suites. Click **More** to configure Custom SSL Cipher Suites in the Broker Administration Preferences window. If a **Cipher Suite** is not specified, all of the other fields in the SSL section are unavailable.

3. Click **Finish** to connect to the remote broker.

Results

Importing broker definitions into the WebSphere Message Broker Explorer

Import broker connection details that have been created by another user into your session of the WebSphere Message Broker Explorer or WebSphere Message Broker Toolkit, to use the broker.

About this task

The properties of a broker connection can be exported from one instance of the WebSphere Message Broker Explorer, and imported into a different instance. You can also import a broker connection into an instance of the WebSphere Message Broker Toolkit. The properties of the broker connection are stored in a `.broker` file.

Importing a broker definition into the WebSphere Message Broker Toolkit

About this task

To import broker connection properties from a `.broker` file into the WebSphere Message Broker Toolkit:

Procedure

1. In the Brokers view, right-click the Brokers folder and click **Add Remote Broker From *.broker**.
2. Navigate to the broker connection files that you want to import, and click **Open**.

Results

The `.broker` file is imported, and the broker is displayed in the Brokers folder. You can now connect to the broker.

Importing a broker definition into the WebSphere Message Broker Explorer

About this task

To import broker connection properties from a `.broker` file into the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view, right-click the Brokers folder and click **Import *.broker**.
2. Navigate to the broker connection files that you want to import, and click **OK**.

Results

The `.broker` file is imported, and the broker is displayed in the Brokers folder. You can now connect to the broker.

Automatically reconnecting to a broker

You can configure each broker so that the WebSphere Message Broker Explorer automatically reconnects to it if the connection is lost; for example, if the network connection to a remote queue manager fails.

About this task

If you manually disconnect a broker, the broker is not automatically reconnected until the next time that you close and restart the WebSphere Message Broker Explorer. To configure a broker to automatically reconnect when you start the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view, expand the Brokers folder.
2. Right-click your broker, and select **Properties**.
3. Ensure **Autoreconnect** is selected in the General tab.
4. Click **OK**.

Results

The broker is automatically reconnected when you next start the WebSphere Message Broker Explorer.

What to do next

If you want to configure the broker so that it is not automatically reconnected when you start the WebSphere Message Broker Explorer, clear **Autoreconnect** in the broker properties window.

Using the Administration Queue

The Administration Queue shows pending and submitted tasks that have been sent to the broker, and are waiting to be processed. Use the WebSphere Message Broker Explorer to view details of the tasks, and to cancel tasks in the queue.

About this task

Each broker that is connected in the WebSphere Message Broker Explorer displays an icon labeled **Administration Queue**. When you click the Administration Queue icon, tasks submitted to the broker are displayed in the Administration Queue QuickView in the Content pane. The Administration Queue icon changes to indicate the number of messages on the Administration Queue.

The following properties are displayed for each task on the Administration Queue:
- Order
- Status
- Username
- Operation Type
- Object Name
- Object Type
- Creation Time
- Elapsed Time
- Identifier

You can remove tasks from the Administration Queue if you want to cancel requests that have been sent to a broker. To remove tasks from the Administration Queue:

Procedure

1. In the Navigator view, expand the Brokers folder.
2. Expand the broker with which you want to work, and right-click **Administration Queue**.
3. Click **Cancel Work Items** The Administration Queue window is displayed.
4. Select the task or tasks that you want to remove from the Administration Queue, and click **Cancel Work Items**.

Results

The selected tasks are removed from the Administration Queue.

You can change various aspects of your broker configuration to tune brokers and message flows, and monitor message flows and publish/subscribe applications.

Working with Service Federation Management (SFM)

You can use a broker as a connectivity server that can be administered by a Service Federation Management (SFM) console provided with WebSphere Service Registry and Repository (WSRR) V7.0. The SFM console can then configure SFM proxies in the broker.

Your enterprise might have separate enterprise service buses (ESBs) in different business units. Each ESB and associated service registry constitute a separate domain of connected service applications. This configuration can result in expensive duplication of applications between domains and also in increased development effort to implement application connectivity across domains.

SFM, provided in WebSphere Service Registry and Repository (WSRR) V7.0, allows you to establish bridges between separate ESBs, allowing services and applications to be shared between domains. SFM provides:

- A federation model which provides a unifying view of federation-relevant content.
- A protocol, Service Control Management Protocol (SCMP), which accesses the service connectivity and registry components supporting a domain. SCMP is based on the Atom Publishing Protocol (Atom).
- A console for controlling service domains.

By using SFM, you can configure services in one domain so that they are available to service consumers in another domain; the service endpoints in one domain are manifested as service proxy endpoints in another domain.

You can use the SFM console to administer a broker as an SFM connectivity server to enable the creation of proxies running in a broker execution group. You can share services between domains by using proxies. You must use the **mqsichangeproperties** command to enable a broker to be administered by the SFM console. You can then use the SFM console federation facilities so that SCMP Atom requests can be issued to the broker on the configured HTTP or HTTPS port.

After you enable WebSphere Message Broker as an SFM connectivity server, the execution groups in a broker are available to act as SFM connectivity providers. Connectivity providers are added in the SFM console to domains to provide an ESB facility which can then create and host proxy instances to enable the sharing of services.

Service federation proxy instances are runtime resources that are separate from WebSphere Message Broker message flows, and are therefore not listed in the

execution group. The service federation proxy instances of an execution group can be reported by the Service Federation Management properties of that execution group.

To enable a broker for SFM, or configure the SFM properties of an execution, follow the appropriate link:

- "Enabling a broker for Service Federation Management"
- "Configuring the Service Federation Management properties of an execution group" on page 914

For more information about SFM, see the WebSphere Service Registry and Repository V7.0 Information Center at http://publib.boulder.ibm.com/infocenter/sr/v7r0/topic/com.ibm.sr.sfm.doc/wsrr_sfm_homepage.html.

Enabling a broker for Service Federation Management

Use the **mqsichangeproperties** command to enable a broker for Service Federation Management (SFM).

Before you begin

Before you start:

- Create a broker

About this task

Procedure

1. Run the **mqsichangeproperties** command to enable SFM in the broker.

   To enable SFM in the broker and to use HTTP as the protocol for communication between SFM and the broker, run the following command:

   ```
   mqsichangeproperties broker_name -b servicefederation -o scmp
   -n enabled,enableSSL -v true,false
   ```

   To enable SFM in the broker and to use HTTPS as the protocol for communication between SFM and the broker, run the following command:

   ```
   mqsichangeproperties broker_name -b servicefederation -o scmp
   -n enabled,enableSSL -v true,true
   ```

2. You must also set the hostname and context root for the service document URL that will be required when you add the broker to the Service Federation Console. Use the full domain qualified hostname for your broker to ensure reliable addressing.

   ```
   mqsichangeproperties broker_name -b servicefederation -o scmp
   -n hostname,contextRoot -v brokerhost.ibm.com,/scmp
   ```

3. Use the **mqsireportproperties** command to review the SFM properties that you have set by using the **mqsichangeproperties** command:

   ```
   mqsireportproperties broker_name -b servicefederation -o scmp -r
   ```

4. Run the **mqsichangeproperties** command to configure the properties relating to the HTTP or HTTPS port to be used. If you are using HTTP:

   ```
   mqsichangeproperties broker_name -b servicefederation -o HTTPConnector -n port
   -v 8085
   ```

   If you are using HTTPS:

   ```
   mqsichangeproperties broker_name -b servicefederation -o HTTPSConnector
   -n port,keystoreFile,keystorePass -v 8086,keys.jks,keypwd
   ```

5. If you need to secure the SFM HTTP or HTTPS port with basic access authentication user name and password credentials, run the **mqsisetdbparms** command and use a resource type of `sfm::scmp`:

   ```
   mqsisetdbparms broker_name -n sfm::scmp -u ConsoleUsername -p
   ConsolePwd
   ```

6. Stop the broker by using the **mqsistop** command.
7. Start the broker by using the **mqsistart** command. Review the system log to ensure that the Service Federation listener has successfully started. The message BIP3769 also confirms the service document URL value that must be configured into the SFM console.

   ```
   Service Federation SCMP listener initialized. Additional information :
   ''SCMP Service Document URL''
   ''http://brokerhost.ibm.com:8085/scmp/servicedocument''
   ```

What to do next

You have now enabled the broker for SFM. As a consequence of enabling the broker for SFM, the execution groups in the broker are also enabled for SFM; they can now create and host the proxy instances to provide service availability. You might want to configure the properties of the execution group that relate to the creation of proxy instances; see "Configuring the Service Federation Management properties of an execution group" on page 914.

Configuring the Service Federation Management properties of an execution group

Using the **mqsichangeproperties** command, you can configure the Service Federation Management (SFM) properties of an execution group in a broker that has been enabled for SFM. These properties determine how proxies are created.

Before you begin

Before you start:

- Create a broker
- Start the broker
- Create an execution group
- Enable SFM in the broker

About this task

When you enable a broker for SFM, the execution groups in the broker are also enabled for SFM; they act as connectivity providers and create and host the proxy instances for use by service consumers in other domains.

Procedure

Run the **mqsichangeproperties** command to configure the properties that relate to the SFM capability of an execution group.
For example, to set a host name, insecure port, and secure port to be used in the endpoint address of SFM proxies created in an execution group:

```
mqsichangeproperties TEST -e exgroup1 -o ServiceFederationManager
-n proxyURLHostName,port,securePort -v mbhost.ibm.com,8811,8844
```

If an SFM proxy is configured to use SSL, its input proxy URL transport is HTTPS; it will need to use the keystore at either the execution group level or broker level to obtain its private key. If an SFM proxy has a target service that requires SSL, its target service URL transport is HTTPS; it will need to use the truststore at either the execution group level or the broker level to obtain the public key of the service. In such cases, you must configure either the execution group or the broker to reference keystores and truststores that have been loaded with these certificates. If both are set, the execution group level setting is used.
To review the properties that relate to the SFM capability of an execution group, run the **mqsireportproperties** command with the **-a** all properties option:

```
mqsireportproperties broker_name -e execution_group_name -o
ServiceFederationManager -a
```

To review details of SFM proxies that have been created in an execution group, run the **mqsireportproperties** command with the **-r** all recursive child properties option:

```
mqsireportproperties broker_name -e execution_group_name -o
ServiceFederationManager -r
```

Grouping brokers by using broker sets

You can create a manual or an automatic broker set to visually group your brokers in the WebSphere Message Broker Explorer.

About this task

If you have a large number of brokers displayed in the WebSphere Message Broker Explorer, you might find it helpful to group the brokers by using broker sets. You can create manual broker sets, automatic broker sets, or a combination of both types. When you create a broker set for the first time, two sets are created; a set called All and a set with a name that you provided when you created it. The All broker set contains all your local brokers, and any remote brokers definitions in your workspace. If you delete all of the broker sets that you have created, the All broker set is automatically removed. You cannot rename, modify, or delete the All broker set manually.

A manual broker set is empty until you add brokers to the broker set from the All broker set or another broker set. You can add or remove brokers from the manual broker set at any time.

An automatic broker set uses broker tags to dynamically add and remove brokers from a set based on values you provide or the current state of the brokers.

See the following topics for more information about how to create and use broker sets in the WebSphere Message Broker Explorer:
- "Creating a manual broker set in the WebSphere Message Broker Explorer"
- "Adding and modifying broker tags in the WebSphere Message Broker Explorer" on page 917
- "Creating an automatic broker set in the WebSphere Message Broker Explorer" on page 918
- "Modifying broker sets in the WebSphere Message Broker Explorer" on page 920

Creating a manual broker set in the WebSphere Message Broker Explorer

You can create a manual broker set, and add brokers to visually group your brokers in the WebSphere Message Broker Explorer.

Before you begin

Before you start:

- Create a broker

About this task

A manual broker set is empty until you add brokers to the broker set from the All broker set, or from another broker set. You can add or remove brokers from the manual broker set at any time.

To create a manual broker set in the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view right-click the Brokers folder, and click **Broker Sets** > **New Broker Set**. The Create New Broker Set wizard is displayed.
2. Enter a name for the broker set.
3. Ensure **Manual** is selected as the set type.
4. Click **Finish**.

Results

The broker set is added to the Brokers folder. If this set was the first broker set that you have created, the All broker set is also added to the Brokers folder. The All broker set contains all your local brokers, and all remote brokers definitions in your workspace.

What to do next

You can now move brokers from your All broker set, or other broker sets, into the manual broker set that you have created.

Adding and modifying broker tags in the WebSphere Message Broker Explorer

Add or modify the broker tags on your brokers to change the brokers that are grouped in an automatic set in the WebSphere Message Broker Explorer.

Before you begin

Before you start:

- Create a broker

About this task

An automatic broker set uses broker tags to dynamically add and remove brokers from a set based on values you provide or the current state of the brokers. You must add the appropriate tags to your brokers before they can be dynamically added to an automatic broker set. You can select from the following included broker tags, or you can configure your own custom broker tags:

- brokerEnvironment:Development
- brokerEnvironment:Test
- brokerEnvironment:QA
- brokerEnvironment:Production

You can also remove tags that you have previously added to a broker to stop the broker being added to an automatic set.

To add or modify broker tags in the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view, expand the Brokers folder.
2. Right-click the broker for which you want to add or modify broker tags, and click **Modify Broker Tags**.
3. Select the broker tags to add to the broker:
   - Select broker tags from the available list.
   - Add a custom broker tag:
     a. Enter a name for the tag in the **Tags** field.
     b. Click **Add**.

        You can also select a tag and click **Remove** to remove it from the list of available broker tags.
   - Clear tags that you want to remove from the broker.
4. Click **Finish**.

Results

The selected broker tags are added to the broker. If the broker tags are matched in an automatic broker set, the broker appears in the broker set. If the broker tags no longer match in an automatic broker set, the broker no longer appears in the broker set.

What to do next

You can create or modify an automatic broker set to use one or more of the broker tags that you have created.

Creating an automatic broker set in the WebSphere Message Broker Explorer

Create an automatic broker set in the WebSphere Message Broker Explorer to group brokers dynamically based on values you provide, or their current state.

Before you begin

Before you start:

- Create a broker
- Add broker tags to your brokers

About this task

An automatic broker set uses broker tags to dynamically add and remove brokers from a set based on values you provide or the current state of the brokers. You must add the appropriate tags to your brokers before they can be dynamically added to an automatic broker set. You can select a single tag, or multiple tags, for an automatic broker set.

You can select from the following included broker tags, or any custom tags you have added:

- brokerEnvironment:Development

- brokerEnvironment:Test
- brokerEnvironment:QA
- brokerEnvironment:Production
- brokerStatus:Started
- brokerStatus:Stopped
- brokerStatus:Connected
- brokerStatus:Disconnected

To create an automatic broker set:

Procedure

1. In the Navigator view right-click the Brokers folder, and click **Broker Sets** > **New Broker Set**. The Create New Broker Set wizard is displayed.
2. Enter a name for the broker set.
3. Ensure **Automatic** is selected as the set type.
4. Click **Next**.
5. Select the conditions under which you want the broker to be a part of the broker set from the list of available filters. Click the **Add** button to move them into the selected filters pane.
6. Decide if you want the broker to match all the selected conditions, or one or more of them:
   - If you want the broker to match all the selected conditions ensure **matches ALL of the selected filters** is selected.
   - If you want the broker to match one or more of the selected conditions ensure **matches ANY of the selected filters** is selected.
7. Click **Finish**.

Results

The broker set is added to the Brokers folder, and all brokers that match the selected filters are added to the broker set. If this set is the first broker set that you have created, the All broker set is also added to the Brokers folder. The All broker set contains all your local brokers, and all remote brokers definitions in your workspace.

Modifying broker sets in the WebSphere Message Broker Explorer

Modify an automatic broker set in the WebSphere Message Broker Explorer to change or add broker tags used to filter brokers in the broker set.

Before you begin

Before you start:

- Create a broker
- Create an automatic broker set

About this task

An automatic broker set uses broker tags to dynamically add and remove brokers from a set based on values you provide or the current state of the brokers. You must add the appropriate tags to your brokers before they can be dynamically added to an automatic broker set. You can select from the following included broker tags or any custom tags you have added:

- brokerEnvironment:Development
- brokerEnvironment:Test
- brokerEnvironment:QA
- brokerEnvironment:Production
- brokerStatus:Started
- brokerStatus:Stopped
- brokerStatus:Connected
- brokerStatus:Disconnected

To modify an automatic broker set in the WebSphere Message Broker Explorer

Procedure

1. In the Navigator view expand the Brokers folder.
2. Right-click the broker set that you want to modify, and click **Modify Broker Set**.
3. Select the conditions under which you want the broker to be a part of the broker set from the list of available filters:
   - Click the **Add** button to move them into the selected filters pane.
   - Click the **Remove** button to remove them from the selected filters pane.
4. Decide if you want the broker to match all the selected conditions or one or more of them:
   - If you want the broker to match all the selected conditions ensure **matches ALL of the selected filters** is selected.
   - If you want the broker to match one or more of the selected conditions ensure **matches ANY of the selected filters** is selected.
5. Click **Finish**.

Results

The broker set is modified, and all brokers that match the selected filters are added to the broker set.

Starting and stopping a broker

Run the appropriate command to start or stop a broker.

Before you begin

Before you start:

- Ensure that your user ID has the correct authorizations to perform the task. Refer to "Security requirements for administrative tasks" on page 3644.
- On Linux, UNIX, and Windows systems, you must set up your command-line environment before performing this task, by running the product profile or console; refer to "Setting up a command environment" on page 213.

About this task

To start and stop a broker, you can use the **mqsistart** and **mqsistop** commands from the command line. Alternatively, on Windows and Linux, use the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer to start and stop brokers.

To start or stop a broker using the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer, follow the appropriate link:

- "Starting a local broker using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer" on page 925
- "Stopping a local broker using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer" on page 926

To start or stop a broker using commands from the command line, follow the link for the appropriate platform:

Procedure

- "Starting and stopping a broker on Linux and UNIX systems"
- "Starting and stopping a broker on Windows" on page 923
- "Starting and stopping a broker on z/OS" on page 924

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

Related tasks:

"Setting up a command environment" on page 213
After you have installed the product on one of the distributed systems, you must initialize the environment before you can use a runtime component or command.

Related reference:

"Security requirements for administrative tasks" on page 3644
You can configure access permissions to govern which users and groups can manipulate objects in the broker network. Security requirements for administrative tasks depend on the platform that you use.

"**mqsistart** command" on page 3965
Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

Starting and stopping a broker on Linux and UNIX systems

Run the appropriate command to start or stop a broker.

Procedure

1. Run '*./install_dir*/bin/mqsiprofile' to source the mqsiprofile script and set up the environment for a single targeted runtime environment. You must complete this setup before you can run a WebSphere Message Broker command.
2. To start a broker, enter the following command on the command line:

   mqsistart MB7BROKER

   Substitute your own broker name for MB7BROKER. The broker and its associated queue manager are started.

   Check the system log to ensure that the broker has initialized successfully. The log contains messages about verification procedures; if all tests are successful, only an initial start message is recorded. If any verification test is unsuccessful, the log also includes messages that provide details of the tests that have failed. If errors have been reported, review the messages and take the suggested actions to resolve these problems.
3. To stop a broker, enter the following command on the command line:

   mqsistop MB7BROKER

   Substitute your own broker name for MB7BROKER.

   You can also request that the broker queue manager is stopped by this command. Refer to "Stopping a WebSphere MQ queue manager when you stop a broker" on page 929.

Related concepts:

"The broker environment" on page 46

Starting and stopping a broker on Windows

Run the appropriate command to start or stop a broker.

Procedure

1. Open the WebSphere Message Broker command console. When you open the console, it sets up the environment that you need to run the WebSphere Message Broker commands.

   If you prefer, you can run the *install_dir*/bin/mqsiprofile command to set up the environment.

2. To start a broker, enter the following command on the command line:

   ```
   mqsistart MB7BROKER
   ```

   Substitute your own broker name for MB7BROKER.

   You can also request that the broker queue manager is started as a Windows service. Refer to "Starting a WebSphere MQ queue manager as a Windows service" on page 929.

   The broker and its associated queue manager are started. The command initiates the startup of the broker's Windows service.

   Check the Application Log in the Event Viewer to ensure that the broker has initialized successfully. The log contains messages about verification procedures; if all tests are successful, only an initial start message is recorded. If one or more verification tests are unsuccessful, the log also includes messages that provide details of the tests that have failed. If errors have been reported, review the messages and take the suggested actions to resolve these problems.

3. To stop a broker, enter the following command on the command line:

   ```
   mqsistop MB7BROKER
   ```

   Substitute your own broker name for MB7BROKER.

   You can also request that the broker queue manager is stopped by this command. Refer to "Stopping a WebSphere MQ queue manager when you stop a broker" on page 929.

If you are preparing to stop a broker, you can stop the broker's WebSphere MQ queue manager at the same time.

"Windows: Viewing the local error log" on page 3527
The Windows Event Viewer is where WebSphere Message Broker writes records to the local system. Use Windows system facilities to view this log.

Related reference:

"**mqsistart** command" on page 3965
Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

Starting and stopping a broker on z/OS

Run the appropriate command from SDSF to start or stop a broker.

Procedure

1. Start the component by using the command **/S <broker name>**. This command produces the following output, where MQP1BRK is the name of the broker:

   ```
   +BIP9141I MQP1BRK 0 The component was started
   ```

   Substitute your own broker name for MQP1BRK.

   The verification step runs, followed by starting the control process and any DataFlowEngine (execution group) address spaces.

   If the verification step fails, the errors are reported to the STDOUT stream in the JOBLOG. The control process and DataFlowEngine address spaces are not started. Review the messages to see what errors have been reported, and take the suggested actions to resolve these problems.

2. Alternatively, start the control process only by using the command:

   ```
   /S broker_name,STRTP=MAN
   ```

   If the verification step fails for any reason, the errors are reported to the STDOUT stream in the JOBLOG; the control process is not started. Review the messages to see what errors have been reported, and take the suggested actions to resolve these problems.

   No DataFlowEngine address spaces are started automatically if you specify STRTP=MAN. If the verification step is successful and the control process starts successfully, fully start the broker by issuing the console command:

   ```
   /F <broker name>, SC
   ```

3. To stop a broker, run the following command:

   ```
   /P <broker name>
   ```

"**mqsistart** command" on page 3965
Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

Starting a local broker using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer

You can start your local brokers by using the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.

About this task

On Windows and Linux use the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer to start and stop brokers. Alternatively, you can use the **mqsistart** and **mqsistop** commands from the command line to start or stop a broker.

Starting a local broker using the WebSphere Message Broker Toolkit: About this task

To start a local broker by using the WebSphere Message Broker Toolkit:

Procedure

1. Open the WebSphere Message Broker Toolkit, and switch to the Broker Application Development perspective.
2. In the Brokers view, right-click the broker, and click **Start**.

Results

You have started the selected broker.

Starting a local broker using the WebSphere Message Broker Explorer: About this task

To start a local broker by using the WebSphere Message Broker Explorer:

Procedure

1. Open the WebSphere Message Broker Explorer.
2. In the Navigator view, expand the Brokers folder.
3. Right-click the broker you want to start, and click **Start**.

Results

You have started the selected broker.

Viewing broker properties

You can view broker properties by using the **mqsireportbroker** command. You can also use the WebSphere Message Broker Explorer to view broker properties.

Before you begin

Before you start:

You must have completed the following tasks:

- Ensure that your user ID has the correct authorizations to perform the task; see "Security requirements for administrative tasks" on page 3644.
- Create a broker.
- On Windows, Linux, and UNIX systems, you must set up your command-line environment before performing this task by running the product profile or console; see "Setting up a command environment" on page 213.

About this task

Use the **mqsireportbroker** command or domain to view all the properties associated with a broker. The command shows both parameters entered on the command line and viewable in the workbench.

Procedure

1. Run the **mqsireportbroker** command. For example, to view the properties of the broker SOAPBR, run the following command:

   ```
   mqsireportbroker SOAPBR
   ```

2. View responses of the **mqsireportbroker** command to check on current settings. Examples are given in "**mqsireportbroker** command" on page 3919.
3. If you want to make any changes, run the **mqsichangebroker** command, specifying the required parameters.

Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

Starting a WebSphere MQ queue manager as a Windows service

On Windows, you can start a WebSphere MQ queue manager as a Windows service to ensure the queue manager starts when you start your other components.

Before you begin

Before you start:

You must complete the following task:

- Stop the queue manager for the Broker component by using the **endmqm** command. If you prefer, you can use the WebSphere MQ Explorer.

About this task

When you start a broker, the "**mqsistart** command" on page 3965 starts the associated queue manager if it is not already running.

When you start a broker on Windows, the broker starts as a service on Windows, but the associated queue manager does not.

You can change the properties of the queue manager service to set the startup type to automatic to enable the queue manager to run as a Windows service.

This change ensures that the operation of the queue manager is independent of the logged-on status of the user that starts the broker.

To start a WebSphere MQ queue manager as a Windows service:

Procedure

1. Click **Start** > **Programs** > **IBM WebSphere MQ** > **WebSphere MQ Explorer**.
2. In the left pane, right-click the queue manager and select **Properties**. The Properties dialog opens. The General properties are displayed.
3. Find the Startup property and set it to *Automatic*.
4. Click **OK**. The Properties dialog closes and the change is applied.
5. Restart the queue manager for the broker by using the **strmqm** command or WebSphere MQ Explorer. The changes to the queue manager's startup type take effect when you restart Windows.
6. Start the broker by using the **mqsistart** command.

Related tasks:

"Starting and stopping a broker" on page 921
Run the appropriate command to start or stop a broker.

Related reference:

Stopping a WebSphere MQ queue manager when you stop a broker

If you are preparing to stop a broker, you can stop the broker's WebSphere MQ queue manager at the same time.

About this task

You can specify a `-q` parameter on the **mqsistop** command to initiate a controlled shutdown of the queue manager for a broker.

Procedure

To stop a WebSphere MQ queue manager enter the following command on the command line:

```
mqsistop MB7BROKER  -q
```

where:
`MB7BROKER` is the name of the broker.
`-q` stops the WebSphere MQ queue manager associated with the component. The command cannot complete until shutdown of the queue manager has completed.

Related tasks:

"Starting and stopping a broker" on page 921
Run the appropriate command to start or stop a broker.

Related reference:

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

Deleting a broker

Delete a broker using the command line on the system where the broker component is installed.

Before you begin

Before you start: Check that your user ID has the correct authorizations to perform the task; for details, see "Security requirements for administrative tasks" on page 3644.

About this task

On Windows and Linux systems, you can delete a broker using the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer. For instructions on deleting the broker using the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer, see "Deleting a broker using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer" on page 933.

On Windows, Linux, and UNIX systems, you must set up your command-line environment before deleting a broker, by running the product profile or console; see "Setting up a command environment" on page 213.

Follow the link for the appropriate platform:

Procedure

Use the **mqsideletebroker** command to delete a named broker. The command also deletes the queues on the associated queue manager (created when the broker was created). You can also specify that the queue manager is to be deleted.

Deleting a broker on Linux and UNIX systems

Delete the physical broker component.

About this task

To delete a broker on Linux and UNIX systems:

Procedure

1. Stop the broker by using the **mqsistop** command.
2. Enter the following command to delete the broker:

   ```
   mqsideletebroker MB7BROKER
   ```

   where `MB7BROKER` is the broker name.
3. If you have created execution group profiles for this broker, delete these profiles if they are no longer required.
4. If you have created execution group `shared-classes` directories for this broker, delete these directories if they are no longer required.

Results

On completion of this task, you have:

- Removed the broker data from the database.
- Removed the record for the component in the broker registry. It is therefore removed from the list of components that are displayed when you run the **mqsilist** command.
- Removed any execution group profile scripts that are no longer needed.
- Removed any execution group `shared-classes` directories that are no longer needed.

Deleting a broker on z/OS

Delete the physical broker component.

About this task

To delete a broker:

Procedure

1. Stop the broker, by stopping the started task.
2. Customize and submit the delete job `BIPDLBK` in your component PDSE to delete the broker component and WebSphere MQ. This action does not delete all files from the component directory in the file system.
3. If you have created an execution group `shared-classes` directory for this broker, delete this directory if it is no longer required.

Deleting a broker using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer

On Windows and Linux on x86 you can delete brokers by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer.

Before you begin

Before you start: Check that your user ID has the correct authorizations to perform the task; for details, see "Security requirements for administrative tasks" on page 3644.

About this task

You can delete a local broker using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer. You cannot delete a remote broker using the

WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer, but you can remove the connection to the remote broker from your workspace. To remove the connection to a remote broker in the WebSphere Message Broker Toolkit, right-click the broker in the Brokers view, and click **Remove Connection**. To remove the connection to a remote broker in the WebSphere Message Broker Explorer, right-click the broker in the Navigator view, and click **Remove**.

Deleting a broker using the WebSphere Message Broker Toolkit:
About this task

To delete a broker using the WebSphere Message Broker Toolkit:

Procedure

1. Open the WebSphere Message Broker Toolkit, and switch to the Broker Application Development perspective.
2. In the Brokers view, right-click the broker, and click **Delete**. If the broker is a remote broker, the connection to the broker is removed from your workspace.

   If the broker is a local broker, the Delete Local Broker wizard is displayed:

   a. Optional: If you want to delete the queue manager associated with the broker, ensure **Delete the broker's queue manager** is selected.
   b. Click **Finish** to delete the broker. The wizard stops the broker if it is running.

Results

You have deleted the broker.

Deleting a broker using the WebSphere Message Broker Explorer:
About this task

To delete a broker using the WebSphere Message Broker Explorer:

Procedure

1. Open the WebSphere Message Broker Explorer.
2. In the Navigator view, expand the broker's queue manager, or the Brokers folder.
3. Right-click the broker, and click **Delete** > **Broker**. The Delete Broker wizard is displayed.
4. If you want to delete the queue manager associated with the broker, ensure **Delete the broker's queue manager** is selected.
5. Click **Next**. The wizard stops the broker if it is running.
6. Click **Finish** to close the wizard.

Results

You have deleted the broker. If you choose to delete the queue manager, the queue manager continues to be displayed in the Navigator view until the views are refreshed. The time this takes depends on your queue manager refresh settings, but the default refresh value is 15 seconds.

Creating an execution group

Create execution groups by using WebSphere Message Broker Toolkit, the WebSphere Message Broker Explorer, or the command line.

Before you begin

Before you start:

Complete the following tasks:

- Create a broker
- Connect to the broker:
  - "Connecting to a local broker using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer" on page 901
  - "Connecting to a remote broker" on page 902
  - "Connecting to a remote broker on z/OS in the WebSphere Message Broker Explorer" on page 904

About this task

The mode that your broker is working in can affect the number of execution groups that you can use; see "Restrictions that apply in each operation mode" on page 3657.

Use one of the following methods to complete this task:

- The WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer. See "Creating an execution group using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer" on page 937 for more information.
- The **mqsicreateexecutiongroup** command. Details are provided in "Creating an execution group using the **mqsicreateexecutiongroup** command" on page 939.

You can also use the CMP API to create execution groups on all platforms; see "Developing applications that use the Administration API" on page 956.

For information about why you might want to create multiple execution groups, see "Execution groups" on page 53.

Creating an execution group using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer

Use the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer to create execution groups on your broker.

Before you begin

Before you start: Check that you have completed the prerequisite tasks, and see what other options you can use to create execution groups, in "Creating an execution group" on page 936.

About this task

You must create an execution group before you can deploy message flows and related resources to a broker.

Creating an execution group using the WebSphere Message Broker Toolkit: Before you begin

Before you start:

- Create a broker
- Optional: "Connecting to a remote broker" on page 902

About this task

To add an execution group to a broker:

Procedure

1. In the Brokers view, right-click the broker to which you want to add an execution group, and click **New Execution Group**.
2. In the New Execution Group dialog, enter the **Execution Group name**.
3. Click **OK** to add the execution group to the broker.

Results

The execution group is added to the appropriate broker, and can be viewed as a child of the selected broker.

Creating an execution group using the WebSphere Message Broker Explorer: Before you begin

Before you start:

- Create a broker
- Connect to a local broker or "Connecting to a remote broker" on page 902

About this task

To add an execution group to a broker:

Procedure

1. In the Navigator view, expand the Brokers folder.
2. Right-click the broker to which you want to add an execution group, and click **New** > **Execution Group**.
3. In the New Execution Group dialog, enter the **Execution Group name**.
4. Click **OK** to add the execution group to the broker.

Results

The execution group is added to the appropriate broker, and can be viewed as a child of the selected broker.

Note: If you do not immediately see the execution group that you added, you can refresh the broker by right-clicking on it and selecting **Refresh**.

You can delete an execution group by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer.

Creating an execution group using the `mqsicreateexecutiongroup` command

Use the **mqsicreateexecutiongroup** command to create execution groups on your broker.

Before you begin

Before you start: Check that you have completed the prerequisite tasks, and see what other options you can use to create execution groups, in "Creating an execution group" on page 936.

You must create an execution group before you can deploy message flows and related resources to a broker.

Procedure

1. If you are creating an execution group on Linux, UNIX, and Windows systems:
   a. Open a command prompt that has the environment configured for your current installation.
   b. Enter the **mqsicreateexecutiongroup** command, specifying the parameters for the execution group that you want to create.
      - If the broker is local, specify the broker name. For example:

        ```
        mqsicreateexecutiongroup MB7BROKER -e EGroup_2
        ```

      - If the broker is remote, you can specify a configuration file. For example:

        ```
        mqsicreateexecutiongroup -n MB7BROKER.broker -e EGroup_2
        ```

      - If the broker is remote, you can alternatively specify one or more of the connection parameters **-i**, **-p**, **-q**. For example:

        ```
        mqsicreateexecutiongroup -q MB7QMGR -e EGroup_2
        ```

      See the **mqsicreateexecutiongroup** command description for more details about these options.
2. If you are creating an execution group on z/OS:
   a. Configure the `BIPCREG` job to specify the properties for the execution group that you want to create.
   b. Run the `BIPCREG` job.

Results

On completion of this task, the execution group has been created on the specified broker.

What to do next

Next: You can deploy message flows to the execution group by using the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.

Related concepts:

"Execution groups" on page 53
An execution group is a named grouping of message flows that have been assigned to a broker. The broker enforces a degree of isolation between message flows in distinct execution groups by ensuring that they run in separate address spaces, or as unique processes.

Renaming an execution group using the WebSphere Message Broker Explorer

You can rename an execution group by using the WebSphere Message Broker Explorer.

Before you begin

Before you start:

- Create a broker
- Start the broker
- Connect to a local broker, connect to a remote broker, or connect to a remote broker on z/OS
- Create an execution group

About this task

To rename an execution group:

Procedure

1. Open the WebSphere Message Broker Explorer.
2. In the Navigator view, expand the Brokers folder.
3. Expand your broker.
4. Right-click the execution group that you want to rename, and click **Rename**.
5. Enter a name for the execution group, and click **OK**.

Results

You have renamed the selected execution group.

Administering brokers and associated broker resources includes the tasks that you perform frequently to activate and manage those resources. Choose the method you prefer to administer your brokers and associated resources.

Starting an execution group using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer

You can start an execution group and all the deployed message flows in an execution group by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer.

About this task

If resources are deployed to your execution group, the started or stopped state of the message flows is retained when you next start the execution group. You can use the menu to start or stop all message flows after the execution group has been started.

If you prefer, you can start execution groups by using the **mqsistartmsgflow** command.

Starting an execution group with the WebSphere Message Broker Toolkit

About this task

To start an execution group by using the WebSphere Message Broker Toolkit:

Procedure

1. Open the WebSphere Message Broker Toolkit, and switch to the Broker Application Development perspective.
2. In the Brokers view, expand your broker.
3. Right-click the execution group, and click **Start**.

Results

A message is sent to the broker to start the selected execution group. Right-click the message flows that you want to start, and click **Start** to start the message flows deployed to the execution group.

Starting an execution group with the WebSphere Message Broker Explorer

About this task

To start an execution group by using the WebSphere Message Broker Explorer:

Procedure

1. Open the WebSphere Message Broker Explorer.
2. In the Navigator view, expand the Brokers folder.
3. Expand your broker.
4. Right-click the execution group, and click **Start** > **Execution Group**.

Results

A message is sent to the broker to start the selected execution group. Click **Start** > **All Flows** to start all the message flows deployed to the execution group.

Starting an execution group with the `mqsistartmsgflow` command

About this task

To start an execution group by using the **mqsistartmsgflow** command:

Procedure

1. Open a command prompt that has the environment configured for your current installation.
2. Enter the **mqsistartmsgflow** command, specifying the parameters for the execution group that you want to start.
   - If the broker is local, specify the broker name. For example:

     ```
     mqsistartmsgflow MB7BROKER -e EGroup_2
     ```

   - If the broker is remote, you can specify a configuration file. For example:

     ```
     mqsistartmsgflow -n MB7BROKER.broker -e EGroup_2
     ```

- If the broker is remote, you can alternatively specify one or more of the connection parameters **-i**, **-p**, **-q**. For example:

  ```
  mqsistartmsgflow -q MB7QMGR -e EGroup_2
  ```

What to do next

If you want to start all the execution groups on a broker, specify the **-g** flag instead of **-e**.

See the **mqsistartmsgflow** command description for more details about these options.

Stopping an execution group using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer

You can stop all the message flows in an execution group by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer.

About this task

If resources are deployed to your execution group, the started or stopped state of the message flows is remembered when you stop the execution group. You can use the menu to start or stop all message flows before the execution group has been stopped.

If you prefer, you can stop execution groups by using the **mqsistopmsgflow** command.

The broker processes all inflight messages and associated transactions for each message flow before stopping it. See "Message flow transactions" on page 1281 for information on how outstanding units of work are handled in this situation.

Stopping an execution group with the WebSphere Message Broker Toolkit

About this task

To stop an execution group by using the WebSphere Message Broker Toolkit:

Procedure

1. Open the WebSphere Message Broker Toolkit, and switch to the Broker Application Development perspective.
2. In the Brokers view, expand your broker.
3. Right-click the execution group, and click **Stop**.

Results

A message is sent to the broker to stop the selected execution group.

Deleting an execution group

Delete execution groups by using WebSphere Message Broker Toolkit, the WebSphere Message Broker Explorer, or the command line.

Before you begin

Before you start:

Complete the following tasks:

- Create an execution group
- Check that the execution group is running; you cannot delete an execution group that is stopped.

About this task

Use one of the following methods to complete this task:

- The WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer. See “Deleting an execution group by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer” on page 947 for more information.
- The **mqsideleteexecutiongroup** command. Details are provided in “Deleting an execution group by using the **mqsideleteexecutiongroup** command” on page 949.

You can also use the CMP API to delete execution groups on all platforms; see “Developing applications that use the Administration API” on page 956.

For information about why you might want to create multiple execution groups, see “Execution groups” on page 53.

Deleting an execution group by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer

You can delete an execution group by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer.

Before you begin

Before you start: Check that you have completed the prerequisite tasks, and see what other options you can use to delete execution groups, in "Deleting an execution group" on page 946.

Deleting an execution group by using the WebSphere Message Broker Toolkit: About this task

To delete an execution group by using the WebSphere Message Broker Toolkit

Procedure

1. Open the WebSphere Message Broker Toolkit, and switch to the Broker Application Development perspective.
2. In the Brokers view, expand your broker.
3. Right-click the execution group that you want to delete, and click **Delete** > **Execution Group**.

Results

Your execution group and all resources deployed to it are deleted. If you have created any execution group profiles, or an execution group `shared-classes` directory, for this execution group, delete them manually if they are no longer required.

Deleting an execution group by using the WebSphere Message Broker Explorer: About this task

To delete an execution group by using the WebSphere Message Broker Explorer:

Procedure

1. Open the WebSphere Message Broker Explorer.
2. In the Navigator view, expand the Brokers folder.
3. Expand your broker.
4. Right-click the execution group, and click **Delete** > **Execution Group**.
5. If you have deployed resources, you must confirm that you want to remove all deployed resources before the execution group is deleted. Click **OK** to remove the deployed resources.

Results

Your execution group and all resources deployed to it are deleted. If you have created any execution group profiles, or an execution group `shared-classes` directory, for this execution group, delete them manually if they are no longer required.

Deleting an execution group by using the mqsideleteexecutiongroup command

Use the command line to delete an execution group from the broker.

Before you begin

Before you start: Check that you have completed the prerequisite tasks, and see what other options you can use to delete execution groups, in "Deleting an execution group" on page 946.

Procedure

1. If you are deleting an execution group on Linux, UNIX, and Windows systems:
   a. Open a command prompt that has the environment configured for your current installation.
   b. Enter the **mqsideleteexecutiongroup** command, specifying the parameters for the execution group that you want to delete.
      - If the broker is local, specify the broker name; for example:
        ```
        mqsideleteexecutiongroup MB7BROKER -e EGroup_2
        ```
      - If the broker is remote, you can specify a configuration file; for example:
        ```
        mqsideleteexecutiongroup -n MB7BROKER.broker -e EGroup_2
        ```
      - If the broker is remote, you can alternatively specify one or more of the connection parameters **-i**, **-p**, and **-q**; for example:
        ```
        mqsideleteexecutiongroup -q MB7QMGR -e EGroup_2
        ```

      See the **mqsideleteexecutiongroup** command description for more details about these options.
   c. If you have created execution group profiles and they are no longer required, delete them manually.
   d. If you have created an execution group `shared-classes` directory and it is no longer required, delete it manually.
2. If you are deleting an execution group on z/OS:
   a. Configure the `BIPDLEG` job to specify the properties for the execution group that you want to delete.
   b. Run the `BIPDLEG` job.
   c. If you have created an execution group `shared-classes` directory and it is no longer required, delete it manually.

Results

On completion of this task, the execution group has been deleted from the specified broker. In addition:

- All message flows that were running on the execution group are stopped.
- Any execution group profile scripts that are no longer needed have been removed.
- Any execution group `shared-classes` directory that is no longer needed has been removed.

Setting user-defined properties dynamically at run time using the WebSphere Message Broker Explorer

Use the WebSphere Message Broker Explorer to view and set user-defined properties on a message flow dynamically at run time.

Before you begin

For user-defined properties on a message flow to be discoverable, the message flow must comply with the following conditions:

- The message flow must contain at least one of the following nodes:
  - JavaCompute
  - Compute
  - Database
  - Filter
  - PHPCompute
- The message flow must define the relevant user-defined property and provide an override value.

About this task

Tip: Use meaningful names and values for the properties that you define, so that you can understand their purpose and intent quickly. For example, a user-defined property named `property01`, with an initial value of `valueA` is not as useful as a property named `RouteToAorB` with an initial value of `RouteA`.

Use the following instructions to view and modify user-defined properties on your message flows using the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view, expand the Brokers folder, and navigate to the message flow on which you want view the user-defined properties.
2. Right-click the message flow, and click **Properties**.
3. Click **User Defined Properties** to display a list of the user-defined properties and their value defined on the message flow.
4. Optional: if you want to modify the user-defined properties, change the value in the appropriate rows in the Value column, and click **Apply**. A message is sent to the broker to change the value of the user-defined property.
5. Click **OK** to close the Properties window.

The WebSphere Message Broker Explorer is a graphical user interface based on the Eclipse platform for administering your brokers.

"User-defined properties" on page 1147
A user-defined property (UDP) is a property that is defined when you construct a message flow by using the Message Flow editor. This property can be used by the ESQL or Java program inside message flow nodes, such as a Compute node.

"User-defined properties in ESQL" on page 2376
Access user-defined properties (UDPs) as variables in your ESQL program by specifying the EXTERNAL keyword on a DECLARE statement. For example, the ESQL statement `DECLARE today EXTERNAL CHARACTER 'monday'` defines a user-defined property called today with an initial value monday.

Related tasks:

"Configuring a message flow at deployment time with user-defined properties" on page 2626
Use user-defined properties (UDPs) to configure message flows at deployment and run time, without modifying program code. You can give a UDP an initial value when you declare it in your program, or when you use the Message Flow editor to create or modify a message flow.

"Accessing message flow user-defined properties from a JavaCompute node" on page 2659
Customize a JavaCompute node to access properties that you have associated with the message flow in which the node is included.

Related reference:

"ESQL variables" on page 5048
ESQL variables can be described as *external variables*, *normal variables*, or *shared variables*; their use is defined in the DECLARE statement.

"Configurable message flow properties" on page 4020
When you add a message flow to a broker archive (BAR) file in preparation for deploying it to a broker, you can set additional properties that influence its run time operation. These properties are available for review and update when you

select the **Manage and Configure** tab for the broker archive file.

Developing applications that use the Administration API

Develop Java applications that use the Administration API (also known as the CMP API) to communicate with, deploy to, and manage brokers and their associated resources.

Before you begin

Before you start:

Read an overview of the "The Administration API for WebSphere Message Broker" on page 54, and how you can use it to manage the resources associated with your brokers.

Samples are provided to demonstrate typical CMP scenarios. Run and explore the samples to learn about what you can do with the CMP; see "The Administration API samples" on page 958.

About this task

To write administrative applications that run tasks in your brokers, see the following information:

- Configuring the environment
- Connecting to a broker
- Navigating brokers and broker resources
- Deploying resources
- Setting message flow user-defined properties at run time
- Working with UserDefined configurable service properties in JavaCompute nodes
- Managing brokers
- Managing brokers from JavaCompute nodes
- Working with resource manager statistics
- Submitting batch requests

Results

When you have created your applications, test their operation in your test environment. Check the results of the operations that the programs have performed by using the Deployment Log view.

What to do next

When you have written and tested your applications, distribute them to the computers from which you want your administrators to perform the tasks that you have developed.

Related concepts:

Related information:

Administration API for WebSphere Message Broker (CMP API)

The Administration API for WebSphere Message Broker

The Administration API for WebSphere Message Broker is a programming interface that your applications can use to control brokers and their resources through a remote interface.

> The Administration API for WebSphere Message Broker is also known as the Configuration Manager Proxy, or CMP API
>
> The Configuration Manager has been removed from Version 7, and the full name of the API has changed. However, the terms CMP application and CMP API have been retained, and are used in this information center to refer to the Administration API, for continuity and consistency with the JAR file `ConfigManagerProxy.jar` that supplies all the classes.

The Administration API for WebSphere Message Broker (CMP API) consists solely of a Java implementation, and is referred to as the Message Broker Java API. Your applications have complete access to the broker functions and resources through the set of Java classes that constitute the CMP. Use the CMP API to interact with the broker to perform the following tasks:

- Deploy BAR files
- Change the broker configuration properties
- Create, modify, and delete execution groups
- Inquire and set the status of the broker and its associated resources, and to be informed if status changes
  - Execution groups
  - Deployed message flows
  - Deployed files used by the message flows (for example, JAR files)
- View the Administration log

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

"Execution groups" on page 53
An execution group is a named grouping of message flows that have been assigned to a broker. The broker enforces a degree of isolation between message flows in distinct execution groups by ensuring that they run in separate address spaces, or as unique processes.

"WebSphere Message Broker Toolkit" on page 31
The WebSphere Message Broker Toolkit is an integrated development environment and graphical user interface based on the Eclipse platform.

The Administration API samples

Explore the samples to learn the basic features that are provided by the Administration API (also known as the CMP API). Run the samples to deploy a BAR file or manage a broker, or use the CMP API Exerciser to implement various tasks.

Deploy BAR

The Deploy BAR sample deploys a BAR file to an execution group, and displays the outcome. Read about this sample in "Running the CMP Deploy BAR sample" on page 959.

Broker management

The broker management sample uses the CMP API to display to the screen the complete run state of the broker. "Running the CMP broker management sample" on page 960 describes this sample in more detail.

The CMP API Exerciser

The CMP API Exerciser is a graphical interface to the CMP that you can use to view and manipulate brokers. Use the CMP API Exerciser sample to view and manage a broker, or record and play back configuration scripts. You can also customize the CMP API Exerciser to tailor the tasks to suit your requirements. See "Running the CMP API Exerciser sample" on page 962 for more information.

Modify CMP API samples

You can modify the CMP API samples, and change various parameters that affect how the samples run. Read "Modifying the CMP samples" on page 968 and follow the guidance given about possible changes.

Administration API for WebSphere Message Broker (CMP API)

Running the CMP Deploy BAR sample

Run the CMP Deploy BAR sample to deploy a broker archive file to a broker.

Before you begin

Before you start:

The BAR file and execution group name, and the connection details that define the target broker, are hard coded into the application. You can run this sample unchanged, or you can modify the values and parameters that it uses to apply them to your own configuration.

If you modify the Deploy BAR sample, you must update and recompile the source file before you run it. The source file for this sample is located in the following directory:

install_dir/sample/ConfigManagerProxy/cmp/DeployBar.java

About this task

Use the Deploy BAR sample to deploy a BAR file to an execution group, and display the outcome.

Procedure

1. Run the Deploy BAR sample by entering the appropriate command for your platform:
   - Windows On Windows, open a Command Console and run the following command:

     install_dir\sample\ConfigManagerProxy\StartDeployBAR.bat
   - Linux UNIX z/OS On other platforms:
     a. Start a broker command environment by running **mqsiprofile**, or follow the guidance provided in the StartDeployBar shell script to configure the correct CLASSPATH for your environment.
     b. Run the shell script:

        install_dir\sample\ConfigManagerProxy\StartDeployBAR

The default connection parameters used by the sample are shown in the following table.

Connection parameter	Description
`"localhost"`	Host name of the computer where the broker is running.
`"MB7QMGR"`	Name of the broker queue manager.
`2414`	Port on which the broker queue manager is listening
`"default"`	Name of the execution group.
`"mybar.bar"`	Fully qualified name of the BAR file to deploy.

The CMP connects to the broker that is running on the local computer (defined by `localhost`). The queue manager `MB7QMGR` must be listening on port `2414`. Next, the CMP deploys the file `mybar.bar` to the predefined execution group `default`.

2. Check the results of the sample by viewing the broker in the WebSphere Message Broker Toolkit, or by using the CMP API Exerciser.

What to do next

Next: Run another sample, or work with the CMP API Exerciser.

Related concepts:

Running the CMP broker management sample

Run the broker management sample to display the complete run state of a broker.

Before you begin

Before you start:

You can run this sample unchanged, or you can modify the values and parameters that it uses to apply them to your own configuration.

If you modify this management sample, you must update and recompile the source file before you run it. The source file for this sample is located in the following directory:

install_dir/sample/ConfigManagerProxy/cmp/BrokerInfo.java

About this task

Use the broker management sample to display the complete run state of the target broker.

Procedure

- Run the broker management sample by entering the appropriate command for your platform. Replace *connection_file* with the fully qualified file path to the broker file (with extension `.broker`).
  - Windows On Windows, use the Command Console to run the following command:

    install_dir\sample\ConfigManagerProxy\StartBrokerInfo.bat *connection_file*
  - Linux UNIX z/OS On other platforms:
    1. Start a broker command environment by running **mqsiprofile**, or follow the guidance provided in the StartBrokerInfo shell script to configure the correct CLASSPATH for your environment.
    2. Run the shell script:

       install_dir\sample\ConfigManagerProxy\StartBrokerInfo *connection_file*

  The complete run state of the broker is displayed. You can see responses like the following output:

```
(28/01/09 11:47:43) Connecting. Please wait...
(28/01/09 11:47:46) Successfully connected to the broker's queue manager.
(28/01/09 11:47:49) Successfully connected to the broker.
(28/01/09 11:47:49) Broker 'MB7BROKER' is running.
(28/01/09 11:47:50)   Execution group 'default' on 'MB7BROKER' is running.
(28/01/09 11:47:51)     Message flow 'simpleflow' on 'default' on 'MB7BROKER' is running.
(28/01/09 11:47:51) Disconnected.
```

- If you prefer, you can run this sample in interactive mode, which causes the sample to listen for changes to the broker.
  1. To run the sample in interactive mode, specify the **-i** option on the command.

     For example:

```
\sample\ConfigManagerProxy\StartBrokerInfo.bat
 c:\myBroker.broker  -i
```

     In interactive mode, you see the output shown earlier, and the additional response:

```
(13/08/08 15:53:46) Listening for changes to the broker...
```

  2. To stop the sample when it is running in interactive mode, force it to end by using CTRL+C.

What to do next

Next: Run another sample, or work with the CMP API Exerciser.

Viewing and managing a broker in the CMP API Exerciser:

Use the CMP API Exerciser sample to view and manage a broker.

About this task

To view and manage a broker by using the CMP API Exerciser, complete the following steps:

Procedure

1. Start the CMP API Exerciser:
   - Windows On Windows, click **Start** > **All Programs** > **IBM WebSphere Message Broker 7.0** > **Java Programming APIs** > **CMP API Exerciser**.
   - Linux UNIX z/OS On other platforms:
     a. Start a broker command environment by running **mqsiprofile**, or follow the guidance provided in the `StartConfigManagerProxyExerciser` shell script to configure the correct CLASSPATH for your environment.
     b. Ensure that your user ID has writer permission to the current directory. The CMP API Exerciser stores its configuration settings in a file in this directory.
     c. Run the shell script:
        install_dir`\sample\ConfigManagerProxy\StartConfigManagerProxyExerciser`

   The CMP API Exerciser window opens.
2. Connect to a running broker by clicking either **File** > **Connect to Local Broker** or **File** > **Connect to Remote Broker**.

   The Connect to a Broker dialog opens.
3. Enter the connection parameters to the broker, then click **Submit**.

   Broker information is retrieved and displayed in the CMP API Exerciser window. You have now connected to the broker.

   The upper left of the screen contains a hierarchical representation of the broker to which you are connected. Selecting objects in the tree causes the table on the right to change, reflecting the attributes of the object that you select. The Method column lists CMP API methods that you can call in your own Java applications, and the Result column indicates the data that is returned by calling the CMP API method on the selected object.
4. Run a CMP API method against a broker object. CMP API methods are used to manage objects in a broker.

a. In the navigation tree, right-click a broker.

   A pop-up menu opens to show all the available CMP API methods.

b. Select **Create execution group**. The Create execution group dialog opens.

c. Enter the name for a new execution group and click **Submit**. The output from the method is displayed in the log window at the bottom of the screen. For example:

```
(31/03/09 16:53:50) ----> cmp.exerciser.ClassTesterForBrokerProxy.testCreateEG
 (MB7BROKER, "eg1")
(31/03/09 16:53:50) The request was successfully sent to the broker.
(31/03/09 16:53:50) <---- cmp.exerciser.ClassTesterForBrokerProxy.testCreateEG
```

You also see messages that are returned from the broker when the method is called. For example:

```
(31/03/09 16:53:50) ----> cmp.exerciser.ExerciserAdministeredObjectListener.processActionResponse(...)
(31/03/09 16:53:50) affectedObject = MB7BROKER
(31/03/09 16:53:50) completionCode = success
(31/03/09 16:53:50) (Reference property) commsmessage.lastinbatch=true
(31/03/09 16:53:50) (Reference property) uuid=595e1d10-3875-11d4-a485-000629be5bf8
(31/03/09 16:53:50) (Reference property) child.uuid=1d8b3c5d-2001-0000-0080-c2000502e620
(31/03/09 16:53:50) (Reference property) configmanagerproxy.osname=Windows XP
(31/03/09 16:53:50) (Reference property) child.name=eg1
(31/03/09 16:53:50) (Reference property) userid=Matt
(31/03/09 16:53:50) (Reference property) configmanagerproxy.hostname=lucas
(31/03/09 16:53:50) (Reference property) commsmessage.configobjecttype=Broker
(31/03/09 16:53:50) (Reference property) type=Broker
(31/03/09 16:53:50) (Reference property) child.type=ExecutionGroup
(31/03/09 16:53:50) (Reference property) commsmessage.operationtype=createchild
(31/03/09 16:53:50) (Reference property) configmanagerproxy.noeventlog=false
(31/03/09 16:53:50) (Reference property) eg.arch=0
(31/03/09 16:53:50) <---- cmp.exerciser.ExerciserAdministeredObjectListener.processActionResponse()
```

In this example, `completionCode = success` means that the request to create the execution group is successful. The lines marked `(Reference property)` describe the request to which the response refers.

Results

During these steps you connected to a broker, viewed the broker information, and performed a management task by using the CMP API Exerciser.

What to do next

Next: Continue to work with the CMP API Exerciser, or run another sample.

Customizing the CMP API Exerciser:

Enable or disable a selection of options to customize the CMP API Exerciser to meet your requirements.

About this task

To customize the CMP API Exerciser, complete the following steps:

Procedure

1. Start the CMP API Exerciser.
   - Windows On Windows, click **Start** > **All Programs** > **IBM WebSphere Message Broker 7.0** > **Java Programming APIs** > **CMP API Exerciser**.
   - Linux UNIX z/OS On other operating systems, run the following shell script:

     ```
     install_dir\sample\ConfigManagerProxy\StartConfigManagerProxyExerciser
     ```

   The CMP API Exerciser window opens.
2. Customize the CMP API Exerciser by selecting one or more of the following options from the **File** menu.
   a. Optional: Click **File** > **Discover Subcomponent Tree Recursively** to enable or disable this option.
      - If you enable this option, the CMP API Exerciser connects to a broker and discovers all defined broker objects.
      - If you disable this option, only the top-level objects are discovered; you must select the context-sensitive option, **Discover subcomponents**, to iterate down the object hierarchy.

   b. Optional: Click **File** > **Use Incremental Deployment** to enable or disable this option.
      - If you enable this option, all deploy operations cause a delta (incremental) deploy where relevant.
      - If you disable this option, all deploy operations cause a complete deploy.

   c. Optional: Click **File** > **Show Advanced Properties** to enable or disable this option.
      - If you enable this option, output from all available methods is displayed in the right pane of the CMP API Exerciser.
      - If you disable this option, output from a subset of the available methods is displayed in the right pane of the CMP API Exerciser.

   d. Optional: Click **File** > **Connect Using .broker Properties File** to enable or disable this option.

- If you enable this option, a file dialog opens when you connect to a broker. Use the file dialog to navigate to a file with a `.broker` extension, which provides the connection parameters to the queue manager that hosts the broker.
- If you disable this option, you are prompted to enter the queue manager connection parameters, security exit parameters, host name, and port.

e. Optional: Click **File** > **Enable MQ Java Client Service Trace** to enable or disable this option.
   - If you enable this option, a level 5 service trace of the WebSphere MQ Classes for Java runs. A trace dialog opens; specify a file name to which trace records are written.
   - If you disable this option, level 5 service tracing of the WebSphere MQ Classes for Java is not done.

f. Optional: Click **File** > **Enable Broker Administration Service Trace** to enable or disable this option.
   - If you enable this option, a service trace of the CMP API run. A trace dialog opens; specify a file name to which trace records are written.
   - If you disable this option, service tracing of the CMP API is not done.

g. Optional: Click **File** > **Set Timeout Characteristics**.

   Specify the time, in seconds, that the CMP API Exerciser waits for responses from the broker. The default wait interval is 6 seconds.

What to do next

Next: Continue to work with the CMP API Exerciser, or run another sample.

Recording and playing back configuration scripts using the CMP API Exerciser:

Use the CMP API Exerciser to record and play back configuration scripts.

About this task

You can run a script file from the command line, a shell window, or from a batch file. If you run the script by using one of these methods, ensure the first action completed by the script is to connect to a broker.

Procedure

1. Start the CMP API Exerciser.
   - Windows On Windows, click **Start** > **All Programs** > **IBM WebSphere Message Broker 7.0** > **Java Programming APIs** > **CMP API Exerciser**.
   - Linux UNIX z/OS On other operating systems, run the following shell script:

     ```
     install_dir\sample\ConfigManagerProxy\StartConfigManagerProxyExerciser
     ```

   The CMP API Exerciser window opens.
2. Start recording a script by clicking **Scripting** > **Record New Script**. The Save dialog opens. Type a name for the script file, select an appropriate file location, and click **Save**.
   a. Complete one or more actions on a broker by using the CMP API Exerciser.

      If you start recording before you run actions against the broker, the first action taken is to connect to the broker; however, you can start recording a script at any point during the management of a broker.
   b. Optional: Insert a pause by clicking **Scripting** > **Insert a pause**.

      The CMP API Exerciser pauses so that responses can be returned before the next action is issued. Use this option to avoid naming conflicts if you are deleting and recreating objects of the same name.

      The Insert a pause dialog opens; specify the duration of the pause in seconds.
   c. Stop recording the script by clicking **Scripting** > **Stop Recording**.

      Information about the actions taken are saved to the script file.
3. To replay the script file:
   a. Click **Scripting** > **Play Back Recorded Script**.

      The Open dialog opens.
   b. Select the appropriate script file and click **Open**. The script file is replayed.

What to do next

Modifying the CMP samples

Modify the CMP samples to change the parameters that they use to complete their tasks.

About this task

If you change a sample, you must recompile the source code to implement those changes. For example, you might choose to change the default connection parameters. If you modify these and other values, you change the behavior of the sample.

To modify a sample, perform the following steps:

Procedure

1. Set up the environment by following the instructions provided in "Configuring an environment for developing and running CMP applications" on page 969.
2. Locate the source file for the sample that you want to change.

   The source files for the samples are located in the following directories:

   Deploy BAR sample
   install_dir/sample/ConfigManagerProxy/cmp/DeployBar.java

   Broker management sample
   install_dir/sample/ConfigManagerProxy/cmp/BrokerInfo.java

   CMP API Exerciser sample
   install_dir/sample/ConfigManagerProxy/cmp/exerciser.java
3. Open the source file, and modify the appropriate parameters.
4. Save and recompile the source file.

What to do next

Next: Run the modified sample by following the instructions in the appropriate link:

- "Running the CMP Deploy BAR sample" on page 959
- "Running the CMP broker management sample" on page 960
- "Running the CMP API Exerciser sample" on page 962

Related information:

Administration API for WebSphere Message Broker (CMP API)

Configuring an environment for developing and running CMP applications

Prepare the environment in which you want to run your CMP applications.

Before you begin

Before you start:

To develop and run Java applications that use the CMP API, you must install the following prerequisite software in your local computer environment:

- The WebSphere MQ Classes for Java.

  These classes provide the internal wire protocol that your applications use to communicate with the broker.

  You can install the classes from the media supplied with WebSphere Message Broker.
- An IBM Java Development Kit (JDK) at a supported Java level. Java support is defined in "Additional software requirements" on page 3598.

  WebSphere Message Broker does not supply a JDK; you must acquire and install a suitable product yourself.

  You must use an IBM JDK to develop CMP applications and an IBM Java Runtime Environment (JRE) to run these applications.

About this task

To set up your computer in preparation for building and running CMP applications, you must configure your class path environment variable so that it includes the WebSphere MQ Classes for Java, and the JAR file that defines the CMP.

Follow the instructions provided for the appropriate environment:

- "Configuring the Windows command-line environment to run CMP applications" on page 970
- "Configuring Linux, UNIX, and z/OS command-line environments to run CMP applications" on page 971
- "Configuring the Eclipse environment to run CMP applications" on page 972

You can also run CMP applications, and therefore control one or more broker components, from computers on which you have not installed WebSphere Message Broker. For more information, see "Configuring environments without the broker component installed" on page 973.

The JAR file `ConfigManagerProxy.jar` contains the English message catalog for displaying broker (BIP) messages from the Administration log of the broker. If you want a CMP application to display broker messages in a language other than English, you must also add the directory that contains the localized message catalogs to your class path; for example, `C:\Program Files\IBM\MQSI\v.r\messages` on Windows operating systems. The default directory includes the version and release of the product, in the format v.r (version.release).

You can also use the CMP to display or log messages from a catalog that you create yourself.

Configuring the Windows command-line environment to run CMP applications

Use system facilities to configure environment variables on your Windows computers to run your CMP applications.

About this task

Update the CLASSPATH environment variable:

Procedure

1. Add the CMP JAR file to your CLASSPATH. For example:

```
set CLASSPATH = %CLASSPATH%;%install_dir%\classes\ConfigManagerProxy.jar
```

2. Add the WebSphere MQ Classes for Java JAR file `com.ibm.mq.jar` to your CLASSPATH in the same way.

   On 32-bit operating system editions, the file is typically stored in the directory `C:\Program Files\IBM\WebSphere MQ\java\lib`. On 64-bit operating system editions, the file is typically stored in the directory `C:\Program Files (x86)\IBM\WebSphere MQ\java\lib`.

   For more information about the WebSphere MQ Classes for Java, see the *Using Java* section in the WebSphere MQ information center.
3. Add your Java development directory to the CLASSPATH in the same way.

What to do next

Next: Use the tools that are provided by your JDK to build and run your CMP applications.

Configuring the Eclipse environment to run CMP applications

Use Eclipse facilities to configure the environment to run your CMP applications.

About this task

Update the CLASSPATH environment variable:

Procedure

1. In your Eclipse environment, select **File** > **New** > **Project**. The New Project wizard opens.
2. Select **Java Project** from the options displayed. Click **Next**. The New Java Project window opens.
3. Enter a name for your new project. Click **Next**.
4. Select the **Libraries** tab, and click **Add External Jars**.
5. To set up the build environment, navigate to the *install_dir*/classes subdirectory. For example, for Version 7.0 on Windows 32-bit operating system editions, navigate to the directory C:\Program Files\IBM\MQSI\7.0\classes. Select the file ConfigManagerProxy.jar, and click **Open**. The file is added to the list in the window for the **Libraries** tab.
6. When you have added the file ConfigManagerProxy.jar to the build path, set up the runtime environment. Click **Add External Jars** again, and navigate to the *WebSphere_MQ_installation_directory*/java/lib subdirectory. For example, on Linux on x86, navigate to the directory /opt/mqm/java/lib. Select the file com.ibm.mq.jar, and click **Open**. This file is also added to the list.

   For more information about the WebSphere MQ Classes for Java, see the *Using Java* section in the WebSphere MQ information center.

7. Click **Finish** to close the New Project wizard.

What to do next

Next: Use the Eclipse development tools to build and run your CMP applications.

Configuring environments without the broker component installed

Install and run CMP applications and other utilities on computers, when you are using a local ID only, on which you have not installed the broker component.

About this task

You can run Java applications that use the CMP API even where you have not installed the broker component. These CMP applications include your own applications, and the following command utilities:

- **mqsicreateexecutiongroup**
- **mqsideleteexecutiongroup**
- **mqsimode**
- **mqsireloadsecurity**; the CMP application version of **mqsireloadsecurity** is called mqsireloadsecurityscript.
- **mqsistartmsgflow**
- **mqsistopmsgflow**

To install CMP applications in an environment that does not have the broker component installed, complete the following steps:

Procedure

1. Ensure that the target computer has a compatible Java Runtime Environment (JRE). Because you are not installing the broker component, which includes a JRE, you must use an alternative option.

Note, that you must also set MQSI_JREPATH to the installation path of your JRE.

Java support is defined in "Additional software requirements" on page 3598.

2. Copy the following set of files from a computer that has the broker component installed to the target computer:
   a. `ConfigManagerProxy.jar` from the `classes` directory.
   b. The WebSphere MQ Classes for Java.
      - On Windows, these classes are located in the file `com.ibm.mq.jar`.
      - On other platforms, these classes are located in the component's installation image.
   c. Your CMP application and all configuration files, for example `.broker` files.
   d. If you want to run the broker commands on the target computer, complete the following steps:
      1) Copy `brokerutil.jar` from the `classes` directory.
      2) Copy the required utility bat files, or shell scripts, from the `bin` directory. Shell scripts have a `.bat` extension on Windows or no extension on UNIX platforms:
         - **`mqsicreateexecutiongroup`** or **`mqsicreateexecutiongroup.`**`bat`
         - **`mqsideleteexecutiongroup`** or **`mqsideleteexecutiongroup.`**`bat`
         - **`mqsimode`** or **`mqsimode.`**`bat`
         - **`mqsireloadsecurity`** or **`mqsireloadsecurity`**`script.bat`
         - **`mqsistartmsgflow`** or **`mqsistartmsgflow.`**`bat`
         - **`mqsistopmsgflow`** or **`mqsistopmsgflow.`**`bat`
   e. If you want to display broker (BIP) messages in English environments other than US English, copy all BIPmsgs*.properties files from the `messages` directory.
3. On the target computer, use system facilities to update the CLASSPATH environment variable to include the following files:
   - The JAR file that contains the definitions of the CMP classes, `ConfigManagerProxy.jar`.
   - Your applications that import the CMP classes.
   - The WebSphere MQ Classes for Java, `com.ibm.mq.jar`, and any additional JAR files required by this package.
   - Any other required JAR files and directories. For example, if you require any of the available command utilities on the target computer, include `brokerutil.jar`; if you require the broker (BIP) messages to be displayed in locales other than US English, include a directory that contains BIPmsgs*.properties.
4. Ensure that the user ID that the target computer uses has the following authorities:
   - Authority to connect to the queue manager that the broker uses.
   - Authority to manipulate broker objects.

What to do next

Next: You can run your CMP applications, and the specified command utilities, on the target computer.

Connecting to a broker from a CMP application

Connect an application that uses the CMP API to a broker, to send requests about its status and its resources.

Before you begin

Before you start

Before starting this step, you must have completed "Configuring an environment for developing and running CMP applications" on page 969.

About this task

Consider the following program `BrokerRunStateChecker.java`. It connects to a broker that is running on the default queue manager of the local computer.

```
import com.ibm.broker.config.proxy.*;

public class BrokerRunStateChecker {
```

```
    public static void main(String[] args) {

      // The ip address of where the broker is running
       // and the port number of the queue manager listener.
        displayBrokerRunState("localhost", 2414, "");
    }

    public static void displayBrokerRunState(String hostname,
                                             int port,
                                             String qmgr) {
        BrokerProxy b = null;
        try {
            BrokerConnectionParameters bcp =
                new MQBrokerConnectionParameters(hostname, port, qmgr);
            b = BrokerProxy.getInstance(bcp);
            String brokerName = b.getName();

            System.out.println("Broker '"+brokerName+
                "' is available!");
            b.disconnect();
        } catch (ConfigManagerProxyException ex) {
            System.out.println("Broker is NOT available"+
                " because "+ex);
        }
    }
}
```

The first line of the program requests Java to import the CMP API classes, which are supplied in the package `com.ibm.broker.config.proxy`.

The first line of code inside the `try` block of the displayBrokerRunState() method instantiates a `BrokerConnectionParameters` object. This method is an interface which states that implementing classes are able to provide the parameters to connect to a broker.

The class MQBrokerConnectionParameters implements this interface; it defines a set of WebSphere MQ connection parameters. The constructor used here takes three parameters:

1. The host name of the computer that the broker is running on
2. The port on which the WebSphere MQ listener service for the broker is listening
3. The name of the queue manager that is associated with the broker

When you have defined this object, you can connect to the queue manager that is defined by those characteristics. The connection is achieved by the static getInstance() factory method just inside the `try` block. When a valid handle to the queue manager is returned, the application requests the name of the broker by using b.getName(), and displays it.

getName(), and other methods that request information from the broker, block until the information is supplied, or a timeout occurs. Therefore, if the broker is not running, the application hangs for a period. You can control the timeout period by using the BrokerProxy.setRetryCharacteristics() method. Typically, blocking only occurs when a given resource is accessed for the first time within an application.

Finally, the program calls the disconnect() method. This method frees up resources associated with the connection in both the CMP and the broker.

When a `BrokerProxy` handle is first returned from the getInstance() method, the broker service does not have to be running. It is only when the application uses the handle (by calling getName() in this example) that the application can be assured that a two-way connection with the broker is active.

Administration API for WebSphere Message Broker (CMP API)

Navigating brokers and broker resources in a CMP application

Explore the status and attributes of the broker that your CMP application is connected to, and discover information about its resources.

Before you begin

Before you start

Before starting this step, you must have completed "Connecting to a broker from a CMP application" on page 975.

About this task

Each resource that the broker can control is represented as a single object in the CMP API. An application can request status and other information about the following objects:

- Brokers
- Execution groups
- Deployed message flows
- Administration log

The CMP also handles deployed message sets; these resources are handled as attributes of deployed execution groups.

Collectively known as *administered objects*, these objects provide most of the interface to the broker, and are therefore fundamental to an understanding of the CMP.

Each administered object is an instance of a Java class that describes the underlying type of object in the broker. The main Java classes are shown in the following table.

Java class	Class function
BrokerProxy	Describes brokers.
ExecutionGroupProxy	Describes execution groups.

Java class	Class function
MessageFlowProxy	Describes message flows that have already been deployed to execution groups; does not describe message flows in the Broker Application Development perspective of the WebSphere Message Broker Toolkit.
LogProxy	Represents the log of recent administrative activity on the broker, for all users.

Each administered object describes a single object that can be controlled by the broker. For example, every execution group within a broker has one `ExecutionGroupProxy` instance that represents it within the application.

The `LogProxy` object includes messages, created as `LogEntry` objects, that record recent changes made to the administered objects. These messages include the following information:

- Administration requests; for example, a request to deploy a BAR file
- Results of administration requests
- Changes that have been made to objects; for example, a change to a property value through an administration task
- Changes that have been made to objects as a result of starting a broker at a new fix pack level or version.

You can use the `AdminQueueProxy` object to examine what items of work are in progress or are waiting for processing by the broker. The following code shows how you can access the queue:

```
BrokerConnectionParameters bcp =
  new MQBrokerConnectionParameters("localhost", 1414, "QMGR");
BrokerProxy b = BrokerProxy.getInstance(bcp);
AdminQueueProxy l = b.getAdministrationQueue();
```

A set of public methods is available for each administered object, which applications can use to inquire and manipulate properties of the underlying broker to which the instance refers. To access an administered object through its API, your application must first request a handle to that object from the object that logically owns it.

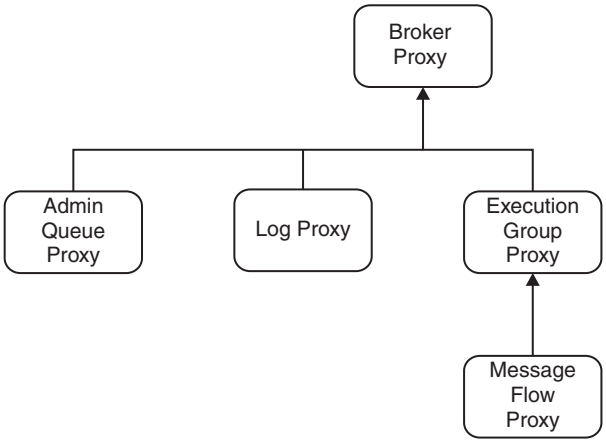
For example, because brokers logically own execution groups, to gain a handle to execution group `EG1` running on broker `B1`, the application must ask the `BrokerProxy` object represented by `B1` for a handle to the `ExecutionGroupProxy` object represented by `EG1`.

On a `BrokerProxy` object that refers to broker `B1`, the application can call methods that cause the broker to reveal its run-state, or cause it to start all its message flows. You can write applications to track the changes that are made to the broker objects by reading the messages maintained as `LogEntry` objects.

In the following example, a handle is requested to the `BrokerProxy` object. The `BrokerProxy` is logically the root of the administered object tree, therefore your application can access all other objects in the broker directly, or indirectly.

The broker directly owns the execution groups, therefore applications can call a method on the `BrokerProxy` object to gain a handle to the `ExectionGroupProxy` objects. Similarly, the execution group logically contains the set of all message flows, therefore the application can call methods on the `ExecutionGroupProxy` object to access the `MessageFlowProxy` objects.

The complete hierarchy of these access relationships is shown in the following diagram.



The following application traverses the administered object hierarchy to discover the run-state of a deployed message flow. The application assumes that message flow MF1 is deployed to EG1 on broker B1; you can substitute these values in the code for other values that are valid in the broker.

```
import com.ibm.broker.config.proxy.*;

public class GetMessageFlowRunState {

  public static void main(String[] args) {

    BrokerProxy b = null;
    try {
      BrokerConnectionParameters bcp =
         new MQBrokerConnectionParameters(
           "localhost",
           1414,
           "");
      b = BrokerProxy.getInstance(bcp);
    } catch (ConfigManagerProxyException cmpex) {
      System.out.println("Error connecting: "+cmpex);
    }

    if (b != null) {
      System.out.println("Connected to broker!");
      displayMessageFlowRunState(b, "EG1", "MF1");
      b.disconnect();
    }
  }

  private static void displayMessageFlowRunState(
                                 BrokerProxy b,
                                 String egName,
                                 String flowName) {
    try {
      ExecutionGroupProxy eg =
        b.getExecutionGroupByName(egName);

      if (eg != null) {
        MessageFlowProxy mf =
          eg.getMessageFlowByName(flowName);

        if (mf != null) {
          boolean isRunning = mf.isRunning();
```

```
          System.out.print("Flow "+flowName+" on " +
            egName+" on "+b.getName()+" is ");

          if (isRunning) {
            System.out.println("running");
          } else {
            System.out.println("stopped");
          }
        } else {
          System.err.println("No such flow "+flowName);
        }
      } else {
        System.err.println("No such exegrp "+egName+"!");
      }

    } catch(ConfigManagerProxyPropertyNotInitializedException
                                                    ex) {
      System.err.println("Comms problem! "+ex);
    }
  }
}
```

The method displayMessageFlowRunState() does most of the work. This method takes the valid `BrokerProxy` handle gained previously, and discovers the run-state of the message flow in the following way:

1. The `BrokerProxy` instance is used to gain a handle to the `ExecutionGroupProxy` object with the name described by the string `egName`
2. If a valid execution group is returned, the `ExecutionGroupProxy` instance is used to gain a handle to the `MessageFlowProxy` object with the name described by the string `flowName`.
3. If a valid message flow is returned, the run-state of the `MessageFlowProxy` object is queried, and the result is displayed.

The application does not have to know the names of objects that it can manipulate. Each administered object contains methods to return sets of objects that it logically owns. The following example demonstrates this technique by looking up the names of all execution groups within the broker.

```
import java.util.Enumeration;
import com.ibm.broker.config.proxy.*;

public class DisplayExecutionGroupNames {

  public static void main(String[] args) {

    BrokerProxy b = null;
    try {
      BrokerConnectionParameters bcp =
         new MQBrokerConnectionParameters(
           "localhost",
           1414,
           "");
      b = BrokerProxy.getInstance(bcp);
    } catch (ConfigManagerProxyException cmpex) {
      System.out.println("Error connecting: "+cmpex);
    }

    if (b != null) {
      System.out.println("Connected to broker!");
      displayExecutionGroupNames(b);
      b.disconnect();
    }
  }
```

```
  private static void displayExecutionGroupNames(BrokerProxy b)
  {
    try {
      Enumeration<ExecutionGroupProxy> allEGs = b.getExecutionGroups(null);

      while (allEGs.hasMoreElements()) {
        ExecutionGroupProxy thisEG =
          allEGs.nextElement();
        System.out.println("Found EG: "+thisEG.getName());
      }
    } catch(ConfigManagerProxyPropertyNotInitializedException
                                                        ex) {
        System.err.println("Comms problem! "+ex);
    }
  }
}
```

The key method is BrokerProxy.getExecutionGroups(Properties). When supplied with a null argument, this method returns an enumeration of all the `ExecutionGroupProxy` objects in the broker. The application uses this method to look at each `ExecutionGroupProxy` in turn, and display its name.

The Properties argument of the method BrokerProxy.getExecutionGroups(Properties) can be used to exactly specify the characteristics of the execution groups that are sought. The application can use this argument for nearly all the methods that return administered objects, and is a powerful way of filtering those objects with which the application needs to work.

Examples of the characteristics that can be used to filter object lookups are the run-state and short description, as well as more obvious properties such as the name and UUID. To write logic to achieve filtered lookups, you must understand how each administered object stores its information.

The properties of each administered object are stored locally inside the object by using a hash table, where each property is represented as a {`key, value`} tuple. Each key is the name of an attribute (for example, `name`) and each value is the value (for example, `BROKER1`).

Each key name must be expressed by using a constant from the `AttributeConstants` class (`com.ibm.broker.config.proxy`). A complete set of keys and possible values for each administered object is described in the Java documentation for the `AttributesConstant` class, or by using the `Show raw property table for this object` function in the CMP API Exerciser sample application. The latter displays the complete list of {`key, value`} pairs for each administered object.

The Properties argument that is supplied to the lookup methods is a set of those {`key, value`} pairs that must exist in each administered object in the returned enumeration. Consider the following code fragment:

```
Properties p = new Properties();

p.setProperty(AttributeConstants.OBJECT_RUNSTATE_PROPERTY,
              AttributeConstants.OBJECT_RUNSTATE_RUNNING);

Enumeration<MessageFlowProxy> mf = executionGroup.getMessageFlows(p);
```

Providing that the variable `executionGroup` is a valid `ExecutionGroupProxy` object, the returned enumeration contains only active message flows (that is, OBJECT_RUN_STATE_PROPERTY equal to OBJECT_RUNSTATE_RUNNING).

When property filtering is applied to a method that returns a single administered object rather than an enumeration of objects, only the first result is returned (which is non-deterministic if more than one match applies). Therefore the following code:

```
Properties p = new Properties();
p.setProperty(AttributeConstants.NAME_PROPERTY,
              "EG1");
ExecutionGroupProxy eg1 = brokerProxy.getExecutionGroup(p);
```

is an alternative to the following statement:

```
ExecutionGroupProxy eg1 = brokerProxy.getTopicByName("EG1");
```

If multiple {key, value} pairs are added to a property filter, all properties must be present in the child object for an object to match. If you want a method to perform a logical OR, or a logical NOT, on a filter, you must write specific application code for this purpose.

When AdministeredObjects are first instantiated in an application, the CMP API asks the broker for the current set of properties for that object. This action happens asynchronously, therefore the first time a property is requested, the CMP API might pause while it waits for the information to be supplied by the broker. If the information does not arrive within a certain time (for example, if the broker is not running), a ConfigManagerProxyPropertyNotInitializedException is thrown. Your application can control the maximum time that the CMP API waits by using the BrokerProxy.setRetryCharacteristics() method.

Deploying resources to a broker from a CMP application

Deploy BAR files to the brokers in your broker network from a CMP application.

About this task

You can also check the result of a deployment by using the CMP.

Example

An example

This example connects to a broker that is running on the local computer. Its queue manager, MB7QMGR, is listening on port 2414. The code deploys a BAR file called MyBAR.bar to an execution group called default that is running on the broker, and displays the result.

```
import com.ibm.broker.config.proxy.*;
public class DeployBAR {

  public static void main(String[] args) {
    BrokerConnectionParameters bcp =
       new MQBrokerConnectionParameters("localhost", 2414, "MB7QMGR");
    try {
      BrokerProxy b = BrokerProxy.getInstance(bcp);
      ExecutionGroupProxy eg = b.getExecutionGroupByName("default");
      DeployResult dr = eg.deploy("MyBAR.bar", true, 30000);
      System.out.println("Result = "+dr.getCompletionCode());
    } catch (Exception e) {
      e.printStackTrace();
    }
  }
}
```

CMP API Exerciser

About this task

You can also use the CMP API Exerciser to deploy files and check the results. For example:

Procedure

1. Connect to the broker by clicking **File** > **Connect to Broker**. This action opens the Connect to Broker dialog.
2. Enter the relevant connection parameters in the dialog. A hierarchical representation of the broker and its resources is displayed.
3. Complete one or more of the following operations:
   - Click an object in the tree to display the attributes of that object.
   - Right-click an object in the tree to call CMP API methods that manipulate that object. For example, right-clicking a broker opens a menu that includes the items **Start user trace**.
   - Use the log pane at the bottom of the screen to view useful information that relates to the operation in progress.

Related information:

Administration API for WebSphere Message Broker (CMP API)

Checking the results of deployment in a CMP application

When you deploy from a CMP application, you can check the results of that action.

About this task

Code your application to test the results of the deploy actions that it takes. You can use code like the following snippet:

```
DeployResult dr = eg.deploy("MyBAR.bar", true, 30000);
System.out.println("Overall result = "+dr.getCompletionCode());

// Display log messages
Enumeration logEntries = dr.getLogEntries();
while (logEntries.hasMoreElements()) {
  LogEntry le = (LogEntry)logEntries.nextElement();
  System.out.println("General message: " + le.getDetail());
}
```

The deploy method blocks other processes until the broker has responded to the deployment request. When the method returns, the `DeployResult` object represents the outcome of the deployment at the time when the method returned; the object is not updated by the CMP API.

If the deployment message could not be sent to the broker, a `ConfigManagerProxyLoggedException` exception is thrown at the time of the deployment. If the broker receives the deployment message, log messages for the overall deployment are displayed, followed by completion codes specific to each broker that is affected by the deployment. The completion code, shown in the following table, is one of the static instances from the `CompletionCodeType` class.

Completion code	Description
pending	The deployment is held in a batch and is not sent until you call BrokerProxy.sendUpdates().
submitted	The deploy message was sent to the broker, but no response was received before the timeout period expired.
success	The broker has successfully completed the deployment.
failure	The broker has generated one or more errors during deployment. You can call the getLogEntries() method of the `DeployResult` class to get more information about the deployment failure. This method returns an enumeration of available `LogEntry` objects.

Administration API for WebSphere Message Broker (CMP API)

Setting message flow user-defined properties at run time in a CMP application

Use the CMP API to query, discover, and set message flow user-defined properties dynamically at run time. You can use the CMP API to set properties with a data type of character.

Before you begin

For user-defined properties on a message flow to be discoverable, the message flow must comply with the following conditions:

- The message flow must contain at least one of the following nodes:
  - JavaCompute
  - Compute
  - Database
  - Filter
  - PHPCompute
- The message flow must define the relevant user-defined property and provide an override value.

About this task

Tip: Use meaningful names and values for the properties that you define, so that you can understand their purpose and intent quickly. For example, a user-defined property named `property01`, with an initial value of `valueA` is not as useful as a property named `RouteToAorB` with an initial value of `RouteA`.

To query, discover, and set user-defined properties on a message flow, use the CMP API to issue the following calls. For details about the calls, including the syntax and parameters to use, see the CMP API documentation ("Administration API" on page 3672).

Procedure

1. Call MessageFlowProxy.getUserDefinedPropertyNames() to retrieve a list of all the user-defined properties that were defined by the Message Flow editor on the message flow or subflows.

   A string array is returned that contains the property names.
2. Call MessageFlowProxy.getUserDefinedProperty() to retrieve the value of the specified user-defined property.

   The value of the property is returned as a Java.lang.String value.
3. Call MessageFlowProxy.setUserDefinedProperty() to set a new value for the specified user-defined property.

   The property must exist. You cannot change the data type of the existing user-defined property (Java.lang.String); therefore, you must ensure that the new value complies with the existing data type. The value that you set with the MessageFlowProxy.setUserDefinedProperty() call is populated to all relevant nodes in the message flow, including nodes in subflows.

Related concepts:

"User-defined properties" on page 1147
A user-defined property (UDP) is a property that is defined when you construct a message flow by using the Message Flow editor. This property can be used by the ESQL or Java program inside message flow nodes, such as a Compute node.

"User-defined properties in ESQL" on page 2376
Access user-defined properties (UDPs) as variables in your ESQL program by specifying the EXTERNAL keyword on a DECLARE statement. For example, the ESQL statement `DECLARE today EXTERNAL CHARACTER 'monday'` defines a user-defined property called today with an initial value monday.

"Configurable message flow properties" on page 4020
When you add a message flow to a broker archive (BAR) file in preparation for deploying it to a broker, you can set additional properties that influence its run time operation. These properties are available for review and update when you select the **Manage and Configure** tab for the broker archive file.

Working with properties of a configurable service of type UserDefined at run time in a JavaCompute node

Use the CMP API in a JavaCompute node to query, set, create, and delete properties dynamically at run time in configurable services that you have defined with type UserDefined.

Before you begin

Before you start:

Complete the following tasks.

- Read the concept topic, "Configurable services" on page 1296.
- "Creating a message flow" on page 1431.

About this task

If you have created a UserDefined configurable service, and created properties for that service, you can work with those properties in a JavaCompute node. For example, you can create a UserDefined configurable service to set timeouts for processing HTTP messages.

You can create and delete configurable services in JavaCompute nodes, in the WebSphere Message Broker Explorer, and by using the **mqsicreateconfigurableservice** and **mqsideleteconfigurableservice** commands.

Procedure

1. Right-click the JavaCompute node and click **Open Java** to create and open a Java file in the Editor view, or open an existing file.
2. Create the Java class for the node in which you want to include CMP methods.
3. Add the CMP JAR file *install_dir*/classes/ConfigManagerProxy.jar to the Java build path for the associated Java project.
4. Import com.ibm.broker.config.proxy.* in your code.
5. Add the following static method to the class you have created:

   ```
   BrokerProxy b = BrokerProxy.getLocalInstance();
   ```

   This method returns an instance of the BrokerProxy object for the broker to which the message flow (that contains this node) is deployed.
6. To ensure that the BrokerProxy object has been populated with data from the broker before you access the configurable service, add the following code:

   ```
   while(!b.hasBeenPopulatedByBroker()) { Thread.sleep(100); }
   ```
7. Access the appropriate UserDefined configurable service:
   a. If you know the name of the configurable service, use the following code to access it:

      ```
      ConfigurableService myUDCS = b.getConfigurableService("UserDefined", "UD1");
      ```

b. If you want to select from a set of UserDefined configurable services, use the following code to get a list of all services of a particular type:

```
ConfigurableService[] UD_set = b.getConfigurableServices("UserDefined");
```

8. Add further code to access and use the specific properties that you are interested in. For example:
   - Retrieve the properties that are defined to that service:

     ```
     String[] props = myUDCS.getProperties();
     ```

   - Create a new property:

     ```
     String newprop = 'VerifyRequestTimeout';
     String newval = '15';
     myUDCS.setProperty(newprop, newval);
     ```

   - Delete a property:

     ```
     myUDCS.deleteProperty(newprop);
     ```

     You can also use the deleteProperties() method to delete more than one property.

     You can delete properties in UserDefined configurable services only. If you use this method on a configurable service of a different type, a `ConfigManagerProxyLoggedException` is generated.

9. Deploy the JAR file, and all associated message flows, in a BAR file. You do not have to deploy the `ConfigManagerProxy.jar` file to the target execution group, because the broker can access these classes independently.

Managing brokers in a CMP application

Manage the brokers and their resources from a CMP application.

Before you begin

Before you start

Before you start this task, you must have completed the task "Connecting to a broker from a CMP application" on page 975.

About this task

Use the CMP API to change the state of objects in the domain; you can create, delete, modify, and deploy objects stored within it. The following example sets the long description field of the broker:

```
import com.ibm.broker.config.proxy.*;

public class SetLongDescription {

  public static void main(String[] args) {

    BrokerProxy b = null;
    try {
      BrokerConnectionParameters bcp =
         new MQBrokerConnectionParameters(
           "localhost",
           1414,
           "");
      b = BrokerProxy.getInstance(bcp);
      b.setLongDescription("this is my broker");
      b.disconnect();
    } catch (ConfigManagerProxyException cmpex) {
      System.out.println("Error connecting: "+cmpex);
    }
  }
}
```

The broker processes requests to change properties from the CMP asynchronously, therefore if your application calls getLongDescription() immediately following the call to setLongDescription(), the response might return the old value of the property. For more information, see "Checking the results of broker management with the most recent completion code in a CMP application" on page 992.

What to do next

Next:

Most state-changing CMP methods return control immediately without informing the calling application of the outcome of the request. To discover this information, see “Checking the results of broker management in a CMP application” on page 991.

Related concepts:

You can use the CMP API to manage brokers and their associated resources from JavaCompute nodes in deployed message flows.

Related information:

Administration API for WebSphere Message Broker (CMP API)

Creating objects in a CMP application

Create new objects associated with a broker.

About this task

The following example adds an execution group called `EG2` to the connected broker.

```
import com.ibm.broker.config.proxy.*;

public class AddExecutionGroup {

  public static void main(String[] args) {

    BrokerProxy b = null;
    try {
      BrokerConnectionParameters bcp =
         new MQBrokerConnectionParameters(
           "localhost",
           1414,
           "");
      b = BrokerProxy.getInstance(bcp);
      ExecutionGroupProxy e = b.createExecutionGroup("EG2");
      b.disconnect();
    } catch (ConfigManagerProxyException cmpex) {
      System.out.println("Error connecting: "+cmpex);
    }
  }
}
```

Because requests are processed asynchronously by the broker, the `ExecutionGroupProxy` object that is returned from the createExecutionGroup() method is a skeleton object when it is returned to your application, because it refers to an object that might not yet exist in the broker. The application can manipulate the object as if it existed on the broker, although the actual creation of the underlying object might not happen for some time.

If the request to create the object described by the skeleton fails, all requests that use the skeleton also fail. Therefore, if execution group EG2 cannot be created, all subsequent requests that concern the skeleton object fail. However, unless the application explicitly checks for errors, it works in the same way as it does in the successful case, because no exception is thrown unless, because of a communication problem, a message cannot be sent to the broker.

See "Checking the results of broker management in a CMP application" for further information about how to detect problems such as these.

Administration API for WebSphere Message Broker (CMP API)

Checking the results of broker management in a CMP application

When you have made a change to the broker, use one of the supplied methods to check if the change has been successful.

About this task

Choose one of three methods in the CMP API to determine the outcome of requests to create, delete, modify, and deploy resources:

- If you have initiated a deployment method, you can use the return code from the deployment API; this technique is shown in "Checking the results of deployment in a CMP application" on page 984.
- You can query an object's most recent completion code; this option is shown in "Checking the results of broker management with the most recent completion code in a CMP application" on page 992.
- You can use the administered object notification mechanism; by using this approach, you can code specific routines to handle the responses and take appropriate action, and improve the efficiency of your program. See "Checking the results of broker management with object notification in a CMP application" on page 993.
- If you prefer to make property changes synchronously, call the method BrokerProxy.setSynchronous() before making your changes.

  If subsequent property change methods give a successful return, the request has been successfully completed by the broker. If the changes are rejected by the broker, or time out (they cannot be completed successfully by the broker before

the timeout period expires), the methods throw either a `ConfigManagerProxyRequestFailure` or a `ConfigManagerProxyRequestTimeout` exception.

For more information on synchronous property changes, see the description of the BrokerProxy.setSynchronous() method in the CMP API Javadoc information.

Related concepts:

Related information:

Administration API for WebSphere Message Broker (CMP API)

Checking the results of broker management with the most recent completion code in a CMP application:

Use an object's most recent completion code to determine the outcome of a request that your application made against that object.

About this task

Most state-changing methods in the CMP API do not provide return code that indicates the success or failure of a specific action. For these methods, you must write different code to discover the outcome of the action. Assuming that administered objects are not shared across threads, the following code fragment can be used to discover the outcome of a request to modify a broker's `LongDescription`, where `b` is an instance of a `BrokerProxy` object:

```
GregorianCalendar oldCCTime =
                         b.getTimeOfLastCompletionCode();
b.setLongDescription(newDesc);
GregorianCalendar newCCTime = oldCCTime;
while ((newCCTime == null) || (newCCTime.equals(oldCCTime))) {
  newCCTime = b.getTimeOfLastCompletionCode());
  Thread.sleep(1000);
}
CompletionCodeType ccType = b.getLastCompletionCode();
if (ccType == CompletionCodeType.success) {
  // etc.
}
```

In this example, the application initially determines when an action on the broker was last completed, using the getTimeOfLastCompletionCode() method. This method returns the time that the topology last received a completion code or, if no

return codes have been received, a null value. The application updates the broker's `LongDescription`, then continually monitors the topology, waiting for the results of the setLongDescription() command to be returned to the CMP. When the results are returned, control breaks out of the `while` loop and the last completion code is determined.

As well as being unsuitable for a multi-threaded application, this algorithm for determining the outcome of commands is inefficient, because it causes the CMP application to wait while the broker processes the request.

For a more efficient application, and one that is suitable for a multi-threaded environment, code the alternative approach that uses administered object notifications; see "Checking the results of broker management with object notification in a CMP application."

If you prefer, you can make property changes synchronously by using the methodBrokerProxy.setSynchronous() method. When you make synchronous property changes, methods such as setLongDescription() do not return until the change has been processed by the broker. For more information on synchronous property changes, see the description of the BrokerProxy.setSynchronous()) method in the CMP API Javadoc information.

Use object notification to determine the outcome of a request that your application made against the object.

Related information:

Administration API for WebSphere Message Broker (CMP API)

Checking the results of broker management with object notification in a CMP application:

Use object notification to determine the outcome of a request that your application made against the object.

About this task

The CMP can notify applications whenever commands complete, or whenever changes occur to administered objects. By making use of the `OBSERVER` design pattern, your CMP application can define a handle to a user-supplied object that has a specific method that is called if an object is modified or deleted, or whenever a response to a previously submitted action is returned from the broker.

The user-supplied code must implement the `AdministeredObjectListener` interface. This interface defines methods that are invoked by the CMP when an event occurs on an administered object to which the listener is registered. The following methods are defined:

processModify(...)

processModify(...) is called when the administered object to which the listener is registered has one or more of its attributes modified by the broker. The following information is included in the notification through the use of the processModify() method arguments:

1. A handle to the `AdministeredObject` to which the notification refers.
2. A list of strings that contain the key names that have been changed.
3. A list of strings that describe new subcomponents that have been created for the object; for example, new execution groups in a broker.
4. A list of strings that describe subcomponents that have been removed from the object.

The format of the strings passed to the final two parameters is an internal representation of the administered object. You can turn this representation into an administered object type by using the getManagedSubcomponentFromStringRepresentation() method.

Consider the following additional information:

1. Strings are passed within these lists to enhance performance; the CMP does not use resource instantiating administered objects, unless they are specifically requested by the calling application.
2. The first time you call the processModify() method for a listener, the `changed attributes` parameter can include a complete set of attribute names for the object, if the application is using a batch method, or if the CMP is experiencing communication problems with the broker.

processDelete(...)

processDelete(...) is called if the object with which the listener is registered is completely removed from the broker. Supplied to `processDelete(...)` is one parameter – a handle to the administered object that has been deleted; when this method returns, the administered object handle might no longer be valid. At about the same time that a processDelete(...) event occurs, a processModify(...) event is sent to listeners of the deleted object's parent, to announce a change in the parent's list of subcomponents.

processActionResponse(...)

processActionResponse(...) is the event that informs the application that a previous action submitted by that application is complete. Only one processActionResponse(...) event is received for each state-changing operation issued by the CMP application. This event contains the following items of information:

1. A handle to the administered object for which a request was submitted.
2. The completion code of the request.
3. A set of zero, or more, informational (BIP) messages associated with the result.
4. A set of (`key, value`) pairs that describes the submitted request in more detail. Check the documentation for information about how to parse these pairs.

To register a listener, each administered object has a registerListener() method that is used to tell the CMP to call the supplied code whenever an event occurs on that object. You can register the same `AdministeredObjectListener` for notifications from multiple administered objects. You can also register multiple `AdministeredObjectListeners` against the same administered object.

The following example demonstrates this technique by registering a listener on the broker object, and displaying a message whenever it is modified:

```
import com.ibm.broker.config.proxy.*;
import com.ibm.broker.config.proxy.CompletionCodeType;
import java.util.List;
import java.util.ListIterator;
import java.util.Properties;

public class MonitorBroker implements AdministeredObjectListener {

  public static void main(String[] args) {

    BrokerProxy b = null;
    try {
      BrokerConnectionParameters bcp =
         new MQBrokerConnectionParameters(
           "localhost",
           1414,
           "");
      b = BrokerProxy.getInstance(bcp);
    } catch (ConfigManagerProxyException cmpex) {
      System.out.println("Error connecting: "+cmpex);
    }

    if (b != null) {
      System.out.println("Connected to broker");
      listenForChanges(b);
      b.disconnect();
    }
  }

  private static void listenForChanges(AdministeredObject obj)
  {
    if (obj != null) {
      obj.registerListener(new MonitorBroker());
      while(true) {
        // thread could do something else here instead
        try {
          Thread.sleep(10000);
        } catch (InterruptedException ex) {
          // ignore
        }
      }
    }
  }

  public void processActionResponse(AdministeredObject obj,
                                    CompletionCodeType cc,
                                    List bipMessages,
                                    Properties refProperties) {
    // Event ignored in this example
  }

  public void processDelete(AdministeredObject deletedObject) {
         // Event ignored in this example
  }

  public void processModify(AdministeredObject affectedObject,
                            List changedAttributes,
```

```
                            List newChildren,
                            List removedChildren) {
    try {
      System.out.println(affectedObject+" has changed:");
      ListIterator e = changedAttributes.listIterator();
      while (e.hasNext()) {
        String changedAttribute = (String) e.next();
        System.out.println("Changed: "+changedAttribute);
      }
      ListIterator e2 = newChildren.listIterator();
      while (e2.hasNext()) {
        String newChildStr = (String) e2.next();
        AdministeredObject newChild =
          affectedObject.getManagedSubcomponentFromStringRepresentation(newChildStr);
        System.out.println("New child: "+newChild);
      }
      ListIterator e3 = removedChildren.listIterator();
      while (e3.hasNext()) {
        String remChildStr = (String) e3.next();
        AdministeredObject removedChild =
          affectedObject.getManagedSubcomponentFromStringRepresentation(remChildStr);
        System.out.println("Removed child: "+removedChild);
      }
    } catch (ConfigManagerProxyPropertyNotInitializedException ex) {
      ex.printStackTrace();
    }
  }
}
```

The listenForChanges() method attempts to register an instance of the `MonitorBroker` class for notifications of broker changes. If successful, the main thread pauses indefinitely to prevent the application from ending when the method returns. When the listener is registered, whenever the broker changes (for example, if an execution group is added), the processModify() method is called. This method displays details of each notification on the screen.

You must register separate listeners for each administered object on which you want to receive notifications. You can use the same listener instance for multiple administered objects.

You can stop receiving notifications in three ways:

- AdministeredObject.deregisterListener(AdministeredObjectListener)
- ConfigManagerProxy.deregisterListeners()
- ConfigManagerProxy.disconnect()

The first method de-registers a single listener from a single administered object; the other two methods deregister all listeners connected with that `BrokerProxy` instance. In addition, the final method shows that all listeners are implicitly removed when connection to the broker is stopped.

You can also implement the AdvancedAdministeredObjectListener interface which, when registered, yields additional information to applications.

Managing brokers from JavaCompute nodes

You can use the CMP API to manage brokers and their associated resources from JavaCompute nodes in deployed message flows.

Before you begin

Before you start

Before starting this step, you must create a "JavaCompute node" on page 4514 in a message flow.

About this task

Use CMP methods and classes in your JavaCompute node to explore and manage brokers and other resources.

Procedure

1. Create the Java class for the node in which you want to include CMP methods.
2. Add the CMP JAR file *install_dir*/classes/ConfigManagerProxy.jar to the Java build path for the associated Java project.
3. Add the following static method to the class:

   ```
   BrokerProxy thisBroker = BrokerProxy.getLocalInstance();
   ```

   This method returns an instance of the BrokerProxy object for the broker to which the message flow (that contains this node) is deployed.
4. To work with an execution group on this broker, add the following static method to your code:

   ```
   ExecutionGroupProxy thisEG = ExecutionGroupProxy.getLocalInstance();
   ```

   This method returns an instance of the ExecutionGroupProxy object for the execution group to which the message flow is deployed.
5. If you want to connect to a different broker that you have created on the computer to which your node and message flow are deployed, you can use a variant of this class:

   ```
   BrokerProxy secondBroker = BrokerProxy.getLocalInstance(string)
   ```

   Specify the name of the alternative local broker as the value of the variable *string*. Your code can manage this second broker, and its associated resources, by using the BrokerProxy object that is returned by this call.
6. Include additional CMP methods in your Java code to run the operations that you want against the broker or execution group by using the objects obtained in previous steps. You can follow the guidance that is provided in other topics in this section for further information and examples that show how to use CMP methods in CMP applications.

If you include methods that affect the message flow in which your CMP application is running, it might not be able to receive all notifications that these operations have successfully completed. Stopping, deleting, and redeploying the message flow are examples in this category; consider carefully the consequences of using these methods.

7. Deploy the JAR file, and all associated message flows, in a BAR file. You do not have to deploy the `ConfigManagerProxy.jar` file to the target execution group, because the broker can access these classes independently.

Working with resource statistics in a CMP application

Start, stop, and review status of resource statistics collection in your CMP applications.

Before you begin

Before you start:

- Read the concept topic about resource statistics.

About this task

You can create CMP applications to examine and control the collection of resource statistics.

Checking what resource types can return statistics

```
////////////////////////////////////////////////////
// Sample CMP API code that connects to a local broker
// called 'testbrk' and writes out available
// resource types on the broker that have the
// ability to emit resource-level statistics.
BrokerProxy b = null;
try {
    b = BrokerProxy.getLocalInstance("testbrk");
 String[] resourceNames = b.getResourceTypeNames();
 for (String thisResource : resourceNames) {
  System.out.println(thisResource);
 }
} catch (ConfigManagerProxyLoggedException e) {
```

```
 e.printStackTrace();
} catch (ConfigManagerProxyPropertyNotInitializedException e) {
 e.printStackTrace();
}
```

Checking for resource names associated with a specific resource type

```
//////////////////////////////////////////////////////
// Sample CMP API code that connects to a local broker
// called 'testbrk' and writes out resource property
// names reported for a specific resource type.
BrokerProxy b = null;
try {
    b = BrokerProxy.getLocalInstance("testbrk");
 String[] resourcePropertyNames =
    b.getResourceTypeStatisticsPropertyNames("JVM");
 for (String thisResourceProperty : resourcePropertyNames) {
  System.out.println(thisResourceProperty);
 }
} catch (ConfigManagerProxyLoggedException e) {
 e.printStackTrace();
} catch (ConfigManagerProxyPropertyNotInitializedException e) {
 e.printStackTrace();
}
```

Starting statistics collection

```
//////////////////////////////////////////////////////
// Sample CMP API code that connects to a local broker
// called 'testbrk' and gets a reference to the execution
// group called 'default'. It then enables resource
// statistics for all the execution group's resource types.
BrokerProxy b = null;
try {
    b = BrokerProxy.getLocalInstance("testbrk");
 ExecutionGroupProxy eg = b.getExecutionGroupByName("default");
 if (eg != null) {
  eg.setResourceStatisticsEnabled(null, true);
 }
} catch (ConfigManagerProxyLoggedException e) {
 e.printStackTrace();
} catch (ConfigManagerProxyPropertyNotInitializedException e) {
 e.printStackTrace();
}
```

Stopping statistics collection

```
//////////////////////////////////////////////////////
// Sample CMP API code that connects to a local broker
// called 'testbrk' and gets a reference to the execution
// group called 'default'. It then disables resource
// statistics for all the execution group's resource types.
BrokerProxy b = null;
try {
    b = BrokerProxy.getLocalInstance("testbrk");
 ExecutionGroupProxy eg = b.getExecutionGroupByName("default");
 if (eg != null) {
  eg.setResourceStatisticsEnabled(null, false);
 }
} catch (ConfigManagerProxyLoggedException e) {
 e.printStackTrace();
} catch (ConfigManagerProxyPropertyNotInitializedException e) {
 e.printStackTrace();
}
```

Viewing statistics collection status

```
//////////////////////////////////////////////////////
// Sample CMP API code that connects to a local broker
// called 'testbrk' and gets a reference to the execution
// group called 'default'. It then writes out if resource
// statistics is enabled.
```

```
BrokerProxy b = null;
try {
    b = BrokerProxy.getLocalInstance("testbrk");
 ExecutionGroupProxy eg = b.getExecutionGroupByName("default");
 if (eg != null) {
  System.out.println(eg.getResourceStatisticsEnabled(null));
 }
} catch (ConfigManagerProxyLoggedException e) {
 e.printStackTrace();
} catch (ConfigManagerProxyPropertyNotInitializedException e) {
 e.printStackTrace();
}
```

Submitting batch requests from a CMP application

Use the CMP API to group multiple requests that are destined for the same broker, and submit them as a single unit of work.

About this task

To start a batch, your application must call the beginUpdates() method on the `BrokerProxy` handle. The CMP API delays submitting any state-changing requests to the broker until it is told a batch of requests is ready to be sent.

The sendUpdates() method tells the CMP API to submit as a batch all requests received since the last beginUpdates() call. The clearUpdates() method can be used to discard a batch without submitting it to the broker. The application can check if a batch is currently in progress by using the isBatching() method. Only one batch for a CMP API handle can be in progress at any one time.

One advantage of using a batch method is that it provides an assurance that no other applications can have messages processed by the broker during the batch. When a broker receives a batch of requests, it processes each request in the batch in the order it was added to the batch (FIFO), and requests from no other CMP application are processed until the entire batch is completed.

Consider the following sequence of commands:

```
ExecutionGroupProxy e = b.createExecutionGroup("EG2");
e.deploy("mybar.bar");
```

Without using a batch method, the application cannot guarantee the success of these actions. For example, even if each command would otherwise succeed, a second (possibly remote) application might delete the execution group EG2 after it has been created by the first application, but before the other command is processed.

If the sequence is extended to use a batch method, the broker is now guaranteed to process all the commands together, therefore no other application can disrupt the logic intended by the application.

```
b.startUpdates();
ExecutionGroupProxy e = b.createExecutionGroup("EG2");
e.deploy("mybar.bar");
b.sendUpdates();
```

Another advantage of using a batch method is performance. The CMP typically sends one WebSphere MQ message to the broker for each request.

In a situation that requires lots of requests to be sent in quick succession, the use of a batch has a significant effect on performance, reducing both time taken to process the requests, and the memory used. For example, your application might create a number of execution groups on a single broker. Each batch of requests is sent in a single WebSphere MQ message, therefore reducing the processing that is required for each method.

Batch mode does not provide transactional (commit and backout) capability; some requests in a batch might succeed and others fail. If the broker processes a request in a batch that fails, it continues to process the next request in the batch until it has attempted all requests in the batch.

Quiescing a database

The broker and database exhibit specific behaviors when you quiesce the database.

If you access databases from one or more message flows, your database administrator might occasionally want to issue the quiesce instruction on a database. This action is a function of the database, not of the broker.

The following three assumptions are made for the database that you are quiescing:

- The database can be quiesced (not all databases support this function).
- New connections to the database are blocked by the database when it is quiescing.
- Message flows that access the database eventually become idle.

The following list shows the behavior that is expected while a database is quiescing:

- Run the command that quiesces the database. When this command starts, the connections that are in use remain in use, but no new connections to the database are allowed.
- Messages that are being processed by message flows, which use existing connections to the database, continue to use their connections until the connections become idle. Therefore if messages continue to be received by the message flow, it might be a long time before the quiesce occurs. To ensure that messages are no longer processed, stop the message flow. Stopping the message flow stops messages being processed, and releases the database connections that the flow was using. This action ensures that the database connections that the flow holds become idle.
- Database connections for the message flow become idle. This situation causes the broker to release the connections to the user databases that the message flow is using. When all connections to the database from the broker, and from any other applications that are using the database, are released, the database can complete its quiesce function.

For more information, see "User database connections" on page 2110.

Using a JDBC connection pool to manage database resources used by an execution group

Use broker JDBC provider resources to configure the use of thread pools independently of message flow and input node thread pools.

About this task

WebSphere Message Broker manages JDBC connections in the following ways:

- Non-pooled connections:
  - WebSphere Message Broker creates a JDBC connection on demand for each message flow instance that requires one.
  - Each JDBC connection is associated with the message flow instance for which it was created. This association is maintained until the connection is closed.
  - Each JDBC connection that is idle for 60 seconds is closed, and is no longer associated with a message flow instance.
  - After a JDBC connection that was associated with a message flow instance is closed, if the same message flow instance requires a JDBC connection, WebSphere Message Broker creates a new JDBC connection on demand.
- Pooled connections:
  - When a message flow instance requires a JDBC connection, WebSphere Message Broker assigns an unused connection from the pool.
  - If all pooled JDBC connections are being used, and the maximum pool size has not been reached, WebSphere Message Broker creates a new pooled JDBC connection. The maximum pool size is specified in the `maxConnectionPoolSize` property of the "JDBCProviders configurable service" on page 3778.
  - Each pooled JDBC connection remains associated with a message flow instance only for the processing of one input message.
  - When a message flow instance completes the processing of an input message, the association with a JDBC connection is removed, and the JDBC connection is returned to the pool.
  - Each pooled JDBC connection that is idle for 15 minutes is closed, and is removed from the pool.
  - Pooled JDBC connections are not applicable to the DatabaseRetrieve and DatabaseRoute nodes.

Using a JDBC connection pool enable you to scale database access independently of the number of message flow threads.

You can create a JDBC connection pool by setting the `maxConnectionPoolSize` property of the "JDBCProviders configurable service" on page 3778 to a non-zero integer value. The `maxConnectionPoolSize` property acts at the execution group level to specify the maximum number of JDBC connection threads that can be used. A value of zero defaults to the standard WebSphere Message Broker Version 7.0 behavior, where one JDBC connection is created for each message flow thread.

All message flows within an execution group that use the same `JDBCProviders` configurable service also share a connection pool. You can monitor the behavior of a JDBC connection pool by using broker resource statistics

The `maxConnectionPoolSize` property is applicable to JDBC connections obtained using the `getJDBCType4Connection()` API of the JavaCompute node.

Note: The `maxConnectionPoolSize` property does not apply to the JDBC connections used by the DatabaseRetrieve or DatabaseRoute nodes.

Administering Java applications

Manage the Java applications that are deployed to a broker.

About this task

You can deploy message flows that contain Java applications to a broker. The Java code is run within a JVM that is created by the execution group. The JVM runs in the same process as other broker components such as message parsing and nodes that are not Java-based.

Administration of Java applications includes the following tasks:

- "Tuning JVM parameters"
- "Configuring classloaders for Java user-defined nodes"
- "Configuring classloaders for JavaCompute nodes" on page 1006

Tuning JVM parameters

About this task

Use the **mqsichangeproperties** command to tune the JVM parameters to ensure that there are sufficient resources for all the Java applications that are deployed to the execution group. For more details, see "**mqsichangeproperties** command" on page 3756 and "JVM parameter values" on page 3813.

Configuring classloaders for Java user-defined nodes

About this task

Java user-defined nodes are manually installed onto a broker as either a PAR file or a JAR file. Because PAR and JAR files are only loaded by the broker on startup, the broker must be restarted. For more details, see "Packaging a Java user-defined node" on page 3118.

A PAR file is given its own Java classloader, ensuring that the node classes are isolated from any other node classes.

For more details, see “User-defined node class loading” on page 3120.

Configuring classloaders for JavaCompute nodes

About this task

A JavaCompute node is deployed to an execution group as part of a BAR file. A JavaCompute node can specify a JavaClassLoader configurable service to be used by the node. A JavaClassLoader configurable service defines the behavior of the classloaders that are used by the node. For more details, see “JavaCompute node classloading” on page 2635.

If a JavaCompute node specifies a JavaClassloader configurable service, you must define a configurable service with the name specified by the node on the broker. For more details, see “JavaCompute node classloading using a configurable service” on page 2636.

Accessing Administration log information

Active brokers record information about their operations in the Administration log. Access the events that are written by the broker by using the WebSphere Message Broker Explorer and the WebSphere Message Broker Toolkit. For some actions, you can also use the Administration API (also known as the CMP API).

About this task

- “Viewing Administration log information” on page 1007

The Administration Log view shows administration requests and their results, changes made to objects, and the result of deployment actions on brokers. The Administration Log view can also describe configuration changes that have been automatically applied as a result of moving the broker from one version to another; for example, after applying maintenance.

Related information:

Administration API for WebSphere Message Broker (CMP API)

Viewing Administration log information

You can view Administration log information by using either the WebSphere Message Broker Explorer, or the CMP API.

About this task

Follow the instructions in this topic to use the WebSphere Message Broker Explorer. If you prefer to use the CMP API, see "Developing applications that use the Administration API" on page 956 and "Administration API" on page 3672.

Administration log information is written to the Administration Log view in the WebSphere Message Broker Explorer. The Administration Log view displays actions performed on the broker by all users. Alternatively, you can view the results of deployment actions from a single user using the Deployment Log view in the WebSphere Message Broker Toolkit, see "Deployment Log view" on page 6797.

The Administration Log view contains information about events that occur within your brokers. These events can be information, errors, or warnings and relate to your own actions. To view events for a particular broker, look for the name of the broker in the Source column.

Each event contains the following information:

- Message: The event number.
- Source: Where the event has come from.
- TimeStamp: The date and time that the event occurred. Time stamps are taken from the computer that is hosting the broker.
- Details: What has caused the event and what action is needed to rectify it.

You can only view Administration log information for a specific broker using the WebSphere Message Broker Explorer if the broker is both running and connected. Local brokers are automatically connected, but you must manually connect to remote brokers.

Procedure

1. To view Administration log information in the WebSphere Message Broker Explorer, ensure that the Administration Log view is visible. If the Administration Log view is not visible, from the menu, click **Window** > **Show View** > **Administration Log**.
2. Expand the Brokers folder, and select the broker with which you want to work. The Administration log information for the selected broker is displayed in the Administration Log view. The Administration log information is displayed in time and date order.

3. Double-click the message to display the full details for a message. The message is opened in a new window.

The Administration Log view can also describe configuration changes that have been automatically applied as a result of moving the broker from one version to another; for example, after applying maintenance.

Saving Administration log information

Save the Administration log information that is written to the Administration Log view in the WebSphere Message Broker Explorer.

About this task

Administration log information is deleted automatically from the broker when the broker restarts. You can save the log contents to file if you want to retain them. You cannot save the Administration log information from the Deployment Log view in the WebSphere Message Broker Toolkit.

Procedure

1. In the WebSphere Message Broker Explorer, expand the Brokers folder in the Navigator view.
2. Select the broker with which you want to work, to display the Administration log information in the Administration Log view.
3. Right-click in the Administration Log view, and click **Save Log As**.
4. Enter an appropriate directory in which to save the log information.
5. Enter a name for the log file, and click **Save Log**.

Results

Each message recorded in the Administration log is written to the text file with the same information that is detailed in the Administration log itself.

To view the saved log, open the log file in an appropriate text editor.

Clearing Administration log information

Clear Administration log information to reduce the size of the log by using either the WebSphere Message Broker Explorer or the CMP API.

About this task

Follow the instructions in this topic to use the WebSphere Message Broker Explorer to clear the log. If you prefer to use the CMP API, see "Developing applications that use the Administration API" on page 956 and "Administration API" on page 3672. You can empty the contents of the Deployment Log view in the WebSphere Message Broker Toolkit by right-clicking in the Deployment Log view, and clicking **Clean Log**. Emptying the contents of the Deployment Log view does not remove the entries from the Administration log.

To clear all the Administration log information from the Administration log:

Procedure

1. Expand the Brokers folder in the Navigator view.
2. Select the broker with which you want to work, to display the Administration log information in the Administration Log view.
3. Right-click in the Administration Log view, and click **Clear Administration Log**.

   If you have set the Broker Explorer preference to *warn before deleting log events*, a prompt asks you to confirm deletion. Click **OK**.

   If you have not set the Broker Explorer preference to *warn before deleting log events*, the Administration log is cleared automatically.

   All log entries will be deleted for this user.

Changing Administration Log view preferences

You can change preferences for the Administration Log view by using the Broker Explorer preferences page in the WebSphere Message Broker Explorer.

About this task

You can choose not to display a warning before deleting log events. The default is to display a warning. You can also choose how long to wait for responses from the broker after a deployment.

To change preferences:

Procedure

1. Click **Window>Preferences**.
2. Expand the **Broker Explorer** category in the left pane.
3. Make your selections.
4. Click **OK**.

Related tasks:

"Accessing Administration log information" on page 1006
Active brokers record information about their operations in the Administration log. Access the events that are written by the broker by using the WebSphere Message Broker Explorer and the WebSphere Message Broker Toolkit. Changing the location of the work path

The work path directory is the location where a component stores internal data, such as installation logs, component details, and trace output. The shared-classes directory is also located in the work path directory and is used for deployed Java code. If the work path directory does not have enough capacity, redirect the directory to another file system that has enough capacity.

About this task

The work path is fixed at installation time so that WebSphere Message Broker can always find the information that it needs, and always knows where to store new information.

If you need to change the location (for example, if you do not have enough capacity on the automatically-designated file system), do not change the path to the directory; instead, redirect the old work path directory to a new location.

Changing the location of the work path on Windows systems

About this task

When you change the location of the work path, you mount the new partition at the location of the old work path directory.

To change the location of the work path on Windows:

Procedure

1. Shut down all WebSphere Message Broker services and processes.
2. Create a new partition on the system. The new partition can be on the same drive as the old work path, or on a different drive.
3. Locate the work path directory for your installation on the local system by running the following command:
   ```
   echo %MQSI_WORKPATH%
   ```
4. Copy the contents of the work path directory to the new partition.
5. Delete the contents of the old work path directory.
6. Open the Computer Management dialog: click **Start** > **Settings** > **Control Panel** > **Administrative Tools** > **Computer Management**; the Computer Management dialog opens.
7. In the left pane of the Computer Management dialog, click **Disk Management**. The new partition that you added, and any existing partitions, are listed in the right pane.
8. Right-click the new partition, then click **Change Drive Letter and Paths**. The Change Drive Letter and Paths dialog opens.
9. Click **Add**. The Add Drive Letter or Path dialog opens.
10. Ensure that **Mount in the following empty NTFS folder** is selected, then browse to the old work path location.

11. Click **OK**, then click **OK** again.

Results

Any files that WebSphere Message Broker creates in the work path location are stored on the new partition.

Changing the location of the work path on Linux and UNIX systems

About this task

When you change the location of the work path, you can either mount the new partition at the location of the old work path directory, or you can replace the old work path directory with a soft link that points to the new work path directory.

To change the location of the work path on UNIX and Linux:

Procedure

1. Shut down all WebSphere Message Broker services and processes.
2. Create a new directory on a suitable file system.
3. Locate the work path directory for your installation on the local system by running the following command:
   ```
   echo $MQSI_WORKPATH
   ```
4. Copy the contents of the work path directory to the new partition.
5. Delete the contents of the old work path directory.
6. Perform one of the following tasks so that the WebSphere Message Broker installation uses the new work path location:
   - Use the **mount** command to mount the new work path directory at the location of the old work path directory.
   - Delete the old work path directory and replace it with a soft link. Give the soft link the same name as the old work path directory and point the link to the new work path directory.

Results

Any files that WebSphere Message Broker creates in the work path location are stored in the new location.

Backing up resources

Back up your broker components, and the working files associated with brokers, the WebSphere Message Broker Explorer, and the WebSphere Message Broker Toolkit, so that you can restore these resources if required.

About this task

Back up your broker components regularly to ensure that you can return to a known operational state if necessary. In addition to configuration and operation state, the broker maintains additional resources in its work path, and you can request that these resources are also backed up.

Back up the workspaces and connection files that you have created in the WebSphere Message Broker Explorer.

Back up the workspaces you have created in the WebSphere Message Broker Toolkit; these resources contain your application development resources; for example message flows and message sets. If you use a development repository to store application resources, such as Rational ClearCase, see the documentation associated with that repository to check how you can back up this data.

The following topics tell you how to back up and restore brokers and the WebSphere Message Broker Toolkit workspace:

- "Backing up the broker"
- "Restoring the broker" on page 1015
- "Backing up the WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit workspace" on page 1016

On distributed systems, you can use the backed up components to restore the broker only on an identical operating environment. The operating system must be at the same level, and the broker and queue manager names must be identical.

Backing up the broker

Back up the broker configuration and all associated resources.

Before you begin

Before you start: Create the broker.

About this task

You can back up the broker and its resources to preserve the current state of the broker configuration. You can use the backup file that is created to restore a broker in an identical operating environment: the operating system must be at the same level, and the broker and queue manager names must be identical.

You can run this command for a broker that is active. However, you must not take a backup while the broker is processing configuration changes and deployments; the backup file created might contain incomplete information. If the file contains partial records, you cannot use it to restore the broker at a later time.

To ensure that the backup is complete and correct, take a backup either when the broker is not processing a configuration change (such as a deployment or change property) or when the broker is stopped.

Procedure

1. If you want to back up an active broker, check that no configuration change requests are in progress. For example, if you are changing broker properties, or have initiated a deployment, wait for these actions to complete before you back up the broker. Active message flows are unaffected by the backup process.

   If you prefer, you can stop the broker before you take a backup by using the **mqsistop** command.
2. Back up the broker. Specify the broker name and the location in which the backup file is created. You can also optionally specify the name of the backup file, and the name of a file to which a detailed trace is written.
   - Linux UNIX Windows Run the **mqsibackupbroker** command, specifying the broker name and the directory to which the backup file is written.

     For example, to back up a broker on Windows, enter the following command:

     ```
     mqsibackupbroker MB7BROKER -d c:\MQSI\BACKUP
     ```
   - z/OS Customize and submit the JCL member BIPBUBK.
3. When the command has completed successfully, you can continue to use the broker. If you stopped the broker, restart it by using the **mqsistart** command.

Results

The current broker configuration is saved in the backup file. Keep the file safe so that you can restore the broker at a later date if required.

Related tasks:

Use the **mqsistop** command to stop the specified component.

Restoring the broker

Restore a broker configuration that you backed up previously.

Before you begin

Before you start: Back up the broker.

About this task

You can restore a broker on a computer that has an identical configuration by using the backup file that you created. The operating system must be at the same level, and the broker and queue manager names must be identical.

Procedure

1. If you have deleted the broker and it no longer exists, or if you are restoring it on a different computer, create it by using the **mqsicreatebroker** command. Use the same name and parameters that you used for the broker that you backed up, including the name of the queue manager.
2. If the broker is running, stop it by using the **mqsistop** command. If you intend to restore common configuration information from other brokers that you have configured on this computer, you must also stop all the brokers that share this common information. For example, you can restore profile information from common files.
3. Restore the broker. Specify the broker name and the name and location of the backup file. If you want to restore common configuration information, or if you want a trace of the actions taken, specify the appropriate parameters for your platform.
   - Linux UNIX Windows Run the **mqsirestorebroker** command.

     For example, to restore a broker on Windows, enter the following command:

     ```
     mqsirestorebroker WBRK_BROKER -d c:\MQSI\BACKUP -a mybroker.zip
     ```
   - z/OS Customize and submit the JCL member BIPRSBK.
4. When the command has completed successfully, start the broker by using the **mqsistart** command.

What to do next

Next: The broker configuration has been restored; you can continue your work with this broker.

Backing up the WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit workspace

The WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit workspaces contain your personal settings and data, such as message flow and message set resources. You can have multiple workspaces in different locations, and you can also have references to projects that are in other locations, therefore consider all these locations when you back up your resources.

About this task

The default workspace directory for the WebSphere Message Broker Explorer depends on the platform on which it is running:

- Windows On Windows XP and Windows Server 2003: `C:\Documents and Settings\<userid>\Application Data\IBM\MQ Explorer\<server project>\`.
- Windows On Windows Vista and Windows Server 2008, the default workspace directory is created at `C:\Users\`*`user_ID`*`\IBM\MQ Explorer\<server project>\`.
- Linux On Linux, the default workspace directory is created at `/home/`*`user_ID`*`/IBM/MQ Explorer\/<server project>/`.

where *user_ID* is the user name with which you are logged on. Back up files in these locations, and in all other locations in which you have saved workspace files.

The default workspace directory for the WebSphere Message Broker Toolkit depends on the platform on which it is running:

- Windows On Windows XP and Windows Server 2003: `C:\Documents and Settings\`*`user_ID`*`\IBM\wmbt70\workspace`.
- Windows On Windows Vista and Windows Server 2008: `C:\Users\`*`user_ID`*`\IBM\wmbt70\workspace`.

- Linux On Linux: `/home/user_ID/IBM/wmqi70/workspace`.

where *user_ID* is the user name with which you are logged on. Back up files in these locations, and in all other locations in which you have saved workspace files.

The WebSphere Message Broker Toolkit workspace directory contains a directory called `.metadata`, which contains your personal settings and preferences for the WebSphere Message Broker Toolkit. If the `.metadata` directory gets corrupted, you lose these settings, and the WebSphere Message Broker Toolkit reverts to the default layout and preferences. If you have not backed up the `.metadata` directory, you must manually set all preferences again, and import all projects, such as message flow projects, that were displayed in the Broker Development view. To back up the `.metadata` directory, take a copy of the directory.

The WebSphere Message Broker Toolkit workspace also contains a directory for each project (for example, a message flow project) that you have created in the WebSphere Message Broker Toolkit. These directories contain your data, which you must back up.

Use one of the following methods to back up the data in your workspace; the instructions are the same for both the WebSphere Message Broker Explorer and the WebSphere Message Broker Toolkit.

Procedure

- Export your working projects. You can export the projects directly as a compressed file. For further information, see Exporting in the Eclipse Workbench User Guide.
- Copy the project directories from the workspace directory to another location.
- WebSphere Message Broker Explorer only: Export all `.broker` connection files to save the details of connections to all your brokers.
- WebSphere Message Broker Toolkit only: Take copies of all your BAR files to back up their contents. Include all the associated source files when you build your broker archive (BAR) files; you can then save all content by saving only the BAR file. To add resources to a BAR file that is ready for deployment, select **Include source files**, which adds the message flow and message set source files, and the compiled files.

What to do next

If you want to restore the resources, copy the directories back into your workspace directory and import the projects. For instructions, see Importing in the Eclipse Workbench User Guide.

Related concepts:

"Resources" on page 36
The projects, folders, and files that you work with in the WebSphere Message Broker Toolkit workspace are called *resources*. By default, these resources are stored with their metadata in the workspace directory in your local file system. The workspace directory is created the first time that you start the WebSphere Message Broker Toolkit.

Related tasks:

"Backing up resources" on page 1013
Back up your broker components, and the working files associated with brokers, the WebSphere Message Broker Explorer, and the WebSphere Message Broker Toolkit, so that you can restore these resources if required.

Chapter 9. Developing message flow applications

Develop message flows to process your business messages and data.

About this task

WebSphere Message Broker provides several ways in which you can develop the message flow applications that you need to support your business processes. Your client applications can use many different techniques to interact with a broker, and the message flows that you have deployed to it.

The following steps provide a typical route that you might take through this section of the information center to understand the concepts associated with message flows, develop your own, and establish the ways in which your client applications can use message flows. When you are familiar with the basic concepts and behavior, you can progress to more complex options by adding further resources for your message flows to use.

Procedure

1. If you are not familiar with WebSphere Message Broker, read "Processing messages" on page 1021. This section defines the concepts associated with message flows, and is essential reading whatever your planned use of the broker. It also covers the general processing performed by a broker on all messages, regardless of origin. For example, it explains how a broker handles errors in your message flows, and how you can set up coordinated transactions.
2. When you have reached an understanding of what a message flow is, and how it can process your messages and data, you can review the different ways in which you can create your own message flows. Choose from the following options:
   - "Developing message flow applications by using patterns" on page 1309. The supplied patterns provide reusable solutions that encapsulate a tested approach to solving a common architecture, design, or deployment task in a particular context. Much of the work of design and development has been done for you when you use a pattern.

     You can use these patterns unchanged, or modify them to meet your own requirements. You must create additional resources to complement the pattern and complete the solution.
   - "Developing message flow applications by using samples" on page 1406. The supplied samples provide tested message flows that focus on a particular feature or function supported by WebSphere Message Broker. They are more limited in scope than patterns, but provide comprehensive examples of typical message processing in particular scenarios. They are stand-alone applications; you can use them without having to create and configure additional resources.

     Because they are created to demonstrate a particular facet of the product, the samples are not always designed to use the preferred techniques for a particular task. Therefore, use them as examples to learn how particular functions work, not as complete production-level solutions. You might find them helpful as a starting point to developing your own message flows, or as part of a larger solution.

- "Developing message flow applications from a wizard" on page 1408. You can run one of several Quick Start wizards in the WebSphere Message Broker Toolkit. These wizards create message flows and associated resources that are dependent on particular requirements; for example, adapter connections. You can use the messages flows created by these wizards as the basis for other message flows that change or add to the original result.
- "Developing message flow applications from scratch" on page 1423. If you prefer, you can create a message flow by using the basic building blocks available in the Message Flow editor. You decide which nodes are appropriate, and how to connect them together, to provide the processing that your messages require.

3. Connect your business process applications and data to your message flows. You can use a number of different protocols to communicate with the broker. You can also interact from your message flows with other products and services. Find out what options are available in "Connecting client applications" on page 1537.
4. You can design your message flows to handle your messages and data in different ways. You can choose from a range of nodes that support:
   - "Routing messages" on page 2209
   - "Transforming and enriching messages" on page 2227
   - "Processing events" on page 2717
   - "Handling errors in message flows" on page 2823
5. Message flows can process self-defining messages, predefined messages, or both. Predefined messages might provide extra value in your environment, and offer additional processing options within your message flows, Learn about these benefits, and how you can define your own message models, in "Constructing message models" on page 2838.
6. Your message processing environment might need some special processing that is not provided by WebSphere Message Broker. You can explore further options in "Developing user-defined extensions" on page 2970, and learn about how to customize your broker in additional ways.

What to do next

When you develop your message flows, and when you run them in the broker, you can tune the way the message flows work to improve message flow performance. For further information, see "Message flow performance" on page 3260.

When you create a project, it is recommended to avoid using spaces in the project name. Although using spaces in the name is valid, you might encounter problems. For example: A scenario where an XML schema file located in project X references an XML schema file project Y, either through import or include statements. If the referenced schema in the project contain spaces in project name, the name does not resolve, and you receive errors

Related tasks:

Package resources that you create in the WebSphere Message Broker Toolkit, such as message flows, and deploy them to execution groups on brokers.

Processing messages

Process your business messages and data by interacting with a broker, which you can configure to provide services and to communicate with other applications and systems.

About this task

You can use WebSphere Message Broker to integrate client applications that use different protocols and message formats. A broker provides a flexible environment that you can configure to route and transform messages in many ways from one application to all other applications. In many cases, you can reuse existing applications with little or no change, to use the services provided by a broker.

A broker manages three sets of resources to integrate your applications, messages, and data:

- Message flows
- Nodes
- Message models

You can configure message flows to support your applications that use one or both of the supported communication models, point-to-point and publish/subscribe. You can connect your client applications to the message flows that are running in a broker by using one of several supported protocols.

This section introduces you to conceptual details of message flows, message models, and their associated resources. It also describes the default behavior taken by a broker when it runs message flows. Read this section to gain an overall understanding of applications, messages, and brokers, and understand the generic tasks that are independent of the protocol your applications use.

- "Message flows overview" on page 1022
- "Message modeling" on page 1154
- "Message flow behavior" on page 1277

Some of the examples used in these topics have characteristics that apply to specific environments; these characteristics are clearly stated where applicable. Exceptions to the default behavior of the broker for particular protocols, or message formats, are stated in the sections where they apply. Additional characteristics of specific protocols of messages are also described where they apply.

Message flows overview

A message flow is a sequence of processing steps that run in the broker when an input message is received.

You define a message flow in the WebSphere Message Broker Toolkit by including a number of message flow nodes, each of which represents a set of actions that define a processing step. The way in which you join the message flow nodes together determine which processing steps are carried out, in which order, and under which conditions. The path that you create between one node and another is known as a connection.

A message flow must include an input node that provides the source of the messages that are processed. You can process the message in one or more ways, and optionally deliver it through one or more output nodes; see "Connecting client applications" on page 1537. The message is received as a bit stream, and is converted by a parser into a tree structure that is used internally in the message flow. Before the message is delivered to a final destination, it is converted back into a bit stream. For more information about these conversions, see "Parsers" on page 1072 and "The message tree" on page 1041.

When you want to exchange messages between multiple applications, you might find that the applications do not understand or expect messages in the same format. You might must provide some processing between the sending and receiving applications that ensures that both can continue to work unchanged, but can exchange messages successfully. For more information about the options available, see "Transforming and enriching messages" on page 2227.

You define the processing that is required when you create and configure a message flow. You can include built-in nodes, nodes that are supplied by a vendor, nodes that you have created yourself (user-defined nodes), or other message flows (known as subflows).

The processing that you set up determines what actions are completed on a message when it is received, the order in which the actions are completed, and the final destinations of the message. All these actions manage the route that a message takes through a message flow; more information about these actions is provided in "Routing messages" on page 2209. To complete more complex processing involving more than one message, you can use the nodes described in "Processing events" on page 2717.

You can configure additional properties to make your message flow transactional, or multithreaded. You can also add error paths that ensure every message is handled in an appropriate way.

When you want to run a message flow to process messages, you deploy it to a broker, where it is run in an execution group.

The mode in which your broker is working can affect the number of execution groups and message flows that you can deploy, and the types of node that you can use. See "Restrictions that apply in each operation mode" on page 3657.

The following topics describe the concepts that you must understand to design, create, and configure a message flow and its associated resources:

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

"Execution groups" on page 53
An execution group is a named grouping of message flows that have been assigned to a broker. The broker enforces a degree of isolation between message flows in distinct execution groups by ensuring that they run in separate address spaces, or as unique processes.

"Message modeling" on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

"Message flow behavior" on page 1277
Message flow behavior is initially defined by the broker, but you can change or add to that behavior in some situations.

"Nodes for connectivity" on page 1028
WebSphere Message Broker supports direct connections from applications, and can send direct requests to other application endpoints. WebSphere Message Broker can also connect to various subsystems including WebSphere MQ, files, and databases, to read and write existing application data.

"Properties" on page 1143
You can view and change properties that define broker characteristics, and those properties of associated resources such as message flows.

Use the reference information in this section to develop your message flows and related resources.

Message flow nodes

A message flow node is a processing step in a message flow. It can be a built-in node, a user-defined node, or a subflow node.

A message flow node receives a message, performs a set of actions against the message, and optionally passes the original message, and none or more other messages, to the next node in the message flow.

A message flow node has a fixed number of input and output points known as terminals. You can make connections between the terminals to define the routes that a message can take through a message flow. Message flow nodes are displayed in the node palette that is associated with the Message Flow editor. The palette is arranged in categories, which group together nodes that provide related processing; for example, transformation.

Input nodes do not have input terminals. The message flow starts when a message is retrieved from an input device; for example, a WebSphere MQ queue. The message flow ends when none or more output messages have been sent by one or more output nodes, and control returns back to the input node. The input node either commits or rolls back the transaction. Input and output nodes can be protocol-specific, to interact with particular systems such as Web Services.

Most nodes are processing nodes, that you can include between your input and output nodes and connect together to define the flow of control. These nodes typically transform a message from one format to another, or route a message along a particular path, or provide more complex options such as aggregation or filtering.

You can configure a node by setting or changing the values for its properties. Some nodes have *mandatory properties*, for which you must set a value. Other properties must have a value, but are assigned a default value which you can leave unchanged. The remaining properties are *optional properties*; no value is required.

When you develop a message flow, the way in which you set the properties of the nodes in that flow influences the way in which the messages are processed by that flow. For example, by setting properties that define input and output WebSphere MQ queue names, you determine where the message flow receives the message from, and where it delivers the message.

You can also configure nodes by using *promoted properties*; promote one or more node properties to become properties of the message flow that contains those nodes. You can then change these properties at the flow level, rather than having to update one or more individual nodes. You can also promote equivalent properties from more than one node to the same message flow property; for example, you might use this technique to set, at the flow level, the name of the database that all the nodes in the message flow must connect to.

A subset of node properties is *configurable properties*; that is, you can change their values when you deploy the message flow to a broker for execution. You might find this ability useful if you deploy a message flow to more than one broker, and want it to behave in a slightly different way on each broker. For example, when you deploy the message flow to a test broker, you can set a configurable property to force the flow to interact with a test database. When you deploy the same message flow to a production broker, you can set the same property to the value of a production database, without having to update the message flow itself.

The mode that your broker is working in can affect the types of node that you can use; see "Restrictions that apply in each operation mode" on page 3657.

You can add nodes of three types into your message flows:

Built-in node
A built-in node is a message flow node that is supplied by WebSphere Message Broker. The built-in nodes provide input and output, manipulation and transformation, decision making, collating requests, and error handling and reporting functions.

For information about all of the built-in nodes supplied by WebSphere Message Broker, see "Built-in nodes" on page 4293.

For information about the nodes that you can use to connect WebSphere Message Broker to your applications, see "Nodes for connectivity" on page 1028.

User-defined node
A user-defined node is an extension to the broker that provides a new message flow node in addition to the nodes that are supplied with the product. A user-defined node must be written to the user-defined node API provided by WebSphere Message Broker for both C and Java languages. The following sample demonstrates how you can write your own nodes in both C and Java languages.

- User-defined Extension

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Subflow
A subflow is a directed graph that is composed of message flow nodes and connectors and is designed to be embedded in a message flow or in another subflow. To connect your subflow to other nodes in the main flow, you can add Input and Output nodes to the subflow. A subflow must include at least one Input node or one Output node. A subflow can be executed by a broker only as part of the message flow in which it is embedded, and therefore cannot be independently deployed.

A message is received by an Input node and processed according to the definition of the subflow. That might include being stored through a Warehouse node, or delivered to another message target, for example through an MQOutput node. If required, the message can be passed through an Output node back to the main flow for further processing.

The subflow, when it is embedded in a main flow, is represented by a subflow node, which has a unique icon. The icon is displayed with the correct number of terminals to represent the Input and Output nodes that you have included in the subflow definition.

The most common use of a subflow is to provide processing that is required in many places within a message flow, or is to be shared between several message flows. For example, you might code some error processing in a subflow, or create a subflow to provide an audit trail (storing the entire message and writing a trace entry).

For more information, see "Subflows" on page 1030.

A node does not always produce an output message for every output terminal: often it produces one output for a single terminal based on the message received or the result of the operation of the node. For example, a Filter node typically sends a message on either the True terminal or the False terminal, but not both.

If you have connected more than one terminal to another node, the processing in the node determines the order in which the message is propagated to the nodes that it is connected to; you cannot change this order. The node sends the output message on each terminal, but sends on the next terminal only when the processing has completed for the current terminal.

Updates to a message are never propagated to nodes which have been previously executed, only to nodes that follow the node in which the update has been made. The order in which the message is propagated to the different output terminals is determined by the broker; you cannot change this order. The only exception to this rule is the FlowOrder node, in which the terminals indicate the order in which the message is propagated to each.

All built-in nodes include error handling as part of their processing. If an error is detected within the node, the message is propagated to the failure terminal. What happens then depends on the structure of your message flow. You can use only the basic error handling provided by the broker, or you can enhance your flow by adding error processing nodes and flows to provide more comprehensive failure processing. For more information about these options, see “Handling errors in message flows” on page 2823.

The message flow can accept a new message for processing only when all paths through the message flow (that is, all connected nodes from all output terminals) have been completed, and control has returned to the input node which commits or rolls back the transaction.

The following sample uses environment variables in the XML_Reservation sample to store information that has been taken from a database table and to pass that information to a node downstream in the message flow.

- Airline Reservations

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Message flow node palette:

The palette in the Message Flow editor contains all the built-in nodes, which are organized into categories, or drawers. A drawer is a container for a list of icons, such as the **Favorites** drawer.

When you first open the WebSphere Message Broker Toolkit, the default drawers contain built-in nodes that are related in function. For example, one drawer contains all the nodes that handle input and output to WebSphere MQ queues. Another drawer, **Transformation**, groups the nodes that you can use to convert the input message into a different form, including the Compute and JavaCompute nodes.

You can drag the nodes that you use most often into the **Favorites** drawer for easy access. If you create your own nodes, you can also add them to the palette. You can drag a node from the palette onto the canvas, and create a connection between two nodes. You can also use the palette to create an annotation on a message flow or node.

Right-click the palette to add a selected node to the canvas, or customize the appearance and behavior of the palette.

Use the Customize Palette dialog box to reorder node categories, set the drawer behavior for individual categories, and rename or hide nodes or categories.

You cannot move a category above the Favorites category. You can hide the Favorites category, but you cannot delete or rename it.

Use the Palette Settings dialog box to set the palette layout, determine the behavior of palette drawers, and choose a particular font.

The following topics explain how to change the palette layout and settings:

- "Changing the palette layout" on page 1490
- "Changing the palette settings" on page 1490

- "Customizing the palette" on page 1491

Nodes for connectivity:

WebSphere Message Broker supports direct connections from applications, and can send direct requests to other application endpoints. WebSphere Message Broker can also connect to various subsystems including WebSphere MQ, files, and databases, to read and write existing application data.

You can connect WebSphere Message Broker to your applications by adding the appropriate nodes to your message flow. The nodes you use can be tailored to support the protocols and subsystems that your applications already use. WebSphere Message Broker supplies nodes to support different protocols and subsystems; you can also create your own nodes to support additional protocols and subsystems if required.

- Nodes are supplied to support the protocols that are described in "Connecting client applications" on page 1537; for example, WebSphere MQ and HTTP.
- Nodes are supplied to support the subsystems listed in "External systems and resources" on page 61.

Within your message flow, you can include the following types of nodes to communicate with your applications. The icons for the nodes in each group described are based on a common appearance, which is shown with that group.

Input nodes

The input node reads data from a subsystem or input application, which might be in the form of a message, or a record (for example, from a file). The input node calls a parser to interpret the data and create an internal message tree structure. The node can split the input message into records if required. When the message is ready, the input node sends it to the rest of the message flow for processing.

Input nodes are represented by icons that conform to this template: 

Output nodes

An output node takes data from the message tree, calls a parser to serialize the tree into the appropriate message or record format, and writes out the message or record to one or more specified end applications or subsystems. If appropriate, you can configure your message flow to continue processing a message after it has generated one or more output messages through output nodes.

Output nodes are represented by icons that conform to this template:

Reply nodes

A reply node is a specialized form of an output node. Typically, the reply node is associated with an input node in the same flow, and uses context information from that input node to decide where to send the reply. Depending on the protocol of the input node, the context information might be created for you by that node; for other protocols, the context information might be contained within the message itself.

Reply nodes are represented by icons that conform to this template: 

Get and receive nodes

A get (receive) node reads extra data from a subsystem, and includes it in the current message tree, during message flow processing.

Get nodes are represented by icons that conform to this template: 

Request nodes

A request node writes a request to an external system, reads the response, and incorporates some or all that response data into the current message tree.

Request nodes are represented by icons that conform to this template:

Asynchronous request and response nodes

These two nodes are specialized form of a request node, in which you can generate a request and handle the response in a second message flow. Typically, you use these nodes when you are making a request that might take some time to complete. By using this technique, you can have several outstanding requests, without suspending flow processing.

Asynchronous request nodes are represented by icons that conform to this template: 

Asynchronous response nodes are represented by icons that conform to this template: 

You can connect applications that use different protocols by choosing an appropriate mix of input and output nodes. You must also include nodes that can transform the input message into the appropriate output format between the input and output nodes.

Because of the extent of the support provided by the nodes in WebSphere Message Broker, you can configure your brokers to act as clients to many different subsystems, and to interact with them based on the contents of the message tree created for each individual input message.

Related concepts:

Transform and enrich messages by using one or more of the techniques described in this section.

Subflows

You can include subflows in your message flows in the same way as you include built-in or user-defined nodes. You can also connect subflows to other nodes in the same way.

You can define a subflow once, and use it in more than one message flow, and in more than one message flow project. Therefore, a subflow provides the following benefits:

- Reusability and reduced development time.
- Consistency and increased maintainability of your message flows (consider a subflow as analogous to a programming macro, or to inline code that is written once but used in many places).
- Flexibility to tailor a subflow to a specific context (for example, by updating the output queue or data source information).

However, remember that a subflow is not a single node, and its inclusion increases the number of nodes in the message flow, which might affect its performance.

Consider these examples of subflow use:

- You can define a subflow that provides a common sequence of actions that applies to several message flows if an error is encountered. For example, you might have a common error routine that writes the message to a database through the Warehouse node, and puts it to a queue for processing by an error recovery routine. The use of this routine in multiple message flows, or in several places within one message flow, provides an efficient and consistent use of resources and avoids reinventing such routines every time an error is encountered.
- You might want to perform a common calculation on messages that pass through several different message flows; for example, you might access currency exchange rates from a database and apply them to calculate prices in several different currencies. You can include the currency calculator subflow in each of the message flows in which it is appropriate.

Use the Passthrough node to enable version control of a subflow at run time. By including a Passthrough node, you can add a label to your message flow or subflow. By combining this label with keyword replacement from your version control system, you can identify which version of a subflow is included in a deployed message flow. You can use this label for your own purposes. If you have included the correct version keywords in the label, you can see the value of the label:

- Stored in the broker archive (BAR) file, by using the **mqsireadbar** command
- As last deployed to a particular broker, on the properties of a deployed message flow in the WebSphere Message Broker Toolkit
- In the runtime environment, if you enable user trace for that message flow

The message that it propagates on its Out terminal is the same message that it received on its In terminal; for example, if you develop an error processing subflow to include in several message flows, you might want to modify that subflow. However, you might want to introduce the modified version initially to just a subset of the message flows in which it is included. Set a value for the instance of the Passthrough node that identifies which version of the subflow you have included.

The use of subflows is demonstrated in the following samples:

- Error Handler
- Coordinated Request Reply

Error Handler uses a subflow to trap information about errors and store the information in a database. Coordinated Request Reply uses a subflow to encapsulate the storage of the ReplyToQ and ReplyToQMgr values in a WebSphere MQ message so that the processing logic can be reused in other message flows, and to allow alternative implementations to be substituted.

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Promoted properties" on page 1145
A promoted property is a message flow node property that has been promoted to the level of the message flow in which it is included.

Related tasks:

"Designing a message flow" on page 1455
A message flow can perform a wide range of operations, depending on your business and operational requirements. For best performance and capability, you must design it to include the most appropriate nodes.

"Adding a subflow" on page 1501
In a message flow, you can include an embedded message flow, also known as a *subflow*. For example, you might define a subflow that provides error handling, and include it in a message flow connected to a failure terminal on a node that can generate an error in some situations.

"Defining a promoted property" on page 1297
When you create a message flow, you can promote properties from individual nodes in that message flow to the message flow level. Properties promoted in this way override the property values that you have set for the individual nodes.

"Creating a message flow" on page 1431
Create a message flow to specify how to process messages in the broker. You can create one or more message flows and deploy them to one or more brokers.

"Defining message flow content" on page 1488
You can define message flow content by adding and configuring message flow nodes and connecting them to form flows.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Message flow connections

A connection is an entity that connects an output terminal of one message flow node to an input terminal of another. The connection represents the flow of control and data between two message flow nodes.

Most nodes have one input terminal, and many have more than one output terminal. You can connect an output terminal to more than one target node, so that the same message can be processed in a number of different ways. For example, you might want to send the same information to more than one remote application for further processing.

The connections of the message flow, represented by black lines in the Message Flow editor, determine the path that a message takes through the message flow. You can add bend points to the connection to alter the way in which it is displayed.

For a description of bend points, see "Bend points" on page 1033. For a description of terminals, see "Message flow node terminals" on page 1034.

Related concepts:

"Bend points" on page 1033
A bend point is added to a connection between two message flow nodes where the line that represents the connection changes direction.

A terminal is the point at which one node in a message flow is connected to another node.

"Message flow nodes" on page 1024
A message flow node is a processing step in a message flow. It can be a built-in node, a user-defined node, or a subflow node.

"Message flow projects" on page 1035
A message flow project is a specialized container in which you create and maintain all the resources associated with one or more message flows.

Related tasks:

Chapter 9, "Developing message flow applications," on page 1019
Develop message flows to process your business messages and data.

Related reference:

"Message flow projects and files" on page 6822

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Bend points:

A bend point is added to a connection between two message flow nodes where the line that represents the connection changes direction.

Use bend points to change the visual path of a connection to display node alignment and processing logic more clearly and effectively. Bend points have no effect on the behavior of the message flow; they are visual modifications only.

A connection is initially made as a straight line between the two connected nodes or brokers. Use bend points to move the representation of the connection, without moving its start and end points.

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Message flow node terminals:

A terminal is the point at which one node in a message flow is connected to another node.

Use terminals to control the route that a message takes, depending on whether the operation that is performed by a node on that message is successful. Terminals are wired to other node terminals by using message flow node connections to indicate the flow of control.

Every built-in node has a number of terminals to which you can connect other nodes. Input nodes (for example, MQInput) do not have input terminals; all other nodes have at least one input terminal through which to receive messages to be processed. Most built-in nodes have failure terminals that you can use to manage the handling of errors in the message flow. Most nodes have output terminals through which the message can flow to a subsequent node.

If you have any user-defined nodes, these might also have terminals that you can connect to other built-in or user-defined node terminals.

Dynamic terminals are terminals that you can add to certain nodes after you have added them to a message flow in the Message Flow editor. For example, you can add dynamic output terminals to the PHPCompute, Route, and DatabaseRoute nodes, or you can add dynamic input terminals to the Collector node. You can also delete and rename dynamic terminals. If a node has five or more terminals, they are displayed in a group. For example, the following example shows a node with more than four output terminals. 

Related concepts:

Message flow projects

A message flow project is a specialized container in which you create and maintain all the resources associated with one or more message flows.

You can create a message flow project to contain a single message flow and its resources, or you can group together related message flows and resources in a single message flow project to provide an organizational structure to your message flow resources.

Message flow project resources are created as files, and are displayed in the project in the Broker Development view. These resources define the content of the message flow, and additional objects that contain detailed configuration information. For example, a project might contain ESQL modules or message mappings, used by one or more nodes in the message flow.

Import one of the following samples to see how the message flow resources of the sample are stored in a message flow project. If the sample has a message set, the message set resources are stored in a Message Set project.

- Video Rental
- Comma Separated Value (CSV)

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Broker schemas

A broker schema is a symbol space that defines the scope of uniqueness of the names of resources defined within it. The resources include message flows and other optional resources such as ESQL files, Java files, and mapping files.

The broker schema is defined as the relative path from the project source directory to the flow name. When you first create a message flow project, a default broker schema named `(default)` is created within the project.

You can create new broker schemas to provide separate symbol spaces within the same message flow project. A broker schema is implemented as a folder, or subdirectory, within the project, and provides organization within that project. You can also use project references to spread the scope of a single broker schema across multiple projects to create an application symbol space that provides a scope for all resources associated with an application suite.

If you create a new broker schema while in category mode, the empty schema is not visible in the Broker Development view. To show the empty schema in the Broker Development view, click **Hide Categories**  on the toolbar.

A broker schema name must be a character string that starts with a Unicode character followed by zero or more Unicode characters or digits, and the underscore. You can use the period to provide a structure to the name, for example `Stock.Common`. A directory is created in the project directory to represent the schema, and if the schema is structured using periods, further subdirectories are defined. For example, the broker schema `Stock.Common` results in a directory `Common` within a directory `Stock` within the message flow project directory.

If you create a resource (for example, a message flow) in the default broker schema within a project, the file or files associated with that resource are created in the directory that represents the project. If you create a resource in another broker schema, the files are created within the schema directory.

For example, if you create a message flow in the default schema in the message flow project Project1, its associated files are stored in the Project1 directory. If you create another message flow in the `Stock.Common` broker schema within the project Project1, its associated files are created in the directory `Project1\Stock\Common`.

Because each broker schema represents a unique name scope, you can create two message flows that share the same name within two broker schemas. The broker schemas ensure that these two message flows are recognized as separate resources. The two message flows, despite having the same name, are considered unique.

If you move a message flow from one project to another, you can continue to use the message flow within the original project if you preserve the broker schema. If you do this, you must update the list of dependent projects for the original project by adding the target project. If, however, you do not preserve the broker schema, the flow becomes a different flow because the schema name is part of the fully qualified message flow name, and it is no longer recognized by other projects. This action results in broken links that you must manually correct. For further information about correcting errors after moving a message flow, see "Moving a message flow" on page 1439.

Do not move resources by moving their associated files in the file system; you must use the WebSphere Message Broker Toolkit to move resources to ensure that all references are corrected to reflect the new organization.

The following scope and reuse conditions apply when you create functions, procedures, and constants in a broker schema:

Functions

- Functions are locally reusable and can be called by module-scope subroutines or mappings within the same schema.
- Functions are globally reusable and can be called by other functions or procedures in ESQL or mapping files within any schema defined in the same or another project.

Procedures

- Procedures are locally reusable and can be called from module-scope subroutines in ESQL files within the same schema.
- Procedures are globally reusable and can be called by other functions or procedures in ESQL files within any schema defined in the same or another project.

Procedures cannot be used in mapping files.

Constants

- Constants are locally reusable and can be used where they are defined in any ESQL or mapping file within the same broker schema.
- Constants are not globally reusable; you cannot use a constant that is declared in another schema.

If you want to reuse functions or procedures globally:

- Specify the path of the function or procedure:
  - If you want to reuse a function or procedure in an ESQL file, either provide a fully-qualified reference, or include a PATH statement that defines the path.

    If you define the path, code the PATH statement in the same ESQL file as that in which the function is coded, but not within any MODULE.
  - If you want to reuse a function in a mapping file, do one of the following:
    - Qualify the function in the Composition Expression editor.
    - Select **Organize Schema References** in the outline view. This detects dependent PATHs and automatically updates the reference.
    - Select **Modify Schema References** in the outline view. You can then select the schema in which the function is defined.

    (You cannot reuse a procedure in a mapping file.)
- Set up references between the projects in which the functions and procedures are defined and used.

WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Client application programming interfaces

You can configure the nodes in your message flows to customize the behavior of those nodes by using one or more of the supported programming interfaces.

You can use one of the following options for converting message formats in your message flows:

Mappings
: The Message Mapping editor in the WebSphere Message Broker Toolkit is a graphical interface that displays a visual representation of messages. You can use this editor to:

  - Drag fields from a source message to a target message
  - Map data from databases to the message structure
  - Apply functions

  You can use mappings in the DataDelete, DataInsert, DataUpdate, Mapping, and Warehouse nodes.

  Use this option if the transformations you want to perform are not complex, or you do not want to use a programming language.

ESQL Use ESQL to manipulate data in both messages and database tables. ESQL

is a programming language that is specific to WebSphere Message Broker, and based on SQL. You can code ESQL statements to create, reference, and update message fields and database content. ESQL provides a rich set of statements and functions that you can use to achieve sophisticated transformations.

You can use ESQL in the Compute, Database, and Filter nodes.

Use this option if the transformations you want to perform are complex, and your message flow designers are familiar with procedural programming languages.

Java Use the Java programming language to route or transform your messages. You can use XPath to create, reference, and update message fields. You can also use JDBC to access database tables.

You can use Java only in the JavaCompute node.

Use this option if your message flow designers are familiar with the Java programming language.

XSL style sheets
Use standard XSL style sheets to convert XML messages to other formats supported by the broker.

You can use XSL only in theXSLTransform node.

Use this option if your message flows are processing XML messages, and your message flow designers are familiar with the XSL style sheets.

PHP Use the PHP programming language to route or transform your messages. You can use PHP to create, reference, and update message fields.

You can use PHP only in the PHPCompute node.

Use this option if your message flow designers are familiar with the PHP scripts and the programming language.

When you configure your message flows and nodes, you create a set of files that are stored in your workspace.

The files created are of the following types:

- A message flow definition file, `<message_flow_name>.msgflow`. This file is mandatory, and is created automatically for you. It contains details about the message flow characteristics and contents; for example, what nodes it includes and its promoted properties.
- One or more message mappings files, `<message_flow_name><_nodename>.msgmap`. A unique file is required for each node in the message flow that uses the Message Mapping editor. This file is required only if your message flow contains one or more of the nodes that you can customize by using mappings. You can create this file yourself, or you can cause it to be created for you by requesting specific actions against a node.

  You can customize the following built-in nodes by specifying how input values map to output values.

Node	Usage
"DataDelete node" on page 4382	Use this node to delete one or more rows from a database table without creating an output message.

Node	Usage
"DataInsert node" on page 4386	Use this node to insert one or more rows in a database table without creating an output message.
"DataUpdate node" on page 4390	Use this node to update one or more rows in a database table without creating an output message.
"Mapping node" on page 4571	Use this node to construct output messages and populate them with information that is new, modified from the input message, or taken from a database. You can also use the Mapping node to update, insert, or delete rows in a database table.
"Warehouse node" on page 4963	Use this node to store all or part of a message in a database table without creating an output message.

You can use built-in ESQL functions and statements to define message mappings, and you can use your own ESQL functions.

The "Extract node" on page 4412 also uses mappings to create an output message that contains a subset of the contents of the input message. However, the Extract node is deprecated in WebSphere Message Broker Version 6.0 and later releases. Although message flows that contain an Extract node remain valid in WebSphere Message Broker Version 6.0, redesign your message flows to replace Extract nodes by Mapping nodes to take advantage of later enhancements.

- One or more ESQL resources files, `<message_flow_name>.esql`. An ESQL file is required only if your message flow includes one or more of the nodes that must be customized by using ESQL modules, or contains functions that are called by your message mappings. You can create this file yourself, or you can cause it to be created for you by requesting specific actions against a node.

  You can customize the following built-in nodes by creating free-form ESQL statements that use the built-in ESQL statements and functions, and your own user-defined functions:
  - Compute
  - Database
  - Filter
- One or more Java programming files, `<message_flow_name>.java`. A Java file is required only if your message flow includes one or more JavaCompute nodes. You can create this file yourself, or you can cause it to be created for you by requesting specific actions against a node.
- One or more XSL stylesheets, `<message_flow_name>.xslt`. An XSLT file is required only if your message flow includes one or more XSLTransform nodes. You can create this file yourself, or you can cause it to be created for you by requesting specific actions against a node.
- One or more PHP scripts, `<message_flow_name>.php`. A PHP script file is required only if your message flow includes one or more PHPCompute nodes. You can create this file yourself, or you can cause it to be created for you by requesting specific actions against a node.

You can include other files in your message flow project so that they are deployed to the broker with your message flow. The broker stores these extra files but does not process them in any way.

For details of how to create the files to support these transform options, and create their content, see "Transforming and enriching messages" on page 2227.

The message tree

A message tree is a structure that is created, either by one or more parsers when an input message bit stream is received by a message flow, or by the action of a message flow node.

A message is used to describe:

- A set of business data that is exchanged by applications
- A set of elements that are arranged in a predefined structure
- A structured sequence of bytes

WebSphere Message Broker routes and manipulates messages after converting them into a logical tree. The process of conversion, called parsing, makes obvious the content and structure of a message, and simplifies later operations. After the message has been processed, the parser converts it back into a bit stream.

WebSphere Message Broker supplies a range of parsers to handle the many different messaging standards in use. See Parsers.

After a message has been parsed, it can be processed in a message flow.

The logical tree has contents that are identical to the message, but the logical tree is easier to manipulate in the message flow. The message flow nodes provide an interface to query, update, or create the content of the tree.

Related concepts:

"Parsers" on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

"Message modeling" on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

Related tasks:

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

"ESQL reference" on page 5019
SQL is the industry standard language for accessing and updating database data and ESQL is a language derived from SQL Version 3, particularly suited to manipulating both database and message data.

Logical tree structure:

The logical tree structure is the internal (broker) representation of a message. It is also known as the message assembly.

When a message arrives at a broker, it is received by an input node that you have configured in a message flow. Before the message can be processed by the message flow, the message must be interpreted by one or more parsers that create a logical tree representation from the bit stream of the message data.

The tree format contains identical content to the bit stream from which it is created, but it is easier to manipulate in the message flow. Many of the built-in message flow nodes provide an interface for you to query and update message content in the tree, and perform other actions against messages and databases to help you to provide the required function in each node.

Several interfaces are provided:

- ESQL, a programming language that you can code in the Compute, Database, and Filter nodes.
- Java, a programming language that you can code in the JavaCompute node.
- Mappings, a graphical method of achieving transformation from input to output structures, available in the DataDelete, DataInsert, DataUpdate, Mapping, and Warehouse nodes.
- XSL, a language for transforming XML that you can use in the XSLTransform node.
- PHP, a scripting language that you can code in the PHPCompute node.

The tree structure that is created by the parsers is largely independent of any message format (for example, XML). The exception to this is the subtree that is created as part of the message tree to represent the message body. This subtree is message dependent, and its content is not further described here.

The input node creates this message assembly, which consists of four trees:
- "Message tree structure" on page 1045
- "Environment tree structure" on page 1055
- "Local environment tree structure" on page 1056
- "Exception list tree structure" on page 1066

The first of these trees is populated with the contents of the input message bit stream, as described in "How the message tree is populated" on page 1047; the remaining three trees are initially empty.

Each of the four trees created has a root element (with a name that is specific to each tree). Each tree is made up of a number of discrete pieces of information called *elements*. The root element has no *parent* and no *siblings* (siblings are elements that share a single parent). The root is parent to a number of *child* elements. Each child must have a parent, can have zero or more siblings, and can have zero or more children.

The four trees are created for both built-in and user-defined input nodes and parsers.

The input node passes the message assembly that it has created to subsequent message processing nodes in the message flow:

- All message processing nodes can read the four trees.
- You can code ESQL in the Database and Filter nodes, or use mappings in the nodes that support that interface to modify the Environment and LocalEnvironment trees only.
- The Compute node differs from other nodes in that it has both an input message assembly and at least one output message assembly. Configure the Compute node to determine which trees are included in the output message assembly; the Environment tree is an exception in that it is always retained from input message assembly to output message assembly.

  To determine which of the other trees are included, you must specify a value for the `Compute mode` property of the node (displayed on the Advanced tab). The default action is for only the message to be created. You can specify any combination of message, LocalEnvironment, and ExceptionList trees to be created in the output message assembly.

  If you want the output message assembly to contain a complete copy of the input message tree, you can code a single ESQL SET statement to make the copy. If you want the output message to contain a subset of the input message tree, code ESQL to copy those parts that you want. In both cases, your choice of `Compute mode` must include `Message`.

  If you want the output message assembly to contain all or part of the input LocalEnvironment or ExceptionList tree contents, code the appropriate ESQL to copy information you want to retain in that tree. Your choice of `Compute mode` must include LocalEnvironment, or Exception, or both.

  You can also code ESQL to populate the output message, Environment, LocalEnvironment, or ExceptionList tree with information that is not copied from the input tree. For example, you can retrieve data from a database, or calculate content from the input message data.
- You can produce similar results in the JavaCompute node. See "Writing Java" on page 2638 for more information.
- You can also achieve results like these in the PHPCompute node. See "Using PHP" on page 2670 for more information.

You can define your own nodes to use in WebSphere Message Broker message flows.

"MQRFH2 header" on page 6397
The MQRFH2 header is used to pass messages to and from a message broker that belongs to WebSphere Message Broker.

Message tree structure:

The message tree is a part of the logical message tree in which the broker stores its internal representation of the message body.

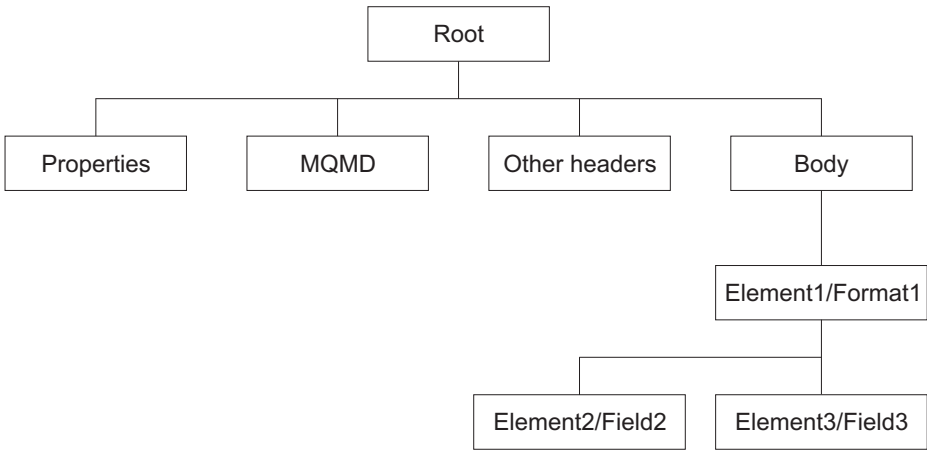
The root of a message tree is called Root. The message tree is always present, and is passed from node to node in a single instance of a message flow.

The message tree includes all the headers that are present in the message, in addition to the message body. The tree also includes the Properties subtree (described in "Parsers" on page 1072), if that is created by the parser. If a supplied parser has created the message tree, the element that represents the Properties subtree is followed by zero or more headers.

If the message has been received across the WebSphere MQ Enterprise Transport or WebSphere MQ Mobile Transport, the first header (the second element) must be the MQMD. Any additional headers that are included in the message appear in the tree in the same order as in the message. The last element beneath the root of the message tree is always the message body.

If a user-defined parser has created the message tree, the Properties tree, if present, is followed by the message body.

The message tree structure is shown in the following section. If the input message is not a WebSphere MQ message, the headers that are shown might not be present. If the parser that created this tree is a user-defined parser, the Properties tree might not be present.



The Body tree is a structure of child elements that represents the message content (data), and reflects the logical structure of that content. The Body tree is created by a body parser (either a supplied parser or a user-defined parser), as described in "Parsers" on page 1072.

Each element in the parsed tree is one of three types:

Name element

A name element has a string associated with it, which is the name of the element. An example of a name element is `XMLElement`, as described in "XML element" on page 4267. A name element also has a second string associated with it, which is the namespace of the element; this string might be empty.

Value element

A value element has a value associated with it. An example of a value element is `XMLContent`, as described in "XML content" on page 4267.

Name-value element

A name-value element is an optimization of the case where a name element contains only a value element and nothing else. The element contains both a name and a value. An example of a name-value element is `XMLAttribute`, as described in "XML attribute" on page 4264.

For information about how the message tree is populated, see "How the message tree is populated" on page 1047.

Properties folder: The Properties folder is the first element of the message tree and holds information about the characteristics of the message.

The root of the Properties folder is called Properties. It is the first element under Root. All message trees that are generated by the built-in parsers include a Properties folder for the message. If you create your own user-defined parser, you can choose whether the parser creates a Properties folder. However, for consistency, you should include this action in the user-defined parser.

The Properties folder contains a set of standard properties that you can manipulate in the message flow nodes in the same way as any other property. Some of these fields map to fields in the supported WebSphere MQ headers, if present, and are passed to the appropriate parser when a message is delivered from one node to another.

For example, the MQRFH2 header contains information about the message set, message type, and message format. These values are stored in the Properties folder as MessageSet, MessageType, and MessageFormat. To access these values using ESQL or Java in the message processing nodes, refer to these values in the Properties folder; do not refer directly to the fields in the headers from which they are derived.

The Properties parser ensures that the values in the header fields match the values in the Properties folder on input to, and output from, every node. For any field, if only one header is changed (the Properties header or a specific message header), that value is used. If both the Properties header and the specific message header are changed, the value from the Properties folder is used.

When the message flow processing is complete, the Properties folder is discarded.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

"ESQL reference" on page 5019
SQL is the industry standard language for accessing and updating database data and ESQL is a language derived from SQL Version 3, particularly suited to manipulating both database and message data.

How the message tree is populated:

The message tree is initially populated by the input node of the message flow.

When the input node receives the input message, it creates and completes the Properties tree (the first subtree of the message tree). See "Message tree structure" on page 1045.

The node then examines the contents of the input message bit stream and creates the remainder of the message tree to reflect those contents. This process depends to some extent on the input node itself, which is governed by the transport across which the message is received:

WebSphere MQ Enterprise Transport protocol
: If your application communicates with the broker across these protocols, and your message flow includes the corresponding MQInput node, all messages that are received must start with a Message Queue Message Descriptor (MQMD) header. If a valid MQMD is not present at the start of the message, the message is rejected, and no further processing takes place.

  The input node first invokes the MQMD parser and creates the subtree for that header.

  A message can have zero or more additional headers following the MQMD. These headers are chained together, with the **Format** field of one header defining the format of the following header, up to and including

the last header, which defines the format of the message body. If an MQRFH and an MQRFH2 header exist in the chain, the name and value data in either of these two headers can also contain information about the format of the following data. If the value that is specified in **Format** is a recognized parser, this value always takes precedence over the name and value data.

The broker invokes the appropriate parser to interpret each header, following the chain in the message. Each header is parsed independently. The fields in a single header are parsed in an order that is governed by the parser. You cannot predict the order that is chosen, but the order in which fields are parsed does not affect the order in which the fields are displayed in the header.

The broker ensures that the integrity of the headers that precede a message body is maintained. The format of each part of the message is defined, either by the **Format** field in the immediately preceding header (if the following part is a recognized WebSphere MQ format), or by the values that are set in the MQRFH or MQRFH2 header:

- The format of the first header is known because it must be MQMD.
- The format of any subsequent header in the message is set in the **Format** field in the preceding header.
- The format of the body corresponds to the message domain and the parser that must be invoked for the message body (for example, XMLNSC). This information is set either in the MQRFH or MQRFH2 header, or in the *Message Domain* property of the input node that receives the message.

This process is repeated as many times as required by the number of headers that precede the message body. You do not need to populate these fields yourself; the broker handles this sequence for you.

The broker completes this process to ensure that **Format** fields in headers correctly identify each part of the message. If the broker does not complete this process, WebSphere MQ might be unable to deliver the message. The message body parser is not a recognized WebSphere MQ header format, therefore the broker replaces this value in the last headers **Format** field with the value MQFMT_NONE. The original value in that field is stored in the **Domain** field in the MQRFH or MQRFH2 header to retain the information about the contents of the message body.

For example, if the MQRFH2 header immediately precedes the message body, and its **Format** field is set to XMLNSC, which indicates that the message body must be parsed by the XMLNSC parser, the MQRFH2 **Domain** field is set to XMLNSC, and its **Format** field is reset to MQFMT_NONE.

These actions might result in information that is stored explicitly by an ESQL or Java expression being replaced by the broker.

The **CodedCharSetId** and **Encoding** fields are not populated in the same way as the **Format** field. In particular, the message body is not used to determine the **CodedCharSetId** and **Encoding** values. Rather, these values affect the way in which the message body is written. This can cause unexpected results if an intermediate header (for example MQRFH2) is removed without updating the preceding header in the chain with the removed header values.

When all the headers have been parsed, and the corresponding sub-trees have been created in the message tree, the input node associates the specified parser with the message body. Specify the parser that is to be associated with the message body content, either in a header in the message (for example, the <mcd> folder in the MQRFH2 header), or in the input node properties (if the message does not include headers). The input node makes the association as described in the following list:

- If the message has an MQRFH or MQRFH2 header, the domain that is identified in the header (either in **Format** or the name and value data) determines the parser that is associated with this message.
- If the message does not have an MQRFH or MQRFH2 header, or if the header does not identify the domain, the *Message Domain* property of the input node indicates the domain of the message, and the parser that is to be used. You can specify a user-defined domain and parser.
- If the message domain cannot be identified by header values or by the *Message Domain* property of the input node, the message is handled as a binary object (BLOB). The BLOB parser is associated with the message. A BLOB can be interpreted as a string of hexadecimal characters, and can be modified or examined in the message flow by specifying the location of the subset of the string.

By default, the message body is not parsed straight away, for performance reasons. The message body might not need to be parsed during the message flow. It is parsed only when a reference is made to its contents.

For example, the message body is parsed when you refer to a field in the message body, for example: `Root.XMLNSC.MyDoc.MyField`. Depending on the paths that are taken in the message flow, this can take place at different points. This parsing when first needed approach is also referred to as "partial parsing" or "on-demand parsing", and in typical processing does not affect the logic of a message flow. However, there are some implications for error handling scenarios; see “Handling errors in message flows” on page 2823.

If you want a message flow to accept messages from more than one message domain, include an MQRFH2 header in your message from which the input nodes extract the message domain and related message definition information (message set, message type, and message format).

If you set up the message headers or the input node properties to identify a user-defined domain and parser, the way in which it interprets the message and constructs the logical tree might differ from that described here.

WebSphere Broker File Transport, WebSphere Broker Adapters Transport, WebSphere MQ Web Services Transport, and WebSphere Broker JMS Transport protocols

If your application communicates with the broker across these supported protocols, and your message flow includes the corresponding input nodes, messages that are received do not have to include a particular header. If recognized headers are included, the input node invokes the appropriate parsers to interpret the headers and to build the relevant parts of the message tree, as described for the other supported protocols.

If there are no headers, or these headers do not specify the parser for the message body, set the input node properties to define the message body parser. If you do not set the node properties in this way, the message is treated as a BLOB. You can specify a user-defined parser.

The specified parser is associated with the message body by the input node (in the same way as it is for the WebSphere MQ Enterprise Transport protocol), and by default the message body is not parsed immediately.

If you set up the message headers or the input node properties to identify a user-defined domain and parser, the way in which it interprets the message and constructs the logical tree might differ from that described here.

All other protocols

If you want your message flow to accept messages from a transport protocol for which WebSphere Message Broker does not provide built-in support, or you want it to provide some specific processing on receipt of a message, use either the Java or the C language programming interface to create a new user-defined input node.

This interface does not automatically generate a Properties subtree for a message (this subtree is discussed in "Message tree structure" on page 1045). A message does not need to have a Properties subtree, but you might find it useful to create one to provide a consistent message tree structure, regardless of input node. If you are using a user-defined input node, you must create a Properties subtree in the message tree yourself.

To process messages that do not conform to any of the defined message domains, use the C language programming interface to create a new user-defined parser.

Refer to the node interface to understand how it uses parsers, and whether you can configure it to modify its behavior. If the node uses a user-defined parser, the tree structure that is created for the message might differ slightly from that created for built-in parsers. A user-defined input node can parse an input message completely, or it can participate in partial parsing in which the message body is parsed only when it is required.

You can also create your own output and message processing nodes in C or Java.

Properties versus MQMD folder behavior for various transports

Differences exist in the way the Properties folder and the MQMD folder are treated with respect to which folder takes precedence for the same fields. This treatment is characterized by the transport type (for example, HTTP or WebSphere MQ) that you use.

When the message flow is sourced by an MQInput node, you have an MQMD to parse. In this case, the Properties folder is sourced by the MQMD values and so the MQMD folder takes precedence over the Properties folder in terms of value propagation between the folders. This scenario means that you can perform ESQL, for example, `SET OutputRoot.MQMD.CorrelId` and this command updates the Properties folder value.

When the message flow is sourced from an input node that is not the MQInput node (such as the HTTPInput node or a user-defined input node), no MQMD is parsed. In this scenario, the Properties folder is not sourced from an input MQMD; it is created and populated with transport values that come from other transport specific headers. When you create an MQMD folder in a message flow that was not sourced from the WebSphere MQ transport, the MQMD header does not take

precedence over the Properties folder because the WebSphere MQ transport did not populate the Properties folder. Therefore, in this case, the Properties folder overwrites any values in MQMD.

The Properties folder is constructed and represents a message received on the transport. In this scenario two entirely different transports are being used which have different meanings and, therefore, different requirements of the Properties folder. When sourced from an HTTPInput node, the HTTP headers have control over the Properties folder for like fields. When sourced from an MQInput node the MQMD has control over the Properties folder for like fields.

Therefore, when you add an MQMD folder to a tree that was created by the HTTP Transport, this MQMD folder does not have control over the Properties folder, and the value propagation direction is not MQMD to Properties, it is Properties to MQMD. The correct approach is to set the **replyIdentifier** field of the Properties folder and to use it to populate the MQMD:

```
SET OutputRoot.Properties.ReplyIdentifier = X' ..... ';
```

The behavior is not unique to just the **CorrelId** to **ReplyIdentifier** fields. It applies for all like fields between the MQMD and Properties folder:

- **CorrelId**
- **Encoding**
- **CodedCharSetId**
- **Persistence**
- **Expiry**
- **Priority**

In summary:

1. When your message flow is sourced by an MQInput node, the MQMD takes precedence over the Properties folder in terms of value propagation between the folders.
2. When your message flow is sourced from an input node that is not the MQInput node (such as the HTTPInput node or a user-defined input node), the MQMD header does not take precedence over Properties folder .
3. When an MQMD folder is added in a tree that was created by the HTTP Transport, this MQMD does not have control over the Properties folder and the value propagation direction is not MQMD to Properties; it is Properties to MQMD.

Example

```
SET OutputRoot.Properties = InputRoot.Properties;
SET OutputRoot.MQMD.Version = 2;
SET OutputRoot.MQMD.CorrelId = X'4d454e53414a4533202020202020202020202020202020202020';
SET OutputRoot.MQMD.Encoding = 785;
SET OutputRoot.MQMD.CodedCharSetId = 500;
SET OutputRoot.MQMD.Persistence = 1;
SET OutputRoot.MQMD.Expiry = 10000;
SET OutputRoot.MQMD.Priority = 9;
SET OutputRoot.BLOB.BLOB = X'01';
```

When sourced from an HTTPInput node none of these changes take effect and the MQMD output from the Compute node is:

```
(0x01000000):MQMD       = (
    (0x03000000):Version        = 2
    (0x03000000):CorrelId       = X'000000000000000000000000000000000000000000000000'
```

```
(0x03000000):Encoding       = 546
(0x03000000):CodedCharSetId = 1208
(0x03000000):Persistence    = FALSE
(0x03000000):Expiry         = -1
(0x03000000):Priority       = 0
```

The MQRFH2 header is used to pass messages to and from a message broker that belongs to WebSphere Message Broker.

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

Message tree contents after an exception:

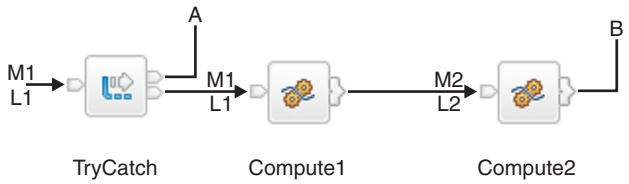
The contents of the message tree are updated if an exception is raised.

If no exception occurs while processing the message, the tree structure and content received by an individual node is determined by the action of previous nodes in the flow. If an exception occurs in the message flow, the content of the four trees depends on the following factors:

- If the exception is returned to the input node, and the input node Catch terminal is not connected, the trees are discarded. If the message is in a transaction, it is returned to the input queue for further processing. When the message is processed again, a new tree structure is created. If the message is not in a transaction, it is discarded.
- If the exception is returned to the input node and the Catch terminal is connected, the message and local environment trees that were created originally by the input node, and propagated through the Out terminal, are restored, and any updates that you made to their content in the nodes that followed the input node are lost. The environment tree is not restored, and its contents are preserved. If the nodes following the input node include a Compute node that creates a new local environment or message tree, those trees are lost. The exception list tree reflects the one or more exceptions that have been recorded.
- If the exception is caught in the message flow by a TryCatch node, the message and local environment trees that were previously propagated through the Try terminal of the TryCatch node are restored and propagated through the Catch terminal. Any updates that you made to their content in the nodes that followed the TryCatch node are lost. The environment tree is not restored, and its contents are preserved. If the nodes following the TryCatch node include a Compute node that creates a new local environment or message tree, those trees are lost. The exception list tree reflects the one or more exceptions that have been recorded.

Exception handling paths in a message flow: Exception handling paths start at a failure terminal (most message processing nodes have these), the Catch terminal of an input node, a TryCatch node, or an AggregateReply node, but are no different in principle from a normal message flow path. Such a flow consists of a sequence of nodes connected together by the designer of the message flow. The exception handling paths differ in the kind of processing that they do to record or react to the exception. For example, they might examine the exception list to determine the nature of the error, and take appropriate action or log data from the message or exception.

The local environment and message tree that are propagated to the exception handling message flow path are those at the start of the exception path, not those at the point when the exception is thrown. The following figure illustrates this point:



- A message (M1) and local environment (L1) are being processed by a message flow. They are passed through the TryCatch node to Compute1.
- Compute1 updates the message and local environment and propagates a new message (M2) and local environment (L2) to the next node, Compute2.

- An exception is thrown in Compute2. If the failure terminal of Compute2 is not connected (point **B**), the exception is propagated back to the TryCatch node, but the message and local environment are not. The exception handling path starting at point **A** has access to the first message and local environment, M1 and L1. The environment tree is also available and retains the content it had when the exception occurred.
- If the failure terminal of Compute2 is connected (point **B**), the message and local environment M2 and L2 are propagated to the node connected to that failure terminal. The environment tree is also available and retains the content it had when the exception occurred.

"TryCatch node" on page 4949
Use the TryCatch node to provide a special handler for exception processing.

Environment tree structure:

The environment tree is a part of the logical message tree in which you can store information while the message passes through the message flow.

The root of the environment tree is called Environment. This tree is always present in the input message; an empty environment tree is created when a message is received and parsed by the input node. You can use this tree as you choose, and create both its content and structure.

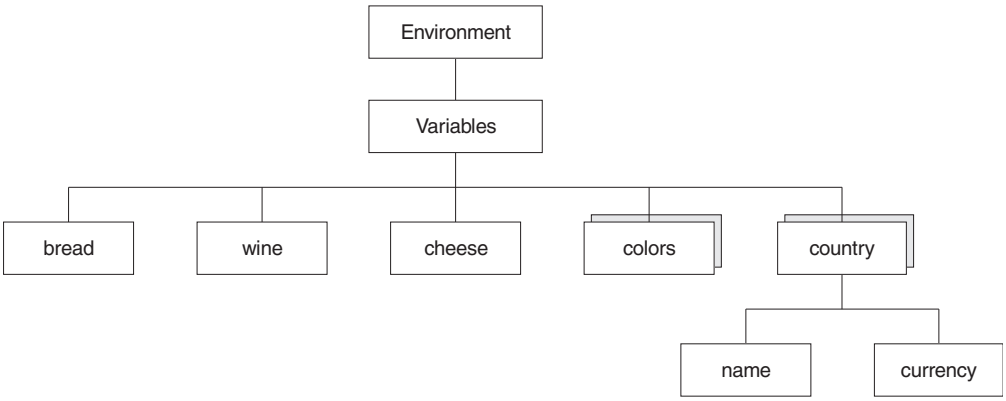
WebSphere Message Broker uses fields in the Environment tree in only two situations. (Contrast this with the "Local environment tree structure" on page 1056, which the broker uses in many situations):

- If you have requested data collection for message flow accounting and statistics, and have indicated that accounting origin basic support is required, the broker checks for the existence of the field Environment.Broker.AccountingOrigin. If the field exists, the broker uses its value to set the accounting origin for the current data record. For further information about the use of this field, see "Setting message flow accounting and statistics accounting origin" on page 3290.
- If you have activated a message flow to emit monitoring events the broker stores correlation attributes in the Environment tree. For further information, see "Correlation and monitoring events" on page 6778

The environment tree differs from the local environment tree in that a single instance of it is maintained throughout the message flow. If you include a Compute node, a Mapping node, or a JavaCompute node in your message flow, you do not have to specify whether you want the environment tree to be included in the output message. The environment tree is included automatically, and the entire contents of the input environment tree are retained in the output environment tree, subject to any modifications that you make in the node. Any changes that you make are available to subsequent nodes in the message flow, and to previous nodes if the message flows back (for example, to a FlowOrder or TryCatch node).

If you want to create your own information, create it in the environment tree in a subtree called Variables.

The following figure shown an example of an environment tree:



You could use the following ESQL statements to create the content shown above.

```
SET Environment.Variables =
      ROW('granary' AS bread, 'riesling' AS wine, 'stilton' AS cheese);
SET Environment.Variables.Colors[] =
      LIST{'yellow', 'green', 'blue', 'red', 'black'};
SET Environment.Variables.Country[] = LIST{ROW('UK' AS name, 'pound' AS currency),
     ROW('USA' AS name, 'dollar' AS currency)};
```

When the message flow processing is complete, the Environment tree is discarded.

When you create a message flow, you include input nodes that receive messages and, optionally, output nodes that send out new or updated messages. If the message processing requires it, you can include other nodes after the input node that are customized in Java to complete the actions that your applications need.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Local environment tree structure:

The local environment tree is a part of the logical message tree in which you can store information while the message flow processes the message.

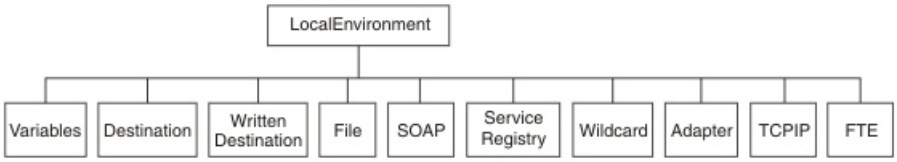
The root of the local environment tree is called `LocalEnvironment`. This tree is always present in the input message, it is created when a message is received by the input node. Some input nodes create local environment fields, others leave it empty.

The local environment tree is made up of the following structure:

- Anything in the format of `LocalEnvironment.Destination.`*`output_or_request_node_name`*, for example; LocalEnvironment.Destination.Email, decides what happens when information is going into an output or request node.
- Anything in the format of `LocalEnvironment.WrittenDestination.`*`output_or_request_node_name`*, for example; LocalEnvironment.WrittenDestination.FTE, gives you information about the processed output of an output or a request node.
- Anything in the format of `LocalEnvironment.`*`input_node_name`*`.input`, for example; LocalEnvironment.Adapter.Input, contains information that has been stored by an input node.

Use the local environment tree to store variables that can be referred to and updated by message processing nodes that occur later in the message flow. You can also use the local environment tree to define destinations (that are internal and external to the message flow) to which a message is sent. WebSphere Message Broker also stores information in LocalEnvironment in some circumstances, and references it to access values that you might have set for destinations. (Contrast this to the Environment tree structure, which the broker uses only in specific situations, see "Environment tree structure" on page 1055.)

The following figure shows an example of the local environment tree structure. The children of Destination are protocol-dependent.



In the tree structure shown, LocalEnvironment has several children:

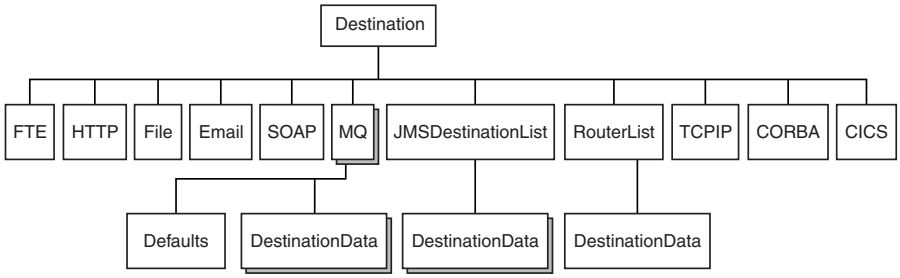
LocalEnvironment.Variables

This subtree is optional. If you create local environment variables, store them in a subtree called Variables. It provides a work area that you can use to pass information between nodes. This subtree is never inspected or modified by any supplied node.

Variables in the local environment can be changed by any subsequent message processing node, and the variables persist until the node that created them goes out of scope.

The variables in this subtree are persistent only within a single instance of a message flow. If you have multiple instances of a message passing through the message flow, and need to pass information between them, you must use an external database.

LocalEnvironment.Destination



This subtree consists of a number of children that indicate the transport types to which the message is directed (the Transport identifiers), or the target Label nodes that are used by a RouteToLabel node.

- Transport information

  Transport information is used by some input and output nodes, including Email, File, FTE, HTTP, JMS, MQ, SOAP, and TCPIP.

  LocalEnvironment.Destination.CICS

  If the message flow includes a CICSRequest node, you can override the following properties with elements in this subtree:
  - `Program name`
  - `Commarea length`
  - `Mirror transaction ID`
  - `Set EIBTRNID only`
  - `Message domain`
  - `Message set`
  - `Message type`
  - `Message format`
  - `Message coded character set ID`
  - `Message encoding`

  For more information, see "Local environment overrides for the CICSRequest node" on page 2191.

  You can also set LocalEnvironment values for CICS channels and containers. For more information, see "COMMAREA or channel data structures" on page 2183.

  LocalEnvironment.Destination.CORBA

  If the message flow includes a CORBARequest node, you can override its `Operation name` property by specifying a value in the following location:

  ```
  $LocalEnvironment/Destination/CORBA/Request/OperationName
  ```

  For more information about the operation name, see "CORBARequest node" on page 4349.

  LocalEnvironment.Destination.Email

  If the message flow includes an EmailOutput node, then information defined in this subtree will specify or override the SMTP server connection information and attachments associated with each email sent by the node. Multiple attachments can be specified for inclusion in the email sent, including the specification of the attachment name, content, and type. See "EmailOutput node" on page 4400.

  LocalEnvironment.Destination.File

If the message flow includes a FileOutput node, you can override its `directory` and `name` properties with elements in this subtree. See "Using local environment variables with file nodes" on page 1820.

LocalEnvironment.Destination.FTE

If the message flow includes an FTEOutput node, you can override its properties with elements in this subtree. See "Using local environment variables with file nodes" on page 1820.

LocalEnvironment.Destination.HTTP

If the message flow starts with an HTTPInput node, a single name element HTTP is added to Destination. The element HTTP.RequestIdentifier is created and initialized so that it can be used by an HTTPReply node. You can also create other fields in the HTTP structure for use by the HTTPRequest node; for example, the URL of the service to which the request is sent. For more information, see *Local environment overrides* in the topic "HTTPRequest node" on page 4488, and examples in "Populating Destination in the local environment tree" on page 2467.

LocalEnvironment.Destination.JMSDestinationList

A JMSOutput node can be configured to send to multiple JMS Queues or to publish to multiple JMS Topics using a destination list created in the local environment by a transformation node.

The JMSOutput node searches the local environment for data elements called DestinationData under the folder Destination.JMSDestinationList. The node sends the JMS message to each DestinationData entry found in that folder. See the example in "Populating Destination in the local environment tree" on page 2467.

LocalEnvironment.Destination.MQ

If the message flow includes an MQOutput node, each element is a name element, *MQ* (A deprecated alternative exists, called *MQDestinationList*. Use *MQ* for all new message flows). If more than one element exists, each is processed sequentially by the node. See the example in "Populating Destination in the local environment tree" on page 2467.

You can configure MQOutput nodes to examine the list of destinations and send the message to those destinations, by setting the property `Destination Mode` to Destination List. If you do so, you must create this subtree and its contents to define those destinations, giving it the name Destination. If you do not do so, the MQOutput node cannot deliver the messages.

If you prefer, you can configure the MQOutput node to send messages to a single fixed destination, by setting the property `Destination Mode` to Queue Name or Reply To Queue. If you select either of these fixed options, the destination list has no effect on broker operations and you do not have to create this subtree.

You can construct the MQ element to contain a single optional Defaults element. The Defaults element, if created, must be the first child and must contain a set of name-value elements that give default values for the message destination and its PUT options for that parent.

You can also create a number of elements called DestinationData within MQ. Each of these can be set up with a set of name-value elements that defines a message destination and its PUT options.

The set of elements that define a destination is described in "Data types for elements in the MQ DestinationData subtree" on page 4240.

The content of each instance of DestinationData is the same as the content of Defaults for each protocol, and can be used to override the default values in Defaults. You can set up Defaults to contain values that are common to all destinations, and set only the unique values in each DestinationData subtree. If you do not set a value either in DestinationData or Defaults, the value that you have set for the corresponding node property is used. Similarly, if you specify a field name or value with the wrong spelling or case, it is ignored, and the value that you have set for the corresponding node property is used.

The information that you insert into DestinationData depends on the characteristic of the corresponding node property: This information is described in "Accessing the local environment tree" on page 2463.

LocalEnvironment.Destination.SOAP

You can place outbound WS-Addressing header information in the local environment to override the defaults that are generated by the SOAPReply, SOAPRequest, or SOAPAsyncRequest nodes. See "WS-Addressing information in the local environment" on page 1656.

If the message flow includes SOAPRequest or SOAPAsyncRequest nodes, you can override their HTTP Transport and JMS transport properties in this subtree. See "SOAPRequest node" on page 4828, "SOAPAsyncRequest node" on page 4750, or "Local environment overrides for the SOAPRequest node" on page 4850.

If the message flow includes a SOAPAsyncRequest node, you can use this subtree to pass state and correlation information to a SOAPAsyncResponse node in another message flow. See "WS-Addressing with the SOAPAsyncRequest and SOAPAsyncResponse nodes" on page 1655.

If the message flow includes SOAPReply, SOAPRequest, or SOAPAsyncRequest nodes, you can override their use of outbound MTOM messages in this subtree. See "Using SOAP MTOM with the SOAPReply, SOAPRequest, and SOAPAsyncRequest nodes" on page 1678.

LocalEnvironment.Destination.TCPIP

If the message flow includes a TCPIPClientOutput node or a TCPIPServerOutput node, you can override its TCPIP connection with elements in this subtree. See "TCPIPClientOutput node" on page 4867 and "TCPIPServerOutput node" on page 4903.

- Routing information

  The child of Destination is *RouterList*. It has a single child element called *DestinationData*, which has a single entry called labelName. If you are using a dynamic routing scenario involving the RouteToLabel and Label nodes, you must set up the Destination subtree with a RouterList that contains the reference labels.

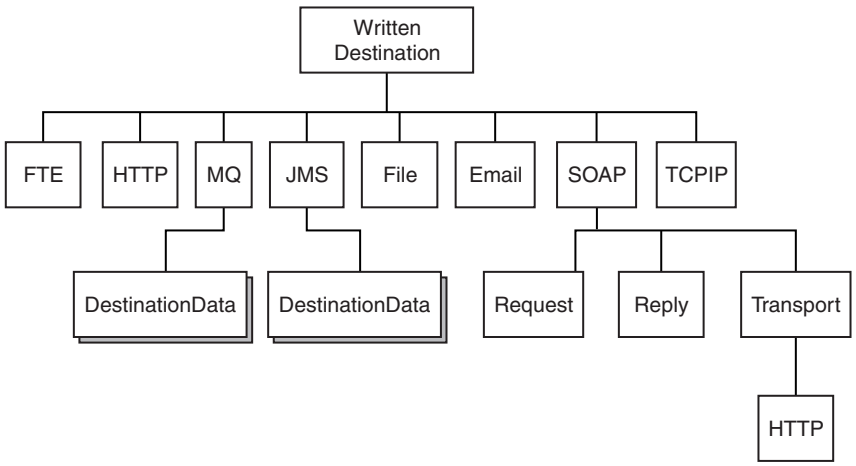
LocalEnvironment.Wildcard

This subtree contains information about the wildcard characters that are stored by the FileInput node.

On the FileInput node you can specify a file name pattern that contains wildcard characters.

More details about the information that is stored in this subtree are in "Using local environment variables with file nodes" on page 1820.

LocalEnvironment.WrittenDestination



This subtree contains the addresses to which the message has been written. Its name is fixed and it is created by the message flow when a message is propagated through the Out terminal of a request, output, or reply node. The subtree includes transport-specific information (for example, if the output message has been put to a WebSphere MQ queue, it includes the queue manager and queue names).

You can use one of the following methods to obtain information about the details of a message after it has been sent by the nodes:

- Connect a transformation node to the Out terminal.
- Configure a user exit to process an output message callback event, as described in "Exploiting user exits" on page 2985.

The topic for each node that supports WrittenDestination information contains details about the data that it contains.

LocalEnvironment.Adapter

This subtree contains information that is stored by the WebSphere Adapters nodes.

For a WebSphere Adapters input node:

- **MethodName** is the name of the business method that corresponds to the Enterprise Information System (EIS) event that triggered this message delivery.

  The bindings for EIS events or business methods are created by the Adapter Connection wizard.
- **Type** describes the type of adapter that is being used:
  - SAP
  - Siebel
  - PeopleSoft
  - JD Edwards

For a WebSphere Adapters request node:

MethodName is the name of the business method that the request node must use.

LocalEnvironment.CD and LocalEnvironment.CD.Transfer

These subtrees contain information that is stored by the CDInput node. The LocalEnvironment.CD subtree contains information about the current

record. The LocalEnvironment.CD.Transfer subtree contains information received from IBM Sterling Connect:Direct regarding the file.

More details about the information that is stored in these subtrees are in "Using local environment variables with file nodes" on page 1820.

LocalEnvironment.Database
This subtree contains information that is propagated from the DatabaseInput node.

The LocalEnvironment.Database.Input.Event.Usr subtree contains user-defined data associated with an event. It is initialized in the ReadEvents procedure of the ESQL module associated with the DatabaseInput node.

LocalEnvironment.Database.Input.Event.Key holds a unique key for an event. It is set in the ReadEvents procedure of the ESQL module associated with the DatabaseInput node.

LocalEnvironment.Database.Input.Event.FailureCount contains a value for the number of times an attempt to process an event has failed. This count includes all unhandled exceptions occurring either in the ESQL module or the message flow.

LocalEnvironment.File
This subtree contains information that is stored by the FileInput node.

This information describes the file, and also contains data about the current record.

More details about the information that is stored in this subtree are in "Using local environment variables with file nodes" on page 1820.

LocalEnvironment.FTE and LocalEnvironment.FTE.Transfer
These subtrees contain information that is stored by the FTEInput node. The LocalEnvironment.FTE subtree contains information about the current record. The LocalEnvironment.FTE.Transfer subtree contains information received from WebSphere MQ File Transfer Edition regarding the file.

More details about the information that is stored in these subtrees are in "Using local environment variables with file nodes" on page 1820.

LocalEnvironment.ServiceRegistry
This subtree contains information for queries by the EndpointLookup and RegistryLookup nodes.

More details about the information that is stored in this subtree are in "Dynamically defining the search criteria" on page 1891, "EndpointLookup node output" on page 1894, and "RegistryLookup node output" on page 1897.

LocalEnvironment.SOAP
This subtree contains information that is stored by SOAPInput, SOAPAsyncResponse, or SOAPRequest nodes.

More details about the information that is stored in this subtree are in "WS-Addressing information in the local environment" on page 1656.

If the message flow includes a SOAPAsyncResponse node, you can use this subtree to receive state and correlation information passed by a SOAPAsyncRequest node in another message flow.

More details about the information that is stored in this subtree are in "WS-Addressing with the SOAPAsyncRequest and SOAPAsyncResponse nodes" on page 1655.

LocalEnvironment.TCPIP

If the message flow includes a TCPIPClientReceive node or a TCPIPServerReceive node, you can override its TCPIP connection with elements in this subtree. See "TCPIPClientReceive node" on page 4877 and "TCPIPServerReceive node" on page 4913.

This subtree contains information that is stored by the TCPIPClientInput, TCPIPClientReceive, TCPIPServerInput, and TCPIPServerReceive nodes.

This information describes the connection that the node is using.

More details about the information that is stored in this subtree are in "TCPIPClientInput node" on page 4854, "TCPIPClientReceive node" on page 4877, "TCPIPServerInput node" on page 4890, and "TCPIPServerReceive node" on page 4913.

When the message flow processing is complete, the local environment tree is discarded.

The following samples demonstrate how to use the local environment to dynamically route messages based on the destination list:

- Airline Reservations
- Message Routing
- Managed File Transfer

The following samples use the local environment tree to store information that is later added to the output message that is created by the message flow:

- User-defined Extension
- Managed File Transfer

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Use the CORBARequest node to call an external CORBA application over Internet Inter-Orb Protocol (IIOP).

Exception list tree structure:

The exception list tree is a part of the logical message tree in which the message flow writes information about exceptions that occur when a message is processed.

The root of the exception list tree is called ExceptionList, and the tree consists of a set of zero or more exception descriptions. The exception list tree is populated by the message flow if an exception occurs. If no exception conditions occur during message flow processing, the exception list that is associated with that message consists of a root element only. This list is, in effect, an empty list of exceptions.

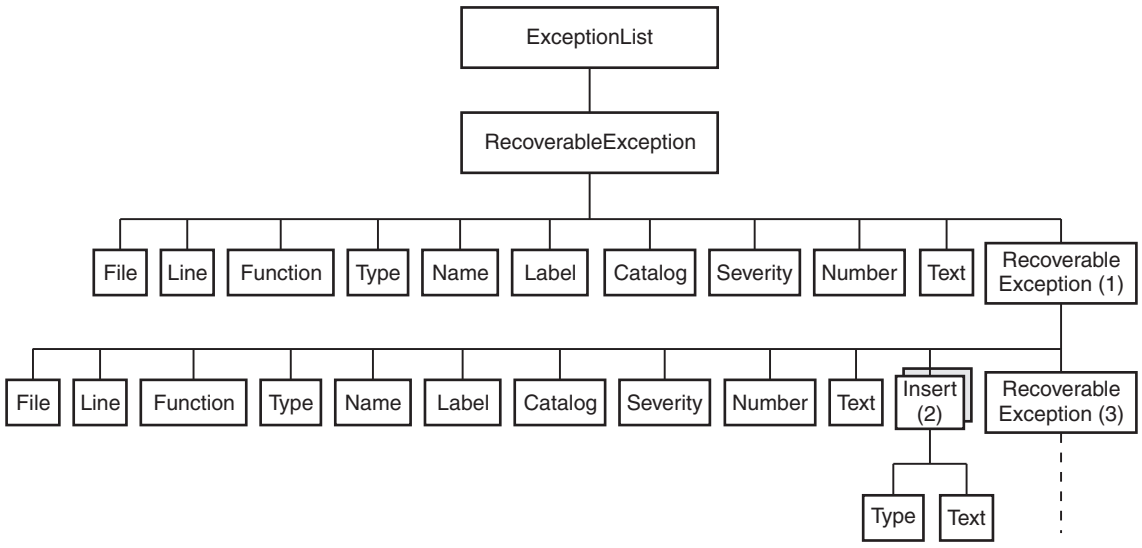
The exception list tree can be accessed by other nodes in the message flow that receive the message after the exception has occurred. You can modify the contents of the exception list tree only in a node that provides an interface to modify the outbound message tree; for example, the Compute node.

If an exception condition occurs, message processing is suspended and an exception is thrown. Control is passed back to a higher level; that is, an enclosing catch block. An exception list is built to describe the failure condition, and the whole message, together with the local environment tree, and the newly-populated exception list, is propagated through an exception-handling message flow path.

The child of ExceptionList may be any one of the exception types that is included in the following list. Typically, only one child of the root is created, although more than one might be generated in some circumstances. The child of ExceptionList contains a number of children, each of which may also be any one of the types in the following list. The last of these children provides further information specific to the type of exception.

- FatalException
- RecoverableException
- ConfigurationException
- SecurityException
- ParserException
- ConversionException
- DatabaseException
- UserException
- CastException
- MessageException
- SqlException
- SocketException
- SocketTimeoutException
- UnknownException

The following figure shows the structure of the exception list tree for a recoverable exception:



The exception description structure can be both repeated and nested to produce an exception list tree. In this tree:

- The depth (that is, the number of parent-child steps from the root) represents increasingly detailed information for the same exception.
- The width of the tree represents the number of separate exception conditions that occurred before processing was abandoned. This number is usually one, and results in an exception list tree that consists of a number of exception descriptions that are connected as children of each other.
- At the numbered points in the tree:
  1. This child can be any one of the exception types that are listed earlier in this topic. All of these elements have the children shown; if present, the last child is the same element as its parent.
  2. This element might be repeated.
  3. If present, this child contains the same children as its parent.

The children in the tree take the form of a number of name-value elements that give details of the exception, and zero or more name elements whose name is Insert. The NLS (National Language Support) message number identified in a name-value element identifies a WebSphere Message Broker error message. The Insert values are used to replace the variables in this message and provide further detail about the cause of the exception.

The name-value elements in the exception list shown in the figure above are described in the following table.

Name	Type	Description
File[1]	String	C++ source file name
Line[1]	Integer	C++ source file line number
Function[1]	String	C++ source function name
Type[2]	String	Source object type
Name[2]	String	Source object name
Label[2]	String	Source object label
Text[1]	String	Optional non-NLS text

Name		Type	Description
Catalog[3]		String	NLS message catalog name[4]
Severity[3]		Integer	1 = information 2 = warning 3 = error
Number[3]		Integer	NLS message number[4]
Insert[3]	Type	Integer	The data type of the value: 0 = Unknown 1 = Boolean 2 = Integer 3 = Float 4 = Decimal 5 = Character 6 = Time 7 = GMT Time 8 = Date 9 = Timestamp 10 = GMT Timestamp 11 = Interval 12 = BLOB 13 = Bit Array 14 = Pointer
	Text	String	The data value

Notes:

1. Do not use the File, Line, Function, and Text elements for exception handling decision making. These elements ensure that information can be written to a log for use by IBM Service personnel, and are subject to change in both content and order.
2. The Type, Name, and Label elements define the object (usually a message flow node) that was processing the message when the exception condition occurred.
3. The Catalog, Severity, and Number elements define an NLS message: the Insert elements that contain the two name-value elements shown define the inserts into that NLS message.
4. NLS message catalog name and NLS message number refer to a translatable message catalog and message number.

When the message flow processing is complete, the exception list tree is discarded.

The following sample uses the exception list in the XML_Reservation message flow to pass error information to the Throw node, which generates an error message that includes the information from ExceptionList:

- Airline Reservations

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

"Compute node" on page 4340
Use the Compute node to construct one or more new output messages.

Correlation names:

A correlation name is a field reference that identifies a well-defined starting point in the logical message tree and is used in field references to describe a standard part of the tree format.

When you access data in any of the four trees (message, environment, local environment, or exception list), the correlation names that you can use depend on the node for which you create ESQL or mappings, and whether the node creates an output message. For example, a Trace node does not alter the content of the message as it passes through the node, but a Compute node can construct a new output message.

You can introduce new correlation names with SELECT expressions, quantified predicates, and FOR statements. You can create non-correlation names in a node by using reference variables.

Correlation names in nodes that do not create an output message: Most message flow nodes do not create an output message; all ESQL expressions that you write in ESQL modules or in mappings in these nodes refer to just the input message. Use the following correlation names in the ESQL modules that you write for Database and Filter nodes:

Root The root of the message passing through the node.

Body The last child of the root of the message; that is, the body of the message. This name is an alias for `Root.*[<]`.

For a description of how to use the asterisk (*) in field references, see "Using anonymous field references" on page 2430.

Properties
The standard properties of the input message.

Environment
The structure that contains the current global environment variables that are available to the node. Environment can be read and updated from any node for which you can create ESQL code or mappings.

LocalEnvironment
The structure that contains the current local environment variables that are available to the node. LocalEnvironment can be read and updated from any node for which you can create ESQL code or mappings.

DestinationList
The structure that contains the current local environment variables available to the node. Its preferred name is LocalEnvironment, although the DestinationList correlation name can be used for compatibility with earlier versions.

ExceptionList
The structure that contains the current exception list to which the node has access.

You cannot use these correlation names in the expression of any mapping for a Mapping, Extract, Warehouse, DataInsert, DataUpdate, or DataDelete node.

Correlation names in nodes that create an output message: If you are coding ESQL for a Compute node, the correlation names must distinguish between the two message trees involved: the input message and the output message. The correlation names in ESQL in these nodes are:

InputBody
The last child of the root of the input message. This name is an alias for `InputRoot.*[<]`.

For a description of how to use *, see "Using anonymous field references" on page 2430.

InputRoot
The root of the input message.

InputProperties
The standard properties of the input message.

Environment
The structure that contains the current global environment variables that are available to the node. Environment can be read and updated.

InputLocalEnvironment
The structure that contains the local environment variables for the message passing through the node.

InputDestinationList
The structure that contains the local environment variables for the message passing through the node. Use the correlation name InputDestinationList for compatibility with earlier versions; if compatibility is not required, use the preferred name InputLocalEnvironment

InputExceptionList
The structure that contains the exception list for the message passing through the node.

OutputRoot
The root of the output message.

In a Compute node, the correlation name OutputBody is not valid.

OutputLocalEnvironment
The structure that contains the local environment variables that are sent out from the node.

While this correlation name is always valid, it has meaning only when the `Compute Mode` property of the Compute node indicates that the Compute node is propagating the LocalEnvironment.

OutputDestinationList
The structure that contains the local environment variables that are sent out from the node. Use the correlation name OutputDestinationList for compatibility with earlier versions; if compatibility is not required, use the preferred name OutputLocalEnvironment

OutputExceptionList
The structure that contains the exception list that the node is generating.

While this correlation name is always valid, it has meaning only when the `Compute Mode` property of the Compute node indicates that the Compute node is propagating the ExceptionList.

Parsers

A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

A parser is called when the bit stream that represents an input message is converted to the internal form that can be handled by the broker; this invocation of the parser is known as *parsing*. The internal form, a logical tree structure, is described in “Logical tree structure” on page 1042. It is described as a tree because messages are typically hierarchical in structure; a good example of this structure is XML. The way in which the parser interprets the bit stream is unique to that parser; therefore, the logical message tree that is created from the bit stream varies from parser to parser.

The parser that is called depends on the structure of a message, referred to as the *message template*. Message template information comprises the *message domain*, *message set*, *message type*, and *physical format* of the message. Together, these values identify the structure of the data that the message contains.

A parser is also called when a logical tree that represents an output message is converted into a bit stream; this action by the parser is known as *writing*. Typically, an output message is generated by an output node at the end of the message flow. However, you can connect more nodes to an output node to continue processing of the message.

The message domain identifies the parser that is used to parse and write instances of the message. The remaining parts of the message template, message set, message type, and physical format, are optional, and are used by model-driven parsers such as the MRM parser.

The logical structure of the message typically maps to the business content of the message; for example, it contains a customer name, address, and account number. It is only when you send a message across a connection that the physical characteristics are important, and influence the construction of the bit stream.

The broker requires access to a parser for every message domain to which your input messages and output messages belong. In addition, the broker requires a parser for every identifiable message header that is included in the input or output message. Parsers are called when required by the message flow.

Body parsers

WebSphere Message Broker provides built-in support for messages in the following message domains by providing message body parsers:

- MRM ("MRM parser and domain" on page 1111)
- XMLNSC, XMLNS, and XML ("XML parsers and domains" on page 1084)
- SOAP ("SOAP parser and domain" on page 1082)
- DataObject ("DataObject parser and domain" on page 1114)
- JMSMap and JMSStream ("JMS parsers and domains" on page 1116)
- MIME ("MIME parser and domain" on page 1117)
- BLOB ("BLOB parser and domain" on page 1124)
- IDOC ("IDOC parser and domain" on page 1126)
- JSON ("JSON parser and domain" on page 1128)

See "Which body parser should you use?" on page 1077 for a discussion about which message body parser to use under what circumstances.

You specify which message domain to use for your message at the place in the message flow where parsing or writing is initiated.

- To parse a message bit stream, typically you set the *Message Domain* property of the input node that receives the message. But, if you are initiating the parse operation in ESQL, use the **DOMAIN** clause of the **CREATE** statement.

  The message tree that is created is described in "Message tree structure" on page 1045. Its exact form might change as it progresses through the message flow, depending on what the nodes are doing.

  The last child element of the Root element of the message tree takes the name of the body parser that created the tree. For example, if the *Message Domain* property was set to `MRM`, the last child element of Root is called MRM, which indicates that the message tree is owned by the MRM parser.
- To write a message, the broker calls the owning body parser to create the message bit stream from the message tree.

Some body parsers are *model-driven*, which means that they use predefined messages from a message set when parsing and writing. The MRM, SOAP, DataObject, IDOC, and (optionally) XMLNSC parsers are model-driven parsers. To use these parsers, messages must be modeled in a message set and deployed to the broker from the WebSphere Message Broker Toolkit.

Other body parsers are *programmatic*, which means that the messages that they parse and write are *self-defining* messages, and no message set is required. See "Predefined and self-defining messages" on page 1076.

When you use a model-driven parser, you must also specify the *Message Set* and, optionally, the *Message Type* and *Message Format* so that the parser can locate the deployed message definition with which to guide the parsing or writing of the message.

To parse a message bit stream, typically you set the *Message Set*, *Message Type*, and *Message Format* properties of the input node that receives the message. Or, if you are initiating the parse operation in ESQL, you use the **SETTYPE**, and **FORMAT** clauses of the **CREATE** statement. This information is copied into the *Properties* folder of the message tree.

To write a message, the broker calls the owning body parser to create the message bit stream from the message tree. If the parser is a model-driven parser, it uses the *MessageSet*, *MessageType*, and *MessageFormat* fields in the Properties folder.

Whether *Message Type* or *Message Format* are needed depends on the message domain.

Even if the body parser is not model-driven, it is good practice to create and use a message set in the WebSphere Message Broker Toolkit, because it simplifies the development of your message flow applications, even though the message set is not deployed in the broker runtime environment. See "Why model messages?" on page 1158 for information about the advantages of creating a message set.

Header parsers

WebSphere Message Broker also provides parsers for the following message headers, which your applications can include in input or output messages:

- WMQ MQMD ("The MQMD parser" on page 4249)
- WMQ MQMDE ("The MQMDE parser" on page 4251)
- WMQ MQCFH ("The MQCFH parser" on page 4245)
- WMQ MQCIH ("The MQCIH parser" on page 4246)
- WMQ MQDLH ("The MQDLH parser" on page 4248)
- WMQ MQIIH ("The MQIIH parser" on page 4248)
- WMQ MQRFH ("The MQRFH parser" on page 4252)
- WMQ MQRFH2 and MQRFH2C ("The MQRFH2 and MQRFH2C parsers" on page 4253)
- WMQ MQRMH ("The MQRMH parser" on page 4253)
- WMQ MQSAPH ("The MQSAPH parser" on page 4254)
- WMQ MQWIH ("The MQWIH parser" on page 4255)
- WMQ SMQ_BMH ("The SMQ_BMH parser" on page 4256)
- JMS header ("Representation of messages in the JMS Transport" on page 1691)
- HTTP headers ("HTTP headers" on page 1583)

All header parsers are programmatic and do not use a message set when parsing or writing.

User-defined parsers

To parse or write message body data or headers that the supplied parsers do not handle, you can create user-defined parsers that use the WebSphere Message Broker user-defined parser programming interface.

Tip: No parser is provided for messages, or parts of messages, in the WMQ format `MQFMT_IMS_VAR_STRING`. Data in this format is often preceded by an MQIIH header (format `MQFMT_IMS`). WebSphere Message Broker treats such data as a BLOB message. If you change the CodedCharSetId or the encoding of such a message in a message flow, the `MQFMT_IMS_VAR_STRING` data is not converted, and the message descriptor or preceding header does not correctly describe that part of the message. If you need the data in these messages to be converted, use the MRM domain and create a message set to model the message content, or provide a user-defined parser.

Related concepts:

"Message modeling" on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

"Message modeling concepts" on page 1155
Message modeling is a way of predefining the message formats that are used by your applications.

"Why model messages?" on page 1158
WebSphere Message Broker supplies a range of parsers to parse and write message formats. Some message formats are self-defining and can be parsed without reference to a model. Most message formats, however, are not self-defining, and the parser must have access to a predefined model that describes the message, if it is to parse it correctly.

"Message domains and parsers" on page 1159
WebSphere Message Broker supplies a range of *parsers* to parse and write message formats.

"Which body parser should you use?" on page 1077
The characteristics of the messages that your applications exchange indicate which body parser you must use.

"User-defined parsers" on page 3010
A user-defined parser is a program that interprets the bit stream of an incoming message and creates an internal representation of the message in a tree structure. A user-defined parser can also regenerate a bit stream for an outgoing message from the internal message tree representation

"Developing user-defined extensions" on page 2970
A user-defined extension is a component that you design and implement to extend the function of WebSphere Message Broker.

Related tasks:

Chapter 9, "Developing message flow applications," on page 1019
Develop message flows to process your business messages and data.

Related reference:

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

"C language user-defined parser API" on page 6538
The C language user-defined parser API consists of two complementary sets of functions that you can use to define the function of your parser.

Predefined and self-defining messages:

Both predefined and self-defining messages are supported.

Each message that flows through a broker has a specific structure that is meaningful to the applications that send or receive that message.

You can use:

- Messages that you have modeled in the Broker Application Development perspective of the WebSphere Message Broker Toolkit; these messages are referred to as *predefined messages*. A model-driven parser requires predefined messages.
- Messages that can be parsed without a model; these are called *self-defining messages*.

Predefined messages: When you create a message in the WebSphere Message Broker Toolkit, you define the fields (*Elements*) in the message, along with special field types that you might need, and specific values (Value Constraints) to which the fields might be restricted.

Every message that you model in the WebSphere Message Broker Toolkit must be a member of a message set. You can group related messages together in a message set; for example, request and response messages for a bank account query can be defined in a single message set.

When you deploy a message set to a broker, the message model is sent to the broker in a form appropriate to the parser that is used to parse and write the message.

For information about the benefits of predefining messages, see "Why model messages?" on page 1158

The following samples demonstrate how to model messages in XML, CWF and TDS formats:

- Video Rental
- Comma Separated Value (CSV)

The following samples provide message sets for industry-standard message formats:

- EDIFACT
- FIX
- SWIFT
- X12

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Self-defining messages: You can create and route messages that are self-defining. The best example of a self-defining message is an XML document.

You can also model self-defining messages in the WebSphere Message Broker Toolkit. However, you do not need to deploy these message sets to the brokers that

support those message flows. For further information about why you might want to model these messages, see “Why model messages?” on page 1158.

Several samples, including the following, use self-defining XML messages and do not require a message set, consequently fewer resources need to be defined:

- Large Messaging
- Airline Reservations

The following sample demonstrates how you can transform a message from self-defining XML to a predefined binary format:

- Coordinated Request Reply

The following sample demonstrates how you can extract information from an XML message and transform it into BLOB format for storage in a database:

- Data Warehouse

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

“Message modeling” on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

“Parsers” on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

“Why model messages?” on page 1158
WebSphere Message Broker supplies a range of parsers to parse and write message formats. Some message formats are self-defining and can be parsed without reference to a model. Most message formats, however, are not self-defining, and the parser must have access to a predefined model that describes the message, if it is to parse it correctly.

Which body parser should you use?:

The characteristics of the messages that your applications exchange indicate which body parser you must use.

WebSphere Message Broker provides a range of message parsers. Each parser processes either message body data for messages in a particular message domain (for example, XML), or particular message headers (for example, the MQMD).

Review the messages that your applications send to the broker, and determine to which message domain the message body data belongs, using the following criteria as a guide.

If your application data uses SOAP-based web services, including SOAP with Attachments (MIME) or MTOM
Use the SOAP domain. The SOAP domain has built-in support for WS-Addressing and WS-Security standards.

If your application data uses JSON format, as maybe used in RESTful web services
Use the JSON domain.

If your application data is in XML format other than SOAP
The domain that you use depends on the nature of the XML documents and the processing that you want to perform. See "Which XML parser should you use?" on page 1080

If your application data comes from a C or COBOL application, or consists of fixed-format binary data
Use the MRM domain with a Custom Wire Format (CWF) physical format.

If your application data consists of formatted text, perhaps with field content that is identified by tags, or separated by specific delimiters, or both
Use the MRM domain with a Tagged/Delimited String (TDS) physical format.

If your application data is created using the JMS API
The domain that you use depends on the type of the JMS message. For a full description of JMS message processing, see "JMS message as input" on page 1693.

If your application data is from a WebSphere Adapter such as the adapters for SAP, PeopleSoft, or Siebel
Use the DataObject domain.

If your application data is in SAP text IDoc format, such as those exported using the WebSphere MQ Link for R3
Use the MRM domain with a Tagged/Delimited String (TDS) physical format.

If your application data is in MIME format other than SOAP with Attachments (for example, RosettaNet)
Use the MIME domain. If the message is multipart MIME, you might have to parse specific parts of the message with other parsers. For example, you might use the XMLNSC parser to parse the XML content of a RosettaNet message.

If you do not know, or do not have to know, the content of your application data Use the BLOB domain.

"JMS message as input" on page 1693
The JMS message is a Java object, and therefore you cannot parse the message as a bit stream. When the message is received, the header data, property data, and payload data are extracted by using the JMS API.

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Which XML parser should you use?:

If your messages are general-purpose XML documents, you can use one of the dedicated XML domains (XMLNSC or XMLNS) to parse the message, or you can use the MRM domain to parse the message.

Note: Although SOAP XML can be parsed using any namespace-aware XML parser, use the dedicated SOAP domain to parse SOAP XML because the SOAP domain provides full support for SOAP with Attachments, and standards such as WS-Addressing and WS-Security.

Note: The XML domain is deprecated. Do not use it for developing new message flows. The XML domain still works with existing message flows.

Which XML parser you choose depends on the nature of your XML messages, and the transformation logic that you want to use. The differentiating features of each domain are:

- The XMLNSC parser has a new architecture that gives significant performance improvements over the XMLNS and XML parsers.
- The XMLNSC parser can be used with or without an XML Schema that is generated from a message set. Using a message set with the XMLNSC parser allows the parser to operate in validating mode which provides the following capabilities:
  - XML Schema 1.0 compliant validation when parsing and writing.
  - The XML Schema indicates the real data type of a field in the message instead of always treating the field as a character string.
  - Base64 binary data can be automatically decoded.
- The MRM parser must be used with a message dictionary that is generated from a message set. This message dictionary enables the MRM parser to provide the following capabilities: For example:
  - Validation against the dictionary when parsing and writing. Note that validation is not XML Schema 1.0 compliant.
  - The dictionary indicates the real data type of a field in the message instead of always treating the field as a character string.
  - Base64 binary data can be automatically decoded.
- The XMLNS parser is programmatic and does not use a model when parsing.

  This means that:
  - All data in an XML message is treated as character strings.
  - Validation is not possible when parsing and writing.
- The MRM parser uses information from the XML physical format of a message set to simplify the task of creating transformation logic:
  - Date and time information can be extracted from a data value using a specified format string.
  - When creating output messages, the MRM parser can automatically generate the XML declaration, and other XML constraints.
- The XMLNSC and XMLNS parsers do not use XML physical format information from a message set. Transformation logic must explicitly create all constructs in an output message.

- The MRM parser discards some parts of an XML message when parsing; for example, white space formatting, XML comments, XML processing instructions, and inline DTDs. If you use this parser, you cannot create these constructs when building an output message.
- The XMLNSC parser, by default, discards white space formatting, XML comments, XML processing instructions, and inline DTDs. However, options are provided to preserve all of these constructs, except inline DTDs. You can create them all, except inline DTDs, when constructing an output message.
- The XMLNS parser preserves all parts of an XML document, including white space formatting. You can create all XML constructs when constructing an output message.
- The XMLNSC and MRM parsers build compact message trees that use fewer syntax elements than the XMLNS parser for attributes and simple elements. This makes these parsers more suitable than the XMLNS parser for parsing large XML messages.
- The XMLNS parser builds a message tree that conforms more closely than the XMLNSC or MRM parsers to the XML Data Model. You might want to use this parser if you are using certain XPath expressions to access the message tree, and the relative position of parent and child nodes is important, or if you are accessing text nodes directly.
- The XMLNS parser holds the text content of an element as a child of the element, whereas the XMLNSC parser builds a compact tree. To update a text value in the compact tree of the XMLNSC parser, use ESQL to set the VALUE of the target node. For example:

  ```
  Set OutputRoot.XMLNSC.TestMsg.Value3 VALUE = InputRoot.XMLNSC.TestMsg.Value2;
  ```

Tip: If performance is critical, use the XMLNSC domain.

Tip: If you need to validate the content and values in XML messages, use the XMLNSC domain.

Tip: If you need to preserve formatting in XML messages on output, use the XMLNSC domain with the option to retain mixed content.

Tip: If you require the message tree to conform as closely as possible to the XML data model, perhaps because you are using certain XPath expressions to access the message tree, use the XMLNS domain.

Tip: If you are taking non-XML data that has been parsed by the CWF or TDS formats of the MRM domain, and merely transforming the data to the equivalent XML, use the MRM domain. You can achieve this by adding an XML physical format to the message set with default values, and changing the Message Format in the Properties folder of the message tree.

"Message modeling concepts" on page 1155
Message modeling is a way of predefining the message formats that are used by your applications.

"Why model messages?" on page 1158
WebSphere Message Broker supplies a range of parsers to parse and write message formats. Some message formats are self-defining and can be parsed without reference to a model. Most message formats, however, are not self-defining, and the parser must have access to a predefined model that describes the message, if it is to parse it correctly.

"The message model" on page 1160
The message model consists of the following components.

"Which body parser should you use?" on page 1077
The characteristics of the messages that your applications exchange indicate which body parser you must use.

"XML parsers and domains" on page 1084
You can use XML domains to parse and write messages that conform to the W3C XML standard.

"MRM parser and domain" on page 1111
You can use the MRM domain to parse and write a wide range of message formats.

"SOAP parser and domain"
You can use the SOAP parser to create a common WSDL-based logical tree format for working with Web services, independent of the physical bitstream format.

"Physical formats in the MRM domain" on page 1211
Each message definition file within a message set describes both the *logical structure* of your messages, and the *physical formats* that describe the precise appearance of your message bit stream during transmission.

SOAP parser and domain:

You can use the SOAP parser to create a common WSDL-based logical tree format for working with Web services, independent of the physical bitstream format.

Use the SOAP parser in conjunction with the SOAP nodes in your message flow.

Messages in the SOAP domain are processed by the SOAP parser. The SOAP parser creates a common logical tree representation for all SOAP-based Web services and validates the message against a WSDL definition. If a runtime message is not allowed by the WSDL, an exception is thrown, otherwise the `portType` and `operation` names from the WSDL are saved in the logical tree.

The SOAP domain offers `WS-*` processing, together with a canonical tree shape that is independent of the wire format (XML or MIME).

The standards supported are:

- WSDL 1.1
- SOAP 1.1 and 1.2
- MIME 1.0
- Message Transmission Optimization Mechanism (MTOM) 1.0

A WSDL 1.1 definition must be deployed to describe the web service messages that the SOAP domain needs to parse and write at run time. Therefore, the SOAP parser is always model-driven. The bitstream format for these runtime messages can be SOAP 1.1 or SOAP 1.2, optionally wrapped by MIME as an SwA (SOAP with Attachments) or MTOM message.

When a message set that supports the SOAP domain is added to a broker archive (BAR) file, XML schemas are created automatically from the message definition files in the message set, and any WSDL files in the message set are added to the BAR file. The WSDL and XML schema are deployed to the broker and used by the SOAP parser.

If you want the SOAP domain to parse your SOAP Web service, complete the following steps:

1. Create a new message set, or locate an existing message set.
2. Ensure that either the message set has its *Default message domain* project set to `SOAP`, or the *SOAP* check box (under *Supported message domains*) is selected, to indicate that the message set supports the SOAP domain.
3. Import your WSDL file to create a message definition file. The WSDL is also added to the message set. Message definition files for the SOAP envelope and the SOAP logical tree are also added to the message set automatically.
4. Add the message set to a broker archive (BAR) file, which generates the required XML Schema and WSDL in a file with extension .xsdzip, and deploy the BAR file to the broker.
5. If you associate your WSDL with a SOAP node in your message flow, the *Message Set* property is automatically set in the node. The *Message domain* property is always pre-selected as `SOAP`.

Tip: The SOAP parser invokes the XMLNSC parser to parse and validate the XML content of the SOAP Web service. See "XMLNSC parser" on page 1090.

Related concepts:

"What is SOAP?" on page 1604
SOAP is an XML message format used in Web service interactions. SOAP messages are typically sent over HTTP or JMS, but other transport protocols can be used. The use of SOAP in a specific Web service is described by a WSDL definition.

"SOAP message details" on page 1084
A SOAP message consists of an `<Envelope>`, which is the root element in every SOAP message, and this contains two child elements, an optional `<Header>` and a mandatory `<Body>`.

"SOAP tree overview" on page 1611
This tree format allows you to access the key parts of the SOAP message in a convenient way.

"Parsers" on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

"XMLNSC parser" on page 1090
The XMLNSC parser is a flexible, general-purpose XML parser that offers high performance XML parsing and optional XML Schema validation.

"Message modeling" on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

Related tasks:

"Designing a message flow" on page 1455
A message flow can perform a wide range of operations, depending on your business and operational requirements. For best performance and capability, you must design it to include the most appropriate nodes.

Reference information in this section can help you develop and configure message models.

SOAP message details:

A SOAP message consists of an `<Envelope>`, which is the root element in every SOAP message, and this contains two child elements, an optional `<Header>` and a mandatory `<Body>`.

If the SOAP message has attachments, the 'envelope' is wrapped by MIME, or is encoded as MTOM.

For further information on the structure of a SOAP message, see "The structure of a SOAP message" on page 1605.

Related concepts:

"The SOAP body" on page 1608
The SOAP body (the <Body> element) is a mandatory sub-element of the SOAP envelope, which contains information intended for the ultimate recipient of the message.

"The SOAP header" on page 1606
The SOAP header (the <Header> element) is an optional sub-element of the SOAP envelope, and is used to pass application-related information that is processed by SOAP nodes along the message flow.

"What is SOAP?" on page 1604
SOAP is an XML message format used in Web service interactions. SOAP messages are typically sent over HTTP or JMS, but other transport protocols can be used. The use of SOAP in a specific Web service is described by a WSDL definition.

XML parsers and domains:

You can use XML domains to parse and write messages that conform to the W3C XML standard.

The term *XML domains* refers to a group of three domains that are used by WebSphere Message Broker to parse XML documents.

When reading an XML message, the parser that is associated with the domain builds a message tree from the input bit stream. The input bit stream must be a well-formed XML document that conforms to the W3C XML Specification (version 1.0 or 1.1).

When writing a message, the parser creates an XML bit stream from a message tree.

The domains have different characteristics, for guidance about which domain to choose, see "Which XML parser should you use?" on page 1080.

XMLNSC domain

The XMLNSC domain is the preferred domain for parsing all general purpose XML messages, including those messages that use XML namespaces. This parser is the preferred parser for the following reasons:

- The XMLNSC parser has an architecture that results in ultra-high performance when parsing all kinds of XML.
- The XMLNSC parser reduces the amount of memory that is used by the logical message tree that is created from the parsed message. The default behavior of the parser is to discard non-significant white space and

mixed content, comments, processing instructions, and embedded DTDs; however controls are provided to retain mixed content, comments, and processing instructions, if required.

- The XMLNSC parser can operate as a model-driven parser, and can validate XML messages against XML Schemas generated from a message set, to ensure that your XML messages are correct.

XMLNS domain
If the XMLNSC domain does not meet your requirements, use the alternative namespace-aware domain and parser.

XML domain
The XML domain is not namespace-aware. It is deprecated and must not be used to develop new message flows.

The MRM domain also provides XML parsing and writing facilities. For guidance on when you might use MRM XML instead of one of the XML parsers, see "Which XML parser should you use?" on page 1080.

By default, the three XML parsers are *programmatic* parsers and do not use a message set at run time when parsing and writing. However, the XMLNSC parser can operate as a model-driven parser and can validate XML messages for correctness against XML Schemas generated from a message set.

When you use the XMLNS or XML parsers, or the XMLNSC parser without a message set, it is good practice to create and use a message set in the WebSphere Message Broker Toolkit; this action simplifies the development of your message flow applications, even though the message set is not deployed to the broker run time.

For the advantages of creating a message set, see "Why model messages?" on page 1158.

The XML parsers are on-demand parsers. For more information, see "Parsing on demand" on page 4173.

The topics in this information center provide a summary of XML terminology, concepts, and message constructs. These aspects are important when you use XML messages in your message flows.

Tip: For more detailed information about XML, see the World Wide Web Consortium (W3C) Web site.

Example XML message parsing: A simple XML message might take the following form:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE Envelope
PUBLIC "http://www.ibm.com/dtds" "example.dtd"
[<!ENTITY Example_ID "ST_TimeoutNodes Timeout Request Input Test Message">]
>
<Envelope version="1.0">
 <Header>
  <Example>&Example_ID;</Example>
  <!-- This is a comment  -->
 </Header>
 <Body  version="1.0">
  <Element01>Value01</Element01>
  <Element02/>
  <Element03>
```

```
   <Repeated>ValueA</Repeated>
   <Repeated>ValueB</Repeated>
  </Element03>
  <Element04><P>This is <B>bold</B> text</P></Element04>
 </Body>
</Envelope>
```

The following sections show the output that is created by the Trace node when this example message has been parsed in the XMLNS and XMLNSC parsers. They demonstrate the differences in the internal structures that are used to represent the data as it is processed by the broker.

Example XML Message parsed in the XMLNS domain: In the following example, the white space elements within the tree are present because of the space, tab, and line breaks that format the original XML document; for clarity, the actual characters in the trace have been replaced with `'WhiteSpace'`. White space within an XML element does have business meaning, and is represented by using the Content syntax element. The XmlDecl, DTD, and comments, are represented in the XML domain using explicit syntax elements with specific field types.

```
(0x01000010):XMLNS        = (
    (0x05000018):XML      = (
      (0x06000011): = '1.0'
      (0x06000012): = 'UTF-8'
      (0x06000014): = 'no'
    )
    (0x06000002):         = 'WhiteSpace'
    (0x05000020):Envelope = (
      (0x06000004): = 'http://www.ibm.com/dtds'

```

```
      )
      (0x02000000):         = 'WhiteSpace'
      (0x01000000):Repeated = (
        (0x02000000): = 'ValueB'
      )
      (0x02000000):         = 'WhiteSpace'
    )
    (0x02000000):          = 'WhiteSpace'
    (0x01000000):Element04 = (
      (0x01000000):P = (
        (0x02000000):  = 'This is '
        (0x01000000):B = (
          (0x02000000): = 'bold'
        )
        (0x02000000):  = ' text'
      )
    )
    (0x02000000):          = 'WhiteSpace'
  )
  (0x02000000):        = 'WhiteSpace'
)
```

Example XML Message parsed in the XMLNSC domain: The following trace shows the elements that are created to represent the same XML structure within the compact XMLNSC parser in its default mode. In this mode, the compact parser does not retain comments, processing instructions, or mixed text.

The example illustrates the significant saving in the number of syntax elements that are used to represent the same business content of the example XML message when using the compact parser.

By not retaining mixed text, all of the white space elements that have no business data content are no longer taking any space in the broker message tree at run time. However, the mixed text in `Element04.P` is also discarded, and only the value of the child folder, `Element04.P.B`, is held in the tree; the text `This is` and `text` in `P` is discarded. This type of XML structure is not typically associated with business data formats; therefore, use of the compact XMLNSC parser is typically desirable. However, if you want to this type of processing, either do not use the XMLNSC parser, or use it with *Retain mixed text mode* enabled.

The handling of the XML declaration is also different in the XMLNSC parser. The version, encoding, and stand-alone attributes are held as child entities of the XmlDeclaration, rather than as elements with a particular field type.

```
(0x01000000):XMLNSC     = (
    (0x01000400):XmlDeclaration = (
      (0x03000100):Version    = '1.0'
      (0x03000100):Encoding   = 'UTF-8'
      (0x03000100):StandAlone = 'no'
    )
    (0x01000000):Envelope       = (
      (0x03000100):version = '1.0'
      (0x01000000):Header  = (
        (0x03000000):Example = 'ST_TimeoutNodes Timeout Request Input Test Message'
      )
      (0x01000000):Body    = (
        (0x03000100):version   = '1.0'
        (0x03000000):Element01 = 'Value01'
        (0x01000000):Element02 =
        (0x01000000):Element03 = (
          (0x03000000):Repeated = 'ValueA'
          (0x03000000):Repeated = 'ValueB'
        )
```

```
        (0x01000000):Element04 = (
          (0x01000000):P = (
            (0x03000000):B = 'bold'
          )
        )
  )
```

The following samples use the XML parser to process messages:

- Coordinated Request Reply
- Large Messaging
- Message Routing

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Some predefined message models are supplied with the WebSphere Message Broker Toolkit and can be imported by using the New Message Definition File wizard and selecting the IBM supplied message option. See "IBM supplied messages that you can import" on page 6367.

A self-defining XML message carries the information about its content and structure within the message in the form of a document that adheres to the XML specification. Its definition is not held anywhere else.

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

developerWorks

XMLNSC parser:

The XMLNSC parser is a flexible, general-purpose XML parser that offers high performance XML parsing and optional XML Schema validation.

The XMLNSC parser has a range of options that make it suitable for most XML processing requirements. Some of these options are only available in the XMLNSC parser.

Although the XMLNSC parser is capable of parsing XML documents without an XML Schema, extra features of the parser become available when it operates in model-driven mode. In model-driven mode, the XMLNSC parser is guided by an XML Schema, which describes the shape of the message tree (the logical model).

XML Schemas are created automatically from the content of a message set when the message set is added to a broker archive (BAR) file. The XML Schemas are deployed to the broker and used by the XMLNSC parser to validate your XML messages. Validation is fully compliant with the XML Schema 1.0 specification.

For guidance on when to use the XMLNSC domain and parser, see "Which XML parser should you use?" on page 1080.

If you want the XMLNSC domain to parse a message, select *Message Domain* as `XMLNSC` on the appropriate node in the message flow. Additionally, if you want the XMLNSC parser to validate your messages, perform the additional steps that are described in "XMLNSC validation" on page 1099.

Features of the XMLNSC parser

Feature	Present	Description
Namespace support	Yes	Namespace information is used if it is present. No user configuration is required. See "XML parsers namespace support" on page 1109.
On-demand parsing	Yes	See "Parsing on demand" on page 4173.
Compact message tree	Yes	Less memory is used when building a message tree from an XML document. See "Manipulating messages in the XMLNSC domain" on page 2546.
Opaque parsing	Yes	One or more elements can be parsed opaquely. See "XMLNSC opaque parsing" on page 1097.
Ultra high performance	Yes	The architecture of the XMLNSC parser means that the parser's use of processor resources is significantly less than that of the other XML parsers.
Validation	Yes	See the table that follows this one.

Feature	Present	Description
Inline DTD support	Partial	Inline DTDs are processed but discarded. See “XMLNSC DTD support” on page 1103.
XML Data Model compliance	Partial	The compact nature of the message tree means that some XPath queries are not supported.

The following features are only available when message validation is enabled. See “XMLNSC validation” on page 1099.

Feature	Description
Message validation	Validates compliance with the XML Schema 1.0 specification.
xsi:nil support	Sets the value of an element to NULL if it has xsi:nil=”true” and the XML Schema indicates that it is nillable.
Default value support	Sets the value of an empty element, or missing attribute, to its default value, according to XML Schema rules.
Use correct simple types	Allows the use of the simple types that are defined in the XML Schema when building the message tree.
Base64 support	Converts base64 data to BLOB when parsing. Converts BLOB to base64 when writing.

If you specify the SOAP domain as the owner of a SOAP Web Services message, the SOAP parser invokes the XMLNSC parser in model-driven mode to parse the XML content of the SOAP message.

If you specify the DataObject domain as the owner of a WebSphere Adapter message, and the message is written to a destination other than a WebSphere Adapter, the DataObject parser invokes the XMLNSC parser to write the message as XML.

XMLNSC empty elements and null values:

Empty elements and null values occur frequently in XML documents.

A robust message flow must be able to recognize and handle empty elements and null values. Similarly, elements in a message tree might have a NULL value, an empty value, or no value at all. This topic explains the parsing and writing of these values by the XMLNSC domain. For details on processing null values in Graphical Data Maps and ESQL, see "Handling null values" on page 1140.

Parsing

Description	XML input parsed by XMLNSC	Value of 'element' in message tree
Empty element value	`<element/>`	Empty string
Empty element value	`<element></element>`	Empty string
Folder with child elements	`<element><childElement/></element>`	No value
Nil element value	`<element xsi:nil="true"/>`	No value and a child `xsi:nil` attribute with the value 'true'.

Both forms of an empty element result in the same value in the message tree.

Writing

Description	Value of 'element' in message tree	XML output from XMLNSC parser
Empty element value	Empty string	`<element/>`
Null element value	NULL	`<element/>`
Folder with child elements	No value	`<element><childElement/></element>`
Nil element value	Empty string, NULL, or Folder	`<element xsi:nil="true"/>` Note that the XMLNSC parser produces only `xsi:nil` attributes that are already in the message tree. It does not automatically produce `xsi:nil` attributes for all message tree elements that have a NULL value and are 'nillable'.

Empty elements

An empty element can take two forms in an XML document:

- `<element/>`
- `<element></element>`

The XMLNSC parser treats both forms in the same way. The element is added to the message tree with a value of "" (the empty string).

When a message tree is produced by the XMLNSC parser, it always uses the first form for elements that have a value of "" (the empty string) in the input XML message.

Elements with an `xsi:nil` attribute

If validation is enabled for the flow, the XMLNSC parser performs the following validations:

- The 'nillable' property of an element definition in the XML schema is set to 'true'.

  If the element in the document has an `xsi:nil` attribute with the value 'true', the element must not have a value, or contain any child elements.
- The 'nillable' property of an element definition in the XML schema is set to 'false'.

  The element in the input document must not have an `xsi:nil` attribute.

If an element in the input document has an `xsi:nil` attribute, the XMLNSC parser creates an element in the message tree with no value, and a child `xsi:nil` attribute with the value 'true' or 'false'.

When a message tree is written to a bit stream by the XMLNSC parser, if the value of the element is empty, NULL, or no value, and the element has no child

elements, the element is written as <element/>. If the element has an xsi:nil attribute, it is written exactly like any other attribute.

Note that the XMLNSC parser produces only xsi:nil attributes that are already in the message tree. It does not automatically produce xsi:nil attributes for all message tree elements that have a NULL value and are 'nillable'.

"XMLNSC DTD support" on page 1103
The input XML message might contain an inline DTD.

"Handling null values" on page 1140
A business message might contain fields that are either empty or have a specific out-of-range value. In these cases, the application that receives the message is expected to treat the field as if it did not have a value. The logical message tree supports this concept by enabling the value of any element to be set to NULL.

XMLNSC: Using field types:

The XMLNSC parser sets the field type on every syntax element that it creates.

The field type indicates the type of XML construct that the element represents. The XMLNSC parser uses the field type when writing a message tree. The field type can be set by using ESQL or Java to control the output XML. The field types that are used by the XMLNSC parser must be referenced by using constants with names that are prefixed by 'XMLNSC.'

Tip: Field type constants that have the prefix 'XML.' are for use with the XMLNS and XML parsers only, and are not valid with the XMLNSC or MRM parsers.

Field types for creating syntax elements

Use the following field type constants to create syntax elements in the message tree. The XMLNSC parser uses these values when creating a message tree from an input message.

XML construct	XMLNSC Field Type constant	Value
Simple Element	XMLNSC.Field XMLNSC.CDataField	0x03000000 0x03000001
Attribute	XMLNSC.SingleAttribute XMLNSC.Attribute	0x03000101 0x03000100
Mixed content	XMLNSC.Value XMLNSC.CDataValue	0x02000000 0x02000001
Namespace Declaration	XMLNSC.SingleNamespaceDecl XMLNSC.NamespaceDecl	0x03000102 0x03000103
Complex element	XMLNSC.Folder	0x01000000
Inline DTD	XMLNSC.DocumentType	0x01000300
XML declaration	XMLNSC.XmlDeclaration	0x01000400
Entity reference	XMLNSC.EntityReference	0x02000100
Entity definition	XMLNSC.SingleEntityDefinition XMLNSC.EntityDefinition	0x03000301 0x03000300
Comment	XMLNSC.Comment	0x03000400
Processing Instruction	XMLNSC.ProcessingInstruction	0x03000401

Field types for path expressions (generic field types)

Use the following field type constants when querying the message tree by using a path expression; for example:

```
SET str = FIELDVALUE(InputRoot.e1.(XMLNSC.Attribute)attr1)
```

It is good practice to specify field types when querying a message tree built by the XMLNSC parser. This makes your ESQL code more specific and more readable, and it avoids incorrect results in some cases. However, care is required when choosing which field type constant to use. When you use the XMLNSC parser, use a generic field type constant when querying the message tree. This allows your path expression to tolerate variations in the input XML.

The generic field type constants are listed in the following table:

XML construct	XMLNSC Field Type constant	Purpose
Tag	XMLNSC.Element	Matches any tag, whether it contains child tags (XMLNSC.Folder) or a value (XMLNSC.Field)
Element	XMLNSC.Field	Matches a tag which contains normal text, CData, or a mixture of both. Does not match tags which contain child tags.
Attribute	XMLNSC.Attribute	Matches single-quoted and double-quoted attributes
Mixed content	XMLNSC.Value	Matches normal text, CData, or a mixture of both
XML Declaration	XMLNSC.NamespaceDecl	Matches single- and double-quoted declarations

If you write

```
InputRoot.e1.(XMLNSC.DoubleAttribute)attrName
```

your path expression does not match a single-quoted attribute. If you use the generic field type constant *XMLNSC.Attribute*, your message flow works with either single-quoted or double-quoted attributes.

Note that you should always use the field type constants and not their numeric values.

Field types for controlling output format

The following field types are provided for XML Schema and base64 support. Do not use these field type constants in path expressions; use them in conjunction with XMLNSC.Attribute and XMLNSC.Field to indicate the required output format for DATE and BLOB values. See "XMLNSC: XML Schema support" on page 2559 for further information.

XMLNSC Field Type constant	Purpose	Value
XMLNSC.gYear	The value must be a DATE. If the field type includes this value, the DATE value is produced by using the XML Schema gYear format.	0x00000010
XMLNSC.gYearMonth	The value must be a DATE. If the field type includes this value, the DATE value is produced by using the XML Schema gYearMonth format.	0x00000040
XMLNSC.gMonth	The value must be a DATE. If the field type includes this value, the DATE value is produced by using the XML Schema gMonth format.	0x00000020
XMLNSC.gMonthDay	The value must be a DATE. If the field type includes this value, the DATE value is produced by using the XML Schema gMonthDay format.	0x00000050
XMLNSC.gDay	The value must be a DATE. If the field type includes this value, the DATE value is produced by using the XML Schema gDay format.	0x00000030
XMLNSC.base64Binary	The value must be a BLOB. The value is produced with base64 encoding.	0x00000060
XMLNSC.List	The element must be XMLNSC.Attribute or XMLNSC.Field. If the field type includes this value, the values of all child elements in the message tree are produced as a space-separated list.	0x00000070

Field types for direct output

Use the following field types to produce pre-constructed segments of an XML document. Character escaping is not done; therefore, take extra care not to construct a badly-formed output document. Use these constants only after carefully exploring alternative solutions.

XMLNSC Field Type constant	Purpose	Value
XMLNSC.Bitstream	The value of this syntax element must be a BLOB. The value is written directly to the output bit stream. For more information about its usage, see "Working with large XML messages" on page 2543.	0x03000200

XMLNSC Field Type constant	Purpose	Value
XMLNSC.AsisElementContent	The value of this syntax element must be CHARACTER. The value is written directly to the output bit stream. No character substitutions are performed. Use this element with care.	0x03000600

The XMLNSC parser provides full support for namespaces.

XMLNSC opaque parsing:

Opaque parsing is a performance feature that is offered by the XMLNSC domain.

If you are designing a message flow and you know that certain elements in a message are never referenced by the message flow, you can specify that these elements are parsed opaquely. This reduces the costs of parsing and writing the message, and might improve performance in other parts of the message flow.

Use the property *Opaque Elements* on the *Parser options* page of the relevant message flow node to specify the elements that you want to be parsed opaquely. This property specifies a list of element names. If an element in the input XML message is named in this list, the element is parsed as a single string.

An opaque element cannot be queried like an ordinary element; its value is the segment of the XML bit stream that belongs to the element, and it has no child elements in the message tree, even though it can represent a large subtree in the XML document.

When an opaque element is serialized, the value of the element is copied directly into the output bit stream. The string is converted to the correct code page, but no other changes are made. Because this might produce a bit stream that is not valid XML, some care is required.

Do not parse an element opaquely in any of the following cases:

- The message flow must access one of its child elements.
- The message flow changes the namespace prefix in a way that affects the opaque element or one of its child elements **and** the element is to be copied to the output bit stream.

- The element, or any child element, contains a reference to an internal entity that is defined in an inline DTD **and** the element is to be copied to the output bit stream.
- The element contains child attributes that have default values that are defined in an inline DTD **and** the element is to be copied to the output bit stream.

Make sure that you check the above points before you specify an element for opaque parsing.

Using opaque parsing has some drawbacks. When opaque parsing is enabled, some parts of the message are never parsed, and XML that is either badly formed or not valid is allowed to pass through the message flow without being detected. For this reason, if you enable validation, you cannot use opaque parsing.

The XMLNS domain offers a more limited opaque parsing facility, but this is provided only to support existing applications. Use the XMLNSC domain in new message flows if you want to use opaque parsing.

Related tasks:

"Specifying opaque elements for the XMLNSC parser"
Specify an element as an opaque element so that its content is ignored by the XMLNSC parser.

Specifying opaque elements for the XMLNSC parser:

Specify an element as an opaque element so that its content is ignored by the XMLNSC parser.

Before you begin

About this task

To specify the elements that are to be skipped by the XMLNSC parser:

Procedure

1. Right-click the selected message flow node, click **Properties** and select **Parser Options**.
2. At the bottom of the `XMLNSC Parser Options` panel is an area that lists the elements that have already been selected as opaque elements. Click **Add** to add an element to this list. A new pane **Add Opaque elements Entry** opens.
3. In the **Add Opaque elements Entry** pane, specify the new XML element that you want to be opaquely parsed. Each opaque element must be specified as an ESQL element name or an XPath expression of the form `//prefix:name` (or `//name`, if your input document does not contain namespaces).

   Note: A prefix is used rather than a full URI to identify the namespace; for further information, see "XPath namespace support" on page 2650.

What to do next

Click **Edit** or **Delete** to edit the list of opaque elements.

Related concepts:

"XMLNSC opaque parsing" on page 1097
Opaque parsing is a performance feature that is offered by the XMLNSC domain.

"Extracting information from a message by using XPath 1.0 and a JavaCompute node" on page 2648
XPath is a query language designed for use with XML documents, but you can use it with any tree structure to query contents.

XMLNSC validation:

The XMLNSC parser offers high-performance, standards-compliant XML Schema validation at any point in a message flow.

Validation of the input XML message or the message tree is performed against the XML Schemas that are deployed.

Validation is not the same as *parsing*. When parsing, the XMLNSC parser always checks that the input document is well-formed XML, according to the XML specification. If validation is enabled, the XMLNSC parser also checks that the XML document obeys the rules in the XML Schema.

Enabling XML Schema validation in a message flow

You must complete the following tasks to construct a message flow that validates an XML document in accordance with an XML Schema:

- Enable validation at the appropriate point in the message flow. This is typically achieved by setting the *Validate* property of the appropriate node to `Content` or `Content and Value`. See "Validating messages" on page 1478.
- Ensure that all required XML Schema files are deployed. See "Deploying XML Schemas" later in this section.
- Specify the message set in which the XML Schemas are deployed. Typically, you specify the message set by selecting the `Message Set` property on the node.

Deploying XML Schemas

All XML Schemas that are used by WebSphere Message Broker must be created as message definition files within a message set.

To create and deploy a message set for XML Schema validation:

1. Create a new message set or locate an existing message set.
2. Ensure that the message set has its *Default message domain* set to `XMLNSC`, or that the XMLNSC check box under *Supported message domains* is selected, to indicate that the message set supports the XMLNSC domain.
3. Create a message definition file in the message set to represent your message. If you have an existing XML Schema or DTD that describes your message, you can import it. You can repeat this step for each message that you want to validate.
4. Add the message set to a broker archive (BAR) file, which generates the required XML Schema in a file with extension .xsdzip, and deploy the BAR file to the broker.

Standards compliant validation

XMLNSC validation complies fully with XML Schema v1.0 as defined in the specifications that are available at http://www.w3.org/TR/xmlschema-1/ and http://www.w3.org/TR/xmlschema-2/, with the following minor exceptions:

- Any floating point value that is smaller than 10E-43 is treated as zero.

- Any member of a group or complex type, that has both minOccurs > 1024 and maxOccurs > 1024, is validated as if minOccurs = 0 and maxOccurs is unbounded.

Validating XML v1.1 documents

You can validate documents that conform to the XML v1.1 specification, but support is limited by the fact that the XML Schema v1.0 documents must conform to XML v1.0.

As an example, you cannot always declare an XML v1.1 tag name in XML Schema v1.0. This limitation is not imposed by the XMLNSC parser implementation; it is a limitation of XML Schema v1.0.

Interpreting validation errors

A validation error is an error that results when the XML document breaks the rules that are defined in the XML schema. The XML Schema standard specifies exactly what these rules are, and how they should be applied. Validation errors that the XMLNSC parser issues contain information that links the error to the XML Schema rule that has been violated.

All validation errors are reported in BIP5025 or BIP5026 messages. Both messages begin with text in the following form:

```
XML schema validation error '[cvc-error key: error description]'
```

Examples:

```
'cvc-minInclusive-valid: The value "2" is not valid with respect to the minInclusive facet
with value "3" for type "po:itemCountType".'
```

```
'cvc-complex-type.2.4.a: Expecting element with local name "numItems" but saw "totalValue".'
```

To find the XML Schema rule that has been violated, open the XML Schema specification and search for the error key.

Example 1: Open http://www.w3.org/TR/xmlschema-1/ and search for ‘cvc-minInclusive-valid'. Follow the link to the XML Schema rules for the minInclusive facet.

Example 2: Open http://www.w3.org/TR/xmlschema-1/ and search for ‘cvc-complex-type'. Follow the link to the XML Schema rules for validating the content of a complex type. In this case, the error key contains extra information. The ‘2.4.a' refers to the exact sub-rule that was violated. It should not be included when searching for the rule.

If the XML Schema specification does not provide enough information, you can find more information using a search engine. The XML Schema standard is very widely used, and many online tutorials and other resources are available.

Related reference:

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

XMLNSC message tree options:

The XMLNSC options that are described in this section affect the parsing of an XML document by the XMLNSC parser. They have no effect on XML output.

Retain Mixed Content

Mixed content is XML text which occurs between elements.

```
<parent>
     <childElement1>Not mixed content</childElement1>
     This text is mixed content
     <childElement2>Not mixed content</childElement2>
</parent>
```

By default, the XMLNSC parser discards all mixed content. Mixed content is retained in the message tree if you select *Retain mixed content* in the Parser options page of the input node. For further information, see 'Element with mixed content' in "XMLNSC: Element values and mixed content" on page 2556.

Retain Comments

By default, the XMLNSC parser discards all comments in the input XML. Comments are retained in the message tree if you select *Retain comments* in the Parser options page of the input node. For further information, see 'Comments' in "XMLNSC: Comments and Processing Instructions" on page 2558.

Retain Processing Instructions

By default, the XMLNSC parser discards all processing instructions in the input XML. Processing instructions are retained in the message tree if you select *Retain processing instructions* in the Parser options page of the input node. For further information, see 'Processing Instructions' in “XMLNSC: Comments and Processing Instructions” on page 2558.

Build tree using XML Schema data types

By default, the XMLNSC parser uses the CHARACTER data type for all element and attribute values that the parser creates in the message tree. However, if you are using the XMLNSC parser to validate the XML document, you can select *Build tree using XML Schema data types* in the Parser options page of the input node. This causes element and attribute values to be cast to the message broker data type that most closely matches their XML Schema simple type. The exact mapping between XML schema types and message broker types can be found in “XMLNSC data types.”

The input XML message might contain an inline DTD.

Related tasks:

“Manipulating messages in the XMLNSC domain” on page 2546
If you are writing ESQL to process messages in the XMLNSC domain, it is helpful to learn about the structure of the message tree that the XMLNSC parser builds.

XMLNSC data types:

Mapping between XML Schema simple types and the data types that the XMLNSC parser uses in the message tree when `Build tree using XML Schema types` is specified.

For mapping details, see “ESQL to XML Schema data type mapping” on page 5044. Base64 decoding is automatically performed by the XMLNSC parser.

List types

In the message tree, a list type is represented as a parent node with an anonymous child node for each list item. This allows repeating lists to be handled without any loss of information.

If a list element repeats, the occurrences appear as siblings of one another, and each occurrence has its own set of child nodes representing its own list items.

Mapping from XML Schema simple type to ESQL message tree data type.

XMLNSC DTD support:

The input XML message might contain an inline DTD.

Parsing

If the input XML document has an inline DTD, the XMLNSC parser reads and uses information in the DTD while parsing, but does not add the DTD information to the message tree.

Internal entity definitions in the DTD are used to automatically expand entity references that are encountered in the body of the document.

Attributes that are missing from the input document are automatically supplied with the default value specified in the DTD.

The XMLNSC parser never adds the DTD to the message tree because the information that it contains has already been used during the parse. This behavior keeps the message tree compact and reduces CPU usage, and means that the XMLNSC parser does not always produce exactly the same document as it parsed. However, the business meaning of the output document is not altered.

If these restrictions are a problem, the XMLNS domain and parser provide full support for parsing and writing of the DTD. See "XMLNS DTD support" on page 1108.

Writing

The XMLNSC parser can produce a DTD that contains entity definitions only. This behavior allows the XMLNSC parser to be used for writing out XML documents that use internal entities (the most common reason for using a DTD). See "Manipulating messages in the XMLNSC domain" on page 2546 for further details.

External DTDs

No support is offered for external DTDs

"Handling null values" on page 1140
A business message might contain fields that are either empty or have a specific out-of-range value. In these cases, the application that receives the message is expected to treat the field as if it did not have a value. The logical message tree supports this concept by enabling the value of any element to be set to NULL.

Related tasks:

"Manipulating messages in the XMLNSC domain" on page 2546
If you are writing ESQL to process messages in the XMLNSC domain, it is helpful to learn about the structure of the message tree that the XMLNSC parser builds.

XMLNS parser:

The XMLNS parser is a flexible, general-purpose XML parser.

The XMLNS parser is not model-driven and does not use an XML Schema when parsing XML documents.

For guidance on when to use the XMLNS domain and parser, see "Which XML parser should you use?" on page 1080.

If you want the XMLNS domain to parse a particular message, you must select *Message Domain* as `XMLNS` on the appropriate node in the message flow.

Features of the XMLNS parser

Feature	Present	Description
Namespace support	Yes	Namespace information is used if it is present. No user configuration is required. See "Namespace support" on page 1508.
On-demand parsing	Yes	See "Parsing on demand" on page 4173.
Compact message tree	No	
Opaque parsing	Partial	Limited support from ESQL only for parsing a single element opaquely. See "XMLNS opaque parsing" on page 1107.
Ultra high performance	No	
Validation	No	
Inline DTD support	Yes	Inline DTDs are processed and retained in the message tree. See "XMLNS DTD support" on page 1108.
XML Data Model compliance	Yes	The resultant message tree conforms to the XML Data Model.

Related concepts:

The XPath Expression builder provides qualified support for namespaces.

"XMLNSC parser" on page 1090
The XMLNSC parser is a flexible, general-purpose XML parser that offers high performance XML parsing and optional XML Schema validation.

"Which XML parser should you use?" on page 1080
If your messages are general-purpose XML documents, you can use one of the dedicated XML domains (XMLNSC or XMLNS) to parse the message, or you can use the MRM domain to parse the message.

"Why model messages?" on page 1158
WebSphere Message Broker supplies a range of parsers to parse and write message formats. Some message formats are self-defining and can be parsed without reference to a model. Most message formats, however, are not self-defining, and the parser must have access to a predefined model that describes the message, if it is to parse it correctly.

"Message modeling" on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

Related tasks:

"Manipulating messages in the XMLNS domain" on page 2563
When you write ESQL for processing messages in the XMLNS domain, it is helpful to understand the structure of the message tree that the XMLNS parser builds.

Related reference:

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

"Message model reference information" on page 5366
Reference information in this section can help you develop and configure message models.

XMLNS empty elements and null values:

Empty elements and null values occur frequently in XML documents.

A robust message flow must be able to recognize and handle empty elements and null values. Similarly, elements in a message tree might have a NULL value, an empty value, or no value at all. This topic explains the parsing and writing of these values by the XMLNS domain. For advice on good ESQL or Java coding practices see "Handling null values" on page 1140.

Parsing

Description	XML input parsed by XMLNS	Value of 'element' in message tree
Empty element value	<element/>	Empty string
Empty element value	<element></element>	Empty string
Folder with child elements	<element><childElement/ ></element>	No value
Nil element value	<element xsi:nil="true"/>	Empty string

Note that both forms of an empty element result in the same value in the message tree.

Note also that a NULL value is never put into the message tree by the XMLNS parser.

Writing

Description	Value of 'element' in message tree	XML output from XMLNS parser
Empty element value	Empty string	<element/>
Null element value	NULL	<element/>
Folder with child elements	No value	<element><childElement/ ></element>

Empty elements

An empty element can take two forms in an XML document:

```
- <element/>
- <element></element>
```

The XMLNS parser treats both forms in the same way. The element is added to the message tree with a value of "" (the empty string).

When a message tree is produced by the XMLNS parser, it always uses the first form for elements that have a value of "" (the empty string).

Elements with an xsi:nil attribute

The XMLNS parser treats the xsi:nil attribute exactly like any other attribute. When xsi:nil is encountered while parsing, it does not set the value of the parent element to NULL. If you require this behavior you should use the XMLNSC parser. When writing a message tree, if an xsi:nil attribute exists it will be produced in the same way as any other attribute.

Related concepts:

"XMLNS parser" on page 1104
The XMLNS parser is a flexible, general-purpose XML parser.

"XMLNS opaque parsing"
Opaque parsing is a performance feature that is offered by the XMLNS domain.

"Handling null values" on page 1140
A business message might contain fields that are either empty or have a specific out-of-range value. In these cases, the application that receives the message is expected to treat the field as if it did not have a value. The logical message tree supports this concept by enabling the value of any element to be set to NULL.

XMLNS opaque parsing:

Opaque parsing is a performance feature that is offered by the XMLNS domain.

XMLNS opaque parsing has been superseded by the opaque parsing feature of the XMLNSC domain. Do not use the XMLNS parser for opaque parsing unless your message flow requires features that are only offered by the XMLNS parser.

If you are designing a message flow, and you know that a particular element in a message is never referenced by the message flow, you can specify that that element is to be parsed opaquely. This reduces the costs of parsing and writing the message, and might improve performance in other parts of the message flow.

To specify that an XML element is to be parsed opaquely, use an **ESQL CREATE** statement with a PARSE clause to parse the XML document. Set the FORMAT qualifier of the PARSE clause to the constant, case-sensitive string 'XMLNS_OPAQUE' and set the TYPE qualifier of the PARSE clause to the name of the XML element that is to be parsed in an opaque manner.

The TYPE clause can specify the element name with no namespace (to match any namespace), or with a namespace prefix or full namespace URI (to match a specific namespace).

XMLNS opaque elements cannot be specified via the node properties.

Consider the following example:

```
DECLARE soap NAMESPACE 'http://schemas.xmlsoap.org/soap/envelope/';

DECLARE BitStream BLOB ASBITSTREAM(InputRoot.XMLNS
                  ENCODING InputRoot.Properties.Encoding
                  CCSID InputRoot.Properties.CodedCharSetId);
--No Namespace
```

```
  CREATE LASTCHILD OF OutputRoot
    DOMAIN('XMLNS')
          PARSE (BitStream
                 ENCODING InputRoot.Properties.Encoding
                 CCSID InputRoot.Properties.CodedCharSetId
                 FORMAT 'XMLNS_OPAQUE'
                 TYPE 'Body');

--Namespace Prefix
  CREATE LASTCHILD OF OutputRoot
    DOMAIN('XMLNS')
          PARSE (BitStream
                 ENCODING InputRoot.Properties.Encoding
                 CCSID InputRoot.Properties.CodedCharSetId
                 FORMAT 'XMLNS_OPAQUE'
                 TYPE 'soap:Body');

--Namespace URI
  CREATE LASTCHILD OF OutputRoot
    DOMAIN('XMLNS')
          PARSE (BitStream
                 ENCODING InputRoot.Properties.Encoding
                 CCSID InputRoot.Properties.CodedCharSetId
                 FORMAT 'XMLNS_OPAQUE'
                 TYPE '{http://schemas.xmlsoap.org/soap/envelope/}:Body');
```

"CREATE statement" on page 5082
The CREATE statement creates a new message field.

XML parsers namespace support:

Namespaces in XML messages are supported by the XMLNSC and XMLNS parsers. Namespaces are not supported by the XML parser.

Parsing

The XMLNS and XMLNSC parsers can parse any well-formed XML document, whether or not the document contains namespaces. If elements or attributes have namespaces, those namespaces are applied to the elements and attributes in the message tree. Namespace prefix mappings are also carried in the message tree, and are used when serializing the message tree back to XML.

- If an element or attribute in the input XML has a namespace, the corresponding node in the message tree also has that namespace.
- If an element contains a namespace declaration (an xmlns attribute), a child element that contains its prefix and namespace URI is created in the message tree.

While the message is passing through a message flow, namespaces and namespace mappings can be modified using ESQL or any of the other transformation technologies that are offered by message broker.

Writing

Namespaces and their prefixes are preserved in the message tree when parsing, and are used when the XMLNS and XMLNSC parsers convert a message tree to an XML bit stream.

- When serializing a message tree, the parser scans for namespace declarations on each XML element. If any are found, it uses them to select the namespace prefixes in the output document.
- If an element in the message tree has a namespace, but there is no in-scope namespace declaration for its namespace URI, a valid namespace prefix is automatically generated and used in the output XML. Auto-generated prefixes have the form NS1, NS2, and so on.

Tip: If an element in the message tree has a child element that is a 'default namespace' declaration, every child of that element (whether an XML element or an XML attribute, at any nesting depth) must have a namespace. If this rule is not enforced message broker cannot generate correct XML output for the message tree.

Related concepts:

"Manipulating messages in the XMLNS domain" on page 2563
When you write ESQL for processing messages in the XMLNS domain, it is helpful to understand the structure of the message tree that the XMLNS parser builds.

XML parser:

The XML domain is very similar to the XMLNS domain, but the XML domain has no support for XML namespaces or opaque parsing.

The XML domain is deprecated, but existing message flows that use the XML domain continue to work. Use the XMLNSC domain when developing new message flows.

The XML parser is not model-driven and does not use an XML Schema when parsing XML documents.

If you want the XML domain to parse a particular message, you must select *Message Domain* as `XML` on the appropriate node in the message flow.

Tip: The XMLNSC and XMLNS parsers both support XML messages that do not use namespaces, with no extra configuration.

Features of the XML parser

Feature	Present	Description
Namespace support	No	
On-demand parsing	Yes	See "Parsing on demand" on page 4173.
Compact message tree	No	
Opaque parsing	No	
Ultra high performance	No	
Validation	No	
Inline DTD support	Yes	Inline DTDs are processed and retained in the message tree.
XML Data Model compliance	Yes	The resultant message tree conforms to the XML Data Model.

You can manipulate messages in the XML, XMLNS, and XMLNSC domains.

Related reference:

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

"Message model reference information" on page 5366
Reference information in this section can help you develop and configure message models.

MRM parser and domain:

You can use the MRM domain to parse and write a wide range of message formats.

The MRM domain can be used to parse and write a wide variety of message formats. It is primarily intended for non-XML message formats, but it can also parse and write XML. For guidance on when to consider using the MRM parser, instead of one of the XML parsers, to parse XML, see "Which XML parser should you use?" on page 1080

The key features of the MRM domain are:

- Support for messages from applications that are written in C, COBOL, PL/I and other languages, by using the Custom Wire Format (CWF) physical format. This support includes the ability to create a message model directly from a C header file or COBOL copybook.
- Support for text messages, perhaps with field content that is identified by tags, separated by specific delimiters, or both, by using the Tagged Delimited String (TDS) physical format. This includes industry standards such as CSV, HL7, SWIFT, EDIFACT, and X12.
- Support for XML messages, including those that use XML namespaces, by using the XML physical format.

WebSphere Message Broker uses the MRM parser to read and write messages that belong to the MRM domain. When reading a message, the MRM parser constructs

a message tree from a bit stream. When writing a message, the MRM parser creates a bit stream from a message tree. The MRM parser is always model-driven, and it is guided by a message dictionary that describes the shape of the message tree (the logical model) and the physical layout of the bytes or characters in the bit stream (the physical format). A message dictionary is created automatically from the content of a message set when it is added to the broker archive (BAR) file. Therefore, when you create a message set for use with the MRM domain, you must define both the logical model and the appropriate physical format information.

The operation of the parser depends on the physical format that you have associated with the input or output message:

- For a binary message, the parser reads a set sequence of bytes according to information in the CWF physical format, and translates them into the fields and values in the message tree.
- For a text message, the parser uses a key piece of TDS physical format information called *Data Element Separation* to decide how to parse each portion of the message bit stream. This informs the parser whether the message uses delimiters, tags, fixed length elements, patterns, and so on. The parser then reads the data according to information in the TDS physical format, and translates it into the fields and values in the message tree.
- For an XML message, the parser reads the XML markup language (element tags and attributes), guided by information in the XML physical format, and translates them into the fields and values in the message tree.

Because the MRM parser is model-driven, it can perform validation of messages against the model that is defined in the deployed dictionary. The level of validation that is performed by the MRM parser is similar to that defined by XML Schema 1.0, but is not fully compliant. If you use XML messages, and you want fully compliant XML Schema 1.0 validation, use the XMLNSC domain.

The MRM parser is an on-demand parser. See "Parsing on demand" on page 4173.

If you want to use the MRM domain to parse a particular message:

1. Create a new message set with an appropriate CWF, TDS, or XML physical format; or locate an existing message set.
2. Ensure that the message set has its *Default message domain* set to `MRM`, or that the *MRM* check box under *Supported message domains* is selected to indicate that the message set supports the MRM domain.
3. Create a message definition file in the message set to represent your message, ensuring that both logical and physical format information is provided. If you have an existing C, COBOL, XML Schema, or DTD description of your message, you can import the description by using a wizard.
4. Add the message set to a broker archive (BAR) file which will generate a message dictionary for use by the MRM parser, and deploy the BAR file to the broker.
5. Select `MRM` as *Message Domain* on the appropriate node in your message flow.
6. Additionally set values for *Message Set*, *Message Type*, and *Message Format* on the node. *Message Type* is the name of the message in the message definition file.

The following samples all use the MRM parser to process messages:

- Video Rental
- Comma Separated Value (CSV)
- EDIFACT

- FIX
- SWIFT
- X12

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Some predefined message models are supplied with the WebSphere Message Broker Toolkit and can be imported by using the New Message Definition File From IBM supplied Message wizard. The CSV, ALE IDoc, and File IDoc models are specifically for use with the MRM domain. See "IBM supplied messages that you can import" on page 6367.

IBM supplies predefined message sets for industry standard formats SWIFT, X12, EDIFACT, and FIX. For more information, contact Dublin Adapters at dubadapt@ie.ibm.com.

How to use messages that have been modeled in the MRM domain, and that are parsed by the MRM parser.

Related reference:

"IBM supplied messages that you can import" on page 6367
You can import IBM supplied messages to create a new message definition file.

"Message model reference information" on page 5366
Reference information in this section can help you develop and configure message models.

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

DataObject parser and domain:

Use the DataObject domain to parse and write messages for WebSphere Adapters and CORBA applications.

- "Using the DataObject domain with WebSphere Adapters"
- "Using the DataObject domain with CORBA" on page 1115

Using the DataObject domain with WebSphere Adapters: You must use the DataObject domain when you use WebSphere Adapter nodes in your message flow.

WebSphere Message Broker uses the DataObject parser to read and write message from Enterprise Information Systems (EIS) such as SAP, PeopleSoft, and Siebel. Such messages belong to the DataObject domain.

When it receives a message from an adapter, the DataObject parser constructs a message tree from the business object that it receives from the EIS. When it writes a message, the DataObject parser creates from the message tree the business object that it sends to the EIS. The DataObject parser is always *model-driven*, and it is guided by the XML Schemas that model the EIS business objects. The XML Schemas are created automatically from the content of a message set when the message set is added to the broker archive (BAR) file.

If you want to parse a message using the DataObject domain, you must:

1. Create a message set, or locate an existing message set.
2. Ensure that either the message set has its *Default message domain* project set to `DataObject`, or the *DataObject* check box (under *Supported message domains*) is selected, to indicate that the message set supports the DataObject domain.
3. Create a message definition file in the message set to represent your EIS business object. Use the *New adapter connection* wizard to connect to the EIS and retrieve the Business object metadata.

4. Add the message set to a broker archive (BAR) file, which generates XML Schema for the DataObject parser to use, and deploy the BAR file to the broker.
5. If you associate your adapter inbound or outbound message with an adapter node in your message flow, the *Message Set* property is automatically set in the node. The *Message domain* property is always pre-selected as `DataObject`.

Tip: If a message that belongs to the DataObject domain is written to a destination other than a WebSphere Adapter, the DataObject parser invokes the XMLNSC parser to write the message as XML.

The following adapter samples use the DataObject parser to process messages:

- SAP Connectivity
- Twineball Example EIS Adapter

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Using the DataObject domain with CORBA: You must use the DataObject domain when you use CORBA nodes in your message flow.

WebSphere Message Broker uses the DataObject parser to read and write message from CORBA applications. Such messages belong to the DataObject domain.

For information about how to build the tree under the DataObject domain for use with CORBA, see "CORBA operation parameters" on page 2156 and "IDL data types" on page 2150.

JMS parsers and domains:

The JMSMap and JMSStream domains can be used for modeling messages that are produced by the implementations of the Java Messaging Service standard.

Use the JMSMap domain when handling JMS messages of type MapMessage. Use the JMSStream domain when handling JMS messages of type StreamMessage.

These message types appear in the broker in XML format, and are therefore supported in an identical way to XML domain messages.

For a full description of JMS MapMessage and StreamMessage processing, see "WebSphere Broker JMS Transport" on page 1681.

WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

MIME parser and domain:

Use the MIME domain if your messages use the MIME standard for multipart messages.

The MIME (Multipurpose Internet Mail Extension) parser does not support the full MIME standard, but does support common uses of MIME. You can send the messages to the broker over HTTP or over other transport types, such as WebSphere MQ. Use the MIME domain if your messages use the MIME standard for multipart messages.

The MIME domain does not support Content-Type values with a media type of *message*.

To specify that a message uses the MIME domain, select `MIME` as the *Message Domain* on the relevant message flow node.

Use the MIME domain and parser to parse and write MIME messages. The MIME parser creates a logical tree, and sets up the broker ContentType property. You can use Compute nodes and JavaCompute nodes to manipulate the logical tree. Set the Content-Type value using the ContentType property in the MIME domain.

Example MIME message

The following example shows a simple multipart MIME message. The message shown is a SOAP with Attachments message with two parts: the root part and one attachment part. The boundary string *MIME_boundary* delimits the parts.

```
MIME-Version: 1.0
Content-Type: Multipart/Related; boundary=MIME_boundary; type=text/xml
Content-Description: Optional description of message.

Optional preamble text
--MIME_boundary
Content-Type: text/xml; charset=UTF-8
Content-Transfer-Encoding: 8bit
Content-ID: <rootpart@example.com>

<?xml version='1.0' ?>
<SOAP-ENV:Envelope
          xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">

    <SOAP-ENV:Header xmlns:ins="http://myInsurers.com">
       <ins:ClaimReference>abc-123</ins:ClaimReference>
    </SOAP-ENV:Header>

    <SOAP-ENV:Body xmlns:ins="http://myInsurers.com">
       <ins:SendClaim>
          <ins:ClaimDetail>myClaimDetails</ins:ClaimDetail>
          <ins:ClaimPhoto>
            <href>cid:claimphoto@example.com</href>
          </ins:ClaimPhoto>
       </ins:SendClaim>
    </SOAP-ENV:Body>

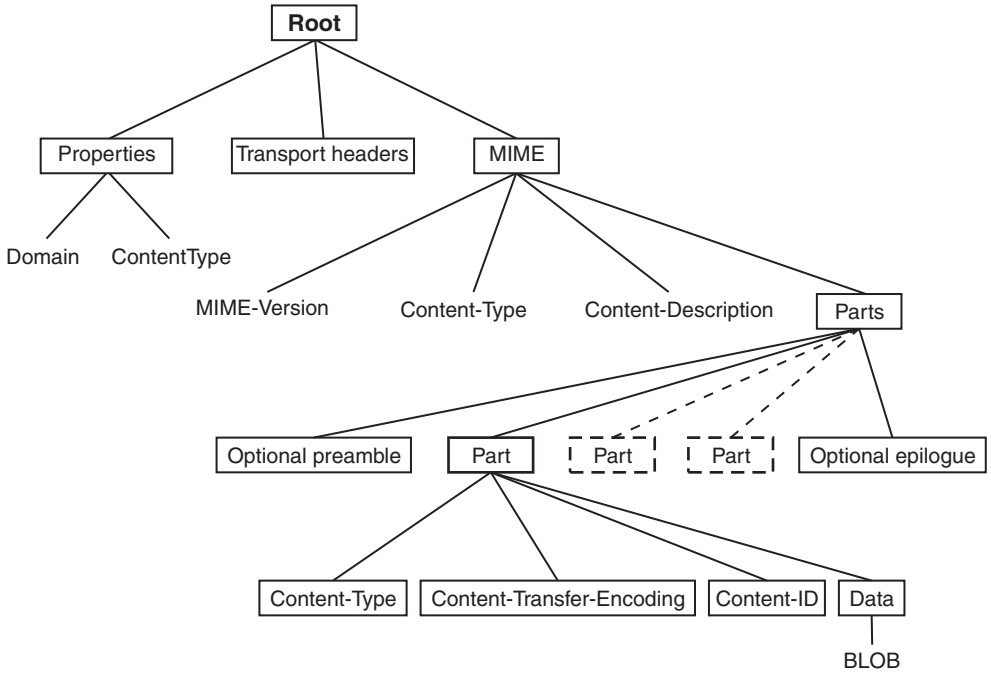
</SOAP-ENV:Envelope>

--MIME_boundary
Content-Type: application/octet-stream
Content-Transfer-Encoding: binary
Content-ID: <claimphoto@example.com>

myBinaryData
--MIME_boundary--
Optional epilogue text
```

Example MIME logical tree

The following diagram shows a MIME logical tree, which is described in "MIME tree details" on page 1123. A MIME logical tree does not need to contain all of the children that are shown in the diagram. The value of the Content-Type header of a MIME message is the same as the ContentType field in the Properties subtree. The Transport-headers are headers from the transport that is used, such as an MQMD or HTTP.



You can further parse the BLOB data in the tree (for example, by using an ESQL CREATE statement) if you know about the format of that MIME part. You might be able to find information about the format from its Content-Type field in the logical tree. Alternatively, you might know the format that your MIME messages take, and be able to parse them appropriately. For example, you might know that the first MIME Part is always an XML message, and that the second MIME Part is a binary security signature.

When the EmailInput node receives an email from an email server that supports Post Office Protocol 3 (POP3) or Internet Message Access Protocol (IMAP), the body of the email message, and any attachments, are propagated in the MIME domain. All other information relating to the email is stored in the `Root.`*`Transport headers`* MIME logical tree; for example, `Root.EmailInputHeader.To`. Where `To` is the storage location of one of the email elements. For a complete list of the email elements that are propagated in the MIME logical tree when you use an EmailInput node, see “EmailInput node” on page 4394.

You must specify how to parse other message formats, such as tagged delimited or binary data, within your message flow, because the MIME parser does not do this. You must also specify how to handle encoded and signed message parts, because the MIME parser does not process these.

Some pre-defined MIME message models are supplied with the WebSphere Message Broker Toolkit and can be imported using the New Message Definition From IBM Supplied Message wizard.

MIME messages:

A MIME message consists of both data and metadata. MIME metadata consists of HTTP-style headers and MIME boundary delimiters.

MIME headers

Each header is a colon-separated name-value pair on a line. The ASCII sequence <CR><LF> terminates the line. A sequence of these headers, called a header block, is terminated by a blank line: <CR><LF><CR><LF>. Any headers that are in this HTTP style can appear in a MIME document. Some common MIME headers are described in "MIME standard header fields" on page 6323.

Content-Type

The only header that must be present is the *Content-Type* header. This header specifies the type of the data in the message. If the Content-Type value starts with "multipart", the message is a multipart MIME message. For multipart messages the Content-Type header must also include a boundary attribute that gives the text that is used to delimit the message parts. Each MIME part has its own

Content-Type field that specifies the type of the data in the part. This can also be multipart, which allows multipart messages to be nested. MIME parts with any other Content-Type values are handled as BLOB data.

If a MIME document is sent over HTTP, the Content-Type header appears in the HTTP header block rather than in the MIME message body. For this reason, the broker manages the value of the Content-Type header as the ContentType property in the *Properties* folder of the logical tree. This allows the MIME parser to obtain the Content-Type value for a MIME document that is received over HTTP. If you need to either create a new MIME tree or modify the value of the Content-Type, set the Content-Type value using the ContentType property in the MIME domain. If you set the Content-Type value directly in the MIME tree or HTTP tree, this value might be ignored or used inconsistently. The following ESQL is an example of how to set the broker ContentType property:

```
SET OutputRoot.Properties.ContentType = 'text/plain';
```

Parsing

The MIME domain does not enforce the full MIME specification. Therefore, you can work with messages that might not be valid in other applications. For example, the MIME parser does not insist on a **MIME-Version** header. The MIME parser imposes the following constraints:

- The MIME headers must be properly formatted:
  - Each header is a colon-separated name-value pair, on a line of its own, terminated by the ASCII sequence <CR><LF>.
  - The header line must use 7-bit ASCII.
  - Semicolons are used to separate parameters:

    ```
    Content-Type: Multipart/Related; boundary=MIME_boundary; type=text/xml
    ```

  - A header might contain a comment in parentheses, for example:

    ```
    MIME-Version: 1.0 (Generated by XYZ)
    ```

- A line that starts with white space is treated as a continuation of the previous line. Therefore, a long header can be split across more than one line.
- If two or more headers in a header block have the same name, their values are concatenated into a comma-separated list.
- A top-level MIME Content-Type header must be available. The header is not case-sensitive. If the transport is HTTP, any Content-Type value in the HTTP header is used as the top-level Content-Type. If the transport is not HTTP, the Content-Type must appear in the initial header block of the MIME message.
- The Content-Type value is a media type followed by the / character and a subtype. Examples of this are `text/xml` and `multipart/related`. The parser does not validate subtypes. The Content-Type value can be followed by one or more parameters that are separated by semicolons.
- If the media type of a message is multipart, a boundary attribute must provide the text that is used to delimit the separate MIME parts.
- Each individual MIME part can have its own Content-Type header. The part header can have a media type of multipart, so that multipart messages can be nested. In this case, a valid boundary attribute must be provided, and its value must be different from any that has been previously defined in the message. MIME parts that have any other Content-Type value are handled as BLOB data.
- MIME multipart boundary delimiters are represented in 7-bit ASCII. The boundary delimiter consists of a line starting with a hyphen pair, followed by a boundary string. This sequence must not occur within the MIME message at any

point other than as a boundary. A MIME end-delimiter is a hyphen pair, followed by the MIME boundary string, followed by a further hyphen pair. All delimiter lines must end in the ASCII sequence <CR><LF>. An example of a delimited message is:

```
--MIME_boundary
message data
--MIME_boundary
message data
--MIME_boundary--
```

where *MIME_boundary* is the boundary delimiter string, and *message data* represents message data.

- The MIME media type *message* is not supported and results in an error at run time.
- Any preamble data (text between the initial MIME header block and the first boundary delimiter) or epilogue data (text after the final boundary delimiter) is stored in the logical tree as a value-only element. Preamble data and epilogue data can appear only as the first and last children, respectively, of a Parts node.
- The MIME parser does not support on-demand parsing and ignores the *Parse Timing* property. The parser does not validate MIME messages against a message model, and ignores the WebSphere Message Broker Toolkit *Validate* property.

Special cases of multipart MIME

The MIME parser is intended primarily for use with multipart MIME messages. However, the parser also handles some special cases:

- Multipart MIME with just one part. The logical tree for the MIME part saves the Content-Type and other information as usual, but the Data element for the attachment is empty.
- Single-part MIME. For single-part MIME, the logical tree has no Parts child. The last child of the MIME tree is the Data element. The Data element is the parent of the BLOB that contains the message data.
- MIME parts with no content.

Secure MIME (S/MIME)

S/MIME is a standard for sending secure email messages. S/MIME has an outer level Content-Type of *multipart/signed* with parameters **protocol** and **micalg** that define the algorithms that are used to encrypt the message. One or more MIME parts can have encoded content. These parts have Content-Type values such as *application/pkcs7-signature* and a Content-Transfer-Encoding of *base64*. The MIME domain does not attempt to interpret or verify whether the message is signed.

Check this quick reference to the common MIME headers.

MIME tree details:

A MIME message is represented in the broker as a logical tree. When it writes a message, the MIME parser creates a message bit stream by using the logical message tree.

Logical tree elements

A MIME message is represented in the broker as a logical tree with the following elements:

- The root of the tree is a node called MIME.
- All correctly formatted headers are stored in the logical tree, regardless of whether they conform to the MIME standard. The headers appear in the logical tree as name=value, as shown here:

  ```
  Content-Type=text/xml
  ```
- A multipart MIME message is represented by a subtree with a root node called Parts.
- Any preamble or epilogue data associated with a multipart MIME message is represented by value-only elements appearing as the first and last children of Parts.
- In the special case of single-part MIME, the content is represented by a subtree with the root called Data.
- Each part of a multipart MIME message is represented by an element called Part with a child element for each MIME header, and a last child called Data.
- The Data element represents the content of a MIME part. This makes it easier to test for the presence of body content by using ESQL because the Data element is always the last child of its parent.

Writing MIME messages

When it writes a message, the MIME parser creates a message bit stream by using the logical message tree. The MIME domain does not enforce all of the constraints that the MIME specification requires, therefore it might generate MIME messages that do not conform to the MIME specification. The constraints that the MIME parser imposes are:

- The tree must have a root called MIME, and constituent Parts, Part, and Data elements, as described in "Logical tree elements."
- Exactly one Content-Type header must be present at the top level of the tree, or be available by using the ContentType property. Media subtypes are not validated.
- If the media type is *multipart*, a valid boundary parameter must also exist.
- Any constituent MIME parts can have exactly one Content-Type header. If the value of this header starts with *multipart*, it must also include a valid boundary parameter. The value of this boundary parameter must not be the same as other boundary parameter values in the definition.

- The MIME Content-Type value "message" is not supported and results in an error at run time.
- All name-value elements in the tree are written as `name: value` followed by the ASCII sequence `<CR><LF>`.

If you have other elements in the tree, the parser behaves in the same way as the HTTP header parser:

- A name-only element or a NameValue element with a NULL value results in `Name: NULL` .
- Any children of a name-value element are ignored.

The message flow must serialize subtrees if they exist; you can use the ESQL command **ASBITSTREAM**.

Related concepts:

"MIME parser and domain" on page 1117
Use the MIME domain if your messages use the MIME standard for multipart messages.

"MIME messages" on page 1120
A MIME message consists of both data and metadata. MIME metadata consists of HTTP-style headers and MIME boundary delimiters.

"Logical tree structure" on page 1042
The logical tree structure is the internal (broker) representation of a message. It is also known as the message assembly.

"Message modeling concepts" on page 1155
Message modeling is a way of predefining the message formats that are used by your applications.

Related tasks:

"Manipulating message body content" on page 2418
The message body is always the last child of root, and is identified by its parser name, for example XML or MRM. You can refer to, modify, and create message body data.

BLOB parser and domain:

The BLOB message domain includes all the messages with content that cannot be interpreted and subdivided into smaller sections of information.

Messages in this domain are processed by the BLOB parser. The BLOB parser is a program that interprets a bit stream or message tree that represents a message that belongs to the BLOB domain. The parser then generates the corresponding tree from the bit stream on input, or a bit stream from the tree on output.

A BLOB message is handled as a single string of bytes, and although you can manipulate it, you cannot identify specific pieces of the byte string using a field reference, in the way that you can with messages in other domains.

You can process messages in the BLOB domain in the following ways:

- You can refer to the message content if you know the location (offset) of particular information within the message. You can specify offset values in ESQL statements within nodes in a message flow to manipulate the information.
- You can store the message in an external database, in whole or in part (where the part is identified by the offset of the data that is to be stored).

- You can use the Mapping node to map to and from a predefined BLOB message, and to map to and from items of BLOB data. The BLOB message cannot be:
  - The message content in a message where `Content Validation` is defined as Open or Open Defined (for example, the message body of a SOAP envelope)
  - The message represented by a wildcard inside another message

  The UnknownParserName field is ignored.

The BLOB message body parser does not create a tree structure in the same way that other message body parsers do. It has a root element BLOB, which has a child element, also called BLOB, which contains the data.

For example, `InputBody.BLOB.BLOB[10]` identifies the tenth byte of the message body; `substring(InputBody.BLOB.BLOB from 10 for 10)` references 10 bytes of the message data starting at offset 10.

If you want to use the BLOB parser to parse a particular message, select `BLOB` as the `Message Domain` on the relevant node in your message flow.

The following sample demonstrates how you can extract information from an XML message and transform it into BLOB format to store it in a database.

- Data Warehouse

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

IDOC parser and domain:

The IDOC domain can be used to process messages that are sent to the broker by SAP R3 clients across the WebSphere MQ link for R3. Such messages are known as SAP ALE IDocs.

Note: The IDOC domain is deprecated and is not recommended for developing new message flows. Instead use the MRM domain with a TDS physical format. See "MRM parser and domain" on page 1111.

A typical ALE IDoc message that has been sent from SAP to the WebSphere MQ link for R3 consists of an MQMD header, an MQSAPH header, and the ALE IDoc itself. The IDoc is made up of fixed size structures:

- The first structure is the Control Structure (DC). This is a complex element 524 bytes long that contains a fixed set of SAP-defined simple elements.
- One or more Data Structures (DDs). Each DD is a complex element 1063 bytes long that contains a fixed set of SAP-defined simple elements that occupies 63 bytes, followed by 1000 bytes of user-defined segment data.

WebSphere Message Broker uses the IDOC parser to read and write ALE IDocs that belong to the IDOC domain. When reading a message, the IDOC parser constructs a message tree from a bit stream. When writing a message, the IDOC parser creates a bit stream from a message tree.

The IDOC parser processes the SAP-defined elements in the DC, then, for each DD, the IDOC parser processes the SAP-defined elements, then calls the MRM parser to process the user-defined segment data, using its CWF physical format.

The IDOC parser is therefore a model-driven parser, and requires that you create a message set in which to model the IDoc message, and deploy it to the broker.

If you want the IDOC domain to parse a particular message, you must:

1. Create a new message set with a CWF physical format, or locate an existing message set.
2. Ensure that either the message set has its *Default message domain* project set to `IDOC`, or the *IDOC* check box (under *Supported message domains*) is selected, to indicate that the message set supports the IDOC domain.
3. Create message definition files in the message set to represent your message. See "Building the message model for the IDOC parser" on page 6330 for the steps involved.
4. Add the message set to a broker archive (BAR) file which generates a message dictionary for use by the MRM parser, and deploy the BAR file to the broker.
5. Select *Message Domain* as `IDOC` on the appropriate node in your message flow.
6. Additionally, select *Message Set* and *Message Format* on the node. (You do not need to select *Message Type*).

JSON parser and domain:

JSON (JavaScript Object Notation) is a simple data-interchange format based on a subset of the JavaScript programming language.

WebSphere Message Broker provides support for a JSON domain. Messages in the JSON domain are processed by the JSON parser and serializer. The JSON parser interprets a bit stream using the JSON grammar, and generates a corresponding JSON domain logical message tree in the broker. When processing data for output, the JSON serializer generates a JSON formatted bit stream from a JSON domain logical message tree.

The JSON parser and serializer do not support message validation because JSON message modeling is not supported by the broker.

To enable function that becomes available in WebSphere Message Broker fix packs, use the **-f** parameter on the **mqsichangebroker** command. For more information, see "**mqsichangebroker** command" on page 3723.

JSON is a language-independent text format, based on two structures:

- Objects (name-value pairs) with the following types:
  - String
  - Number
  - Boolean
  - Null
- Ordered collections of values (arrays)

Objects and arrays can be nested.

For more information about JSON message structure, see "JSON message details" on page 1135.

JSON data streams can be parsed from any coded character set ID (CCSID) that is supported by the broker. The data stream is parsed according to the CCSID that is defined by the transport when the JSON parser is invoked from an input or request node, or defined by the CCSID parameter in a PARSE clause on a CREATE function call. If no CCSID is specified, or if a value of 0 is set, the parser attempts to detect (by examining the first few bytes of the data stream) whether one of the following Unicode encodings is being used:

- UTF-8
- UTF-16BE
- UTF-16LE
- UTF-32BE
- UTF-32LE

If a UTF-* CCSID is explicitly specified, the JSON parser tolerates the corresponding Byte Order Mark (BOM) at the beginning of the data stream.

JSON data streams are parsed into a logical message tree under the `Data` element below the `JSON` parser root. The logical tree structure is shown in the "Example JSON message" on page 1130.

The `Data` element can be accessed and manipulated from ESQL as `JSON.Data`, from Java as `JSON/Data`, from PHP as `JSON->Data`, or from XPath as `$Body/Data`. The JSON parser issues an error if a bit stream is not formatted according to the JSON grammar.

The JSON serializer serializes message trees into a JSON format data stream. The CCSID can be defined by either the broker properties tree, or by transport headers in the message assembly. If no CCSID is defined, the serializer defaults to the queue manager default CCSID for all nodes except HTTP nodes, which default to UTF-8 encoding.

When the JSON serializer is invoked through an `ASBITSTREAM` function call, the CCSID is defined by the CCSID parameter. If no CCSID parameter is provided, or if the value is set to 0, the JSON serializer defaults to using UTF-8 encoding.

To process messages with the JSON parser, select `JSON` as the *Message Domain* on the relevant node in the message flow. The Mapping node and the XSLTransform node do not support the JSON domain.

The broker sets the HTTP Content-Type header to `application/json` when serializing a JSON message tree, unless an explicit value is set by the message flow.

JSON objects are modeled in the broker message tree as a sequence of *NameValue* elements. The parser builds the message tree in the order in which it encounters the members in the bit stream. The serializer writes the object members into the bit stream in the tree order.

JSON arrays are modeled in the broker message tree as a *Name* element with a JSON parser-specific type flag of JSON.Array and ordered children. The children can be any of the following types of array:

- An array containing simple values; for example:

  ```
  "array1" : [ "thing1", 1 ]
  ```

  The following message tree is produced:

  ```
  (0x01001000:Array): array1 = (
      (0x03000000:NameValue):Item = 'thing1' (CHARACTER)
      (0x03000000:NameValue):Item = 1 (INTEGER)
   )
  ```

  The JSON parser assigns the name `Item` to the *NameValue* elements.
- An array containing objects; for example:

  ```
  "array2" : [ {"a" : 1}, {"b" : 2} ]
  ```

  The following message tree is produced:

  ```
  (0x01001000:Array):array2 = (
    (0x01000000:Object):Item = (
      (0x03000000:NameValue):a = 1 (INTEGER)
    )
    (0x01000000:Object):Item = (
      (0x03000000:NameValue):b = 2 (INTEGER)
    )
  )
  ```
- A multidimensional array; for example:

  ```
  "array3" : [ [1.1], [2.1] ]
  ```

The following message tree is produced:

```
(0x01001000:Array):array3 = (
  (0x01001000:Array):Item = (
    (0x03000000:NameValue):Item = 1.1E+0 (FLOAT)
  )
  (0x01001000:Array):Item = (
    (0x03000000:NameValue):Item = 2.1E+0 (FLOAT)
  )
)
```

Example JSON message

The following example shows a simple JSON message:

```
{
    "name" : "John Doe",
    "age" : -1.0,
    "known" : false,
    "address" : { "street" : null,
                  "city" : "unknown" },
    "belongings" : ["item1", "item2", "item3"]
}
```

This JSON input produces the following broker logical message tree:

```
(0x01000000:Object):JSON            = ( ['json' : 0xd55fc8]
  (0x01000000:Object):Data = (
    (0x03000000:NameValue):name       = 'John Doe' (CHARACTER)
    (0x03000000:NameValue):age        = -1E+0 (FLOAT)
    (0x03000000:NameValue):known      = FALSE (BOOLEAN)
    (0x01000000:Object   ):address    = (
      (0x03000000:NameValue):street = NULL
      (0x03000000:NameValue):city   = 'unknown' (CHARACTER)
    )
    (0x01001000:Array    ):belongings = (
      (0x03000000:NameValue):Item = 'item1' (CHARACTER)
      (0x03000000:NameValue):Item = 'item2' (CHARACTER)
      (0x03000000:NameValue):Item = 'item3' (CHARACTER)
    )
  )
)
```

JSONP support in the JSON domain:

JSONP (JavaScript Object Notation with Padding) is an extension of the JavaScript Object Notation (JSON) format.

WebSphere Message Broker provides support for JSONP services. A JSONP service, or Remote JSON Service, is a Web service that returns JSON data padded with a user-defined JavaScript function call. The JSONP response message can be interpreted as an executable script, so this functionality can be used to create cross-domain function calls.

For example:

```
http://brokerhost:7080/flowUrlPathSuffix?jsonp=scriptFn
```

This URL includes a query string, where:

- **jsonp** tells the JSONP service that any response from the URL must be returned as a JSONP message
- **scriptFn** is the name of a client-side executable function

Responses to the URL would therefore be in the JSONP format:

```
scriptFn(response)
```

The JSON message tree provides a top level `Padding` element, into which the JSON parser places the name of the client-side JSONP function. Similarly, the JSON serializer pads a JSON message if the top-level element `Padding` is present in the tree.

For more information about JSON, see "JSON parser and domain" on page 1128.

For information about how to use WebSphere Message Broker to provide a JSONP service, see "Providing a JSONP service" on page 1133.

For information about how to use WebSphere Message Broker to consume a JSONP service response, see "Consuming a JSONP service response" on page 1134.

Example JSONP message

The following example shows a simple JSONP message:

```
scriptFn (
    {
        "name" : "John Doe",
        "age" : -1.0,
        "known" : false,
        "address" : { "street" : null,
                      "city" : "unknown" },
        "belongings" : ["item1", "item2", "item3"]
    }
)
```

This JSONP input produces the following broker logical message tree:

```
  (0x01000000:Object):JSON            = ( ['json' : 0xd55fc8]
    (0x03000000:NameValue):Padding = 'scriptFn' (CHARACTER)
    (0x01000000:Object   ):Data    = (
      (0x03000000:NameValue):name       = 'John Doe' (CHARACTER)
      (0x03000000:NameValue):age        = -1E+0 (FLOAT)
      (0x03000000:NameValue):known      = FALSE (BOOLEAN)
      (0x01000000:Object   ):address    = (
        (0x03000000:NameValue):street = NULL
        (0x03000000:NameValue):city   = 'unknown' (CHARACTER)
      )
      (0x01001000:Array    ):belongings = (
        (0x03000000:NameValue):Item = 'item1' (CHARACTER)
        (0x03000000:NameValue):Item = 'item2' (CHARACTER)
        (0x03000000:NameValue):Item = 'item3' (CHARACTER)
      )
    )
  )
```

Providing a JSONP service:

Configure your WebSphere Message Broker message flow to provide a JSONP service response.

Before you begin

Before you start:

Before completing this task, read the following overview topics about JSON:
- "JSON parser and domain" on page 1128
- "JSONP support in the JSON domain" on page 1131

About this task

You can use ESQL, PHP, or Java to configure your message flow to provide a JSONP response.

The code examples in this task assume that the client application provides a JavaScript call in the following format:

```
<script type="text/javascript"
 src="http://brokerhost:7080/flowUrlPathSuffix?jsonp=scriptFn">
</script>
```

Procedure

1. On the **Advanced** tab of your HTTPInput node, select `Parse Query String`. This option enables you to access the JSONP script prefix that is included in the incoming URL, for example `scriptFn`, from the local environment tree.
2. Insert the following code, as appropriate:
   - If your message flow uses a Compute node:

     ```
     SET OutputRoot.JSON.Padding = InputLocalEnvironment.HTTP.Input.QueryString.jsonp;
     SET OutputRoot.JSON.Data.objectName = 'thing1';
     ```

   - If your message flow uses a PHPCompute node:

```
$output_assembly->JSON->Padding =
     $input_assembly[MB_LOCAL_ENVIRONMENT]->HTTP->input->QueryString->jsonp;
$output_assembly->JSON->Data->ObjectName = "thing1";
```

- If your message flow uses a JavaCompute node:

```
MbMessage outMessage = new MbMessage();
MbElement outRoot = outMessage.getRootElement();
MbElement outParser = outRoot.createElementAsLastChild(MbJSON.PARSER_NAME);
String paddingString =
    assembly.getLocalEnvironment().getRootElement().getFirstElementByPath("HTTP/Input/QueryStr
MbElement padding = outParser.createElementAsLastChild(MbElement.TYPE_NAME_VALUE, "Padding", pa
MbElement data = outParser.createElementAsLastChild(MbElement.TYPE_NAME, "Data", null);
data.createElementAsLastChild(MbElement.TYPE_NAME_VALUE,"objectName","thing1");
```

This code generates the following bit stream, sent as the HTTP reply:

```
scriptFn( {"objectName":"thing1"} )
```

This bit stream causes the JavaScript function `scriptFn` to be called with the JSON object as a parameter.

Consuming a JSONP service response:

When a message flow is configured to use the JSON domain, the JSON parser automatically detects JSONP messages. The JSON parser puts the JSON padding in the top level `Padding` element, and the JSON data under the `Data` element.

Before you begin

Before you start:

Before completing this task, read the following overview topics about JSON:
- "JSON parser and domain" on page 1128
- "JSONP support in the JSON domain" on page 1131

About this task

You can process both JSON and JSONP messages in a single message flow, because the parser puts the JSON data under the `Data` element in the message tree. If JSONP padding is detected, the name of the client-side script is placed in the top level `Padding` element.

Follow these steps to test for the presence of padding:

Procedure

1. Create a message flow with an HTTPInput node, an HTTPReply node, and your choice of a Compute, PHPCompute, or JavaCompute node.
2. On the **Input Message Parsing** tab of your HTTPInput node, set the `Message domain` property to `JSON : For JavaScript Object Notation messages`.
3. Insert the following code, as appropriate:
   - If your message flow uses a Compute node:

     ```
     DECLARE PaddingRef REFERENCE TO InputRoot.JSON.Padding
     IF LASTMOVE(PaddingRef) THEN
        -- JSON Padding is present
     ELSE
         -- No JSON Padding present
     END IF;
     ```

   - If your message flow uses a PHPCompute node:

     ```
     if ($input_assembly->JSON->Padding != null)
        // JSON Padding is present
     else
         // No JSON Padding
     ```

   - If your message flow uses a JavaCompute node:

     ```
     if (message.getRootElement().getFirstElementByPath("JSON/Padding") != null){
         //JSON Padding is present
     }
     else{
         //No JSON Padding
     }
     ```

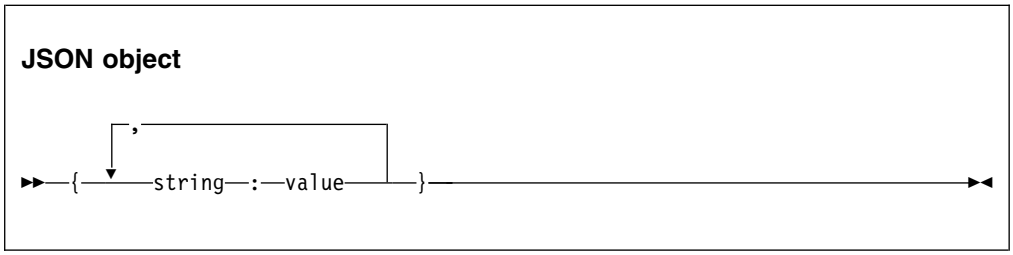
JSON message details:

A JSON message consists of name-value pairs (objects), and ordered collections of values (arrays). Objects, arrays, or both structures can be nested.

For more detailed information about JSON, see the JavaScript Object Notation (JSON) web site.

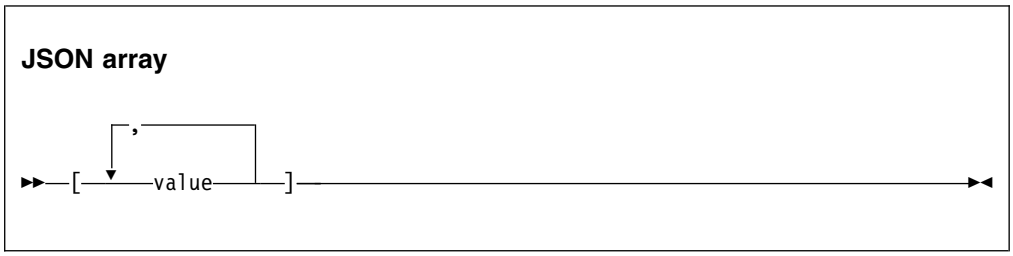
JSON object

In a JSON message, an object is an unordered set of comma-separated name-value pairs that begins with a left brace ({) and ends with a right brace (}). Each name is followed by a colon (:).



JSON array

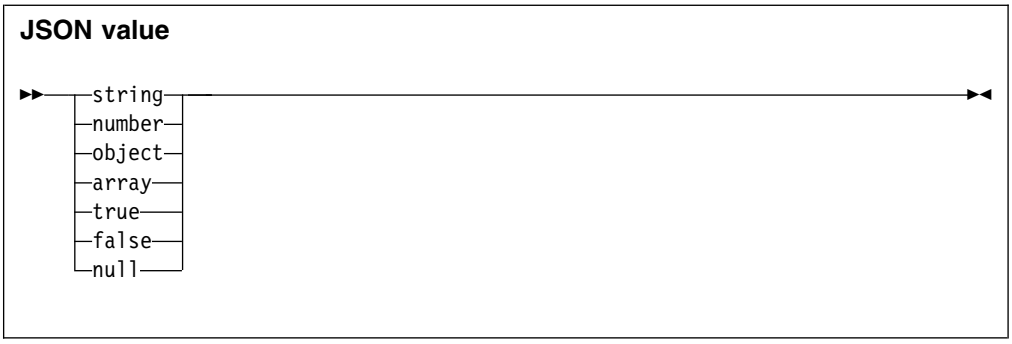
A JSON array is an ordered collection of comma-separated values that begins with left bracket ([) and ends with right bracket (]).



JSON value

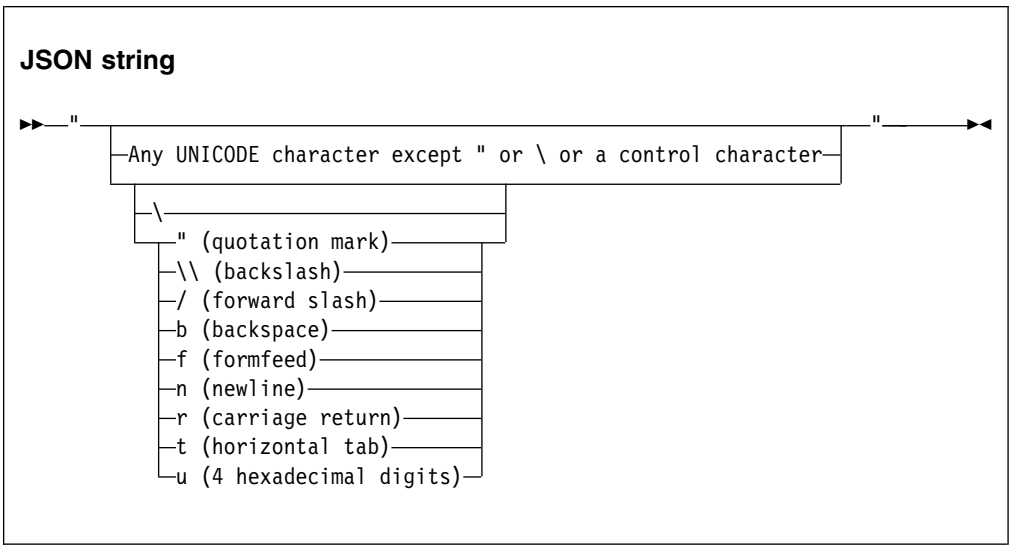
A JSON value can be any of the following structures, any of which can be nested:

- A string in double quotation marks
- A number
- Boolean
- Null
- An object
- An array



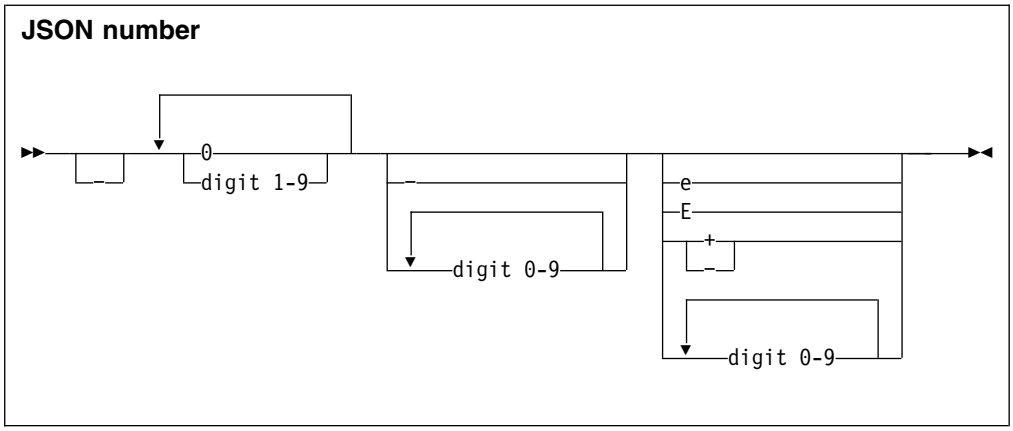
JSON string

A JSON string is very much like a C or Java string. A string is a collection of zero or more Unicode characters, wrapped in double quotation marks, using backslash escapes. A character is represented as a single character string.



JSON number

A JSON number is the same as a C or Java number, except that the octal and hexadecimal formats are not used.



Whitespace can be inserted between any pair of tokens.

Message tree mapping in the JSON domain:

When reading a JSON message, the parser builds a message tree from the input bit stream by mapping JSON values to corresponding message tree element types. When serializing a message tree into the output bit stream, tree element types are mapped to JSON value types.

The following tables show how JSON message values are mapped to message tree element types:

- "JSON bit stream to message tree value mapping"
- "Message tree to JSON message value mapping" on page 1139

JSON bit stream to message tree value mapping

The JSON parser maps JSON values to message tree element types according to the rules in the following table:

JSON value present in bit stream	Parsed as
String	CHARACTER

JSON value present in bit stream	Parsed as
JSON Number value presented as: • A minus sign prefix if the value is negative • At least one digit, which can be zero • No dot fractional part • No exponent	INTEGER
JSON Number value presented as: • A minus sign prefix if the number is negative • At least one digit in the integer part, which can be zero • Either or both of: • A dot and at least one digit in the fractional part, which can be zero • An exponent using uppercase 'E' or lowercase 'e', an optional plus or minus sign, and at least one digit	FLOAT
Boolean	BOOLEAN
Null	NULL

Message tree to JSON message value mapping

The JSON serializer maps message tree elements to JSON value types according to the rules in the following table:

Message tree Element type	JSON Domain serializes as	
	JSON type	Format
BIT	String	Any number of 0 and 1s
BLOB	String	Even number of hexadecimal digits
CHARACTER	String	Char data with JSON string escaping for any double quotation mark (") or backslash (\) character within the CHAR
DATE	String	The standard ESQL string representation, 'yyyy-mm-dd'
TIME, GMTTIME	String	The standard ESQL string representation, 'hh:mm:ss.ffffff'
INTEGER	Number	• A minus sign prefix if the number is negative • At least one digit, which can be zero • No dot fractional • No exponent
FLOAT	Number	• A minus sign prefix if the number is negative • At least one digit in the integer part, which can be zero • At least one digit in the fractional part, which can be zero • An exponent part using uppercase 'E', a plus or minus sign, and at least one digit
DECIMAL	Number	• A minus sign prefix if the number is negative • At least one digit in the integer part, which can be zero • At least one digit in the fractional part, which can be zero Decimal literals ‘NAN', ‘INF', and so on, are not supported when serializing to JSON.
BOOLEAN	Boolean	true or false The serializer only serializes Boolean logical tree elements with true or false values; unknown is not supported

Message tree Element type	JSON Domain serializes as	
NULL	Null	Null

ROW	Object	Note: Assigning a ROW directly to a JSON Domain tree does not produce JSON arrays.
		`DECLARE myRow ROW;`
		`SET myRow.rowData[1].fieldOne = 'Row1Field1';`
		`SET myRow.rowData[1].fieldTwo = 'Row1Field2';`
		`SET myRow.rowData[2].fieldOne = 'Row2Field1';`
		`SET myRow.rowData[2].fieldTwo = 'Row2Field2';`
		`SET OutputRoot.JSON.Data.aRow = myRow;`
		Produces the following JSON bit stream
		`"aRow":{`
		`  "rowData": {"fieldOne":"Row1Field1","fieldTwo":"Row1Field2"},"`
		`  "rowData": {"fieldOne":"Row2Field1","fieldTwo":"Row2Field2"}`
		`}`

ROW	Array	To produce a JSON array from a ROW type the JSON.Array field would also be set.
		`SET OutputRoot.JSON.Data.aRow = myRow;`
		`SET OutputRoot.JSON.Data.aRow TYPE = JSON.Array;`
		Produces the following JSON bit stream
		`"aRow":[`
		`  {"fieldOne":"Row1Field1","fieldTwo":"Row1Field2"},`
		`  {"fieldOne":"Row2Field1","fieldTwo":"Row2Field2"}`
		`]`

Handling null values:

A business message might contain fields that are either empty or have a specific out-of-range value. In these cases, the application that receives the message is expected to treat the field as if it did not have a value. The logical message tree supports this concept by enabling the value of any element to be set to NULL.

Ways to represent a null value: In an XML document, the usual way to represent a null value is to leave the element or attribute empty.

For example: `<price></price>` or `<element price=""/>`

The xsi:nil attribute provides a way to make this more explicit:
`price=<xsi:nil="true"/>`

Some business messages use a special value to represent a null value:
`<price>-999</price>`

This style of null representation is supported only by the MRM parser.

ESQL support for null values: Using ESQL, you can set the value of a message tree element to NULL:

```
SET OutputRoot.XMLNSC.myField VALUE = NULL;
```

Note that this is different from `SET OutputRoot.XMLNSC.myField = NULL;` which would cause myField to be deleted from the message tree.

The same effect can be achieved using Java or a Mapping node.

XMLNSC parser support for null values: Typically, the XML parsers (XMLNSC, XMLNS, and XML) do not create null values in the message tree; an empty element or an empty attribute value merely produces an empty string value in the message tree.

If validation is enabled, the XMLNSC parser detects and processes any xsi:nil attributes in the input document. If the xsi:nil attribute is set to 'true', and the element is nullable, the attribute's parent element in the message tree is given a null value.

For more information about XML parser support for empty elements and null values, see “XMLNSC empty elements and null values” on page 1092 and “XMLNS empty elements and null values” on page 1106.

MRM parser support for null values: **XML physical format**

When parsing, the MRM XML parser can detect and process xsi:nil attributes in the input XML document. If the xsi:nil attribute is set to 'true', and the element is nullable, the attribute's parent element in the message tree is given a null value.

For information about enabling xsi:nil support in the MRM parser, see “XML Null handling options” on page 6258.

The following topics provide more information about handling null values in the MRM parser:
- “MRM Custom wire format: NULL handling” on page 1216
- “MRM XML physical format: NULL handling” on page 1249
- “MRM TDS format: NULL handling” on page 1240

All physical formats

The MRM parser can detect a null value that is represented by an out-of-range value. The null value must be specified in the physical format of the message set.

While parsing, the MRM parser checks the null value for each element in the message. If the value in the bit stream matches the null value in the message set, the MRM parser sets the value in the message tree to NULL.

The same check is performed when converting a message tree to a bit stream. If the value in the message tree is NULL, the MRM parser outputs the null value from the message set.

JSON parser support for null values: The JSON format supports NULL as a JSON value type.

When a JSON message includes an object with a null value, the JSON parser sets the value in the message tree to NULL.

When serializing an element in the message tree with a null value, the JSON bit stream is constructed as a JSON object with a value of null.

Reference information in this section can help you develop and configure message

models.

Properties

You can view and change properties that define broker characteristics, and those properties of associated resources such as message flows.

Broker properties

Each broker has a set of properties that define certain characteristics that you can control:

- You can set some broker properties only at the time that you create the broker by using the **mqsicreatebroker** command; for example, its associated queue manager.
- You can change some of the broker properties by using the **mqsichangebroker** command; for example, timeout values for processing configuration requests.
- You can view all broker properties by using the **mqsireportbroker** command.
- You can access some broker properties from ESQL and Java programs that you run in message flow nodes. For details of these options, see "Broker properties" on page 1144.

Node properties

Each built-in (supplied) node has at least one property that you can configure; some properties are mandatory, others are optional. In addition to setting these properties for each node when you add it to a message flow, you can also use the following configuration techniques:

- You can promote properties, so that you can set them at the message flow level. For information about how and why you might want to use this technique, see "Promoted properties" on page 1145.
- You can configure properties when you add the message flow to a BAR file for deployment. In each node description, the subset of node properties that you can use in this way are identified. For more information, see "Editing configurable properties" on page 3227.

Node properties are discussed in "Message flow nodes" on page 1024.

User-defined properties

You can create your own properties when you create a message flow, and access those properties from ESQL and Java programs in your message flow nodes. For further details, see "User-defined properties" on page 1147

Configurable service properties

You can modify some of the properties of the configurable services that are supplied to enhance your message flow processing options. For example, configurable services are supplied to communicate with enterprise information systems such as SAP.

You can also create your own configurable services, as variants of the supplied services, or to provide additional options.

For further information, see "Configurable services" on page 1296.

Related concepts:

"Message flow nodes" on page 1024
A message flow node is a processing step in a message flow. It can be a built-in node, a user-defined node, or a subflow node.

"Broker properties"
For each broker, WebSphere Message Broker maintains a set of properties. You can access some of these properties from your ESQL programs. A subset of the properties is also accessible from Java programs. It can be useful, at run time, to have real-time access to details of a specific node, flow, or broker.

"Promoted properties" on page 1145
A promoted property is a message flow node property that has been promoted to the level of the message flow in which it is included.

"User-defined properties" on page 1147
A user-defined property (UDP) is a property that is defined when you construct a message flow by using the Message Flow editor. This property can be used by the ESQL or Java program inside message flow nodes, such as a Compute node.

"Configurable services" on page 1296
Configurable services are typically runtime properties. You can use them to define properties that are related to external services on which the broker relies; for example, an SMTP server or a JMS provider.

Related reference:

"**mqsichangebroker** command" on page 3723
Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

"**mqsicreatebroker** command" on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

"**mqsireportbroker** command" on page 3919
Use the **mqsireportbroker** command to display broker registry entries.

Broker properties:

For each broker, WebSphere Message Broker maintains a set of properties. You can access some of these properties from your ESQL programs. A subset of the properties is also accessible from Java programs. It can be useful, at run time, to have real-time access to details of a specific node, flow, or broker.

Broker properties are divided into four categories:

- Properties that relate to a specific node
- Properties that relate to nodes in general
- Properties that relate to a message flow
- Properties that relate to the execution group

For a description of the broker, flow, and node properties that are accessible from ESQL and Java, see "Broker properties that are accessible from ESQL and Java" on page 5302.

Broker properties have the following characteristics.

- They are grouped by broker, execution group, flow, and node.
- They are case-sensitive. Their names always start with an uppercase letter.
- They return NULL if they do not contain a value.

All nodes for which user programs can edit ESQL support access to broker properties. These nodes are:

- Compute nodes
- Database nodes
- DatabaseInput nodes

- Filter nodes
- All derivatives of these nodes

User-defined properties can be queried, discovered, and set at run time to dynamically change the behavior of a message flow. You can use the Administration API for WebSphere Message Broker(CMP API) to manipulate these properties, which can be used by a systems monitoring tool to perform automated actions in response to situations that it detects in the monitored systems. For more information, see "User-defined properties" on page 1147.

A *complex property* is a property to which you can assign multiple values. Complex properties are displayed in a table in the Properties view, where you can add, edit, and delete values, and change the order of the values in the table. You cannot promote complex properties; therefore, they are not shown in the Promote properties dialog box. Nor can you configure complex properties; therefore, they are not supported in the Broker Archive editor. For an example of a complex property, see the `Query elements` property of the DatabaseRoute node.

For more information about editing the properties of a node, see "Configuring a message flow node" on page 1503.

Related concepts:

"User-defined properties in ESQL" on page 2376
Access user-defined properties (UDPs) as variables in your ESQL program by specifying the EXTERNAL keyword on a DECLARE statement. For example, the ESQL statement `DECLARE today EXTERNAL CHARACTER 'monday'` defines a user-defined property called today with an initial value monday.

"User-defined properties" on page 1147
A user-defined property (UDP) is a property that is defined when you construct a message flow by using the Message Flow editor. This property can be used by the ESQL or Java program inside message flow nodes, such as a Compute node.

Related tasks:

You can access broker, message flow, and node properties from ESQL and Java.

"DatabaseRoute node" on page 4373
Use the DatabaseRoute node to route messages using information from a database in conjunction with XPath expressions.

Promoted properties:

A promoted property is a message flow node property that has been promoted to the level of the message flow in which it is included.

A message flow contains one or more message flow nodes. You can promote the properties of a message flow node to apply to the message flow to which it

belongs. In this case, any user of the message flow can override these promoted properties at the message flow level, without being aware of the message flow's internal structure.

You can promote compatible properties (that is, properties that represent comparable values) from more than one node to the same promoted property; you can then set a single property that affects multiple nodes.

For example, you might want to set the name of a data source as a property of the message flow, rather than a property of each individual node in the message flow that references that data source. You create a message flow that accesses a database called SALESDATA. However, while you are testing the message flow, you want to use a test database called TESTDATA. If you set the data source properties of each individual node in the message flow to refer to SALESDATA, you can promote the data source property for each node in the flow that refers to it, and update the property to have the value TESTDATA; this value overrides the data source properties on the nodes while you test the message flow (the promoted property always takes precedence over the settings for the properties in any relevant nodes).

A subset of message flow node properties is also configurable (that is, the properties can be updated at deployment time). You can promote configurable properties: if you do so, the promoted property (which can have a different name from the property or properties that it represents) is the one that is available to update at deployment time. Configurable properties are those associated with system resources; for example, queues and data sources. An administrator can set these properties at deployment time, without the need for a message flow developer.

You cannot promote a complex property, so it does not appear in the Promote properties dialog box. For more information about complex properties, see “Broker properties” on page 1144.

Related concepts:

“Message flows overview” on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

“Packaging and deployment overview” on page 3210
Deployment is the process of transferring data to an execution group on a broker so that it can take effect in the broker. Message flows and associated resources are packaged in broker archive (BAR) files for deployment.

“Broker properties” on page 1144
For each broker, WebSphere Message Broker maintains a set of properties. You can access some of these properties from your ESQL programs. A subset of the properties is also accessible from Java programs. It can be useful, at run time, to have real-time access to details of a specific node, flow, or broker.

Related tasks:

“Promoting a property” on page 1298
You can promote a node property to the message flow level to simplify the maintenance of the message flow and its nodes, and to provide common values for multiple nodes in the flow by converging promoted properties.

“Renaming a promoted property” on page 1302
If you have promoted a property from the node to the message flow level, it is initially assigned the same name that it has at the node level. You can rename the property to have a more meaningful name in the context of the message flow.

"Removing a promoted property" on page 1304
If you have promoted a property from the node to the message flow level, you can remove (delete) it if you no longer want to specify its value at the message flow level. The property reverts to the value that you specified at the node level. If you remove a promoted property that is a mandatory property, ensure that you have set a value at the node level. If you have not, you cannot successfully deploy a broker archive file that includes this message flow.

"Converging multiple properties" on page 1306
You can promote properties from several nodes in a message flow to define a single promoted property, which applies to all those nodes.

"Editing configurable properties" on page 3227
You can edit configurable properties in the deployment descriptor file (`broker.xml`) of your broker archive.

User-defined properties:

A user-defined property (UDP) is a property that is defined when you construct a message flow by using the Message Flow editor. This property can be used by the ESQL or Java program inside message flow nodes, such as a Compute node.

The advantage of UDPs is that their values can be changed by operational staff at deployment and run time. You do not need to change your application programs. For example, if you use the UDPs to hold data about your computer center, you can configure a message flow for a particular computer, task, or environment at deployment time, without having to change the code at the message node level.

When you launch the Message Flow editor to either create a message flow or modify an existing message flow, as well as deciding which nodes are required in the message flow, you also have the option (provided by the tab) of defining and giving initial values to some user-defined properties. Use the **User Defined Properties** tab at the bottom of the edit window. See "Message Flow editor" on page 6810 for more information.

As well as being defined using the Message flow editor, you must also define a UDP either by using a DECLARE statement with the EXTERNAL keyword in all ESQL programs that use it, or by calling the getUserDefinedAttribute method in all JavaCompute nodes that use it.

See the "DECLARE statement" on page 5117 for details of the DECLARE statement, and see "Accessing message flow user-defined properties from a JavaCompute node" on page 2659 for more information about how to use a UDP in a JavaCompute node.

Values that you give to a UDP when you define it in a message flow override the value of that variable in your ESQL program.

You can also modify the value of a UDP at deployment time by using the Broker Archive editor to edit the BAR file. This value overrides the value that was set when you defined the message flow.

The value of the UDP is set at the message flow level, and is the same for all eligible nodes that are contained in the flow. An *eligible node* is a node that supports UDPs and is within the scope of the declaration that declares the UDP to your application. For example, if you use the Message Flow editor to change the value of a user property called `timezone`, which is declared in a schema called

mySchema, in a message flow called *myFlow*, the UDP is available at run time to all the nodes in *myFlow* that support UDPs and that fall within *mySchema*.

Similarly, if you use the Message Flow editor to change the value of a user-defined property in a subflow, the newly edited property is available to all the nodes in the subflow that support UDPs, and that are within the scope of the declaration. The property is not available, for example, to nodes in the parent flow.

A UDP has global scope and is not specific to a particular subflow. If you reuse a subflow in a message flow, and those subflows have identical UDPs, you cannot set the UDPs to different values.

Controlling user-defined properties at run time

User-defined properties can be queried, discovered, and set at run time to dynamically change the behavior of a message flow. You can use the Administration API for WebSphere Message Broker (also known as the CMP API) or WebSphere Message Broker Explorer to manipulate these properties, which can be used by a systems monitoring tool to perform automated actions in response to situations that it detects in the monitored systems.

For example, a message flow contains a Route node, which is used to differentiate between the classes of customer that are defined in the message. The Route node has a user-defined property called `ProcessClasses`, which is set with an initial value of `All`. When `ProcessClasses` is set to `All`, the node routes messages from all classes of customer to its first terminal for immediate processing.

When certain conditions are detected (for example, the monitoring system detects that the request load is causing the service level agreement to fall below its target), the Route node must be set to pass requests from only "Gold" class customers for immediate processing, while other customer requests are sent to another output terminal, which queues them for later batch processing. Therefore, the monitoring application sets `ProcessClasses` to `Gold`, so that the Route node routes the less critical messages to the second terminal.

To make it easier to know what a user-defined property does, and what values it can have, adopt a suitable naming convention. For example, a user-defined property named `property01`, with an initial value of `valueA` is not as useful as a property named `RouteToAorB` with an initial value of `RouteA`.

For more information, see “Setting message flow user-defined properties at run time in a CMP application” on page 985 or “Setting user-defined properties dynamically at run time using the WebSphere Message Broker Explorer” on page 954.

Precedence of UDP value overriding

You can define a user-defined property in the following ways:
- In the ESQL code
- In the Message Flow editor
- Through a BAR file override
- By using the CMP API

A BAR file override takes precedence over changes in the Message Flow editor, and changes in the Message Flow editor take precedence over changes in the ESQL code.

The precedence of the values for user-defined properties is shown in the following sequence:

1. The user-defined property `ProcessClasses` is set to `All` in a message flow BAR file. After deployment of the BAR file, the value of `ProcessClasses` is `All`.
2. The same user-defined property (`ProcessClasses`) is set to `Gold` by using the CMP API to issue the call setUserDefinedProperty("ProcessClasses", "Gold"). After successful completion of this method, the value of `ProcessClasses` is `Gold`.
3. The broker is shut down and restarted. The value of `ProcessClasses` is still `Gold`.
4. The original flow BAR file is redeployed. After deployment, the value of `ProcessClasses` is `All`.

You can find more information about defining user-defined properties in the following related topics.

Related concepts:

"User-defined properties in ESQL" on page 2376
Access user-defined properties (UDPs) as variables in your ESQL program by specifying the EXTERNAL keyword on a DECLARE statement. For example, the ESQL statement `DECLARE today EXTERNAL CHARACTER 'monday'` defines a user-defined property called today with an initial value monday.

"ESQL variables" on page 2374
An ESQL variable is a data field that is used to help process a message.

Related tasks:

"Configuring a message flow at deployment time with user-defined properties" on page 2626
Use user-defined properties (UDPs) to configure message flows at deployment and run time, without modifying program code. You can give a UDP an initial value when you declare it in your program, or when you use the Message Flow editor to create or modify a message flow.

"Setting message flow user-defined properties at run time in a CMP application" on page 985
Use the CMP API to query, discover, and set message flow user-defined properties dynamically at run time. You can use the CMP API to set properties with a data type of character.

"Setting user-defined properties dynamically at run time using the WebSphere Message Broker Explorer" on page 954
Use the WebSphere Message Broker Explorer to view and set user-defined properties on a message flow dynamically at run time.

"Broker Archive editor" on page 6794
Use the Broker Archive editor to create and manage broker archive (BAR) files.

"DECLARE statement" on page 5117
Use the DECLARE statement to define a variable, the data type of the variable and, optionally, its initial value.

"Message Flow editor" on page 6810
The Message Flow editor is the default editor provided by the Broker Application Development perspective for defining a graphical representation of a message flow in the WebSphere Message Broker Toolkit, and for setting properties for individual message flow nodes.

"ESQL variables" on page 5048
ESQL variables can be described as *external variables*, *normal variables*, or *shared variables*; their use is defined in the DECLARE statement.

Impact analysis: analyzing the effects of planned changes to your applications

When developing an application, you might want to change the names of some artifacts, or move them. Impact analysis reports the artifacts that are likely to be affected by a particular change.

You can analyze the effects of renaming the following artifacts:

- Files
  - MXSD files
  - Deployable WSDL files
  - Map files
  - Message flow files (including subflows)
- Global artifacts in message sets (MXSD)
  - Element definitions
  - Complex and simple type definitions
  - Model groups
  - Attribute groups
  - Attributes
  - Message definitions
- ESQL modules
- Schema-scope ESQL constants
- Maps, including submaps
- Schema-scope ESQL routines

You can analyze the effects of moving the following artifacts within the originating project:

- Schema-scope ESQL routines
- Schema-scope ESQL constants
- ESQL modules
- Map files
- Message flow files

Impact analysis lists two types of impact. *Primary impacts* are the immediate consequences if a change is performed. For example, if you analyze the impact of renaming a file, the primary impact is the renaming of that specific file. *Secondary impacts* are any other artifacts or contents of an artifact that are affected by the primary change. A single change can create many secondary impacts. If another artifact called `S2` references the name of the file that you want to rename, there is a secondary impact upon artifact `S2`. Impact analysis does not report third-level impacts; artifacts that depend on the validity of `S2` are not listed.

For example, when a global artifact in a message set, such as message or global element, is renamed, impact analysis generates a list of artifacts that are likely to be affected:

MXSDs

Flows

Deployable WSDLs

Maps

ESQL paths in the ESQL module

See “Impact analysis: reference” on page 4174 for details of artifacts and paths that are not reported under secondary analysis.

Note: Impact analysis does not change any resources.

Impact analysis results are shown either in the Impact Analysis dialog box, or in the Impact Analysis view in the WebSphere Message Broker Toolkit. For more information about how to view information about selected resources, mark changes as complete, and view previous results, see “Impact Analysis view” on page 6801.

Indexing

Indexing must be enabled to support impact analysis. The act of indexing determines what definitions and relationships exist in WebSphere Message Broker artifacts. These definitions and relationships are used to perform impact analysis. By default, indexing is disabled, for performance reasons.

Related tasks:

“Enabling and disabling indexing” on page 1454
Enable indexing to support impact analysis.

“Impact analysis: reference” on page 4174
Some artifacts are excluded from secondary analysis.

Data conversion

Convert data that your message flows are transferring between different environments by using WebSphere MQ or WebSphere Message Broker facilities.

Data conversion is the process by which data is transformed from the format recognized by one operating system into the format recognized by a second operating system with different characteristics such as numeric order.

If you are using a network of systems that use different methods for storing numeric values, or you need to communicate between users who view data in different code pages, you must consider how to implement data conversion.

Code page conversions

Code page conversion might be required for one or more of the following reasons:

- ASCII versus EBCDIC
- Code pages that are specific to national language
- Code pages that are specific to operating systems

In WebSphere MQ, these factors are handled by the CCSID field in the MQMD header. For more information about the MQMD header, see "MQMD - Message descriptor" in the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online. For more information about code page support, see "Code page conversion", also in the *Application Programming Reference* section.

Encoding

Encoding (byte order) conversion might be required for one or both of the following reasons:

- Big endian versus little endian

  Endian is an attribute of data that describes whether it is stored in computer memory or transmitted with the most significant byte first (big endian) or last (little endian).

- Floating point number representations

In WebSphere MQ, these factors are handled by the Encoding field in the MQMD header. For more information about the MQMD header, see "MQMD - Message descriptor" in the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online. For more information about encoding, see "Machine encoding", also in the *Application Programming Reference* section.

If you are configuring a message flow to receive messages:

- Messages received across a WebSphere MQ protocol that uses WebSphere MQ headers, contain code page encoding characteristics in the MQMD header, and optionally in other WebSphere MQ headers.
- Messages received across protocols that do not use WebSphere MQ headers do not include these characteristics. Configure these characteristics by using properties on the nodes in your message flows. For example, set the Message coded character set ID and Message encoding properties on the FileInput node.

If you are configuring a message flow to send messages to other applications or systems:

- Messages sent across a WebSphere MQ protocol contain code page encoding characteristics in the MQMD header, and optionally in other WebSphere MQ headers.
- Messages sent across protocols that do not use WebSphere MQ headers must be modified to include these characteristics in the Properties folder in the logical message tree structure. The parser called by the output node uses these values to generate the correct bit stream.

When you use WebSphere Message Broker, you can use the data conversion facilities of WebSphere Message Broker, WebSphere MQ, or both.

WebSphere Message Broker facilities

You can model your messages in the MRM through the WebSphere Message Broker Toolkit. Predefined elements of the messages are converted according to their type and physical layer characteristics. For further details, see “Configuring physical properties” on page 2912. You can also use self-defining messages. You can then use the Compute, JavaCompute, or PHPCompute node to configure encoding and CCSIDs. You do not need WebSphere MQ data conversion exits.

- String data is converted according to the CCSID setting.
- Decimal integer and float extended decimal types are converted according to the CCSID setting.
- Decimal integer and float (other physical data types) are converted according to the Encoding setting.
- Binary and Boolean data is not converted.

WebSphere Message Broker can also convert the WebSphere MQ headers for which parsers are provided.

When you use WebSphere Message Broker facilities, the whole message is not converted to the specified encoding and CCSID: you can specify a different encoding, or CCSID, or both, in each header to perform a different conversion for the following part of the message. The encoding and CCSID in the last header defines the values for the message body.

WebSphere MQ facilities

Headers and message body are converted according to the values set in the appropriate MQMD fields, and other header format names. You might need to set up data conversion exits to convert the body of your messages.

When you use WebSphere MQ facilities, the whole message is converted to the specified encoding and CCSID, according to the setting of the format in the WebSphere MQ header.

For more detail about data conversion using WebSphere MQ facilities, see "Data conversion" in the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.

Related concepts:

“Message flows overview” on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

“Parsers” on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

Message modeling

Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

Applications typically use a combination of messages, including those that are defined by the following structures or standards:

- C and COBOL data structures
- Industry standards such as SWIFT or EDIFACT
- XML DTD or Schema

You can model a wide variety of message formats so that they can be understood by WebSphere Message Broker message flows.

When the message format is known, the broker can parse an incoming message bit stream and convert it into a logical message tree for manipulation by a message flow. After the message has been processed by the message flow, the broker converts the message tree back into a message bit stream.

The following topics together give an overview of Message modeling:

- "Message modeling concepts" on page 1155
- "Why model messages?" on page 1158
- "Message domains and parsers" on page 1159
- "The message model" on page 1160
- "Physical formats in the MRM domain" on page 1211
- "Ways to create message definitions" on page 1253
- "Generate model representations" on page 1270

You can import either of the following samples to explore message set projects to understand how the sample's messages are modeled in different formats.

- Video Rental
- Comma Separated Value (CSV)

The following samples also have message sets supplied:

- EDIFACT
- FIX
- SWIFT
- X12

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online

information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

If you want to analyze the effect of changing a message model object, see "Analyzing planned changes to message model objects" on page 2897.

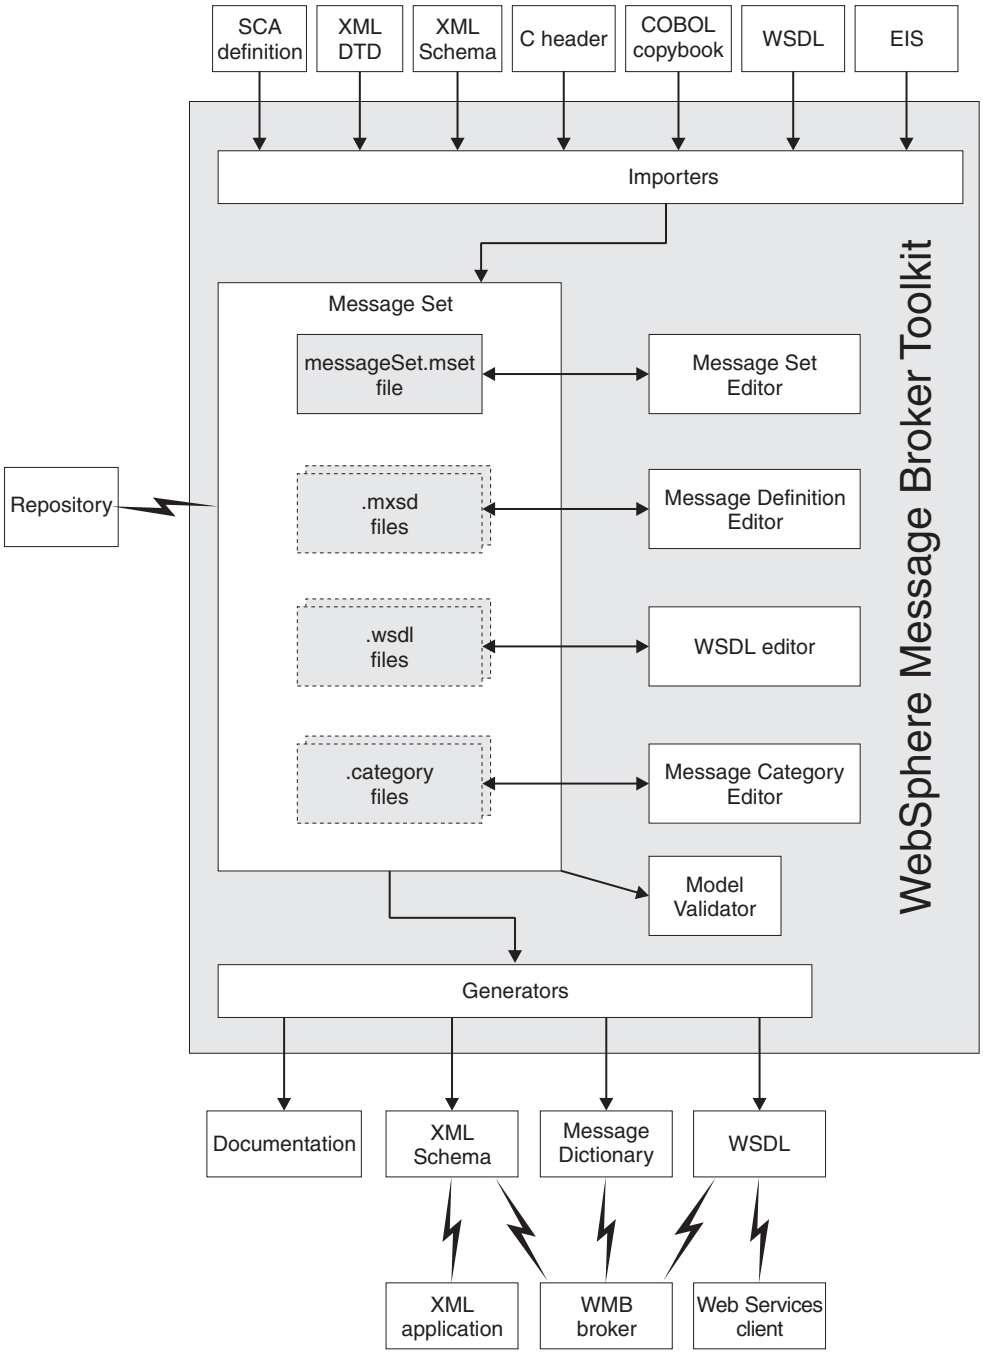
Message modeling concepts

Message modeling is a way of predefining the message formats that are used by your applications.

When you have created your message models, include them in your broker archive (BAR) file with the message flows that use those models. Deploy the BAR file to the broker, which uses your message models to automatically parse and write your message formats.

When you model messages, you must understand the following concepts:

- *Message set projects*
- *Message sets*
- *Message definition files*
- *Web Services Description Language (WSDL) files*
- *SCA definition files*
- *Message categories*
- *Model importers*
- *Model editors*
- *Model generators*
- *Model validator*
- *Domains and parsers*



A *message set project* is a specialized project (container) in which you create and maintain all the resources that are associated with exactly one *message set*.

A message set is a logical grouping of your messages and the objects that comprise them (elements, types, groups). A message set contains the following files:

- Exactly one message set file
- Zero or more message definition files
- Zero or more WSDL files
- Zero or more message category files

The message set file provides message model information that is common to all the messages in the message set. You can create this information using the *message set editor*.

When you have created a message set, you typically import application message formats described by XML DTD, XML Schema, WSDL files, C structures, COBOL structures, or EIS systems, creating and populating *message definition files*. You can then edit the logical structure of your messages, and create and edit physical formats that describe the precise appearance of your message bit stream during transmission, using the *message definition editor*. Alternatively, you can create an empty message definition file and create your messages using just the editor.

When your message definition files are complete, you can then generate the message set in a form that can be used by a broker, parser, or application. This might be in one of the following forms:

- A message dictionary for deployment to a broker
- An XML Schema for use by an application to validate XML messages, or for deployment to a broker
- Web Services Description Language (WSDL) for a Web services client, or for deployment to a broker
- Documentation to give to programmers or business analysts

Messages can be optionally grouped into *message categories* for convenience . You can add messages to message categories using the *message category editor*.

Each time you save a message set file, message definition file, or message category file, the content is *validated* to ensure that the message model that you are creating follows certain rules. There are rules for both the logical structure and the physical formats. This 'model validation' ensures the integrity of your model, but does not necessarily prevent you from saving a message model file that is not valid.

WebSphere Message Broker supplies a range of parsers to parse and write message formats. Each parser is suited to a particular class of messages (for example, fixed-length binary, delimited text, or XML) known as a *message domain*. When you create a message set, you specify which domains the message set supports. This determines which parsers can be used when you parse and write messages that are defined within that message set.

Related concepts:

"Why model messages?" on page 1158
WebSphere Message Broker supplies a range of parsers to parse and write message formats. Some message formats are self-defining and can be parsed without reference to a model. Most message formats, however, are not self-defining, and the parser must have access to a predefined model that describes the message, if it is to parse it correctly.

The Message Category editor is the default editor provided by the Broker Application Development perspective for working with message category (`.category`) files in a message set.

Why model messages?

WebSphere Message Broker supplies a range of parsers to parse and write message formats. Some message formats are self-defining and can be parsed without reference to a model. Most message formats, however, are not self-defining, and the parser must have access to a predefined model that describes the message, if it is to parse it correctly.

An example of a self-defining message format is XML. In XML the message itself contains metadata as well as data values, enabling an XML parser to understand an XML message even if no model is available.

Examples of messages that do not have a self-defining message format are binary messages that originate from a COBOL program, and from SWIFT formatted text messages. Neither contain sufficient metadata to enable a parser to understand the messages.

Even if your messages are self-defining and do not require modeling, the following advantages of modeling them might be useful:

- Runtime validation of messages. Without a model, a parser cannot check whether input and output messages have the correct structure and data values.
- Enhanced parsing of XML messages. Although XML is self-defining, without a model, all data values are treated as strings. If a model is used, the parser knows the data type of data values, and can cast the data accordingly.
- Improved productivity when writing ESQL. When you are creating ESQL programs for WebSphere Message Broker message flows, the ESQL editor can use message models to provide code completion assistance.
- Drag-and-drop operations on message maps. When you are creating message maps for WebSphere Message Broker message flows, the Mapping editor uses the message model to populate its source and target views. Without message models, you cannot use the Mapping editor.
- Reuse of message models, in whole or in part, by creating additional messages that are based on existing messages.

- Generation of documentation.
- Provision of version control and access control for message models by storing them in a central repository.

To make full use of the facilities that are offered by WebSphere Message Broker, model your message formats.

To speed up the creation of message models, importers are provided to read metadata such as C header files, COBOL copybooks, XML Schema and DTDs, WSDL files, and EIS metadata, and create message models from that metadata. Additionally, predefined models are available for common industry standard message formats such as SWIFT, EDIFACT, X12, FIX, HL7, and TLOG.

Message domains and parsers

WebSphere Message Broker supplies a range of *parsers* to parse and write message formats.

A parser is invoked when the bit stream that represents an input message is converted to the internal form that can be handled by the broker. The internal form, a logical tree structure, is described in "Logical tree structure" on page 1042. Similarly, a parser is invoked to convert a logical tree back into a bit stream.

Each parser is suited to a particular class of messages (for example, fixed-length binary, delimited text, or XML) known as a *message domain*.

When you create a message set, you specify which message domains the message set supports. This determines which parsers are used when you parse and write messages that are defined within that message set.

The parsers that are supplied with WebSphere Message Broker are described in "Parsers" on page 1072.

Related concepts:

The message model

The message model consists of the following components.

- Message set projects
- Message sets
- Message definition files
- WSDL files
- Message categories

See "Message modeling concepts" on page 1155 for a summary of these components, and the relationship between them. See Related Concepts later in this section for a detailed description of each component.

The majority of your model content is described by message definition files. These files use XML Schema to represent your messages. XML Schema is an international standard that defines a language for describing the structure of XML documents. It is ideally suited to describing the messages that flow between business applications, and it is widely used in the business community for this purpose. WebSphere Message Broker uses XML Schema to describe the structure of all kinds of message format, not just XML.

Each message definition file describes both the *logical structure* of your messages, and the *physical formats* that describe the appearance of your message bit stream during transmission. If you are using the MRM or IDOC domains, you *must* provide physical format information. This tells the parser exactly how to parse the message bit stream. If you are not using the MRM or IDOC domains, physical format information is not needed

To understand the different ways that you create and populate message definition files, see "Ways to create message definitions" on page 1253. See "Physical formats in the MRM domain" on page 1211 for a description of the physical formats that are available to you.

Related Tasks

"Constructing message models" on page 2838
This topic area describes the concepts behind message modeling, and the tasks that are involved in working with message models.

Message set projects:

A *message set project* is a specialized container in which you create and maintain all the resources associated with one message set.

The content of a message set project is a single message set folder. If the message set is modeling messages from EIS systems, the name of the message set project provides the name of the message set and, optionally, a single Adapters folder. You can create a message set project using the following methods:

- The New Message Set wizard.
- The Quick Start wizards.

These restrictions apply to message set projects:

- A message set project must contain just one message set.
- A message set project cannot refer to any other message set.

Import either of the following samples to see how message set resources are stored in a message set project. The sample's message flow resources are stored separately in a Message Flow project.

- Video Rental
- Comma Separated Value (CSV)

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Related concepts:

"The message model" on page 1160
The message model consists of the following components.

"Message sets overview"
A message set is a container for grouping messages and associated message resources (elements, types, groups).

"Deleting a message set project" on page 2839
Delete a message set project and, optionally, the contents of the associated project directory.

Message sets overview:

A message set is a container for grouping messages and associated message resources (elements, types, groups).

A message set is a folder in a message set project that contains a `messageSet.mset` file. The name of the folder is the name of the message set. A message set project can contain just one message set.

When you create a new message set, a new message set project is automatically created with a name that is the same as that of the message set.

You can base your new message set on an existing message set. In this case, all the definitions in the existing message set are copied into the new message set.

When you have created your message set, you must specify the following key properties:

Supported message domains
The message domains that are supported by the message set. The supported domains determine what is generated for deployment to a broker, and are used when parsing and writing the messages that are defined within the message set.

Default message domain
The default domain of the message set.

Use namespaces
Indicates whether the message definitions that you create within the message set are XML namespace aware.

"Message set editor" on page 6819
The Message set editor is the default editor provided by the Broker Application Development perspective for editing message set (`messageSet.mset`) files.

"Message set properties" on page 5371
Message sets have properties that you can set to define their characteristics and the way in which they are processed.

Message set resources:

Resources in a message set are created as files, and are displayed under the message set folder in the Broker Development view.

- Message set file `messageSet.mset`

There is always one, and only one, `messageSet.mset` file in a message set. This file contains message model properties that are common to all the content of the message set. It is also where you define the physical formats that you want for this message set. These can be Custom Wire Format (CWF), Tagged Delimited String Format (TDS), and XML Wire Format (XML).

The file is created for you when a new message set is created, and you manipulate its content with the Message Set Editor.

- Message definition files that have the suffix `.mxsd`

  You can have many message definition files in a message set. Each file contains the logical model and the associated physical model, in XML Schema form, for a group of related messages.
- Deployable WSDL files that have the suffix `.wsdl`

  These files are used by the SOAP domain. You can have many WSDL files in a message set.
- Message category files that have the suffix `.category`

  These files are optional. You can have many message category files in a message set. A message category provides another way of grouping your messages, perhaps for documentation purposes.

When you have completed the resources in your message set, you can generate the content of the message set in a form that can be used by a broker parser or an application. This might be:

- a message dictionary for deployment to a broker
- XML Schema for use by an application building XML messages, or for deployment to a broker
- Web Services Description Language (WSDL) for a web services client, or for deployment to a broker
- documentation to give to programmers or business analysts

You can analyze the effects of changes to certain resources; see "Analyzing planned changes to message set resources" on page 1165.

Analyzing planned changes to message set resources:

Use impact analysis to analyze the effect of renaming message definition or deployable WSDL files.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Enabling and disabling indexing" on page 1454

You must also have created message set content, for example by importing a WSDL file.

About this task

You can analyze the effect of renaming the following objects:

- Message definition files (`.mxsd`)
- Deployable WSDL files (`.wsdl`)

Procedure

1. In the Broker Development view, right-click the file that you want to rename, then click **Impact Analysis** > **Rename**.
2. In the Impact Analysis - Rename Artifact window, type the new name of the file, then click **Analyze Impact**.

   The Rename Artifact dialog box shows the results of impact analysis, listing primary and secondary impacts.

   You can view the results of impact analysis in the Impact Analysis dialog box, or the Impact Analysis view of the WebSphere Message Broker Toolkit. For more information about how to view information about selected resources, mark changes as complete, copy results to an external application, and view previous results, see "Impact Analysis view" on page 6801.

Message set identification:

A message set is identified by the name of the message set folder in the message set.

When you must refer to a message set from a message flow (for example, when setting the Message Set property of an input node), use the message set name.

A message set also has a 13-character identifier that is guaranteed to be unique. You can use this identifier, instead of the message set name, to refer to a message set, but only if you are using the MRM or IDOC domains. Other domains do not recognize the identifier.

A message set also has an alias. An alias can be used only with MRM multipart messages.

"Message set properties" on page 5371
Message sets have properties that you can set to define their characteristics and the way in which they are processed.

Message set limitations:

A message set is the original container for message models used by WebSphere Message Broker.

You can have as many message definition files as you want within one message set, but you must limit your message sets to a few related message definition files that share the same physical formats.

There are several reasons for the suggested limitations:

- Generation of a message dictionary and other representations is quicker.
- Generated documentation is more manageable.
- MRM physical formats apply to *all* objects within the message set.

  Therefore, for example, if you are using the MRM domain and have an XML message and an unrelated CWF message modeled in the same message set, CWF physical format properties are present for all objects. But the CWF properties are of no interest to the XML message and therefore take default values in those objects, which can result in unwanted task list warnings.
- You cannot use recursion for MRM CWF and TDS physical formats.

  Therefore, if you are modeling XML messages that have a recursive structure, you must ensure that recursive XML messages do not share a message set with MRM CWF or TDS physical formats.

"Message set properties" on page 5371
Message sets have properties that you can set to define their characteristics and the way in which they are processed.

Message set version and keywords:

When you develop a message set, you can define the version of the message set, and other key information that you want to be associated with it.

After you have deployed the message set in a BAR file, you can view the message set properties in the WebSphere Message Broker Toolkit and WebSphere Message Broker Explorer. The properties include the deployment and modification dates and times (the default information that is displayed), and the additional version or keyword information that you have set.

You can define information to give details of the message set that has been deployed; therefore, you can check that it is the message set that you expect.

Version

You can set the version of the message set in the `Version` property.

You can also define a default message set version in the `Default version tag` of the message set preferences. All message sets that you create after you have set this property have this default applied to the `Version` property at the message set level.

Keywords

You must define keywords in the `Documentation` property of the message set. Keywords follow certain rules to ensure that the information can be parsed. The following example shows the type of information that you can define in the `Documentation` property:

```
$MQSI Author=John Smith MQSI$
```

The following table contains the information that is displayed by the WebSphere Message Broker Toolkit or Explorer:

Message set name	
Deployment Time	28-Aug-2004 15:04
Modification Time	28-Aug-2004 14:27
Version	1.0
Author	John Smith

In this display, the version information has been defined by using the `Version` property of the object. If you have not defined version information by using the `Version` property, it is omitted from this display.

Restrictions within keywords

Do not use the following characters within keywords, because they cause unpredictable behavior:

```
^ $ . | \ < > ? + * = & [ ] ( )
```

You can use these characters in the values that are associated with keywords; for example:

- `$MQSI RCSVER=$id$ MQSI$` is acceptable
- `$MQSI $name=Fred MQSI$` is not acceptable

Message definition files:

A *message definition file* contains the messages, elements, types, and groups which make up a message model within a message set.

Every message set requires at least one message definition file to describe its messages. Message definition files use the XML Schema language to describe the *logical format* of one or more messages. Extra information in the form of XML Schema annotations is used to describe any *physical formats* that you define for the messages.

Large message sets can contain several message definition files. This keeps the individual files to a manageable size, making them faster and easier to work with.

Message definition files can be created by using the Message Definition editor, or can be imported from a range of different file formats as described in "Importing from other model representations to create message definitions" on page 1254.

A message definition file can be associated with a namespace, so that all message model objects that are declared within the file belong to that namespace. Namespaces provide a means of avoiding name clashes among similarly named global objects. They are described in detail in "Namespaces in the message model" on page 1201.

One message definition file can reuse message model objects that are defined in another message definition file. XML Schema provides two mechanisms to do this: **`import`** and **`include`**. For more information, see "Reusing message model files" on page 1209.

XML Schema:

XML Schema is an international standard from the World Wide Web Consortium (W3C) that defines a language for describing the structure of XML documents.

The XML Schema language is ideally suited to describing the messages that flow between business applications, and it is widely used in the business community for this purpose.

WebSphere Message Broker uses XML Schema 1.0 to describe the logical structure of messages. At a simple level, the types and elements in the message are modeled by using XML Schema types and elements. However, when the need arises, all of the advanced modeling features of XML Schema are available for modeling messages.

Some important restrictions and extensions of XML Schema exist. These are documented in "XML Schema restrictions in message sets" and "XML Schema extensions in message sets" on page 1173.

Further information about XML Schema: For details about XML Schema, see XML Schema Part 0: Primer on the World Wide Web Consortium (W3C) website.

"XML Schema extensions in message sets"
WebSphere Message Broker provides some additional facilities that are not specified in the XML Schema 1.0 specification. When using a message set, further extensions are provided.

Related reference:

"Importing from XML Schema: unsupported features" on page 6359
A number of features in XML Schema are not supported, or their support is restricted in some way.

XML Schema extensions in message sets:

WebSphere Message Broker provides some additional facilities that are not specified in the XML Schema 1.0 specification. When using a message set, further extensions are provided.

Messages: A message is a global element that represents an entire message (rather than a structure within a message). Within a message definition file, a message is represented by a special global element that carries the extra information required by WebSphere Message Broker.

Composition: The message model in a message set adds the following compositions that are beyond the XML Schema 1.0 specification:

message
: A refinement of *choice* that can contain only a set of references to messages within the same message set. Groups and complex types with composition of *message* are used when modeling multipart messages.

orderedSet
: A set of elements that must be present in the order that they are listed. Groups cannot be used within an *orderedSet*. Elements can repeat, but duplicate elements cannot be used.

unorderedSet
: A set of elements that can be present in any order. Groups cannot be used within an *unorderedSet*. Unlike an *all* group, elements within an *unorderedSet* can repeat. However, duplicate elements cannot be used.

Compositions *orderedSet* and *unorderedSet* enable message models that were produced in earlier versions of the product to be supported.

Content validation: The message model in a message set adds a validation control called 'Content validation' that is used only if the domain is MRM or IDOC, and if validation is selected. It determines how strictly the content of the group is validated. See MRM content validation for more details.

The Content validation property does not affect validation in the XMLNSC or SOAP domains. Validation in these domains follows the rules of XML Schema 1.0.

Physical format information: If one or more physical formats are defined for a message set, the XML Schema objects within the message set can hold extra information about how they must be parsed and serialized.

Further information about XML Schema: For details about XML Schema, see XML Schema Part 0: Primer on the World Wide Web Consortium (W3C) website.

Message model objects:

An introduction to the objects that make up a message model. Message model objects are defined by XML Schema 1.0, except for Message which is a WebSphere Message Broker extension to XML Schema.

Message
A *message* describes the structure and content of a set of data that is exchanged between applications that send and receive the data. A *message* is a special complex element.

Simple element
A *simple element* describes one or more named data fields in a message. It is based on a *simple type* (for example, string, integer or float). A simple element can repeat, and it can define a default or a fixed value.

Simple type
A *simple type* describes a class of data within a message. It describes the type of data (for example, string, integer or float) and it can have value constraints which place limits on the values of any simple elements based on that simple type.

Complex element
A *complex element* describes a named complex structure within the message. The content of a complex element is defined by a *complex type*. A complex element can repeat.

Complex type
A *complex type* describes a complex structure within a message. It contains *elements* (simple or complex), *attributes* (if the data is XML), and *groups* that are organized into a tree-like hierarchy.

Group A *group* describes a list of elements with information about how those elements can appear in a message. Groups can be ordered (sequence), unordered (all), or selective (choice). A group can repeat.

Attribute
An `attribute` describes an XML attribute. Attributes are similar to simple elements, but they require special treatment when used with XML messages. In messages that are not XML messages, attributes are not used.

Global and local objects: Most objects in the message model can be either global or local. A global object must have a unique name, which is used to refer to the object from one or more places in the message model. Local objects are defined and used in only one place in the message model.

Make objects local unless they must be used in more than one place. This reduces the probability of name clashes among the global objects in the message model, and makes the message set easier to work with.

Properties of message model objects: All message model objects have properties. The properties fall into three categories:

Logical
The logical properties of an object are defined by XML Schema. They relate to the format-independent description of the object called the 'logical model'. Logical properties describe *what* data the object contains without saying anything about *how* it is written down.

Physical
If the message model is for a data format that is not XML, additional physical properties are provided for an object that describe how the object is written down. These properties control the parsing and writing of the object. If the message model is in a message set, then the properties are an IBM proprietary set that is understood by the MRM domain and parser.

Documentation
This field is present for all message model objects. It provides a standard place for any description of the object that you might require. Text entered here does not affect the processing of messages in any way.

Related concepts:

"Message modeling concepts" on page 1155
Message modeling is a way of predefining the message formats that are used by your applications.

Message model objects: messages:

A *message* describes the structure and content of a set of data that is passed from one application to another.

A message consists of elements that are organized into a logical structure agreed by the sending and receiving applications. This logical structure can be modeled so that message data can be parsed into a logical tree and manipulated easily by the broker.

In the message model, a message is always based on a global element. The complex type of a global element describes the contents of the global element, and therefore describes all of the content of the message.

Multipart messages: If necessary, a message can contain other messages, and is necessary for modeling certain large and complex messaging standards such as SWIFT and EDIFACT. Such a message is known as a *multipart message*. The contained messages are known as *embedded messages*.

Message identification: Messages are identified by their name. In a message set only, a message can also be identified by an alias. The alias is an optional user-specified string that identifies the (multipart) message. The name and alias of a message must be unique within a message set.

XML Schema model: In the message definition file, a message is modeled as an XML Schema global element declaration. Extra information is provided by XML Schema annotations on the element declaration.

"Multipart messages" on page 1191
A *multipart message* contains one or more other messages within its structure. The contained message is sometimes referred to as an *embedded message*.

"Message model objects: elements"
An *element* is a named piece of information (a field) within a message, with a meaning that is agreed by the applications that create and process the message.

Related reference:

"Message Definition editor" on page 6804
The Message Definition editor is the default editor provided by the Broker Application Development perspective for editing message definition (`.mxsd`) files.

Message model objects: elements:

An *element* is a named piece of information (a field) within a message, with a meaning that is agreed by the applications that create and process the message.

An element has a specific meaning that is agreed by the applications that create and process the message. For example, a message might include a string that your applications have agreed is a 'Customer Name'. An element is always based on a type, either simple or complex.

An element:

- Has a business meaning.
- Is an instantiation of a simple or complex type.
- Can be accessed by name from ESQL, Java, or PHP.
- Is further defined by its type; for example, the type defines the range of values that an element can have.
- Can be defined globally or locally.

Simple and complex elements: Elements can be simple or complex. A simple element is a single, named piece of information such as 'Age' or 'Customer Name'. A simple element is based on a *simple type* that defines its content.

A complex element is a named structure that contains other elements. A complex element named 'Customer Details' might contain the simple elements 'Age' and 'Customer Name'. A complex element can also contain other complex elements. A complex element is based on a *complex type* that defines its content and structure.

Global and local elements: Elements can be global or local. A *global element* can be used in several different messages, or even in several places within the same message. It must be given a unique name by which it can be referenced by an *element reference*. A *local element* is defined in one position within one complex type or group, and is not available for reuse elsewhere in the message model.

Optional and repeating elements: Elements can be defined as optional, mandatory, and repeating, by using the properties `Min Occurs` and `Max Occurs`. For further information, see "Cardinality: optional, required, and repeating elements" on page 1197.

Default and fixed values: An element can be given a default value, so that if no value is supplied by the message, the default value is used. Alternatively, a fixed value can be defined, and the element always takes that value. The precise use of default and fixed values is dependent on the message domain.

Value constraints: The value of an element can be constrained by using *value constraints* which define the range of legal values for the element. The value constraints are associated with the simple type on which the element is based. For further information, see "Message model objects: simple types" on page 1180. The XML Schema term for a value constraint is a *facet*.

Defining substitution groups: If you are modeling XML messages, an element can be marked as a valid substitute for another element by using the substitution group property on the element. In this way, groups of elements can be assembled where any of the elements in the group can substitute for one element, the *head* element. For further information, see "Substitution groups in the message model" on page 1199.

Add, configure, and delete objects.

Message model objects: complex types:

A *complex type* describes the structure of one or more complex elements.

Complex types are an essential part of every message model because they define the logical structure of the messages and elements in the model.

What is a complex type for?: Complex types define the structure of the messages and elements in the message model. By combining elements, attributes, groups, and wildcards, almost any message structure can be modeled.

Contents of a complex type:

Elements

Most complex types contain some elements, and some contain a large hierarchy of complex elements. The elements within a complex type are always contained within a group. This group can be local to the complex type, in which case the Message Definition Editor hides it from view.

Alternatively, the group that contains the elements can be a global group, and this group defines the element content, the composition, and the content validation for the complex type.

If a complex type is derived from a simple type, it cannot contain any element content.

Attributes

If you are modeling XML messages, your complex types can contain attributes. The attributes for a complex type can be local or global, and they can be contained within an attribute group.

Groups

Groups enable sets of elements to be included in a complex type. The members of the group are included as peers of the other elements. For more information about their use, see "Message model objects: groups" on page 1183.

Wildcards

If you are modeling XML messages, your complex types can contain wildcard elements. Wildcard elements enable unmodeled elements to be present in the complex type. Any such, elements must be present within the message at the same position as the wildcard. Complex types can also contain wildcard attributes. Wildcard attribute enable unmodeled attributes to be present within any elements that are based on the complex type.

Global and local complex types: Complex types can be global or local. A global complex type can be used as the basis for more than one complex element. It must be given a unique name by which it can be referenced. A local complex type is associated with a single complex element, and is not available for reuse elsewhere in the message model. Local types do not have a name, and are sometimes referred to as anonymous types.

Composition: The composition of a complex type describes how the members of the type are organized. For more information, see "Message model objects: groups" on page 1183.

Controlling validation of type content: The *Content validation* parameter on a complex type specifies how strictly the contents of the type is validated. For more information, see "Message model objects: groups" on page 1183.

Substitution settings: A complex type has parameters that control whether other types can be derived from it (final) and whether other types can substitute for it (block). For more information, see "Substitution groups in the message model" on page 1199 and "Message model objects: type inheritance" on page 1182.

Related reference:

"Message Definition editor" on page 6804
The Message Definition editor is the default editor provided by the Broker Application Development perspective for editing message definition (`.mxsd`) files.

Message model objects: simple types:

A *simple type* is an abstract definition of an item of data such as a number, a string, or a date.

The purpose of a simple type is to define the content of one or more simple elements. Simple types (and any elements that are based on simple types) cannot contain attributes or child elements. Simple types stand in contrast to complex types, which define the structure of an element, but typically do not define any simple data.

Global and local simple types

Simple types can be global or local. A global simple type can be used as the basis for more than one element. It must be given a unique name by which it can be referenced. A local simple type is associated with a single element, and is not available for reuse elsewhere in the message model. Local types do not have a name and are sometimes referred to as anonymous types.

Variations of simple types

Built-in

XML Schema defines many simple types for you to use, covering all the standard data types such as strings, integers, decimals, and floats.

Restriction

You can define your own simple types by deriving from another simple type (the base type) by restriction. A restriction type can have value constraints applied to it.

A restriction type can derive from a built-in simple type or a restriction simple type.

List

For XML messages only, a list type is a way of rendering a repeating simple value in XML. The notation is more compact than the notation for a repeating element, and offers a way to have multi-valued attributes.

A list type can be based on a union type (introduced later in this section). This can describe a space-separated list of items in which each item can be based on any of the simple types in the union.

A list of lists is not legal. The item type of a list cannot be a list itself, or derived at any level from another list type.

A list type can have the facets of minLength, maxLength, and length applied to it. These facets restrict the number of items in the list. To restrict the values of each item in the list, facets must be applied to the item type and not to the list itself. The message definition editor provides additional support for enumeration and pattern facets directly on a List type, to enable the import of any schema that uses them, but issues a warning that enumeration and pattern facets are ignored by the broker.

Union

A union type is a union of two or more other simple types.

A union type enables a value to conform to any one of several different simple types. The simple types that comprise a union type are known as

its member types. There is no upper limit on how many member types can exist, but there must be at least one. A member type can be defined as a built-in simple type, a user defined simple type, or a local simple type defined anonymously within the union type.

A union type can also include list, union, and restricted simple types, among its members.

MRM domain

The MRM parser does not apply value constraints until the data is in the logical tree. This means that it is not possible to choose between two simple types that are derived from the same fundamental type, but have different value constraints (for example, an integer in the range 1-10 and an integer in the range 11-20). If you attempt to choose between two such types, a warning is displayed in the task list, and the parser ignores the value constraints when it resolves the union. The message definition editor provides additional support for enumeration and pattern facets directly on a Union type, to enable the import of any schema that uses them, but the editor issues a warning that enumeration and pattern facets are ignored by the MRM parser.

Value constraints

Value constraints are known as facets by XML Schema. Any value constraints that are applied to a derived type must further restrict the base type. It is not valid for a derived type to weaken or remove a value constraint that its base type has defined. If no value constraints are applied to the derived type, the derived type is almost identical to its base type, but it is treated as a restriction of the base type in situations where that is relevant (type inheritance and element substitution).

The logical properties of a simple type.

Message model objects: type inheritance:

The XML Schema language allows a type definition to be based on another type definition. In this way, a hierarchy of types can be constructed.

This topic outlines the concepts of *type inheritance*, and highlights some important issues relating to substitution.

A full discussion of XML Schema type inheritance can be found on the World Wide Web Consortium (W3C) website, or in numerous books about XML Schema.

Restriction and extension: A type is a *restriction* of its base type, if elements of the derived type have a smaller range of valid values (or valid type members) than elements of the base type.

- For example, a restriction of a complex type might reduce the number of occurrences of one of its type members, or might omit that type member completely.
- Similarly, a restriction of a simple type might lower the `Max Inclusive` facet value, or raise the `Min Inclusive` facet value.

A type is an *extension* of its base type if elements of the derived type have a wider range of valid values (or valid type members) than elements of the base type.

- For example, an extension of a complex type might add type members that were not present in the base type, or might allow a type member to repeat.
- Similarly, an extension of a simple type must *always* be a complex type that is based on the simple type; you cannot extend a simple type by widening its range of valid values.

Special rules apply to the derivation of simple types. A simple type cannot extend another simple type. This ensures that restrictions that are imposed by a simple type cannot be removed by deriving another simple type from it.

However, a complex type can extend a simple type. This does not affect the range of valid values of the simple type, but it does allow attributes to be added. The result of extending a simple type is always a complex type that contains zero or more attributes.

Controlling type inheritance: The `final` attribute on a complex type can take three values, with the following effects:

- restriction: It is not valid to derive another complex type from this type by restriction.
- extension: It is not valid to derive another complex type from this type by extension.
- all: It is not valid to derive another complex type from this type by either extension or restriction

Type inheritance and substitution: XML Schema provides two different substitution mechanisms, both of which use type inheritance information to allow or disallow substitutions.

Element substitution is controlled by substitution groups, and element substitution can be blocked or allowed for extension and restriction by settings on either the element itself or the type of the element.

Type substitution allows the type of the element to be defined within the instance document, using the xsi:type attribute on the element, so that the real type of the element is not known until the element has been partly parsed. This mechanism can also be blocked or allowed based on the derivation method of the types involved.

Message model objects: groups:

A *group* is a list of elements that defines how those elements appear in a message. Groups define the composition and content validation of a complex type.

Groups can be ordered (sequence or orderedSet) unordered (all or unorderedSet), or selective (choice or message). Groups define the composition and content validation of a set of type members.

What are groups for?: Groups can be used for any of the following purposes:

- To define the entire element content of a complex type.

  A complex type can refer to a global group that completely defines its content. (If it does not, the content of the complex type is defined by an *anonymous local group*, which is hidden within the Message Definition Editor.)
- To represent a common substructure within more than one type.

  Two or more complex types can refer to the same global group, if they both contain the same subset of elements.
- To change the composition midway through a complex type.

  You might have a complex type that is a sequence of three members, but the second member is a choice of two elements. To model this circumstance, a group with `composition` set to choice can be inserted as the second member of the sequence.

Contents of a group: Groups can contain complex elements, simple elements, wildcard elements, and groups.

By combining these components, the structure of any message can be modeled. Wildcard elements can be included to enable the presence of unmodeled elements, thus making the message model robust and flexible.

Global and local groups: Groups can be global or local.

A *global group* can be used in more than one place in the message model. It represents a structure that is present in more than one place in the message model. A global group must be given a unique name by which it can be referenced.

A *local group* is defined in one position within one group, and is not available for reuse elsewhere in the message model. Local groups do not have a name, and are displayed by using the composition of the group.

Composition: In XML Schema, a group can have its `composition` set to sequence, all, or choice.

- A sequence is a set of elements that must be present in the same order as they are listed.
- An all group is a set of elements that can be present in any order, and cannot repeat.
- A choice is a set of elements, only one of which can be present in any given message.

When using a message set, other compositions are also possible. For more information, see "XML Schema extensions in message sets" on page 1173.

Content validation: The `Content validation` property is applied only if the domain is MRM or IDOC, and if validation is selected.

Content validation determines how strictly the content of the group is validated. See "MRM content validation" on page 5422 for more details.

Allowable values of the `Content validation` property are:

Closed
: The contents of the group are validated strictly against the model. Only elements that are defined as children of the group can be present as children.

Open Defined
: Elements that are declared within the same message set can be present as children of the group, even if they are not defined as children.

Open Any elements can be present as children of the group.

The `Content validation` property does not affect validation in the XMLNSC or SOAP domains. Validation in these domains follows the rules of XML Schema 1.0.

The Message Definition editor is the default editor provided by the Broker Application Development perspective for editing message definition (`.mxsd`) files.

Message model objects: attributes:

An *attribute* describes an XML attribute. They are used only when the data is XML.

Attributes are provided to simplify the modeling of XML messages; if none of your messages use the XML physical format, use simple elements instead.

Attributes and XML: The most common use for an attribute is to model an XML attribute within an XML message. In this scenario, each attribute that can be present in the XML message has a corresponding attribute in the logical message definition.

Attributes in other physical formats: Sometimes a message must be parsed as XML, but written in another physical format (Custom Wire Format or Tagged Delimited String Format). In this case, any attributes in the message are treated in the same way as simple elements with the same properties.

Global and local attributes: Attributes can be global or local.

A *global attribute* can be used in more than one place in the message model. It must be given a unique name by which it can be referenced by an *attribute reference*.

A *local attribute* is defined in one position within one complex type, and cannot be used elsewhere in the message model.

Optional attributes: Attributes can be defined in XML Schema as optional, required, or prohibited. Attributes cannot repeat. For further information, see "Cardinality: optional, required, and repeating elements" on page 1197.

Default and fixed values: An attribute can be given a default value so that, if the attribute is missing from the message, the default is used. Alternatively, a fixed value can be defined, and the attribute always takes that value. The precise use of default and fixed values is dependent on the message domain.

Value constraints: The value of an attribute can be constrained by using *value constraints*, which define the range of legal values for the attribute. Value constraints are associated with the simple type on which the attribute is based. For more details, see "Message model objects: simple types" on page 1180. In XML Schema, the term for *value constraint* is *facet*.

Add a local attribute to a message, complex type, or complex element.

Message model objects: Wildcard elements:

For XML messages, a wildcard element represents an element that is not present in the message model, but which might be present at the position of the wildcard element in a message.

Wildcard elements provide a means of adding flexibility to the message model, so that messages can be parsed even if they do not exactly match the message model.

Wildcard elements can be present only within a complex type or group with `Composition` of sequence and `Content Validation` of closed. Wildcard elements provide a similar capability to setting the `Content Validation` property of a complex type or group to Open or Open Defined.

The `Process Content` and `Namespace` properties control the namespace to which elements that are present at the position of the wildcard element must belong.

MRM domain

If you have enabled validation in your message flow, and your message is in the MRM domain, wildcard elements are validated against the model according to the following rules:

- If `Process Content` is set to strict, only elements that are declared in the same message set are able to be present in the position of the wildcard element.
- If `Process Content` is set to lax or skip, any element is able to be present in place of the wildcard element.

If you are working with WebSphere Message Broker Version 6.0 or earlier, the number of elements that can match the wildcard element is unpredictable (`Min Occurs` and `Max Occurs` are ignored).

"MRM content validation" on page 5422
`Content Validation` is applied when the domain is MRM and validation is enabled. The `Content Validation` property specifies how strictly the MRM parser validates the members of a complex type or group.

Message model objects: Wildcard attributes:

For XML messages, a *wildcard attribute* enables unmodeled attributes to be present in a message.

The `Process Content` and `Namespace` properties control the namespace to which attributes that are present in the position of the wildcard must belong.

MRM domain

If you have enabled validation in your message flow, and your message is in the MRM domain, wildcard attributes are validated against the model according to the following rules:

- If `Process Content` is set to strict, only attributes which are declared in the same message set can be present in the position of the wildcard attribute.
- If `Process Content` is set to lax or skip, any attribute can be present in the position of the wildcard attribute.

Tip: If the namespace property is set to the namespace of the message set, these rules are then similar to the behavior of the XMLNSC domain in validating mode.

`Content Validation` is applied when the domain is MRM and validation is enabled. The `Content Validation` property specifies how strictly the MRM parser validates the members of a complex type or group.

Message model objects: attribute groups:

For XML messages, an *attribute group* defines a set of attributes that can be present in a complex type.

An attribute group provides a way to include the same set of attributes in more than one complex type, without duplicating the definitions.

For example, if most of the elements in your message model have the attributes 'amount', 'currency' and 'date', these elements can be contained in a single attribute group, which is referenced by all the complex types that use them.

An *attribute* describes an XML attribute. They are used only when the data is XML.

Message model objects: simple type value constraints:

Value constraints, also known as *facets* in XML Schema, refine a simple type by defining limits on the values that it can represent.

It is often useful to be able to constrain the values that an element or attribute can take, perhaps to ensure that messages conform to business rules. This topic describes how to add value constraints to a simple type, in order to constrain the values of all elements or attributes that are based on that simple type.

If the model is deployed to WebSphere Message Broker, elements and attributes can be validated against value constraints, so that violations are reported as errors or warnings. The XMLNSC domain uses all the different types of value constraint when validating. The MRM domain uses a subset; the restrictions are noted later in this section.

Types of value constraint:

Length Constraints: `Length`, `Min Length`, `Max Length`
Using length constraints, the length of all elements based on the simple type can be constrained, or even limited to a single value.

Length constraints can be applied to simple types that are derived from xsd:hexBinary, xsd:base64Binary or xsd:string (including built-in schema types such as xsd:normalisedString).

Length constraints are inherited from ancestor types, and any length constraints that are defined for a simple type must not relax the constraints that are imposed by any of its ancestor types. For example, a type 'longString' (`Max Length`=100) cannot be derived from a type 'shortString' (`Max Length`=10).

Note: For the MRM domain, by default, `Length` value constraints are converted to `Max Length` constraints when a message set is added to a BAR file. This default avoids WebSphere Message Broker raising spurious validation errors for fixed-length data structures, where the strings tend to be padded to fit a fixed-width field. If strict length validation is required, this default can be changed in the message set properties by changing the flag `Broker treats Length facet as MaxLength`.

Range constraints: `Min Inclusive`, `Max Inclusive`, `Min Exclusive`, `Max Exclusive`
Range constraints specify the allowable range of values for all elements that are based on the simple type. Inclusive constraints include the specified endpoints in the permitted range, whereas exclusive constraints do not. Range constraints can be applied to simple types that are numeric, or that relate to calendar and time values. They cannot be applied to strings, because the ordering of string values depends on the character set that is used.

Range constraints are inherited from ancestor types, and any range constraints that are defined for a simple type must not relax the constraints that are imposed by any of its ancestor types. For example, a type 'largeNumber' (`Max Inclusive`=100) cannot be derived from a type 'smallNumber' (`Max Inclusive`=10).

Note: For the MRM domain, exclusive constraints cannot be applied to non-integral types (float, decimal, double, dateTime, and other non-integral types).

Enumeration constraints
An enumeration constraint specifies a single permitted value for all elements that are based on the simple type. A list of permitted values can be specified by defining more than one enumeration constraint for the same simple type. Enumeration constraints can be applied to all simple types.

Enumeration constraints are inherited from ancestor types, and any set of enumeration constraints that are defined for a simple type must not increase the range of permitted values. For example, a type 'AllColors' (with enumerations for all colors of the rainbow) cannot be derived from a type 'MonoColors' (with enumerations for 'black' and 'white' only).

Precision constraints: Total Digits and Fraction Digits
Precision constraints relate only to decimal and integer values. They limit the number of significant digits (total digits) and, for decimals, the number of decimal places (fraction digits) for all elements that are based on the simple type. Precision constraints can be applied to simple types that are derived from xsd:decimal and xsd:integer.

Precision constraints are inherited from ancestor types, and any precision constraints that are defined for a simple type must not relax the constraints that are imposed by any of its ancestor types. For example, a type 'veryPrecise' (`Fraction Digits`=10) cannot be derived from a type 'notVeryPrecise' (`Fraction Digits`=1).

Note: For the MRM domain, the broker applies these constraints only to xsd:decimal and user types that are derived from it; precision constraints that are applied to an integer simple type are ignored.

Pattern constraints

A pattern constraint is a regular expression that specifies a set of permitted values for all elements that are based on the simple type. Multiple patterns can be defined for the same simple type, permitting complex validation rules to be expressed in logically separate parts. Each pattern constraint on a simple type contributes to the set of permitted values for elements that are based on the simple type; that is, all the patterns are combined by using Boolean OR.

As with all value constraints, a simple type can inherit pattern constraints from the simple type on which it is based. In this case, the set of pattern constraints that are contributed by each ancestor type must be satisfied, in addition to the set that is contributed by the simple type itself; that is, the sets of pattern constraints from each level in the type hierarchy are combined by using Boolean AND.

Note: For the MRM domain, pattern constraints can be applied only to simple types that are derived from xsd:string.

White space constraints

A white space constraint specifies how a parser treats white space for all elements that are based on the simple type.

Note: For the MRM domain, white space constraints are not applied. The MRM physical formats enable white space to be precisely controlled for each physical format that is defined for the message, but these physical properties are separate from the white space constraint in the logical model, and are not used for validation.

The MRM XML physical format generally respects all the settings in the logical model, but shares certain restrictions in common with the other physical formats.

"MRM TDS format: Relationship to the logical model" on page 1243
TDS separation types and logical model properties have some restrictions, such as group composition and group content validation.

Message model object identification:

Objects in a message model (elements, attributes, types, groups) are identified by their name only.

This means that no two objects in the same scope can have the same name. Name clashes can be avoided more easily if global objects are used only when necessary. Local objects are not visible outside of the scope of their parent object, so their names can be reused without causing a name clash.

Namespaces
: If namespaces are enabled for a message set, each message definition file within the message set can specify a namespace. Namespaces are an XML Schema mechanism for organizing groups of related objects into a named 'module'.

  Global objects in different namespaces can share the same name. Therefore, namespaces offer another means of avoiding name clashes among global objects.

Valid names
: Since the message model is based on the XML Schema language, the name of every message model object must be a valid XML Schema identifier. For information about what constitutes a valid XML Schema identifier, see XML Schema Part 0: Primer.

For details about XML Schema, see XML Schema Part 0: Primer on the World Wide Web Consortium (W3C) website.

Multipart messages:

A *multipart message* contains one or more other messages within its structure. The contained message is sometimes referred to as an *embedded message*.

Tip: Multipart messages are used when working with messages that are modeled by using message sets.

A multipart message must contain a group, or a complex type, with its `Composition` property set to Message. This group or complex type can contain a list of references to messages that can be present at that location in the message structure. If the group or complex type is empty, any message can be present. When a message is parsed, only one embedded message can be present in that location.

Message envelopes: A common use of multipart messages is to define an outer message with a fixed structure. This outer message is called the *message envelope*. Within the message envelope a group or complex type is included, as described earlier in this topic. Examples of message standards that can be modeled by using this technique are EDIFACT, X12, SWIFT, SOAP XML, SAP ALE IDoc, multipart MIME, and RosettaNet.

Identifying the embedded message: When a multipart message is parsed, the parser must be able to identify the embedded message; it might be any of the messages that are referenced by the group or complex type, or it might be a message that is not referenced by the group or complex type, perhaps from a different message set. This is achieved by using one of four techniques, *Automatic*, *Message Identity*, *Message Path*, or *Manual*.

Automatic
: Used when parsing XML messages, such as SOAP. The parser automatically identifies and parses embedded messages by using the tag in the XML document.

Message Identity
: Used by the MRM parser. See "Identifying an embedded message by using a Message Identity" on page 1193.

Message Path
: Used by the MRM parser. See "Identifying an embedded message by using a Message Path" on page 1196.

Manual
: Used by the MIME parser. The parser treats embedded messages as BLOBs. If you want to parse the BLOB by using another parser, you must do so manually by using ESQL, or Java, or a ResetContentDescriptor node.

Restrictions: Unless using the *Manual* identification technique, all embedded messages must be of the same physical format as the outermost message, and have the same character set and encoding.

When using the *Automatic* or *Message Path* identification techniques, all embedded messages must be from the same message set as the multipart message.

Related tasks:

"Creating a multipart message" on page 2919
A multipart message occurs when you embed a message in another message.

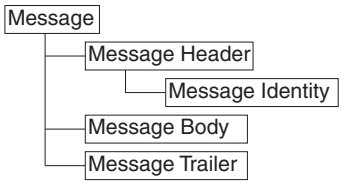
"Accessing embedded messages in the MRM domain" on page 2594
If you have defined a multipart message, you have at least one message embedded within another. Within the overall complex type that represents the outer messages, you can model the inner message in two ways.

Identifying an embedded message by using a Message Identity:

You can identify an embedded message by using the Message Identity. This technique is used by the MRM domain, and replaces the use of the Message Key.

Tip: Multipart messages are used when working with messages that are modeled by using message sets.

The Message Identity technique for identifying embedded messages is useful when a multipart message has a format such as that shown in the diagram:



In this example, the Message Header and Message Trailer act as an envelope for the message body. They typically have a fixed structure, although the Message Body can be defined with many different structures.

A place holder for an embedded message is created by setting the `Composition` property of the complex type or group of the Message Body element to Message. This enables an embedded message to be added within the outer Message, creating a multipart message.

When using the Message Identity technique to parse such a multipart message, the embedded message must be identified earlier in the Message Header by using a Message Identity element. A Message Identity Element is a string element (or attribute) that precedes the embedded message in the model and whose `Interpret Value As` property is set to Message Identity.

When a multipart message is input to a message flow, the Message Identity element must have a value that corresponds to either the `Name` or the `Message`

Alias of the next embedded message in the bit stream. This enables the MRM parser to correctly identify the embedded message in the model.

For cases where the Message Identity element value does not match the Name of the message, use the Message Alias property to specify this value. The MRM parser tries to match on Name first, and if that fails, it tries to match on Message Alias.

When the MRM parser has encountered a Message Identity element, its value applies to all embedded messages that are contained immediately within the current message. This does not apply to embedded messages within embedded messages; any embedded message must have its identity provided by a Message Identity element within its immediate parent message.

If a second Message Identity element is encountered within the current message, its value overrides any previously held. This enables different peer embedded messages to exist within a given message.

Message Identity takes priority over Message Path. If both are specified, Message Identity is used. Use only one of these techniques for a given multipart message.

Embedded messages defined in different message sets

By default, an embedded message is assumed to be defined within the same message set as the current message. This can be overridden by using a Message Set Identity, which works in a similar manner to a Message Identity.

An embedded message that is defined within a different message set must have its message set identified earlier in the message, by using a Message Set Identity element. A Message Set Identity Element is a string element (or attribute) that precedes the embedded message in the model and whose Interpret Value As property is set to Message Set Identity.

When a multipart message is input to a message flow, the Message Set Identity element must have a value that corresponds to either the Identifier, Name, or Message Set Alias of the message set that defines the next embedded message in the bit stream. This enables the MRM parser to correctly identify the message set to use.

If the Message Set Identity element value does not match the Identifier or Name of the message set, use the Message Set Alias property to specify this value. The MRM parser tries to match on Identifier first, then on Name, and finally on Message Set Alias.

After the MRM parser has encountered a Message Set Identity element, its value applies to all embedded messages that are contained within the current message. It also applies to embedded messages within embedded messages, unless an embedded message also contains a Message Set Identity element.

If a second Message Set Identity element is encountered within the current message, its value overrides any previously held. This enables peer embedded messages to be contained within different message sets.

The following example of an X12 message shows the use of both Message Identity and Message Set Identity. The field that contains 004010X092 within the GS segment on line 0002 holds the Message Set Identity as a Message Set Alias. The

207 on line 0003 in the ST segment is the Message Identity held as a `Message Alias`. The embedded message is from line 0004 - 0015 inclusive.

Note: The line numbers and spaces at the beginning of each line are for illustrative purposes only and do not exist in the actual message.

Physical format considerations

Both Message Identity and Message Set Identity are applicable to all physical formats. Versions of the TDS physical format before Version 6.0 included embedded message identification by Message Key, which worked in a similar manner to Message Identity. Message Key has been deprecated and is superseded by Message Identity.

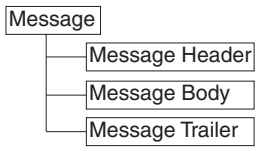
This technique is used by the MRM domain.

In the diagram, the Message Header and Message Trailer act as an envelope for the message body. Typically, they have a fixed structure, but the Message Body can be defined with many different structures.



A place holder for an embedded message is created by setting the `Composition` property of the complex type or group of the Message Body element to Message. This enables an embedded message to be added within the outer message, creating a multipart message.

When using the Message Path technique to parse such a multipart message, the embedded message must be identified by a fixed path to the innermost message from the outermost message. For this example, this would be:

```
Message/Message Body
```

If the path to the innermost message contains intermediate elements, these intermediate elements must also be included in the path. In the following example, these elements are shown in bold:

```
Message/Data1/Data12/Message Body
```

This technique can be used to identify nested embedded messages as well, by extending the path. For example:

```
Message/Data1/Data12/Message Body/Data2/Inner Message
```

The path is specified by using one or both of two properties, the `Message Type` property of a WebSphere Message Broker input node (or MQRFH2 header) and the `Message Type Prefix` property of the containing message set. These two properties are combined to produce a final path that is used to locate embedded messages.

Message Identity takes priority over Message Path. If both are specified, Message Identity is used. Use only one of these techniques for a given multipart message.

You cannot use the Message Path technique to identify multiple peer embedded messages.

Embedded messages defined in different message sets

This option is not supported by the Message Path technique.

Physical format considerations

The Message Path technique is applicable to all physical formats.

Related concepts:

A multipart message occurs when you embed a message in another message.

"Accessing embedded messages in the MRM domain" on page 2594
If you have defined a multipart message, you have at least one message embedded within another. Within the overall complex type that represents the outer messages, you can model the inner message in two ways.

Related reference:

"Message set properties" on page 5371
Message sets have properties that you can set to define their characteristics and the way in which they are processed.

Cardinality: optional, required, and repeating elements:

The number of occurrences of an element can be controlled using the properties `Min Occurs` and `Max Occurs`. Using these properties, an element can be defined as mandatory, optional or repeating.

Elements: A *mandatory*, or required, element has `Min Occurs`>= 1. A mandatory element must occur at least once in the message.

An *optional* element has `Min Occurs` = 0. An optional element can be omitted from the message.

A *repeating* element has `Max Occurs`> 1 to indicate a bounded number of repeats, or `Max Occurs`=unbounded (sometimes displayed as -1), to indicate an unlimited number of repeats. A repeating element occurs more than once in the message, and all the occurrences must appear together without any other elements between them.

If a complex type or a group contains two, or more, members that refer to the same element, the second reference is a *duplicate*. This is different from a repeating element, because the two references are typically separated by other members of the type or group. In the message, the second occurrence typically does not appear immediately after the first occurrence.

Attributes: The number of occurrences of an attribute can be controlled by setting it to *required*, *optional* or *prohibited*.

A *required* attribute is similar to a mandatory element - it must occur in the message.

An *optional* attribute is similar to an optional element - it can be omitted from the message.

A *prohibited* attribute must not appear in the message.

An attribute is not allowed to repeat, and duplicate attribute references are not allowed within an attribute group.

"Message modeling concepts" on page 1155
Message modeling is a way of predefining the message formats that are used by your applications.

"Message model objects" on page 1174
An introduction to the objects that make up a message model. Message model objects are defined by XML Schema 1.0, except for Message which is a WebSphere Message Broker extension to XML Schema.

"Message model objects: elements" on page 1176
An *element* is a named piece of information (a field) within a message, with a meaning that is agreed by the applications that create and process the message.

"Message model objects: types" on page 1177
Types describe the data content of elements.

"Message model objects: attributes" on page 1185
An *attribute* describes an XML attribute. They are used only when the data is XML.

Self-defining elements and messages:

An instance element is *predefined* if it is possible for the parser to find a matching element definition in the message model with an appropriate set of properties and in the correct context. Otherwise, it is *self-defining*. Similarly, an entire message is self-defining if no corresponding message is present in the message model.

Self-defining elements can be used only when the format of the message is a self-describing one, such as XML or JSON. For general text or binary formats (for example, comma separated), you must ensure that your message model defines every message and every element that must be parsed.

If you have chosen not to model your messages, or you have a model but have chosen not to deploy it to the broker, all messages and elements are self-defining. In this situation, you cannot use message definitions to influence the parsing and writing of elements; the self-defining elements are parsed and written according to the default behavior of the parser and writer.

Self-defining elements, and all elements within a self-defining message, are not validated against value constraints, and any missing fields are not assigned default or fixed values, and all data is assumed to be string type unless the parser is able to deduce the type in a reliable manner.

Related concepts:

"Why model messages?" on page 1158
WebSphere Message Broker supplies a range of parsers to parse and write message formats. Some message formats are self-defining and can be parsed without reference to a model. Most message formats, however, are not self-defining, and the parser must have access to a predefined model that describes the message, if it is to parse it correctly.

"Message model objects: simple type value constraints" on page 1188
Value constraints, also known as *facets* in XML Schema, refine a simple type by defining limits on the values that it can represent.

Substitution groups in the message model:

Substitution groups are an XML Schema feature that provides a way of substituting one element for another in an XML message.

A substitution group is a list of global elements that can be present in place of another global element, called the *head element*.

A substitution group is defined by setting the `substitution group` property on one global element (the *member* element) to point at another global element (the *head* element). This adds the member element to the substitution group of the head element.

Head elements

A head element is an element that can be substituted. When a message is parsed, one of its member elements can be present in place of the head element without causing a validation error.

Abstract elements

An abstract element is a head element which must be substituted, and is indicated by the 'abstract' attribute on the element. Typically, abstract elements have other elements in their substitution group, otherwise they are of little use. Wherever an abstract element is present in a message definition, a member of its substitution group must be present instead.

The `block` attribute on elements

The `block` attribute on an element limits the set of global elements that can substitute for the element. The `block` attribute can take any subset of the values restriction, extension, substitution, or all.

- If the `block` attribute contains restriction, an element that is based on a restriction of the type of the element cannot be substituted for the element.
- If the `block` attribute contains extension, an element that is based on an extension of the type of the element cannot be substituted for the element.
- If the `block` attribute contains substitution, an element that is a member of the substitution group of the element cannot be substituted for the element.
- If the `block` attribute contains all, all of the above limits apply.

The `final` attribute on elements

The `final` attribute on an element limits the set of global elements that can be a member of the substitution group of the element. The `final` attribute can take any subset of the values restriction, extension, or all.

- If the `final` attribute contains restriction, an element that is based on a restriction of the type of the element cannot be in the substitution group of the element.
- If the `final` attribute contains extension, an element that is based on an extension of the type of the element cannot be in the substitution group of the element.
- If the `final` attribute contains all, both of the above limits apply.

The `block` attribute on complex types

The `block` attribute on a complex type limits the set of other types that can substitute for that type. The `block` attribute can take values restriction, extension, or all. The meanings for these values are the same as the values that are shown for the block attribute on an element. An element that is a member of a substitution group can substitute only for the head element if its type is compatible with the block attribute on the type of the head element.

Default `block` and `final` attributes

A default for the `block` and `final` attributes can be set at the message definition file level. If a default for one or both of these attributes has been set and the relevant `block` or `final` attribute has not been set at the object level, the default setting is used for that object. You can override the default setting at the object level.

Related concepts:

"XML Schema" on page 1172
XML Schema is an international standard from the World Wide Web Consortium (W3C) that defines a language for describing the structure of XML documents.

"Message model objects: type inheritance" on page 1182
The XML Schema language allows a type definition to be based on another type definition. In this way, a hierarchy of types can be constructed.

Message categories:

Message category files have the suffix `.category`. These files are optional. You can have many message category files in a message set.

A message category provides another way of grouping your messages, perhaps for documentation or convenience purposes. A message category can also be used for assisting in the generation of Web Services Description Language (WSDL) files, but this use is deprecated. For more information, see "Generate WSDL" on page 1274.

A message set category file is created by using the New Message Category File wizard.

When you have created your message category file, you must specify one key property.

`Message Category Kind`

The Message Category Kind indicates whether the message category is to participate in the generation of WSDL files.

You can then add messages to the message category file. If the message category is to participate in WSDL generation, assign appropriate values to the `Role Name` and `Role Type` properties of each member message.

Message category identification: The name of a message category is provided by the name of the `.category` file. You can change the message category name by renaming the file.

A message category provides a way of grouping your messages.

Namespaces in the message model:

Use namespaces to qualify message model object names.

A single XML instance document can contain elements and attributes that are defined for, and possibly used by, multiple applications. Two different elements or attributes within the same document might require the same name. Individual applications must be able to recognize the elements and attributes that they are designed to process. In circumstances such as this, the definitions can be distinguished from each other by qualifying each element with a different namespace. This avoids problems of name collision and mistaken recognition.

XML Schemas can define a target namespace. Global elements, attributes, groups, and types that are defined within an XML Schema are qualified by the target namespace, if it has been defined. Optionally, local elements and attributes can also be qualified by the target namespace. Therefore, namespaces assist in the development of a library of XML Schemas that can be developed independently. If the namespace name that is used for an XML Schema is unique, you do not have to be concerned about name clashes with objects that are defined within other XML Schemas.

The scope of a namespace extends beyond the scope of its containing document and is identified by a Uniform Resource Identifier (URI). In order to serve its purpose, a URI must be unique. You might be more familiar with the concept of a Universal Resource Locator (URL). URIs often use the same syntax as URLs, but the URI definition is broader than the specification of a URL. This is an example of a URI: `http://mycompany.com/xml_schema`

A namespace prefix is declared as a shorthand for the full URI name and this is used to qualify all elements that belong to that namespace. The prefix to be substituted for a namespace in an XML instance document or XML Schema is specified by using an `xmlns` attribute. A default namespace can also be defined by using an `xmlns` attribute. If a default namespace is defined, any element or attribute with no prefix is qualified with the default namespace. If no default namespace is defined, any element or attribute with no prefix is not qualified by a namespace.

Namespaces and the message model

The message model supports namespaces within message sets. However, you can choose whether to enable or disable namespaces for your message set. If you disable namespaces when you create your message set, you can enable namespaces later. However, when you have enabled namespaces for a message set you cannot disable namespaces.

A single message set which has namespaces enabled can contain a number of different namespaces. Each namespace is represented by a different Message Definition File. When you create a Message Definition File, you can choose whether it has an associated namespace, or whether it is in the notarget namespace. If you associate a namespace with a Message Definition File, you must also choose a prefix.

If the Message Definition File has an associated namespace, the following global objects are qualified with the namespace:

- Elements
- Attributes
- Simple Types
- Complex Types
- Groups
- Attribute Groups

Optionally, local elements and attributes can be qualified with the namespace.

Objects that are defined within a Message Definition File can reference objects in other Message Definition Files within the same message set. To do this, import or include one Message Definition file within another Message Definition File.

Message parsing and message flows

WebSphere Message Broker parsers for XML data recognize prefixed names in the XML messages that they parse, and internally map these to the correct namespace. The message tree stores the name and the namespace of the element or attribute.

Namespaces can be used even when the data is not XML. Adapter schema, and message definition files can be created with an associated target namespace. Though the data itself does not contain prefixed names, the namespace is obtained from the corresponding element in the file. Again, the message tree stores the name and the namespace of the element.

If you are using XML format in the MRM domain, elements or attributes are matched, based on the namespace in the dictionary when the parsed message is matched against the dictionary that is generated from the message model. Therefore, for an element or attribute in a message to match with the dictionary, both its name and its namespace must match.

If you are using the DataObject domain, the SOAP domain, or the XMLNSC domain (in validating mode), elements or attributes are matched, based on the namespace in the XML Schema when the parsed message is matched against the XML Schema that is generated from the message model. Therefore, for an element or attribute in a message to match the XML Schema, both the name and the namespace of the element or attribute must match.

You can specify namespaces when writing ESQL or Java. It is not necessary to write ESQL or Java that is namespace aware if you are not using namespaces. However, if you decide to use namespaces it is necessary to write namespace-aware ESQL or Java. The namespace in which an element is contained is stored in the message tree when parsed. This is a logical property and it is held regardless of the physical wire format in which messages are parsed and written. Syntax has been added to ESQL to make it easy to reference namespaces of other elements by using defined prefixes. In Java, XPath expressions are used to reference elements.

Importing from other formats

The message model enables you to create Message Definition files from other formats by importing them into the WebSphere Message Broker Toolkit.

- If you import an XML DTD file, the Message Definition File that is created is in the notarget namespace.
- If you import an XML Schema file, the target namespace of the created Message Definition File depends on whether namespaces have been enabled for the message set.
  - If namespaces are enabled, the target namespace of the Message Definition File that is created is the target namespace of the XML Schema that is being imported.
  - If namespaces are disabled for the message set, the created Message Definition File is in the notarget namespace. This type of import does not provide full namespace support. If you are using WebSphere Message Broker, you do not have to write namespace-aware ESQL or Java to process an XML message that is parsed against the dictionary that is generated from this message model. For reasons why you might want to do this, see “Importing XML Schema into message sets with namespaces disabled” on page 1259
- If you import a COBOL Copybook or a C Header file, the target namespace of the created Message Definition File depends on whether namespaces have been enabled for the message set.
  - If namespaces are enabled, the target namespace of the Message Definition File that is created is the notarget namespace. This default namespace can be overridden by specifying a target namespace in the New Message Definition File wizard. For reasons why you might want to do this, see “Namespaces with non-XML messages” on page 1206.
  - If namespaces are disabled for the message set, the Message Definition File that is created is in the notarget namespace

Namespaces with MRM XML messages:

The namespace that is associated with a message definition file is part of the logical layer of the message model.

Therefore, it is not dependent on an XML Wire Format being present. However, if you have an XML Wire Format, the namespace information from the logical layer is used to populate some of the properties of the XML Wire Format. If namespaces are enabled for a Message Set, in the XML Wire Format, a table of namespace URI/prefix pairs is maintained. This table is initially populated with the namespaces of all of the Message Definition Files with their prefixes when they were created.

If your message set has namespaces enabled, the broker does not store the values of any `xmlns` attributes in the tree when it parses an XML instance document. It also does not store the values of any `Schema Location` and `No Namespace Schema Location` attributes. When an XML document is written out, the broker regenerates this information from the properties of the XML Wire Format of the message set.

The table of namespace URI/prefix pairs is used by the MRM Domain when it produces an XML message. Elements and attributes that are qualified by a namespace are prefixed with the corresponding prefix from the table. The broker also manages the output of the corresponding `xmlns` attributes that map the prefixes to namespaces. You can choose whether `xmlns` attributes for all of the entries in the namespace URI/prefix table are written at the start of the document, or whether they are only written in the document when required.

If namespaces are enabled for a Message Set, in the XML Wire Format there is a table of schema locations that map namespace URIs to file names. You can add entries to this table and you can map a file name to the notarget namespace. If you are using WebSphere Message Broker, this table is used to produce `schemaLocation` and `No Namespace Schema Location` attributes at the start of the XML document.

Namespaces with non-XML messages:

The use of namespaces by WebSphere Message Broker is not necessarily limited to XML message models.

There is one scenario where the use of namespaces by non-XML message models can simplify the ESQL or Java code that you write. Before describing this scenario, it is important to understand that the MRM parser, when parsing messages that are defined in a file that has a target namespace, produces a logical message tree that contains both name and namespace information. For non-XML messages, the namespace is obtained from the element declaration in the file, and not from the data.

Consider a transformation scenario where a message from a COBOL application requires to be transformed into namespace-aware XML; for example, a SOAP XML message. The transform must map the logical message tree that was created for the COBOL message to a logical message tree that matches the XML message. If the COBOL message tree does not contain namespace information, each mapping from a COBOL field to an XML element must set the namespace for the XML element. However, if the COBOL message tree already contains the required namespace information, this mapping is much simpler.

To enable the MRM parser to create namespace information in a message tree that was created from a non-XML message, you must specify a target namespace for the message definition file. For MRM, this must be done as part of the file creation process. Make the target namespace of the file the same as the target namespace of the XML message into which the non-XML message is being transformed.

- If you are creating your non-XML message model by hand in the message editor, use the New Message Definition File wizard to specify a target namespace.
- If you are importing from COBOL or C, use the New Message Definition File wizard, or the **mqsicreatemsgdefs** command options file, to specify a target namespace.

When dealing with both the message tree for the non-XML message and the message tree for the XML message, the ESQL or Java code that you write to perform the transformation must be namespace aware.

Specifying namespaces in the Message Type property:

When using the MRM domain, the *Message Type* property is used to specify the name of the message.

The format of a simple message type is `{namespace-uri}:name` where *name* is the name of the message, and *namespace-uri.* identifies the namespace. The namespace must be the full URI specification and must be enclosed in braces.

The format `{namespace-uri}name` (that is, with no colon) is also valid. This maintains compatibility with previous versions of the broker product.

If you omit `{namespace-uri}`, the first match for the name that is found in the model is used. You can do this if namespaces are not enabled for the message set, or if a name is unique within a message set. However, if a name is not unique, you must specify the namespace to be sure that the correct match is made in the model.

The following are examples of message types:

- A simple message type for a message in a real target namespace: `{http://www.ibm.com/space}:name`
- A simple message type for a message in the notarget namespace: `{}:name`
- A simple message type for a message in a message set that does not support namespaces: `name`

When identifying an embedded message using a message path, a message type path would be entered as A simple message type for a message in a real target namespace: `{http://www.ibm.com/space}:name`

The same name can occur in more than one namespace. To specify that a name is to be qualified with a specific namespace, the name must be prefixed with the namespace within the `Message Type`.

For example a `Message Type` with a single name would be entered as:

`{http://www.ibm.com/space}:id/.../{http://www.ibm.com/space}:name`

Message sets have properties that you can set to define their characteristics and the way in which they are processed.

Reusing message model files:

One message definition file can reuse message model objects defined in another file.

There are two mechanisms that XML Schema provides to reuse message definition files: **import** and **include**. The namespaces of the two files determine which of the **import** or **include** commands is be used:

	Target file has a target namespace	**Target file has notarget namespace**
Parent file has a target namespace	xsd:import	xsd:include[1]
Parent file has notarget namespace	xsd:import	xsd:include

Note: When a target namespace file includes a notarget namespace file, referencing an object in the target file from the parent file causes the object to be present in the namespace of the parent file.

When **import** or **include** are used, global objects from the target file can be used in the parent file. For example, an element in the parent file can be given a complex type defined in the target file.

The namespace of objects in the target file is preserved in the parent file, with the exception noted in the previous table of a target namespace file that includes a notarget namespace file. This exception is sometimes called the chameleon namespace effect.

Chameleon namespaces have limited support when used with the MRM domain. When referenced in the parent file, the objects in the target file are present in the namespace of the parent file, but they are assigned default physical format information. Therefore, physical format information defined in the target file is not available for use in the parent file. Use Chameleon Namespaces in the MRM domain to model XML messages only if physical format information has not changed from the default.

XML Schema provides a variation of xsd:include called xsd:redefine, which is not supported by WebSphere Message Broker. Using xsd:redefine gives a task list error. A Quick Fix is offered to convert occurrences of xsd:redefine into xsd:include when using message definition files.

Message model integrity:

When you create your message model, it is important that it is internally consistent.

To assist with this, whenever you save a message definition file, it is validated as follows:

Logical validation
: This validation ensures that the logical model is correct. For message definition files, this involves ensuring that the rules of XML Schema have been correctly followed.

Physical validation
: This validation ensures that any physical properties that you have specified for your model have been correctly populated and are consistent. There is a set of checks for each of the MRM domain physical formats - CWF, XML, and TDS.

  After model validation has taken place, any errors or warnings are shown in the task list. Double clicking a task list entry opens the file and positions the editor at the object in error. Organize the task list so that errors are shown before warnings. In this way, errors are not hidden. The task list provides a comprehensive filtering capability if you want to hide low priority warnings, or warnings that you are know about and are comfortable with.

  The deployment of a message model in a broker archive (BAR) file is prevented if any errors are present. The presence of warnings alone does

not prevent deployment, but high priority warnings must be reviewed because a model that generates such warnings might be incomplete.

Where task list warnings or errors occur, these are listed in the Problems view of the Broker Application Development perspective. While a majority of these require you to manually investigate and resolve them, a number of warnings and errors that meet specific criteria can be repaired by using a quick fix process.

Physical formats in the MRM domain

Each message definition file within a message set describes both the *logical structure* of your messages, and the *physical formats* that describe the precise appearance of your message bit stream during transmission.

If you are using the MRM domain or the IDOC domain, physical format information *must* be provided, as it tells the parser exactly how to parse the message bit stream.

You can think of a message as a packet of data that is sent from one place to another. The sender and receiver of the message will have agreed the structure of the message and what each field in the message means. This is the platform and protocol independent logical structure.

The sender and receiver will have also agreed on the physical representation of the message, how the data is physically laid out on the wire. For example, if you define a message that conveys information about a debit of an individual's bank account, it can be represented in different physical forms (examples are XML, or a fixed structure such as a COBOL copybook). The meaning and data are the same in both cases: only the physical layout has changed.

If you are using the MRM domain, you can model various different physical representations by using named physical formats.

- Use the Custom Wire Format (CWF) physical format to model fixed-format messages from applications that are written in C, COBOL, PL/I and other languages. This support includes the ability to create a message model directly from a C header file or COBOL copybook.
- Use the Tagged Delimited String Format (TDS) physical format to model formatted text messages, perhaps with field content identified by tags or separated by specific delimiters or both. This support is rich enough to model industry standards such as SWIFT, EDIFACT, and X12.
- Use the XML physical format to model XML messages, including those that use XML namespaces. This support includes the ability to create a message model directly from an XML DTD or XML Schema file.

Different physical representations: The following example shows how a simple logical message can have different physical representations.

The logical model defines the structure and order of the message. In the following example, the three fields are simple integers, and C follows B, which follows A:

```
int   A;
int   B;
int   C;
```

- A typical Custom Wire Format representation for this logical message would be 12 bytes of data, with each of `A`, `B` and `C` occupying 4 bytes. Alternatively, perhaps `A` is 4 bytes long, but `B` and `C` are only 2 bytes long. You supply the precise physical information for each field in the message as CWF properties.
- TDS enables several different representations to be modeled. Each integer can be preceded by a tag to identify it and a delimiter to terminate it, as follows:

  ```
  {A_tag:xxxxxxxx;B_tag:xxxxxxxx;C_tag:xxxxxxxx}
  ```

  An alternative might rely on the data being ordered so only the terminating delimiter must be specified, as follows:

  ```
  [xxxxxxxx;xxxxxxxx;xxxxxxxx]
  ```

  You supply the precise identification regime as TDS properties.
- A typical XML representation of this model is as follows:

  ```
  <Msg><A>xxxxxxxx</A><B>xxxxxxxx</B><C>xxxxxxxx</C></Msg>
  ```

where xxxxxxxx is the value of the integer represented as a string (XML deals only with strings). An alternate representation might be:

```
<Msg A="xxxxxxxx" B="xxxxxxxx" C="xxxxxxxx"/>
```

where the values of the integers are stored as XML attributes rather than XML elements. You supply the precise XML rendering for each field in the message as XML properties.

This shows that the logical model is unchanged. It is constant, regardless of the physical representation that you choose to model on top of it, using the physical format support provided by the MRM domain. The MRM parser is able to transform the message from the input physical representation to any number of output representations, based on the physical format layers that you have defined.

Creating physical formats: When you have created your message set, you can create physical formats. You do this using the Message Set Editor. When you next save the `messageSet.mset` file, any new physical formats are added to all the objects in all the message definition files in that message set.

The next time you edit an object in a message definition file, you see the physical formats in the properties hierarchy pane of the Properties tab. If you click a physical format for an object, you are presented with a property sheet where you can enter the information for that physical format for that object.

Not all objects have properties in all physical formats. For example:

- CWF properties apply only to local elements and attributes, and element and attribute references.
- Complex types and groups have only TDS properties.
- Messages have only XML properties.

These differences occur because of the different nature of each physical format, and are explained in more detail in the section for each physical format.

There is no limit to the number of physical formats you can create in a given message set. However there are some recommendations that apply if you want to mix physical formats of different kinds in the same message set.

Physical formats can be deleted if no longer required.

MRM Custom Wire Format:

Custom Wire Format (CWF) is the physical representation of a message that is composed of a number of fixed-format data structures or elements, which are not separated by delimiters.

Within a CWF messaging environment, it is not possible to distinguish one element from the next without knowledge of the message structure. To correctly determine the values of individual elements, the following information must be made available to the message parser:

- The order (this is defined in the logical properties)
- The length (can be specified in bytes, characters, or character units)
- The cardinality (that is, the number of repeats)
- The type of data contained in each element (this is partly defined in the logical properties but can be further qualified in the CWF physical format)
- A number of characteristics based upon the logical type of the data

A CWF physical format is typically used to describe messages which are mapped to a C structure, a COBOL copybook, or other programming language data structure definition.

You can add more than one CWF physical format to a message set, but within that message set, each physical format must have a unique name. When parsing a CWF message by using the MRM parser, the physical format name specifies the physical properties that are to be used by the parser.

Adding a CWF physical format to a message set enables you to process input messages and construct output messages in this format. Messages can be transformed between CWF and the other physical representations (for example TDS or XML). While the other physical representations support self-defining elements (that is elements which do not have a definition in the logical model) within the MRM domain, the parsing of a CWF message does not. Consequently, any such self-defining elements are discarded during the output of messages in CWF format.

MRM Custom wire format: Message model integrity:

When you save a message definition file, the definitions that it contains are checked to ensure that they make sense and provide sufficient information about the message. This action is called *model validation*.

The CWF physical format depends on fixed-format data structures. Therefore, most tests that are applied to a CWF message confirm that each fragment of a message - and therefore, the message as a whole - has a well-defined length. Therefore, these tests examine properties such as `Length`, `Length Reference` and `Length Units`.

Typically, one or other of `Length` and `Length Reference` must be set. If `Length Reference` is set, it must refer to an element that is of simple type integer and that appears earlier in the message than the current item.

Tests other than these tend to be both simple and obvious so that, for example, the message set property `First Day of Week` must be the name of a day in the week.

The fact that CWF relies on fixed-format data structures also imposes some limitations on the messages that can be represented:

- CWF cannot represent a message that includes the use of XML Schema wild cards; this is a consequence of its inability to handle undefined content.
- CWF cannot represent a message that includes recursive definitions.
- CWF cannot represent a message that includes the use of substitution groups, because there is no way to recognize the substituted element.

MRM Custom wire format: NULL handling:

CWF supports the handling of explicit NULL values within messages, if the logical nillable property of the element is set.

An explicit null is identified by a specific value that identifies an element as being null.

The `Boolean Null Value` can be specified at the message set level, and applies to the Boolean elements of all messages that are defined in that message set. The null value of all other element types can be specified individually for each element.

CWF supports the representation of null values by using the `Encoding Null` and `Encoding Null Value` element properties. Together, this information controls how null values are handled by the MRM parser.

The `Encoding Null` property can be set to one of four values:

NullLogicalValue

The `Encoding Null Value` property is interpreted as a logical value. Therefore, if its value is set to 0, for example, both `0` and `0.00` are interpreted as null values.

NullLiteralValue

The `Encoding Null Value` property is interpreted as a string value. Therefore, the value of the element in the bit stream must match exactly the value that is specified to be interpreted as a null value.

NullPadFill

Used for fixed-length elements. On output, any element with a null value is padded to the appropriate length with the specified padding character.

NullLiteralFill

The `Encoding Null Value` property is interpreted as a single character string value. Therefore, each character of the value of the element in the bit stream must match exactly the character value specified to be interpreted as a null value.

MRM Custom wire format: Multipart messages:

The Custom Wire Format (CWF) supports both the Message Identity technique and the Message Path technique of identifying embedded messages within a multipart message.

Alternatively, you can resolve an embedded message by using ESQL or Java to identify the message. The first message that you reference in this way is assumed to be the selected message. This technique works in an identical manner to `unresolved choice` handling.

Related concepts:

"Multipart messages" on page 1191
A *multipart message* contains one or more other messages within its structure. The contained message is sometimes referred to as an *embedded message*.

"Identifying an embedded message by using a Message Identity" on page 1193
You can identify an embedded message by using the Message Identity. This technique is used by the MRM domain, and replaces the use of the Message Key.

"Identifying an embedded message by using a Message Path" on page 1196
The Message Path technique for identifying embedded messages is useful when the multipart message contains no information about the identity of an embedded message.

MRM Custom wire format: Relationship to the logical model:

Some restrictions exist in relation to the logical model for messages that are defined by using the CWF.

Composition: A CWF message is always written with the elements in the sequence that is specified in the logical message model definition. However, you do not always have to specify the ESQL or Java that builds the elements in that sequence. The following rules for coding ESQL are given for each value of the type `Composition` property.

Sequence

You must build the output message to match the sequence of the elements or groups in the message. You can normally do this using ESQL SET statements to assign a value to each element or type. The first SET statement sets the value of the first element or type in the message, the second SET statement sets the value for the second element or type, and so on. You can vary this sequence of statements by using ESQL ATTACH, CREATE, and MOVE statements.

If the elements or types have default values, and you do not build the message in the correct sequence, those elements that are built out of sequence contain their default values, not the values that you set. This is because elements that are built out of sequence are assumed to be self-defining and, for CWF, these are discarded when the message is written to the bit stream.

Ordered Set

You must build the output message to match the sequence of the elements in the message. You can normally do this using ESQL SET statements to assign a value to each element. The first SET statement sets the value of the first element in the message, the next SET statement sets the value for the second element, and so on. You can vary this sequence of statements by using ESQL ATTACH, CREATE, and MOVE statements.

If the elements have default values, and you do not build the message in the correct sequence, those elements that are built out of sequence contain their default values, not the values that you set. This is because elements

that are built out of sequence are assumed to be self-defining and, for CWF, these are discarded when the message is written to the bit stream.

Unordered Set
You can build elements of the output message in any sequence. On output, the elements are written in the order that is specified in the logical message model definition.

All You can build elements of the output message in any sequence. Each element must be present only once (that is, it must not repeat). On output, the elements are written in the order that is specified in the logical message model definition.

Choice
A choice cannot be resolved purely from the data. The receiving program must interpret the data and decide which option of the choice the message instance contains. This process is known as *unresolved choice* handling. The first reference in the application to any one of the choice elements resolves the choice to the option that contains that element.

Message
Mechanisms for the resolution of embedded messages are discussed in the "MRM Custom wire format: Multipart messages" on page 1217 topic.

Content validation: CWF is a fixed format, and all elements must be present in a message. Therefore, content validation is ignored. On output, all elements must be set explicitly (for example, by using ESQL SET), set implicitly (by using a tree copy function), or must have a default value defined.

Default values: On output of a CWF message in the MRM domain, any element, or occurrence of an element for which a value has not been set (either explicitly or implicitly), inherits the specified default value of the element. If no default value has been specified then an exception is thrown.

Min Occurs and Max Occurs: The logical properties `Min Occurs` and `Max Occurs` specify the permitted number of occurrences of an element, or group, in a message. These properties are used when parsing and writing messages, and when validating the content of a message.

In CWF, `Max Occurs` occurrences are expected when parsing, and `Max Occurs` occurrences are produced when writing. Default values are used for missing elements, and any excess elements are discarded.

- A varying number of occurrences (`Min Occurs` <> `Max Occurs`) is ignored, `Max Occurs` is assumed.
- Optional occurrence (`Min Occurs` = 0) is ignored, `Max Occurs` is assumed.
- Always absent (`Max Occurs` = 0) is allowed.
- An unbounded number of occurrences (`Max Occurs` = -1) is allowed if the element or group is the last child in its parent group, and the group is terminated by the end of the message bit stream. On writing, the writer writes all occurrences in the message tree, if this number is less than `Min Occurs`, additional default values are written.

These rules arise because, in a CWF message format, there are no tags or other markup that can be used to determine the end of a variable number of repeats.

However this behavior is overridden if the CWF property `Repeat Reference` is set, which indicates that the number of occurrences is given instead by an integer element that occurs earlier in the message. In this case `Max Occurs` is ignored.

When validating, `Min Occurs` and `Max Occurs` are both used to check that the content of the message tree matches the model.

Simple types – lists and unions: Lists and unions are XML-specific concepts. An element or attribute of a simple type that is a list or a union causes a task list warning if a CWF physical format is present in the message set. The user can choose whether to make this an error, warning, or information by editing the Validation preferences. The dictionary generator omits messages defined to contain such elements or attributes from the CWF section of the dictionary.

MRM TDS format:

The Tagged/Delimited String format (TDS) is the physical representation of a message that has a number of data elements separated by tags and delimiters.

The TDS physical format is designed to model messages that consist of text strings, but it can also handle binary data. Examples of TDS messages are those that conform to the ACORD AL3, EDIFACT, HL7, SWIFT, or X12 standards. The TDS physical format allows a high degree of flexibility when defining message formats, and is not restricted to modeling specific industry standards; therefore, you can use the TDS format to model your own messages.

TDS message characteristics: There are a number of features of text string messages that are common to many formats. This is an overview of the main features that are supported by the TDS physical format:

Tags The text strings in the message can have a *tag* or a label preceding the data value. The tag is a string that uniquely identifies the data value. The TDS format allows you to associate a tag with each element when you define the element.

Delimiters and tagged data separators
The message can contain various special characters or strings in addition to the tags and text string data values. The TDS format supports a number of different types of special characters or strings.

Some messages have a special character or string that separates each data value from the next. In the TDS format this is a known as a *delimiter*.

In formats that have a tag before each data value, the tag can be separated from its data value by a special character or string. In the TDS format this is known as a *tag data separator*.

Group indicators and terminators
A message can be split into a number of substructures in a similar manner to a COBOL or C structure. You can model each of these substructures separately by defining groups, complex types, or elements for each one.

A substructure can have a special character or string that indicates its start within the data. This is known in the TDS format as a *group indicator*.

A substructure can also have a special character or string that indicates its end in the data. In the TDS format, this is known as a *group terminator*.

A group indicator and group terminator can also be defined for the whole message. Group indicators and group terminators are optional for the message and each substructure.

Fixed-length strings
Some text strings within a message can be of fixed length; therefore, a delimiter between each data value is not necessary. This is supported by the TDS format.

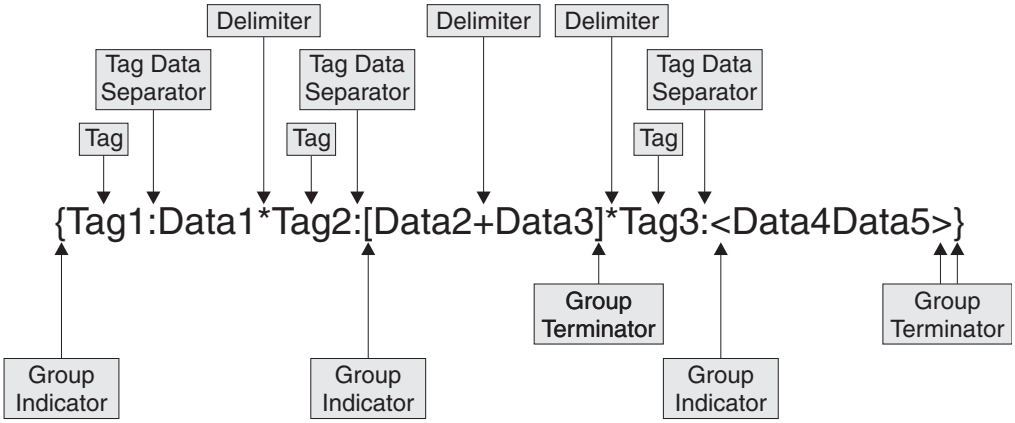
Fixed-length tags
Some tags can be defined as fixed length; therefore, a tag data separator is not necessary.

Separation types
The TDS property that controls the way text strings are separated is `Data Element Separation`. It has several options, for example, whether tags are used, whether strings lengths are fixed or variable, and what types of text strings are permitted.

The substructures within a message can use different types of data element separation and use different special characters. Therefore the TDS format allows you to define different types of data element separation and special characters for each complex type within the message.

Regular Expressions
If you choose the Use data pattern option for `Data Element Separation`, you can use regular expressions to identify parts of the message data to be assigned to sub fields. This is done by setting the regular expression in the `Data Pattern` property.

The following diagram shows an example data message with each of its components labeled.



- At the top level, each data value has a *tag* associated with it, each tag is separated from its data value by using a *tag data separator* of colon (:), and the data values are separated from each other using the asterisk *delimiter* (*).
- The *group indicator* for the message is the left brace ({) and the *group terminator* is the right brace (}).
- The data values `Data2` and `Data3` are in a substructure in which there are no tags, and each data element is separated from the next using the plus delimiter (+). The group indicator for this substructure is the left bracket ([) and the group terminator is the right bracket (]).
- The data values `Data4` and `Data5` are in a substructure in which the values are fixed length, and are therefore not separated by a delimiter. The group indicator for this substructure is the less than symbol (<) and the group terminator is the greater than symbol (>).

MRM TDS format: Determining the length of simple data values:

The TDS format supports two categories of simple data types: textual and non-textual.

The Physical Type of an element determines whether it is categorized as textual or non-textual.

Textual data

Physical Type is either Text or TLOG Specific. For textual data, the Data Element Separation of the parent complex type or group determines how the length of the data is determined. See "MRM TDS format: Data element separation" on page 1225 and its subtopics.

Non-textual data

Elements of all other Physical Types are non-textual. The length of non-textual data is determined by the Physical Type of the element. For non-textual data, the Data Element Separation property of the parent complex type or group does not determine the length, unless Data Element Separation is Use Data Pattern. See "MRM TDS format: Data pattern separation types" on page 1237 for more information.

The following table describes how the length of data is determined for each Physical Type.

Physical Type	Determination of Length
Text TLOG Specific	The Data Element Separation of the parent complex type or group determines how the length of the data is determined.
External Decimal Integer Packed Decimal Float Time Seconds Time Milliseconds	Uses the value of the Length property of the element. If Physical Type is Time Seconds, the Length property is set to 4. If Physical Type is Time Milliseconds, the Length property is set to 8. In neither case can this value be changed.
Length Encoded String 1 Length Encoded String 2	Uses the encoded length value in the data.
Null Terminated String	Uses the null terminator at the end of the data.
Binary	Uses the value of the Length Reference or Length property of the element.

MRM TDS format: Data element separation:

Data element separation defines how a TDS message is to be parsed.

Data element separation defines which method of identifying data elements is to be used and how the data elements are constructed. The different methods vary from full flexibility to fixed format, depending on how they are defined.

The four main types of data element separation are:

Fixed-length types
Fixed-length types are dependent on each element having a length. See "MRM TDS format: Fixed-length separation types" on page 1227.

Tagged separation types
Tagged separation types are dependent on each element having tag prefix to identify it. See "MRM TDS format: Tagged separation types" on page 1228.

Delimited separation types

Delimited separation types use delimiters to identify the end of one data elements and the beginning of the next. See "MRM TDS format: Delimited separation types" on page 1232.

Data pattern types

Data pattern types use a regular expression to identify each element. See "MRM TDS format: Data pattern separation types" on page 1237.

There is a fifth category, which is different from the four described earlier in this topic:

Undefined separation types

Undefined separation types contain no data elements. They are applicable to embedded messages only. They use none of the TDS type-specific parameters other than `Data Element Separation`. See "Multipart messages" on page 1191.

Some objects have TDS wire format properties.

MRM TDS format: Fixed-length separation types:

For fixed-length separation types, each data value is a fixed length.

For fixed-length data element separation types, all textual elements have a length or length reference, and are padded out to their full length in the bit stream. No tags or delimiters are used, and each data value directly follows the preceding data value.

For example:

```
data1data200data30
```

The first element is length 5, the second is length 7, and the third is length 6. The padding character is "0".

For non-textual elements, the length is determined by the `Physical Type` of the element. See "MRM TDS format: Determining the length of simple data values" on page 1224.

Fixed-length type: In fixed-length type, all textual elements must have a length or length reference, and must be written out to that full length. The elements must be presented in the correct order, and all elements must be written in the bit stream. This includes all repeats of any repeating element (that is, the `Maximum Occurrences` must be written out for each element).

For non-textual elements, the length is determined by the `Physical Type` of the element. See "MRM TDS format: Determining the length of simple data values" on page 1224.

For example:

```
data10data2data2data2data300
```

The first element is length 6, the second is length 5, and repeats three times, and the third element is length 7. The padding character is "0".

Applicable parameters: The main parameters for this format are the `Length` or `Length Reference` of the element. All fields must be padded out to their full length for the bit stream to be correctly specified to the parser.

Tag and delimiter parameters are ignored. Group indicators and terminators are observed, because they are of fixed length.

Default values are required for each field that might not be set, because then every field can be produced as output, even if it is not filled with data from the message.

Fixed-length AL3 type (Deprecated): This separation type has been deprecated. ACORD AL3 support will be provided by a different method in a future release, at which time this separation type will be removed from service.

Fixed-length AL3 types are similar to fixed-length types, but follow extra rules that are specified by the ACORD AL3 format regarding truncation and missing elements. If elements are missing from the end of an AL3 type, they can be truncated. They cannot be omitted from the middle of a bit stream. If a field is

missing from the middle of the bit stream, that field is produced for output as the appropriate length string of the "?" character.

Applicable parameters: The main parameters for this format are the `Length` or `Length Reference` of the element. All fields must be padded out to their full length for the bit stream to be correctly specified to a parser.

Tag and delimiter parameters are ignored. `Group Indicators` and `Terminators` are observed, because they are of fixed length.

Some objects have TDS wire format properties.

MRM TDS format: Tagged separation types:

For tagged separation types, each data value is preceded by a tag that is specified as an element property.

The `Tag Data Separator`, or specific `Length of Tag` parameter is used to determine where the tag ends and the data starts. Different methods are used by each separation type to determine the end of the data.

After considering these two parameters, this topic describes the following supported tagged separation types:

- "Tagged Delimited separation"
- "Tagged Fixed Length separation" on page 1230
- "Tagged Encoded Length separation" on page 1230

Tagged separation is a flexible format. The elements do not have to occur in a specific order. They do not all need to be present, and can be absent from any point in the message.

Tag Data Separator and Tag Lengths: Either `Tag Data Separator` and `Length of Tag` are used by all tagged separation types. But only one of these parameters can be set at the same time.

The point at which a tag ends and data starts can be determined by one of two methods. If the `Tag Data Separator` is set, then this character indicates where the data ends. For example, the string might be:

```
tag1:data1
```

where `Tag Data Separator` is :

However if the `Tag Data Separator` is not set and the `Length of Tag` field *is* set, then the tag is the specified length, and is immediately followed by the data. No separating character is required. For example, the string might be:

```
tag1data1
```

where `Length of Tag` is 4

Tagged Delimited separation: Tagged Delimited separation is a flexible format. Elements are separated by a predefined delimiter. The textual elements are not of specific lengths. For non-textual elements, the length is determined by the `Physical Type` of the element. See "MRM TDS format: Determining the length of simple data values" on page 1224.

Applicable parameters: These parameters are used:

- `Group Indicator` indicates the start of a group or complex type.
- `Group Terminator` indicates the end of a group or complex type.
- `Delimiter` separates the data elements within a group or complex type.
- `Tag` for each element, indicates the tag needed to precede the data in that field.
- Either `Tag Data Separator` or `Tag Length` as described earlier in this topic.

Examples: If `Tag Data Separator` is set to :

```
{tag1:data1*tag2222222:data2*tag333:data3}
```

where:

- `Group Indicator` is {.
- `Group Terminator` is }.
- `Delimiter` is *.
- `Tag` defined for each element, is tag1 (for data1), tag2222222 (for data2), and tag333 (for data3).

or, for example, if `Length of Tag` is set to 5

```
{tag11data1*tag22data2*tag33data3}
```

where parameters are as above, except:

- `Tag`, defined for each element (fixed at five characters), is tag11 (for data1), tag22 (for data2), and tag33 (for data3).

Tagged Fixed Length separation: Although Tagged Fixed Length separation is a flexible format, the data must be a specific length. This means that a delimiter is not needed to determine the end of each element.

Applicable parameters: These parameters are used:

- `Group Indicator` indicates the start of a group or complex type.
- `Group Terminator` indicates the end of a group or complex type.
- `Tag` for each element, indicates the tag needed to precede the data in that field.
- For each textual element, `Length` or `Length Reference` indicates the length of the data (this value does *not* include the length of the tag). For non-textual elements, the length is determined by the `Physical Type` of the element. See "MRM TDS format: Determining the length of simple data values" on page 1224.
- Either `Tag Data Separator` or `Tag Length` as described earlier in this topic.

Examples: If `Tag Data Separator` is set to :

```
{tag1:data1tag22222222:data2000tag333:data300}
```

where:

- `Group Indicator` is {.
- `Group Terminator` is }.
- `Delimiter` is *.
- `Tag`, defined for each element, is tag1 (for data1), tag22222222 (for data2000), and tag333 (for data300).
- `Length`, defined for each element, is 5 (data1), 8 (data2000), and 7 (data300).

or, for example, if `Length of Tag` is set to 5

```
{tag11data1tag22data2000tag33data300}
```

where parameters are as above, except:

- `Tag`, defined for each element (fixed at five characters), is tag11 (data1), tag22 (data2000), and tag33 (data300).

Tagged Encoded Length separation: This method has both a tag and a length field before the data. The length field indicates to the parser the length of the data following it.

The length of this length field is itself defined in the `Length of Encoded Length` parameter. Extra lengths to be added in this, such as the length of the field itself, is set in the `Extra Chars in Encoded Length` parameter.

Only textual elements and elements with a Binary logical and physical type are supported within a Tagged Encoded Length separation.

These examples show how the values set in these parameters are applied:

- `tagA007dataAAAtagB006dataBBtagC009dataCCCCC`

  If `Length of Tag` is 4, `Length of Encoded Length` is 3, `Extra Chars in Encoded Length` is 0, then in this bit stream, `TagA` is followed by the three character long length field. This indicates that the following data (`dataAAA`) is seven characters long. The next field, `tagB` is then considered, and so on.

- `tagA012dataAAAAAtagB010dataBBBtagC016dataCCCCCCCCC`

  If `Length of Tag` is 4, `Length of Encoded Length` is 3, `Extra Chars in Encoded Length` is 3, then in this bit stream, `TagA` is followed by the three-character length field. This indicates that the following data, plus extra characters, is 12 characters long: length of the length field (3) + length of data (9) = 12. Therefore the length of the actual data is only 12-3 = 9. The next field, `tagB` is then considered, and so on. In each case the length given in the bit stream is 3 greater than the actual length of the data.

Applicable parameters: These parameters are used:

- `Group Indicator` indicates the start of a group or complex type.
- `Group Terminator` indicates the end of a group or complex type.
- `Tag` for each element, indicates the tag needed to precede the data in that field.
- `Length of Encoded Length` indicates the length of the length field in the bit stream.
- `Extra Chars in Encoded Length` indicates how many extra characters should be included in calculating the value for the length field in the bit stream.
- Either `Tag Data Separator` or `Tag Length` as described earlier in this topic.

Examples: If `Tag Data Separator` is set to :

```
{tag1111:008data1tag222222222:010data2AAtag3333:009data3A}
```

where:

- `Group Indicator` is {
- `Group Terminator` is }
- `Length of Encoded Length` is 3
- `Extra Chars in Encoded Length` is 3
- `Tag`, defined for each element, is tag1111, tag222222222, tag3333, and so on

or, for example, if `Length of Tag` is set to 5

```
{tag11008data1tag22010data2AAtag33009data3A}
```

where parameters are as above, except:

- `Tag`, defined for each element (fixed at five characters), is tag11, tag22, tag33, and so on

MRM TDS format: Delimited separation types:

For delimited separation types, a delimiter is used to separate data fields, but there are no tags present. The data fields must be given in the correct order in the bit stream and elements cannot be omitted from the middle of the bit stream.

The All Elements Delimited separation type means that data fields are delimited by a pre-specified character or string. In this example, four data fields are separated by an asterisk (*) delimiter:

```
data1*data2*data3*data4
```

Delimited separation types are restrictive in the ordering and presence of elements:

- The elements must be given in the order specified.
- No element can be omitted in the middle of a group or complex type, because the parser cannot determine this from the resulting bit stream.
- Elements can sometimes be absent from the end of a complex type or group.

After considering "Delimiter suppression and truncation rules," this topic describes the following delimited separation types:

- "All Elements Delimited" on page 1233
- "Variable Length Elements Delimited" on page 1234

Delimiter suppression and truncation rules:

- Elements cannot be omitted from the middle of a group or complex type. An absent element results in the inclusion of a zero-length string.

  For example, with all elements present, the string might be:

  ```
  data1*data2*data3*data4
  ```

  where `Delimiter` is `*`

  If `data2` is missing, the string would read:

  ```
  data1**data3*data4
  ```

- It is possible to suppress the delimiters at the end of a string for absent elements. The Suppress Absent Element Delimiter property determines whether this is done. If this property is set to End of Type, this can be done (with one exception, shown later in this section).

  In this case, for the example with data3 and data4 missing, the string would read:

  ```
  data1*data2
  ```

  That is, the delimiters have been suppressed from the end of this group or complex type.
- If the Suppress Absent Element Delimiter property is set to Never, delimiter suppression never takes place. The string would read:

  ```
  data1*data2**
  ```

  That is, the delimiters must be present to indicate absent (zero-length) elements.

  An exception to the above rule occurs in the case where the same delimiters are used at multiple levels in the model.

  For example, you have a complex type or group with delimiter * and this contains an element of another complex type (indicated by the element3 prefix on data fields in the following example), which also has delimiter *. If both types use a delimited separation type, with all elements present, you might have:

  ```
  data1*data2*element3Data1*element3Data2*element3Data3*data4
  ```

  If element3Data2 and element3Data3 are missing, and the delimiters are suppressed, it is not possible for the parser to determine which elements are missing.

  Therefore, in this case, you must override the Suppress Absent Element Delimiter property, and write out all the delimiters to clearly define the message to the parser. Therefore, the string must be:

  ```
  data1*data2*element3Data1***data4
  ```

  This restriction also applies where Group Indicators and Group Terminators use the same character strings as delimiters; otherwise, the bit stream is not clear to the parser.

All Elements Delimited: In an All Elements Delimited separation type, all elements are separated by a delimiter; for example:

```
data1*data2*data3*data4*data5
```

where Delimiter is *.

An All Elements Delimited separation type does not use tags or their associated parameters.

For textual elements, the length is determined by the delimiter, and the Length property is ignored unless the Observe Element Length property is set.

For non-textual elements, the length is determined by the Physical Type of the element. See "MRM TDS format: Determining the length of simple data values" on page 1224.

Applicable properties: These properties are used:

- Group Indicator indicates the start of a group or complex type.
- Group Terminator indicates the end of a group or complex type.

- `Delimiter` indicates the separator between the data elements within a group or complex type.
- `Suppress Absent Element Delimiters` indicates whether delimiter suppression is permitted.

For example:

```
{data1*data22222*data3}
```

where:

- `Group Indicator` is {
- `Group Terminator` is }
- `Delimiter` is *

Repeating element rules: If an element must be repeated when the separation type is All Elements Delimited, the `Repeating Element Delimiter` (`RED`), is used to separate the repeated elements.

For example if `data2` repeats five times:

```
data1*data2:data2:data2:data2:data2*data3*data4
```

where:

- `Delimiter` is *
- `Repeating Element Delimiter` is:

If the `Suppress Absent Element Delimiters` property is set to End of Type, you can use delimiter suppression. Therefore, if only the first `data2` element was present in the previous example, the bit stream reads:

```
data1*data2*data3*data4
```

However, if the `Suppress Absent Element Delimiters` property is set to Never, the bit stream reads:

```
data1*data2::::*data3*data4
```

If `Delimiter` and `RED` match, two delimiters are output to indicate that the repeat is ending. Therefore, if the delimiter and `RED` are *, the bit stream reads:

```
data1*data2**data3*data4
```

Variable Length Elements Delimited: In a complex type with Variable Length Elements Delimited separation, some elements are determined by their length, and other elements are delimited. This combination of a delimited and a fixed-length format follows rules that are associated with both formats. Lengths can be given and used, but they are not mandatory.

- If a length is present for a textual element, it is used, and a delimiter is not needed to terminate that element. The element must be padded to the correct length, and cannot exceed that length.
- If no length is given for a textual element, the delimiter is required.
- For non-textual elements, the length is determined by the `Physical Type` of the element. See "MRM TDS format: Determining the length of simple data values" on page 1224.

A complex type with Variable Length Elements Delimited separation that contains only variable length elements resembles a complex type with All Elements Delimited separation. If it contains only fixed-length elements, it resembles a Fixed Length type.

For example:

```
data1*data2*data3*data4000data5
```

where:

- `Delimiter` is *
- `data4` has a length of 8

Applicable properties: The following properties are used:

- `Group Indicator` indicates the start of a group or complex type.
- `Group Terminator` indicates the end of a group or complex type.
- `Delimiter` indicates the separator between the data elements within a group or complex type.
- `Suppress Absent Element Delimiters` indicates whether delimiter suppression is permitted.
- (Optionally) `Length` or `Length Reference` indicates the length of a textual element. If a textual element has a length, this length is used. Because the length of this element is known, it is not necessary to output a delimiter after it. If the length is not known, a delimiter is required. A delimiter is never required for a non-textual element.

In this example, the fourth field (containing `data4`) is of fixed length 8 and its padding character is `0`:

```
{data1*data22222*data3*data4000data5}
```

where:

- `Group Indicator` is {
- `Group Terminator` is }
- `Delimiter` is *

Repeating element rules: The action of a repeating element in a Variable Length Elements Delimited environment is dependent on the minimum and maximum number of repeats and whether the element has a length.

Delimited Element Repeating: If a delimited element (that is, an element with no length) is repeated, a `Repeating Element Delimiter` (`RED`) is required and the rules for All Elements Delimited are followed. A delimiter is therefore required after the last repeat. Delimiter suppression of this repeat can also occur.

For example, if `data2` is repeating:

```
data1*data2:data2:data2:data2:data2:data2*data3*data4000data5
```

where:

- `Delimiter` is *
- `Repeating Element Delimiter` is :
- `data4` has a fixed length of 8

If the Suppress Absent Element Delimiters field is set to End of Type, you can use delimiter suppression.

If in the above example only the first data2 is present:

```
data1*data2*data3*data4000data5
```

However, if Suppress Absent Element Delimiters is set to Never, the bit stream reads:

```
data1*data2:::::*data3*data4000data5
```

If the delimiter and RED match, two delimiters are output to indicate that the repeat is ending. So if the delimiter and RED are both *, the bit stream reads:

```
data1*data2**data3*data4
```

This also applies for a non-fixed length complex type or group inside a Variable Length Elements Delimited environment.

Fixed Length Element Repeating: If an element with a defined length (a fixed-length element) is repeating and the minimum occurrences is not the same as maximum occurrences, an RED is not required, but a delimiter *is* required after the last repeat. Delimiter suppression of this repeat can occur.

For example, if data4 (with a fixed length of 8) is repeating, and its minimum occurrences is 2, maximum occurrences is 4:

```
data1*data2*data3*data400data400data400data400*data5
```

where Delimiter is *

Or, if there are only two occurrences of data4:

```
data1*data2*data3*data4000data4000*data5
```

If an element with a defined length (a fixed-length element) is repeated, and the minimum occurrences is the same as maximum occurrences, an RED is not required. A delimiter is also not required after the last repeat. Truncation of this repeat cannot occur and all elements need to be present.

For example, if data4 (with a fixed length of 8) repeats four times:

```
data1*data2*data3*data4000data4000data4000data4000data5
```

where Delimiter is *

Or, if there are only two occurrences of data4:

```
data1*data2*data3*data4000data400000000000000000000data5
```

This also applies for a non-fixed length complex type or group inside a Variable Length Elements Delimited environment.

If a complex type has Variable Length Elements Delimited separation, a delimiter is always output between an included ('child') complex element and the next element even if the separation of the 'child' complex element is Fixed Length. On input, the parser accepts the bit stream with or without such a delimiter.

Some objects have TDS wire format properties.

MRM TDS format: Data pattern separation types:

For a data pattern separation type, each data value is matched with a regular expression that is specified as a property of each element.

The length of both textual and non-textual data is determined by the `Data Pattern` property of the element. If the `Physical Type` of the element is Length Encoded String 1 or Length Encoded String 2, the regular expression must match both the encoded length and the following data. The length in the encoded length must be consistent with the length matched by the regular expression. If the `Physical Type` of the element is Null Terminated String, the regular expression must match both the data and the following null terminator.

The Data Pattern separation type uses a regular expression that is specified for each element to match the data. The parser matches the data with the regular expression in the `Data Pattern` property for that element. TDS parsing in the MRM parser uses the regular expression in `Data Pattern` to determine the length of the element, whether it is repeating, and whether it is present in the bit stream.

No delimiters or tags, other than those coded as part of the regular expression pattern, are used in the bit stream. See "Using regular expressions to parse data elements" on page 6301 for an explanation of pattern matching.

For example, if the first three `Data Pattern` properties are, respectively:

- [A-Z]{1,3}
- [0-9]+
- [a-z]*

and the message data is:

```
DT31758934information for you
```

Then, in this example:

- First data element = `DT`
- Second data element = `31758934`
- Third data element = `information`

The first data pattern means "from one to three characters in the range A to Z", the second means "one or more characters in the range 0 to 9", and the third means "zero or more characters in the range a to z". Note how each element's data was terminated by the first character that did not match the element's `Data Pattern`.

If the TDS message that is being parsed is encoded in a single-byte code page, the `Data Pattern` property can include hexadecimal values. A hexidecimal value is specified as \xNN, where N is a hexadecimal digit in the range 0 to F. Note, however, that the value \x00 is not valid.

Performance issues

The parsing required in Data Pattern separation type is the slowest of all the different separation types because of its complexity.

Therefore, use Data Pattern separation type only when no other separation type models the message. Do not use it, for example, when you can use Fixed Length separation type.

Applicable parameters: Only one parameter is used:

`Data Pattern` for each element, indicates the regular expression that is used for string matching.

MRM TDS format: Message model integrity:

When you use the TDS wire format, you must conform to a number of rules that apply to the setting of values of properties. This is necessary to avoid any discrepancies when processing a message within the specified model.

Rules of TDS physical format properties: Restrictions to message formats are checked. These restrictions follow the rules specified in "TDS message model integrity" on page 6295. Most rules are applied for at least one of these reasons:

Rules for message definition
Some rules are necessary for the message to be defined.

For example, in a Fixed Length separation type all elements must have some length defined, either directly or by using a Length Reference. Without this information, it is impossible to tell in the message bit stream where one data element ends and the next starts.

Rules for nesting
Nesting rules relate to which separation types can be nested inside each other.

Such rules are applied when an element of a complex type is present inside another complex type. An example is that it is not possible to have a Tagged Delimited separation type inside a Fixed Length type. Because a Tagged Delimited separation type is of variable length, the parent Fixed Length type would be unable to tell where that particular element ended, as there would be no length provided. Therefore the message could not be processed.

Rules linking to the logical model
There are also rules linking TDS to the logical model.

These rules occur where a group composition or group content validation cannot be used with a particular separation type. Again this is for message integrity. For example, a separation type of All Elements Delimited cannot have a group composition of Open, as there is no information as to what the extra elements represent and where they are in the bit stream.

MRM TDS format: NULL handling:

NULL handling dictates the way in which the MRM parser for TDS messages handles elements that have been set to Null.

Null handling takes place only if the logical Nillable property of the element is set. The rules for whether nulls are permitted are described in "TDS Null handling options" on page 6293.

Null properties: The element properties `Encoding Null` and `Encoding Null Value` control how null handling is represented for individual elements.

You can select the `Encoding Null` property from the enumerated values NULLPadFill, NULLLogicalValue, NULLLiteralValue, and NULLLiteralFill. The use of the `Encoding Null Value` property is dependent on the value that you select for the `Encoding Null` property.

NULL values are not defined for schema xsd:hexBinary simple types. The properties `Encoding Null` and `Encoding Null Value` are therefore not set for xsd:hexBinary types.

NULL values for schema `Boolean` simple types are defined at the message set level. The message set property `Boolean Null Representation` specifies the value to be used for Boolean Null representation.

Related reference:

"CWF data conversion" on page 6255
You can convert an MRM message to a different code page or encoding, or both.

MRM TDS format: Relationship to the logical model:

TDS separation types and logical model properties have some restrictions, such as group composition and group content validation.

The rules that govern these options are explained in "Restrictions for nesting complex types" on page 6298.

These rules exist to ensure the integrity of the message. A combination of separation type and group composition or group content validation must not lead to a message that is unclear to a TDS parser.

Default values

In TDS, *Default* values are only observed by fixed-length elements:

Separation Type	**Use of `Default` values**
Tagged Delimited Tagged Fixed Length Tagged Encoded Length All Elements Delimited Data Pattern	`Default` values are never observed.
Fixed Length Fixed Length AL3	`Default` values are observed on output by all elements. An absent element that has no `Default` value defined, causes an error on writing.
Variable Length Elements Delimited	`Default` values are only observed by fixed-length elements on output. Absent fixed-length values must have a `Default` value available to them. An absent element that has no `Default` value defined, causes an error on writing.

Simple types – lists and unions

Lists and unions are XML-specific concepts. An element or attribute of a simple type that is a list or a union causes a task list warning if a TDS physical format is present in the message set. The user can choose whether to make this an error, warning, or information by editing the Validation preferences. If a dictionary is generated from the message set, and an attempt is made to parse a TDS message defined to contain such elements or attributes, a runtime error occurs.

Min Occurs and Max Occurs

The logical properties Min Occurs and Max Occurs specify the permitted number of occurrences of an element or group in a message. They are used when parsing and writing messages, and when validating the content of a message.

When parsing and writing, the exact interpretation of these properties depends on the Data Element Separation property of the parent complex type or group as shown in the following table.

However, this behavior is overridden if the TDS Repeat Reference property is set, which indicates that the number of occurrences is given instead by an integer element that occurs earlier in the message. See "Repeat reference" on page 1245 for more information.

When validating, Min Occurs and Max Occurs are both used to check that the content of the message tree matches the model.

Separation type	Interpretation of Min Occurs and Max Occurs
Tagged Delimited Tagged Fixed Length Tagged Encoded Length	Min Occurs and Max Occurs are effectively ignored when parsing and writing. When parsing, the number of occurrences is identified by the tags in the message. When writing, the writer outputs all occurrences in the message tree. • A varying number of occurrences (Min Occurs <> Max Occurs) is allowed. • Optional occurrence (Min Occurs = 0) is allowed. • Always absent (Max Occurs = 0) is allowed. • An unbounded number of occurrences (Max Occurs = -1) is allowed.
All Elements Delimited	Max Occurs is used only when parsing and writing, with the element's Repeating Element Delimiter property, and the parent type's Suppress Absent Element Delimiters property. A varying number of occurrences (Min Occurs <> Max Occurs) is allowed if Suppress Absent Element Delimiters is set to End of Type. • If the Delimiter is different from the Repeating Element Delimiter, the Delimiter signifies the end of the occurrences. • If the Delimiter is the same as the Repeating Element Delimiter, an empty repeat signifies the end of the occurrences. • In both these cases, Max Occurs is the maximum number of repeats that are expected. If Suppress Absent Element Delimiters is Never, all occurrences are expected when parsing, and produced when writing, although parsing accepts elements being absent. Optional occurrence (Min Occurs = 0) is ignored and a delimiter is still expected when parsing, and produced when writing. Always absent (Max Occurs = 0) is allowed. No delimiter is expected when parsing, nor output when writing. An unbounded number of occurrences (Max Occurs = -1) is only allowed if the Repeating Element Delimiter is different from the Delimiter. The repeats must be terminated by the delimiter, or a containing group's Group Terminator or Delimiter, or by the end of the message bit stream. On writing, the writer outputs all occurrences in the message tree.

Separation type	Interpretation of Min Occurs and Max Occurs
Fixed Length Fixed Length AL3	Max Occurs is used only when parsing and writing. In general, Max Occurs occurrences are expected when parsing, and Max Occurs occurrences are produced when writing; default values are used for missing elements, and any excess elements are discarded. A varying number of occurrences (Min Occurs <> Max Occurs) is ignored, Max Occurs is assumed. Optional occurrence (Min Occurs = 0) is ignored, Max Occurs is assumed. Always absent (Max Occurs = 0) is allowed. Fixed Length only. An unbounded number of occurrences (Max Occurs = -1) is allowed if the element or group is the last child in its parent group, and the group is terminated by a Group Terminator or a containing group's Group Terminator or Delimiter or by the end of the message bit stream. On writing, the writer outputs all occurrences in the message tree, if this number is less than Min Occurs, additional default values are written.
Variable Length Elements Delimited	For fixed length simple elements, the rules for Fixed Length separation above are followed with two differences. 1. A varying number of occurrences (Min Occurs <> Max Occurs) is allowed, the end of the occurrences being signified by an extra delimiter. 2. An unbounded number of occurrences (Max Occurs = -1) is allowed, the end of the occurrences being signified by an extra delimiter. On writing, the writer outputs all occurrences in the message tree, followed by an extra delimiter. For variable length simple elements, all complex elements and groups, the rules for All Elements Delimited above are followed.
Data Pattern	Min Occurs and Max Occurs are effectively ignored when parsing and writing. When parsing, the pattern is matched as many times as possible. When writing, the writer outputs all occurrences in the message tree. Note that on parsing, if the data pattern permits a zero length match, and a zero length match occurs, an element is added to the message tree, and the matching terminates to prevent an infinite loop. A varying number of occurrences (Min Occurs <> Max Occurs) is allowed. Optional occurrence (Min Occurs = 0) is allowed. Always absent (Max Occurs = 0) is allowed. An unbounded number of occurrences (Max Occurs = -1) is allowed.

Repeat reference

The TDS property Repeat reference specifies a field that holds the number of repeats of an object (Element or Group) within a message. The field that holds the number of repeats must be within the message before the object that it refers to.

From a parsing perspective, the Repeat reference property replaces the role of the minOccurs and maxOccurs properties.

If a value for the Repeat reference property is specified for an object, values that are specified for minOccurs and maxOccurs are ignored when parsing and writing. However, values that are specified for minOccurs and maxOccurs are used by logical validation.

When parsing and writing, the exact interpretation of the Repeat reference property depends on the Data Element Separation property of the parent complex type or group as shown in the following table.

Separation type	Interpretation of Repeat reference
Tagged Delimited Tagged Fixed Length Tagged Encoded Length	Repeat reference is effectively ignored when parsing and writing. When parsing, the number of occurrences is identified by the tags in the message. When writing, the writer outputs all occurrences in the message tree.
All Elements Delimited	Repeat reference is used when parsing and writing, with the element's Repeating Element Delimiter property, and the parent type's Suppress Absent Element Delimiters property. A Repeat reference is allowed only if the parent complex type or group has Suppress Absent Element Delimiters set to Never. All Repeat reference occurrences are expected when parsing, and produced when writing. However, parsing accepts elements being absent. Repeat reference = 0 is allowed. No delimiter is expected when parsing, nor produced when writing.
Fixed Length Fixed Length AL3	Repeat reference is used when parsing and writing. Repeat reference occurrences are expected when parsing, and are produced when writing, with default values used for missing elements. Repeat reference = 0 is allowed.
Variable Length Elements Delimited	For fixed length simple elements, the rules for Fixed Length separation above are followed. For variable length simple elements, all complex elements and groups, the rules for All Elements Delimited that are listed above are followed.
Data Pattern	Repeat reference is effectively ignored when parsing and writing. When parsing, the pattern is matched as many times as possible. When writing, the writer outputs all occurrences in the message tree. Note that, on parsing, if the data pattern permits a zero length match, and a zero length match occurs, an element is added to the message tree, and the matching terminates to prevent an infinite loop.

MRM XML physical format:

The MRM XML physical format describes the physical representation of an XML message for use by the MRM parser.

An XML wire format describes the physical representation of a message that is written according to the standards given in the W3C Extensible Markup Language (XML) specification. The wire format defines information that is used to parse or write XML messages in a runtime environment such as a broker. XML versions 1.0 and 1.1 are both supported.

You can add more than one XML physical format to a message set, but within that message set, each physical format must have a unique name. The default name for an XML wire format is XML1. The physical format name identifies the definitions that are to be used by the broker at run time.

After adding an XML physical format, all XML properties for all existing objects in the message set are set to default values. Therefore, immediately after adding the format and deploying the message set to a runtime environment, you can process XML messages by using MRM features.

You can configure XML properties for the message set, and for objects within the message set. Objects that can have XML properties are messages, elements, and attributes. For example, a message object can be customized to define a specific DTD declaration on output; an element can have a tag name assigned to it which is different from its element name in the model.

Adding an XML wire format to a message set allows you to both process input messages, and to construct output messages in this format. You can also transform messages between XML and either CWF or TDS.

XML messages are, by their nature, self-describing: each piece of data is prefixed by a tag name or an attribute name. Therefore, it is possible for an XML message instance to contain elements that are not in the definition for that message.

- If such an element exists in the message set, the model objects for that element are used in parsing or writing the message.
- If the element does not exist in the message set, it is treated as a self-defining element, and its data type is set to string.

Although it is possible to define an XML message 'by hand', using the Message Definition Editor, WebSphere Message Broker also provides importers for both XML Schema and DTD, and these are often quicker and easier than manual definition.

MRM XML physical format: Message model integrity:

When you save a message definition file, the definitions that it contains are checked to ensure that they make sense and provide sufficient information about the message. This action is called *model validation*.

For XML, these checks mostly concern the uniqueness and validity of XML names in global elements and attributes, and also for elements and attributes within complex types or groups.

Tests other than these tend to be both simple and obvious so that, for example, the message set property `First Day of Week` must be the name of a day in the week.

MRM XML physical format: NULL handling:

The purpose of null handling is to specify how messages deal with null values; that is, the absence of a meaningful value for an element.

Null properties for the MRM XML physical format are set for the message set only, and apply to all the defined objects within the message set, by using the four properties `Encoding Null Num`, `Encoding Null Non-Num`, `Encoding Null Num Val` and `Encoding Null Non-Num Val`.

Null handling takes place only if the logical Nillable property of the element is set.

The purpose of these parameters is to specify how messages deal with null values. In an XML message there are several options. Most obviously an element could omit a value, for example:

```
<element1></element1>
```

Or, the element could include a distinctive value that means that no real value is present, for example.

```
<element1>null</element1>
```

Or, the element could follow XML Schema instance rules:

```
<element1 xsi:nil="true"/>
```

The properties `Encoding Null Num` and `Encoding Null Non-Num` specify the style of null handling, for example, that null is represented by an empty element.

The properties `Encoding Null Num Val` and `Encoding Null Non-Num Val` provide a value (if needed) to represent a null value. For an element of type string, this might be `null` or `unspecified` while for a number it might be `0` or `0.0`.

MRM XML physical format: Multipart messages:

Identify embedded messages by using either a Message Identity or a Message Path.

If you are using the MRM XML physical format, an embedded message can be identified in any of the following ways:

- Message Identity

  See "Identifying an embedded message by using a Message Identity" on page 1193.
- Message Path

  See "Identifying an embedded message by using a Message Path" on page 1196.
- Automatic

  The MRM parser identifies the message by matching the next XML tag in the bit stream against the XML Name of a message definition.

If you choose the Message Identity or Message Path technique, the MRM parser still checks that the next XML tag name matches the XML Name of the message that was identified. If the XML Name does not match, an exception is thrown.

Where you have defined the embedded message in a different message set, you must use a Message Set Identity element or attribute value to specify the target message set. Note that the message sets within which the root and subsequent embedded messages are defined must be consistent in their use of the 'Use Namespace' property of the message set. That is, embedded messages that are defined in a namespace-aware message set and that are contained within a parent message that is defined in a message set that is not namespace-aware, are not supported. Similarly, embedded messages that are defined in a message set that is not namespace-aware and that are contained within a parent message that is defined in a namespace-aware message set, are not supported.

If the embedded message definition is a complex type, the message definition contains a complex element based on that complex type. This complex element has

its own tag, which appears in the bit stream before the tag for the embedded message. If you want to avoid this extra tag, you can create the embedded message definition from a group, and insert the group at the appropriate position in the message model.

Tip: Note that the root tag property of an embedded message is not applicable.

Related concepts:

A multipart message occurs when you embed a message in another message.

"Accessing embedded messages in the MRM domain" on page 2594
If you have defined a multipart message, you have at least one message embedded within another. Within the overall complex type that represents the outer messages, you can model the inner message in two ways.

MRM XML physical format: Relationship to the logical model:

The MRM XML physical format generally respects all the settings in the logical model, but shares certain restrictions in common with the other physical formats.

These restrictions are documented in "MRM restrictions" on page 6252.

Default values

The MRM XML physical format ignores default and fixed values on elements and attributes. If validation is enabled in WebSphere Message Broker, this can lead to unexpected validation errors for missing elements, even though they have default or fixed values.

Simple types – unions and lists

The XML properties of an element or attribute of a simple type that is a union or list vary depending on the members of the union or the itemType of the list. If the union or list includes a dateTime type (or other date/time related type) the `Date Format` field is displayed. If the union includes a binary type, the `Encoding` field is displayed.

Min Occurs and Max Occurs

The logical properties `Min Occurs` and `Max Occurs` specify the permitted number of occurrences of an element or group in a message. They are used when validating the content of a message.

When parsing and writing, using the MRM XML physical format, `Min Occurs` and `Max Occurs` are effectively ignored. When parsing, the number of occurrences is identified by the tags in the message. When writing, the writer outputs all occurrences in the message tree.

- A varying number of occurrences (`Min Occurs` <> `Max Occurs`) is allowed.
- Optional occurrence (`Min Occurs` = 0) is allowed.
- Always absent (`Max Occurs` = 0) is allowed
- An unbounded number of occurrences (`Max Occurs` = -1) is allowed.

When validating, `Min Occurs` and `Max Occurs` are both used to check that the content of the message tree matches the model.

An introduction to the objects that make up a message model. Message model objects are defined by XML Schema 1.0, except for Message which is a WebSphere Message Broker extension to XML Schema.

Related reference:

"MRM restrictions" on page 6252
The MRM parser does not exactly follow the XML Schema 1.0 specification.

MRM XML physical format: Handling xsi:type attributes:

The prefix "xsi" is the namespace prefix used by convention for the XML Schema instance namespace. XML documents can contain elements that have an xsi:type attribute. This behavior provides an explicit data type for the element.

The MRM XML parser in sensitive to xsi:type attributes in the XML document. It modifies the data type of the element accordingly and adds the xsi:type attribute into the message tree.

The MRM XML writer is sensitive to xsi:type attributes in the message tree. It produces xsi:type attributes according to XML Wire Format message set property **Output policy for xsi:type attributes**. For example, xsi:type attributes can be removed, output on all elements or output according to rules specified in the SOAP standard.

If validation is enabled for a WebSphere Message Broker message flow, the validation logic is sensitive to xsi:type attributes and uses them to modify the validation of the element. It also validates the values of xsi:type attributes by using the rules described in XML Schema Part 1: Structures on the World Wide Web Consortium (W3C) website.

There are several important points to remember when parsing and writing XML documents that contain xsi:type attributes.

- In order to detect and use xsi:type attributes, the message set must be namespace-enabled. To make a message set namespace-enabled, check the message set property **Use namespaces**.
- If the value of the xsi:type attribute contains a namespace prefix, the prefix is expanded into a fully qualified URI by the MRM XML parser. If the same xsi:type attribute is produced later by the MRM XML writer, the same prefix is

not automatically used for the value. You can control the prefixes used on output by using the **Namespace settings** list in the XML Wire Format message set properties. If no prefix is supplied, the XML writer assigns a default prefix.

- If the xsi:type attribute of an element does not resolve to a type in the model, the behavior depends on whether MRM validation is enabled. If not validating, the MRM assumes that the type of the element is that declared in the model, and continue. If validating, a validation exception occurs.
- If MRM validation is enabled, any required xsi:type attributes must be present in the message tree at the point when validation is performed. An xsi:type attribute is required when its value is different from the data type of the element as defined in the message model (this most commonly occurs when using XML Schema type derivation).
  - If validation is being performed on an input message, the MRM XML parser ensures that xsi:type attributes appear in the message tree, as described above.
  - If validation is being performed on an output message, you must ensure that the correct xsi:type attributes appear in the message tree. Ensure that any required xsi:type attributes are copied from input message tree to output message tree, or are explicitly created in the output message tree.
- If you are using simple types that are xsd:unions, an xsi:type attribute can be used to direct the MRM XML parser when resolving the union.
- If you have migrated from an earlier version of WebSphere Message Broker that was not sensitive to xsi:type attributes, you might notice some changes of behavior. For example, xsi:type attributes are no longer treated as self-defining attributes, so they appear in the message tree with the name 'type' instead of '@type'. If your message flow logic is sensitive to xsi:type attributes in the message tree, change your message flow to comply with the current behavior.

For more information about xsi:type attributes, see XML Schema Part 0: Primer on the World Wide Web Consortium (W3C) website.

"XML Wire Format message set properties" on page 5400
The following tables define the properties for the XML Wire Format for the message set.

Ways to create message definitions

When you have created a message set, you must populate the message set with message definitions.

You can populate the message set in one of the following ways:

- By importing application message formats that are described by XML Schemas, IBM supplied messages, XML DTD, C structures, COBOL structures, SCA imports or exports, or WSDL definitions; use the wizards that are started from the New Message Definition File From wizard.
- By creating empty message definition files, then creating your messages by using the Message Definition Editor; use the New Message Definition File wizard.
- By using the Adapter Connection wizard to import EIS metadata.

Additionally, you can import application message formats by using the **mqsicreatemsgdefs** or **mqsicreatemsgdefsfromwsdl** command line utilities.

The **mqsicreatemsgdefs** command has a bulk import capability, but **mqsicreatemsgdefsfromwsdl** imports only one WSDL definition at a time.

Use the **mqsicreatemsgdefs** command to create message definition files.

"**mqsicreatemsgdefsfromwsdl** command" on page 3712
Use the **mqsicreatemsgdefsfromwsdl** command to import a single WSDL definition.

Importing from other model representations to create message definitions:

You can add message definitions to your message set by importing application message formats that already exist.

You can import the following message formats to create message sets:

- XML Schema files
- IBM supplied messages
- XML DTD files
- C header files
- COBOL copybooks
- WSDL definitions
- SCA imports or exports
- EIS metadata

When you import one of these formats, a new message model is created that consists of the elements, attributes, groups, and types that are required to represent your message format. You can choose the name of the message model; if it already exists, the content is deleted and re-created as part of the import operation.

The new message model that is created can consist of both logical and physical information.

To find out which wizards to use to import message formats, see "Ways to create message definitions" on page 1253.

You can also import C header files, COBOL copybooks, XML DTD files, or XML Schema files by using the **mqsicreatemsgdefs** command-line utility. The **mqsicreatemsgdefs** command allows you to import several middle-format files in a single operation, and allows you to create a message set (based on an existing message set) into which the message definition files are placed.

WSDL definitions can be imported by using the **mqsicreatemsgdefsfromwsdl** command-line utility. This utility imports only one WSDL definition at a time.

Client application access to messages

Client applications must have access to message definitions to be able to construct the messages that they send, and to interpret the messages that they receive.

- If the message formats have been imported from C or COBOL structures by using the WebSphere Message Broker Toolkit, your applications can continue to use the same C and COBOL data structures that were imported to create the message dictionary that is used by the brokers.
- If the messages are self-defining XML, the client applications must construct valid messages by using the structures that can be understood by the recipients of the message.

"Importing from XML DTD" on page 2954
You can create a new message definition from an XML DTD by using the New Message Definition File wizard in the WebSphere Message Broker Toolkit.

Importing from XML Schemas to create message definitions:

You can populate a message set with message definitions by importing XML Schema files, by using the **New Message Definition File From XML Schema file** wizard, the **Start from WSDL and/or XSD files** quick start wizard, or the **mqsicreatemsgdefs** command-line utility.

Each XML Schema file that you import results in a new message definition file within the message set. The root name of the message definition file defaults to the root name of the XML Schema file, but the **New Message Definition File From XML Schema file** wizard allows you to choose a different root file name.

If the message definition file already exists, you must have enabled overwriting to occur for the import to proceed, in which case the existing content is deleted and re-created.

The namespace to which the message definition file created belongs depends on whether namespaces have been enabled for the message set.

- If namespaces have been enabled, the message definition file belongs to the target namespace of the XML Schema file that is imported.
- If namespaces have not been enabled for the message set, the message definition file belongs to the `noTarget` XML namespace irrespective of the target namespace of the imported XML Schema file and therefore is contained in the `(default)` location in your workspace. The implications of importing into a message set with namespaces disabled are described in "Importing XML Schema into message sets with namespaces disabled" on page 1259.

A report file is created during the import operation. This is located by default in the `log` folder of the message set. By default it takes the name of the message definition file, with `.report.txt` appended.

Import by using the New Message Definition File From XML Schema file wizard: When you import by using the **New Message Definition File From XML Schema file** wizard, you can specify which of the global elements or global complex types within the imported XML Schema file are to be messages within the message definition file.

You can import only one XML Schema file with each import operation. If your XML Schema file references other XML Schema files, with import or include elements, these XML Schema files must be imported into the same message set by using a separate import operation.

Import by using the command-line: When you import by using the command line you have the option of either creating no messages or creating a message for each global element and global complex type within the imported XML Schema file. The import operation creates a message and corresponding global element in the message definition file for each global element you specify. If you do not specify that messages are to be created, you must create them manually using the message definition editor after the import has completed.

You can import several XML Schema files in each import operation.

Physical information: In addition to creating logical information, the import can also create physical information. If the message set contains any XML wire format physical formats, the physical format properties for *all* XML Wire Format layers is populated. If the message set does not contain any XML physical formats, only logical information is created. Also, if you import from the command line, only logical information is created in the new message set by default. If you want physical information created as well, see "Importing from the command line" on page 2936 for details.

MRM CWF and TDS physical format properties are *not* populated and so take default values.

If you have one or more CWF or TDS layers, the import can cause entries in the task list, warning you that certain CWF or TDS properties must be set if the XML structures you have imported are to appear in a CWF or TDS message.

If the CWF or TDS physical formats are not applicable to your XML structures, you can ignore these task list entries because they are just warnings, they do not prevent your model being generated in another form; for example, as a message dictionary.

Command-line invocation: The **mqsicreatemsgdefs** command-line utility allows you to import several XML Schema files in a single operation. All the XML Schema files must be in single directory, and the directory location must be passed as a parameter to the utility.

When you import into a message set for which namespaces are not enabled, the action to take for unsupported constructs can be specified by using an XML options file. This must contain an XML element called `<XSD_NO_NS>` that holds a set of information that applies to all XML Schema files that are imported during an invocation of the utility. A default XML options file, called `mqsicreatemsgdefs.xml`, is supplied. If you want to apply different sets of information to different XML Schema files, you must create multiple XML files and run the utility multiple times.

When you are importing into a message set for which namespaces are not enabled, there are two other options that you can specify in the `<XSD_NO_NS>` element in the XML options file:

- The prefix to use for the `http://www.w3.org/2001/XMLSchema-instance` namespace; the default is `xsi`.
- Additional namespace URI and prefix pairs.

The **mqsicreatemsgdefs** utility also allows you to create a message set into which the message definition files are placed, as part of the import operation. You can also choose to base the message set created on an existing message set. This facility enables you to prepare an empty message set that contains an XML physical format and pre-populated message set level XML properties, which are then copied into the message set that is created by the import.

Further information about XML Schema: For details about XML Schema, see XML Schema Part 0: Primer on the World Wide Web Consortium (W3C) website.

Importing XML Schema into message sets with namespaces disabled:

You can import an XML Schema file with a target namespace even if the message set does not have namespaces enabled.

When you import an XML Schema file with a target namespace into a message set for which namespaces have not been enabled, the created message definition file is placed in the XML `no target` namespace. In some cases, this action can lead to name conflicts if global constructs have the same name in different namespaces in the XML Schema files imported into the same message set. These conflicts cause error entries in the task list that you must resolve before generating the model in another format, such as a message dictionary.

Because all the message definition files are in the XML `no target` namespace, the namespace information associated with the XML Schema file is lost. However, the importer provides a limited form of namespace support by prefixing the XML names in the XML Wire Format layers with a namespace prefix. To allow this namespace support to work, an imported XML Schema file must specify an `xmlns` attribute with a non-empty prefix for the target namespace of the XML Schema file. This prefix is used in the XML names in the XML Wire Format layers.

Therefore you cannot specify the target namespace of the XML file as the default namespace. Each namespace in the XML Schema files must use a unique prefix and the same namespace must always use the same prefix. Any XML instance documents against which you match any of the forms generated from the model, must also use the same prefixes for the namespaces.

The XML Schema importer creates a number of optional attributes in an attribute group to represent namespace information. This attribute group is referenced by the type of any message. An attribute is created to represent the location of the XML Schema file, and an attribute is created to represent the mapping of the prefix

to the `http://www.w3.org/2001/XMLSchema-instance` namespace. An attribute is also created for each xmlns attribute in the XML Schema document.

When importing using the Message Definition File wizard the prefix `http://www.w3.org/2001/XMLSchema-instance` namespace can be changed and additional namespace URI/prefix pairs added using the last panel of the Message Definition File wizard. When you use the **mqsicreatemsgdefs** command line utility, the same modifications can be made using the XML options file.

Further information about XML Schema: For details about XML Schema, see XML Schema Part 0: Primer on the World Wide Web Consortium (W3C) Web site.

Importing from IBM supplied messages to create message definitions:

You can add messages to a message set by using the New Message Definition File From IBM supplied messages wizard to import IBM supplied messages.

Each IBM supplied message that you import results in a new message definition file in the message set. The name of the message definition file defaults to the name of the IBM supplied message, but you can use the New Message Definition File From IBM supplied messages wizard to choose a different file name.

For information about what IBM supplied messages can be imported, see "Importing from the command line" on page 2936.

When you import message by using the New Message Definition File From IBM supplied messages wizard, you can specify only one IBM supplied message definition for each import operation.

If the message definition file already exists, you must have permitted overwriting to occur for the import to proceed, in which case the existing content is deleted and re-created.

A report file is generated during the import operation that allows you to examine what occurred during the import process and check any errors that resulted.

Creating an empty message definition file to contain your message model objects.

Message sets: Importing from DTDs to create message definitions:

You can populate a message set with message definitions by importing DTD files, by using either the New Message Definition File From XML DTD file wizard or the **mqsicreatemsgdefs** command.

Each XML DTD file that you import results in a new message definition file within the message set. The root name of the message definition file defaults to the root name of the XML DTD file, but the New Message Definition File From XML DTD file wizard allows you to choose a different root file name.

If the message definition file exists, you must have permitted overwriting to occur for the import to proceed, in which case the existing content is deleted and re-created.

All message definition files that are created as a result of DTD file import belong to the `noTarget` XML namespace and so are contained in the `(default)` location in your workspace.

A report file is created during the import operation, by default in the `log` folder of the message set. By default, it takes the name of the message definition file, with `.report.txt` appended.

Import by using the New Message Definition File From XML DTD file wizard: When you import by using the "New Message Definition File From XML DTD file" wizard, you can specify which of the elements within the imported XML DTD file are to be messages within the message definition file.

You can import only one XML DTD file with each import operation.

Import by using the command line: When you import by using the command line you have the option of either creating no messages or creating a message for each element within the imported XML DTD file. The import operation creates a message and a corresponding element in the message definition file for each element that you specify. If you do not specify that messages are to be created, you must create them manually using the message definition editor after the import has completed.

You can import several XML DTD files in each import operation.

Physical information: In addition to creating logical information, the import can also create physical information. If the message set contains any XML wire format physical formats, the physical format properties for *all* XML Wire Format layers is populated. If the message set does not contain any XML physical formats, only logical information is created. Also, if you import from the command line, only logical information is created in the new message set by default. If you want physical information created as well, see “Importing from the command line” on page 2936 for details.

MRM CWF and TDS physical format properties are *not* populated and therefore take default values.

If you have one or more CWF or TDS layers, the import can cause entries in the task list, warning you that certain CWF or TDS properties must be set if the XML structures that you have imported are to appear in a CWF or TDS message.

If the CWF or TDS physical formats are not applicable to your XML structures, you can ignore these task list entries because they are just warnings; they do not prevent your model being generated in another form, such as a message dictionary.

Command-line invocation: The **mqsicreatemsgdefs** command-line utility allows you to import several XML DTD files in a single operation. All the XML DTD files must be in single directory, and the directory location must be passed as a parameter to the utility.

The **mqsicreatemsgdefs** utility also allows you to create a message set into which the message definition files are placed, as part of the import operation. You can also choose to base the message set created on an existing message set. This facility enables you to prepare an empty message set that contains an XML physical format and pre-populated message set level XML properties, which are then copied into the message set that is created by the import.

Further information about XML DTDs: For details about XML DTDs, see the World Wide Web Consortium (W3C) website.

“Importing from XML DTD” on page 2954
You can create a new message definition from an XML DTD by using the New Message Definition File wizard in the WebSphere Message Broker Toolkit.

“Importing from the command line” on page 2936
This describes how to use the command line importer **mqsicreatemsgdefs** to import C, COBOL copybooks, XML DTD or XML Schema in order to populate a message set with message definitions.

Importing from C header files to create message definitions:

Create a message definition file from a C header file for use in the MRM and IDOC domains.

You can populate your message set with message definitions by importing C header files, by using either the New Message Definition File From C header file wizard or the **mqsicreatemsgdefs** command.

Each C header file that you import results in a new message definition file. The root name of the message definition file defaults to the root name of the C header file, but the "New Message Definition File From C header file" wizard allows you to choose a different root file name.

If the message definition file already exists, you must have permitted overwriting to occur for the import to proceed, in which case the existing content is deleted and re-created.

By default, all message definition files that are created as a result of an import from a C header file belong to the `noTarget` XML namespace and therefore reside in the `(default)` location in your workspace. This default namespace can be overridden by specifying a target namespace. See “Namespaces with non-XML messages” on page 1206 for reasons why you might want to do this.

In your C header file there are typically one or more C structures. You can select which of these structures to import. The import operation then imports those structures, plus any others that they require. All imported structures are converted into the equivalent elements, groups, and types in the message definition file.

You can also specify which of the selected structures are to be messages in the message definition file. The import operation creates a message and a corresponding global element in the message definition file for each structure that you specify. If you do not specify that messages are to be created, you must create them manually using the Message Definition editor after the import has completed.

If you import by using the "New Message Definition File From C header file" wizard you can import only one C header file with each import operation. But, if you import by using the command-line utility, you can import several C header files in each import operation.

If your C header file needs any other header files for a successful compilation, you must provide these and specify their location, because a compilation of your header file is performed as part of the import operation.

A report file is created during the import operation. This is located by default in the `log` folder of the message set. By default, it takes the name of the message definition file, with `.report.txt` appended.

Physical information: In addition to creating logical information, the import can also create physical information.

If the message set contains any Custom Wire Format (CWF) physical formats, the physical format properties for all CWF layers are populated.

If the message set does not contain any CWF physical formats, only logical information is created. Also, if you import from the command line, only logical information is created in the new message set by default.

XML and TDS physical format properties are *not* populated and so take default values.

If you have one or more TDS layers, the import can cause entries in the task list, warning you that certain TDS properties must be set if the C structures you have imported were to appear in a TDS message.

If the TDS physical format is not applicable to your C structures, you can ignore these task list entries because they are just warnings; they do not prevent your model being generated in another form, such as a message dictionary.

Because physical information is created, the application target environment (platform and compiler) is important because it governs the way that, for example, integers appear in the message. You can specify environment-specific information as part of the import operation, and the necessary properties are set accordingly. There is a range of environments supported; if your environment is not shown, choose the closest match and review the created physical information by using the Message Definition Editor after the import has completed.

Command-line invocation: The **`mqsicreatemsgdefs`** command-line utility allows you to import several C header files in a single operation. All the C header files must be placed in the same directory and the directory location passed as a parameter to the utility.

You provide the necessary environment-specific information, and include file location information by using an XML file. This must contain an XML element

called <C> which holds one set of information that applies to all C header files imported during an invocation of the utility. A default XML file called mqsicreatemsgdefs.xml is supplied. If you want to apply different sets of information to different header files, you must create multiple XML files and run the utility multiple times.

The **mqsicreatemsgdefs** utility also allows you to create message set into which the message definition files are placed, as part of the import operation. You can also choose to base this new message set on an existing message set. This facility enables you to prepare an empty message set containing a CWF physical format and message set level CWF properties already populated, which then gets copied into the message set created by the import.

"Importing from the command line" on page 2936
This describes how to use the command line importer **mqsicreatemsgdefs** to import C, COBOL copybooks, XML DTD or XML Schema in order to populate a message set with message definitions.

Importing from COBOL copybooks to create message definitions:

You can populate your message set with message definitions by importing COBOL copybook files, by using either the "New Message Definition File From COBOL file" wizard or the **mqsicreatemsgdefs** command.

Each COBOL copybook that you import results in a new message definition file. The root name of the message definition file defaults to the root name of the COBOL copybook file, but the "New Message Definition File From COBOL file" wizard allows you to choose a different root file name.

If the message definition file already exists, you must have permitted overwriting to occur for the import to proceed, in which case the existing content is deleted and re-created.

By default, all message definition files that are created as a result of COBOL copybook file import belong to the noTarget XML namespace and therefore reside in the (default) location in your workspace. This default namespace can be

overridden by specifying a target namespace. See “Namespaces with non-XML messages” on page 1206 for reasons why you might want to do this.

In your COBOL copybook file there are typically one or more level 01 structures. You can select which of these structures to import. The import operation then imports those structures, plus any others that they require. All imported structures are converted into the equivalent elements, groups, and types in the message definition file.

You can also specify which of the selected level 01 structures are to be messages in the message definition file. The import operation creates a message and corresponding global element in the message definition file for each structure that you specify. If you do not specify that messages are to be created, you must create them manually using the Message Definition Editor after the import has completed.

If you import by using the "New Message Definition File From COBOL file" wizard, you can import only one COBOL copybook file with each import operation. If you use the command-line utility, you can import several COBOL copybook files in each import operation.

If your COBOL copybook file needs any other copybooks in order to compile successfully, you must provide these in the same directory, because a compilation of your copybook is performed as part of the import operation.

A report file is created during the import operation. This is located by default in the `log` folder of the message set. By default it takes the name of the message definition file, with `.report.txt` appended.

The copybook must not contain field names that are COBOL reserved keywords.

Physical information: In addition to creating logical information, the import can also create physical information. If the message set contains any Custom Wire Format (CWF) physical formats, the physical format properties for all CWF layers are populated. If the message set does not contain any CWF physical formats, only logical information is created. If you import from the command line, only logical information is created in the new message set by default. If you want physical information created as well, see “Importing from the command line” on page 2936 for details.

XML and TDS physical format properties are *not* populated and therefore take default values.

If you have one or more TDS layers, the import can cause entries in the task list, warning you that certain TDS properties must be set if the COBOL structures that you have imported were to appear in a TDS message.

If the TDS physical format is not applicable to your COBOL structures, you can ignore these task list entries because they are just warnings, they do not prevent your model being generated in another form, such as a message dictionary.

Because physical information is created, the application target environment (platform and compiler) is important because it governs the way that, for example, integers appear in the message. You can specify environment-specific information as part of the import operation, and the necessary properties are set accordingly. There is a range of environments supported; if your environment is not shown,

choose the closest match and review the created physical information by using the Message Definition Editor after the import has completed.

Command-line invocation: The **mqsicreatemsgdefs** command-line utility allows you to import several COBOL files in a single operation. All the COBOL copybook files must be in single directory, and the directory location passed as a parameter to the utility.

You provide the necessary environment-specific information by using an XML file. This must contain an XML element called `<COBOL>` that holds one set of environment-specific information that applies to all COBOL copybook files that are imported during an invocation of the utility. A default XML file called `mqsicreatemsgdefs.xml` is supplied. If you want to apply different sets of information to different copybooks, you must create multiple XML files and run the utility multiple times.

The **mqsicreatemsgdefs** utility also allows you to create message set into which the message definition files are placed, as part of the import operation. You can also choose to base the message set created on an existing message set. This facility enables you to prepare an empty message set that contains a CWF physical format and pre-populated message set level CWF properties, which are then copied into the message set that is created by the import.

This describes how to use the command line importer **mqsicreatemsgdefs** to import C, COBOL copybooks, XML DTD or XML Schema in order to populate a message set with message definitions.

Importing WSDL files to create message definitions:

Import WSDL files by using the **New Message Definition File From WSDL file** wizard, the **Start from WSDL and/or XSD files** Quick Start wizard, or the **mqsicreatemsgdefsfromwsdl** command.

Each WSDL file that you import results in one or more new message definition files within the message set. A new message definition file is created for each

namespace that is defined for the message set. The name of the message definition file defaults to the name of the WSDL file, but the **New Message Definition File From WSDL file** wizard allows you to choose a different file name.

If the message definition file exists, you must have permitted overwriting to occur for the import to proceed. The existing content is deleted and re-created.

The message set that you are importing the WSDL file into must be namespace-enabled. If it uses the MRM domain, it must have an XML physical format so that the message set is suitable for the runtime parsing of XML messages such as SOAP.

Use the report generated during the import operation to see what happened and to check any errors.

You specify a single WSDL definition for each import operation. If the WSDL definition consists of a hierarchy of files, you must supply the name of the file that contains the WSDL service or binding definitions. The WSDL definition that is imported must contain one or more WSDL bindings for the import to proceed. You can then select multiple bindings from the WSDL definition to define messages to model in the message set.

Importing by using the New Message Definition File wizard

When you import by using the New Message Definition File wizard, you can specify only one WSDL definition for each import operation. A WSDL definition can be held as one or more WSDL files, which are all imported as a result of importing the definition. The WSDL definition that is imported must contain one or more WSDL bindings for the import to proceed.

Importing by using the command line

The WSDL command-line importer (**mqsicreatemsgdefsfromwsdl**) can create a message set or update an existing one. If the message set project exists, it must be namespace-enabled and have an XML physical format layer. If the project does not exist, a new namespace-enabled project is created. If the import succeeds, new message definition files are added to the message set.

The **mqsicreatemsgdefsfromwsdl** command allows you to import one WSDL definition in a single operation.

The **mqsicreatemsgdefsfromwsdl** command copies the WSDL files it needs into the workspace before the import runs. These files are the top-level WSDL files and any imports are resolved by using an absolute or relative location. The files are copied under the specified message set in a folder called `importFiles`. They are not removed after the import; the user can later update or run validation on them in the WebSphere Message Broker Toolkit.

Physical information

An XML physical format layer is required for the MRM domain, and must be added to an existing message set before importing the WSDL definition.

Several objects are generated when you import from WSDL but restrictions might apply.

Relationship of WSDL to Message Model:

If a broker is to communicate with an existing Web service, it typically needs to send and receive SOAP messages. To take this approach, use the MRM domain. You must ensure that the broker message model and the WSDL definition used by the Web service describe the same messages. In general, you can achieve this result by importing the WSDL for the existing Web service by using the broker tooling. Currently only WSDL version 1.1 is supported.

Only the WSDL operation, message, and part definitions are represented in the resulting broker model. Starting with the lowest level, a WSDL definition describes the following resources:

- A number of logical messages and their constituent parts, which are defined in terms of XML Schema. The part definitions are imported directly into the message model to create the corresponding element and type definitions. The definitions are allocated to message definition files according to the target namespace of their schema definition. If no targetNamespace is defined on the <xsd:schema> element, the resulting elements and types have no namespace.
- A number of operations that form the WSDL portType or interface. The operations define the business payload for the SOAP messages at run time. Broker messages are created for each possible payload. In the case of rpc-style WSDL, the message model needs message definitions that correspond to the WSDL operations themselves. The names of these message definitions are derived from the WSDL operation name, and their namespace is given by the namespace attribute on the WSDL <soap:body> definition.
- A SOAP version and encoding style. Message definitions for the SOAP envelope and, if necessary, the SOAP encoding scheme are imported into the message set. Currently the WSDL importer assumes the use of SOAP version 1.1. WSDL version 1.1 can define a Web service that uses SOAP version 1.2, but no standard method exists to achieve this definition. If your Web service does use SOAP

version 1.2, you might have to remove the SOAP version 1.1 definitions manually and import the SOAP version 1.2 definitions.

Resulting message model

The resulting model allows the user to parse incoming SOAP messages by using the MRM XML parser where the message type is Envelope. The message model for the SOAP envelope defines the outer SOAP wrapper with its constituent Header and Body sections and a number of attachment points where the various business payloads can appear. These attachment points are defined with composition message, allowing the broker messages that are created by the WSDL importer to appear at these points.

The allowed attachment points are Envelope.Body, Envelope.Header, and Envelope.Body.Fault.detail. A message from the user's message model might appear at each point (in the case of the Envelope.Header, multiple messages might appear). In the case of rpc-style WSDL, the message expected at Envelope.Body is the automatically-generated message that corresponds to the WSDL operation. In all other cases, the messages expected are those defined by the WSDL message parts for each operation.

Generate model representations

After you have created and populated a message set, you can generate a message model in several different representations for use by a broker, a parser, or your applications.

The following representations are supported:

- A message dictionary, for deployment to a broker.
- A W3C XML Schema, for use by an application building or processing XML messages, or for deployment to a broker.
- Web Services Description Language (WSDL), for a Web services client application, or for deployment to a broker.
- Documentation, to give to programmers or business analysts.

Generation for deployment to a broker takes place automatically when you add your message set to a Broker Archive (BAR) file.

Generation for other purposes is achieved using the **Generate** menu actions.

"Adding files to a broker archive" on page 3223
To deploy files to an execution group, include them in a broker archive (BAR) file.

Generate message dictionaries:

A *message dictionary* is data structure that describes all of the messages in a message set in a form suitable for deployment to the MRM parser.

Purpose of a message dictionary: A dictionary describes the logical structure and content of a set of messages, and typically contains one or more physical formats that describe how those messages are serialized in a bit stream. The MRM parser within WebSphere Message Broker uses this information to parse an incoming message bit stream into a message tree, or to write a message tree into a physical bit stream.

Contents of a message dictionary: A message dictionary contains the same information as the message set from which it was created, but in a compressed form that the MRM parser within WebSphere Message Broker can understand and use. A message dictionary contains all the elements in the message set, the structure of the messages, and all the value constraints. A message dictionary also contains any physical formats that were defined in the message set.

Generating a message dictionary: Before a message dictionary can be used, it must be deployed to WebSphere Message Broker. To do this, add the message set to a BAR file, then deploy the BAR file to a broker. The generation of the message dictionary is performed automatically when a message set is added to a BAR file, if the message set supports the MRM domain.

Before adding a message set to a BAR file, the WebSphere Message Broker Toolkit performs a full validation of the message set. If this validation finds any errors, the message set is not added to the BAR file, and therefore no message dictionary is generated.

Dictionary generation report files:

Whenever a message dictionary is generated, a user log file is also generated and added to the same BAR file. This file contains informational messages and warnings that relate to the use of the generated dictionary. Always check this file after generating a message dictionary.

You can generate a schema file from a message model.

XML schema is a standard way of describing complex message models.

You can generate a schema file for an individual message definition file, or for all message definition files in a message set. If any XML physical formats have been defined for the message set, you can select which of these XML wire formats are to be applied.

Generating from message sets: If any XML physical formats have been defined for the message set, you can select which of these XML wire formats are to be applied.

- If an XML format has been selected, the physical format information is also included.
- If no XML format is selected, the generated schema file contains information about only the logical message model.

You can choose whether 'strict' or 'lax' schema generation is to be performed. This is necessary because the logical extensions to the XML schema model provided by the message definition file cannot be represented in XML schema. So you can choose either to generate a schema with more strict or more lax validation than the equivalent validation performed by the message model parser. The affected model extensions are:

- `Content Validation` = open
- `Content Validation` = open defined
- `Composition` = unordered set

Further information about XML schema: For details about XML schema, see XML Schema Part 0: Primer on the World Wide Web Consortium (W3C) Web site.

"Generating multiple XML Schemas" on page 2963
You can generate an XML Schema for each message definition file in a message set.

Validating an XML message against a schema:

The XMLNSC parser can validate an XML message against any deployed XML schema.

Before you begin

You can validate an XML message against an XML schema when the message is parsed, when the message is serialized, or at any point within a message flow.

About this task

To construct a message flow for schema validation, you must perform the following tasks:

Procedure

1. Enable validation at the appropriate point within the message flow. See "Validating messages" on page 1478.
2. Ensure that you have deployed all XML Schema files that are required. See "Deploying an XML Schema" on page 1274.
3. Specify the message set in which the schema was deployed; this is done using the MessageSet property of the message. See "Accessing the Properties tree" on page 2460.

What to do next

Schemas are deployed within a message set, and are identified by supplying the message set name in the message properties.

Related concepts:

"XML parsers and domains" on page 1084
You can use XML domains to parse and write messages that conform to the W3C XML standard.

"Generate XML schema" on page 1272
You can generate a schema file from a message model.

Deploying an XML Schema:

XML Schemas are created as Message Definition Files within a message set that is then deployed.

Before you begin

To create and deploy a message set for schema validation you must:

Procedure

1. Create or locate a message set that will contain the schemas.
2. Set the Message Domain property of the message set to XMLNSC.
3. Use the New Message Definition File wizard to create a message definition file (mxsd) from the XML Schema file (.xsd).
4. Add the message set to a BAR file and deploy the BAR file.

What to do next

Repeat step 3 for each XML Schema file that you want to deploy.

If your XML Schema imports or includes other XML Schema files, you can use the **mqsicreatemsgdefs** command to create all the message definition files in a single operation.

Generate WSDL:

A *Web Services Description Language* (WSDL) document specifies the interface to a web service, and enables a web service client to start it. A WSDL document that is generated from a message model defines web service requests and responses in terms of the messages that you have defined in that message model.

Use message model files with target namespaces when you generate WSDL. If you do not, WebSphere Message Broker uses the WSDL target namespace as the default target namespace.

In the main WSDL document, operations are defined in terms of logical messages, which are themselves defined in terms of the elements and types that are defined in these message model files.

WSDL operations are grouped into a logical interface or portType, and are then associated with a binding which defines the physical format of the messages. You can select only one of the following bindings when you generate WSDL:
- SOAP (over JMS)
- SOAP (over HTTP)

A WSDL service definition specifies the endpoint where the service is available. You can elect to have the service, binding, and portType definitions generated as a single file or as separate files. Tools that use WSDL are typically more tolerant of the single-file format. If you select single-file, you can also choose whether the associated XML Schema is generated from the message model as a separate file or in-line.

To ensure the highest interoperability of your Web services, use the document style of WSDL whenever possible. If rpc style WSDL is necessary, use literal encoding.

"Importing from WSDL" on page 2946
You can use the New Message Definition File wizard in the WebSphere Message Broker Toolkit to create a new message definition from WSDL.

Relationship to the message model when generating WSDL:

If a broker is to communicate with a Web service client, it must typically accept SOAP messages. You can model your messages in the MRM domain, and the message model you deploy to the broker and the WSDL definition used by the Web service client must describe the same messages.

If the broker has an existing message model (possibly created by importing a C header file or COBOL copybook), you can export the model to create a corresponding WSDL definition for use by the client. At the same time, you must enhance your message model with appropriate definitions for the SOAP envelope and (for rpc-style) the WSDL operations. Currently only WSDL version 1.1 is supported.

To generate WSDL, you need:

1. A way of representing the WSDL operations. The message category performs this service.

2. Away of representing the data for these operations. The message model performs this service
3. A way of soliciting the Web service end-point and binding details. The WSDL Generator wizard performs this service.

A message category is required for each WSDL operation. The category specifies a set of messages from the broker model and associates them with the required WSDL qualifiers for the specified WSDL operation type.

At run time, the format of the SOAP messages depends on the WSDL style specified in the wizard. If you select rpc-style, the SOAP Envelope contains a message that corresponds to a WSDL operation. The WSDL generator adds an appropriate message definition that corresponds to the WSDL operation to your message set. If you select document-style, the SOAP envelope contains messages specified in the category, therefore you do not have to add additional message definitions to your message set.

Message definitions for the SOAP envelope and, if necessary, the SOAP encoding scheme, are imported into the message set.

Resulting message model

The resulting model allows incoming SOAP messages to be parsed by the MRM XML parser, where the message type would be Envelope. The message model for the SOAP envelope defines the outer SOAP wrapper with its constituent header and body sections and a number of attachment points where the various business payloads can appear. These attachment points are defined with composition of type message, allowing broker messages to appear at these points.

The supported attachment points are Envelope.Body, Envelope.Header and Envelope.Body.Fault.detail. A message from your message model might appear at each point (in the case of the Envelope.Header, multiple messages can appear). For rpc-style WSDL, the message expected at Envelope.Body is the automatically generated message that corresponds to the WSDL operation; for example, the message category. In all other cases, the messages expected are those referenced by the message categories.

Message flow behavior

Message flow behavior is initially defined by the broker, but you can change or add to that behavior in some situations.

When a message is received and processed by a message flow, the broker handles both successful and failure processing. The default actions taken by the broker, which are independent of the protocol you are using to exchange messages with your message flows, are described in "Default message flow behavior" on page 1278.

If the default behavior does not meet your processing requirements in some way, you can change some aspects of the behavior by tuning or reconfiguring your message flows.

- Learn about the default behavior supported by the broker.
- Review the options that are available to you if you want to change the behavior.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

"Execution groups" on page 53
An execution group is a named grouping of message flows that have been assigned to a broker. The broker enforces a degree of isolation between message flows in distinct execution groups by ensuring that they run in separate address

spaces, or as unique processes.

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Default message flow behavior

The broker controls the behavior of your message flows, and defines what actions are taken if you do not change that behavior.

The broker provides the following default actions for all messages that are processed by your message flows:

The execution and threading model
When you deploy a message flow to an execution group, the broker allocates a certain number of threads to that message flow. For further information about how this processing works, see "Execution and threading models in a message flow" on page 1279.

Error handling
When you configure your message flows to process messages, you can include error processing of your own. The broker runs default processing if an error occurs that you have not provided additional processing for; this processing is independent of the protocol that you are using to communicate with the broker. It is described in "Default error handling" on page 1280.

Transactional support
The broker handles all messages individually, and does not relate an action taken by the message flow to other actions, processes, or messages. A message flow that is not configured to implement transactional support succeeds or fails regardless of the outcome of interactions with or updates to other resources such as WebSphere MQ queues and databases. Learn more about transactional support in "Message flow transactions" on page 1281.

Data conversion
Different hardware platforms and operating systems operate in different code pages. Operating system code pages are also affected by the locale in which you operate. The broker does not allow for these differences unless you change some aspects of its configuration. If you are exchanging messages between unlike systems, you might have to update broker or WebSphere MQ configuration, or design and supply your own conversion procedures.

For information about how you can change the configuration of your broker, its WebSphere MQ queue manager, and your message flows to influence these behaviors, see "Changing message flow behavior" on page 1288.

Execution and threading models in a message flow:

The execution model is the system used to start message flows which process messages through a series of nodes.

When an execution group is initialized, the appropriate loadable implementation library (LIL) files and Plug-in Archive (PAR) files are made available to the runtime environment. The execution group runtime process starts, and creates a dedicated configuration thread.

The message flow execution environment is conceptually like procedural programming. Nodes that you insert into a message flow are like subroutines that are called by using a function call interface. However, rather than a call-return interface, in which parameters are passed in the form of input message data, the execution model is referred to as a propagation-and-return model.

In the message flow execution environment, the message flow is thread-safe. You can run message flows concurrently on many operating system threads, without having to consider serialization issues.

Each input message that passes through a message flow for processing by a series of nodes executes on a single thread; it is processed only by the thread that received it. If you want to increase the throughput of a message flow, you can increase the number of threads that are assigned to that message flow. The memory requirements of an execution group are not unduly affected by running message flows on more operating system threads.

With a larger number of threads, the message flow can handle peak message loads. At other times, the additional threads are idle.

You can increase or decrease the number of threads servicing a flow by using the `Additional instances` property on the input node of the message flow.

Each instance of a message flow processing node is shared, and used by all the threads that service the message flow in which the node is defined.

"Message flow transactions" on page 1281
A transaction describes a set of updates that are made by an application program, which must be managed together. The updates might be made to one or more systems. The updates made by the program are controlled by the environment in which the program executes, and either all are completed, or none. This property of a transaction is known as *consistency*: transactions might have other properties of *atomicity*, *isolation*, and *durability*.

"Threading considerations for user-defined extensions" on page 2978
Message processing nodes and parsers must work in a multi-instance, multithreaded environment. Many node objects or parser objects are available, each with several syntax elements, and many threads can be executing methods on these objects.

"User-defined extensions execution model" on page 2981
The execution model is the system used to start message flows through a series of nodes.

Related tasks:

"Designing a message flow" on page 1455
A message flow can perform a wide range of operations, depending on your business and operational requirements. For best performance and capability, you must design it to include the most appropriate nodes.

Default error handling:

The broker provides basic error handling for all your message flows.

When an exception is detected within a node, the message and the exception information are propagated to the Failure terminal on the node. If the node does not have a Failure terminal, or it is not connected, the broker throws an exception and returns control to the closest upstream node that can process it. The default behavior is that the message is returned to the input node.

The actions taken by the input node are protocol-dependent; if your message flow starts with an MQInput, its error handling is different from the error handling provided by a FileInput node.

The actions also depend on whether you have configured the message flow to be transactional. Some nodes support transactions; others are non-transactional. If the message is not being processed in a transaction, the message is discarded by the input node. If the flow is transactional, the message is returned to its source; for example, it is restored on the WebSphere MQ queue.

If basic error processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling. For example, you can add in a sequence of nodes to deal with one or more errors that you might expect to occur in your flow. You can also configure your flow to handle unexpected errors (exceptions). For more details about the actions that you can take, see "Handling errors in message flows" on page 2823.

Related tasks:

"Handling errors in message flows" on page 2823

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Message flow transactions:

A transaction describes a set of updates that are made by an application program, which must be managed together. The updates might be made to one or more systems. The updates made by the program are controlled by the environment in which the program executes, and either all are completed, or none. This property of a transaction is known as *consistency*: transactions might have other properties of *atomicity*, *isolation*, and *durability*.

WebSphere Message Broker supports transactions, and every piece of data processed by a message flow has an associated transaction. A message flow transaction is started by the broker when input data is received at an input node in the flow; it is committed when the flow has finished with that message, or rolled back if an error occurs.

If the flow contains more than one input node, one transaction is started for each input node when it receives input data. A transaction is started for every type of input node, including user-defined input nodes.

The nodes that you include in your message flow provide specific processing of a message, according to the defined function of each node. The processing that they do includes internal work, some of which you can influence by configuring the node properties. Some nodes perform additional tasks that might affect systems that are external to the message flow or the broker.

If an external system, such as a database, supports that concept of commit and rollback, and it can take part in a broker transaction, you can configure the node so that the work it does is included in the flow transaction. Depending on the node, you can also specify if the work done in an external system that supports transactions is committed immediately, or when the message flow transaction completes.

Many of the resources with which your message flows can interact are controlled by resource managers that can participate in coordinated transactions; for example, databases, WebSphere MQ messages and queues, and JMS messages. Other resource managers do not provide transactional support; for example, the HTTP protocol and file systems.

Commit or rollback

If the resource can participate in a transaction, you can configure it so that the work it does is committed or rolled back only when the message flow completes, or when the node completes. Databases and WebSphere MQ queues are examples of resources that you can use in this way. If the resource does not have transactional behavior, all the work that it does is committed immediately. For example, files and HTTP connections do not support transactions.

Updates that are made by a message flow are committed when the flow processes the input message successfully. The updates are rolled back if both of the following conditions are met:

- A node in the flow throws an exception that is not caught by a node other than the input node (for example, the node itself, or a TryCatch node)
- The Catch terminal of the input node is not connected

On distributed systems, message flow transactions are managed by the broker, by default. These transactions are known as *broker-coordinated transactions* or *partially coordinated transactions*. When control returns to the input node when the flow finishes processing, the node either commits or rolls back the operations that have been taken, excluding the individual nodes that have been configured to perform their own commits and rollbacks, or that have no support for this option.

If more than one resource is accessed by the message flow, an error might occur that prevents all the resources committing all the work that has been done. The broker raises an exception, and handles exception processing in a way that is determined by the transport that is involved. For example, messages that were read from WebSphere MQ queues are restored to those queues, and fault messages are sent to applications that submitted a message across HTTP (because HTTP has no concept of rollback). Because of these actions, the status of the resources might become inconsistent.

If it is important that your data and operations remain consistent, and that all operations are committed, or rolled back if one or more operations fail, you can coordinate the activity of the message flow. Coordination is provided by an external transaction manager which uses XA protocols to interact with resource managers. The transaction manager is called by the input node when the message flow has concluded (successfully or with errors). The transaction manager, rather than the input node and the broker, interacts with the relevant resource managers to initiate the correct actions for each resource. Transactions that are controlled by a transaction manager in this way are known as *globally coordinated transactions*.

On z/OS, transactions are always globally coordinated; you do not have to choose or configure for this option.

For a more detailed description of the transaction model in the broker, see “The transactional model” on page 1285.

The role of the transaction manager

The result of the actions taken by message flows is the same for both partially and globally coordinated transactions if the message flow is successful in all its actions. The advantage of a globally coordinated transaction is the ability to ensure that either all actions are committed, or none.

The external transaction manager, which operates a two-phase commit strategy, supports cases where one or more external resource managers are temporarily unavailable during commit processing. This potentially small window for failure might be costly for your business environment; the external transaction manager helps to eliminate the occurrence of a failure window. Therefore, the decision to include an external transaction manager, which involves a performance overhead, is an administrative decision, not one to be taken at message flow design time.

An external transaction manager does not prevent message loss; even if you use transaction coordination, you must configure and code your message flows to handle potential errors as much as you can.

To configure a message flow to be globally coordinated, you must also set up your environment so that your resource managers are defined to the supported transaction manager:

- On distributed systems, transactions can be coordinated by WebSphere MQ
- On z/OS, all transactions are globally coordinated by Resource Recovery Service (RRS)

This configuration might require you to change settings in the transaction manager as well as the participating resource managers.

Database access modes and locks

You must use separate ODBC connections if you want to include nodes with Automatic transaction status and nodes with Commit transaction status in the same message flow, where the nodes operate on the same external database. Set up one connection for the nodes that are not to commit until the completion of the message flow, and a second connection for the nodes that are to commit immediately.

- If nodes with Commit transaction status are followed by a node with Automatic transaction status, the nodes with Commit transaction status commit independently of the flow transaction, and the nodes with Automatic transaction status commit at the end of the flow.
- However, if nodes with Automatic transaction status are followed by a node with Commit transaction status, and you do not use separate ODBC connections, error message BIP4001 is issued, because otherwise the node with Commit transaction status commits the work of the Automatic nodes prematurely.

Linux UNIX Windows On systems other than z/OS, individual relational databases might not support this mode of operation.

If you define more than one ODBC connection to the same data source, you might get database locking problems. In particular, if a node with Automatic transaction status carries out an operation, such as an INSERT or an UPDATE, that causes a database object (such as a table) to be locked, and a subsequent node tries to access that database object by using a different ODBC connection, an infinite lock (deadlock) occurs.

The second node waits for the lock acquired by the first to be released, but the first node does commit its operations and release its lock until the message flow completes. However, the flow cannot complete because the second node is waiting for the database lock held by the first node to be released.

Such a situation cannot be detected by a DBMS automatic deadlock-avoidance routine because the two operations are interfering with each other indirectly by using the broker.

You can use either of two options to avoid this type of locking problem:

- Design your message flow so that uncommitted (automatic) operations do not lock database objects that subsequent operations access across a different ODBC connection.

- Configure the lock timeout parameter of your database so that an attempt to acquire a lock fails after a specified length of time. If a database operation fails because of a lock timeout, an exception is thrown that the broker handles in the typical way.

For information concerning which database objects are locked by particular operations, and how to configure the lock timeout parameter of your database, consult your database product documentation.

Example of transactions in message flows

The following sample demonstrates the use of globally coordinated transactions, and the differences in the message flow when database updates are coordinated (the main flow), and when they are not (the error flow).

- Error Handler

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

"Database connections for coordinated message flows" on page 4235
When you configure a message flow to access a database, the broker establishes a connection to that database based on the ODBC DSN.

"Database support for coordinated message flows" on page 4236
If the message flow processing includes interaction with an external database, you can coordinate the transaction by using XA technology.

The transactional model:

The transactional model describes the way in which you can use transactions in message flows to accomplish certain tasks and results.

A message flow consists of the following constituent parts:

- An input source
- The message flow or logic, which is defined by a sequence of nodes
- Zero or more external resources that are accessed during the flow
- Zero or more output targets

The following steps represent a typical sequence of events in the message flow transaction:

1. A message is taken from the input source; for example, a queue.
2. Data is read from or written to one or more external resources; for example, a database.
3. A message is sent to an output target; for example, a queue.
4. The system quiesces and waits for the next input message.

During this sequence of events, the state of the data in the system changes, regardless of the number of external resources that the message flow accesses, and whether it generates an output message.

Consider the following diagram:

```
-----x---------x---x-------x-------------x----x-----
     1         2   3       4             5    6
```

The line represents the data in the system as time passes. At time 1, a message arrives and is taken from the input source. At times 2, 3, 4, and 5, data is used to update external resources; for example, a database table or an output queue. Changes in the state of the data are indicated in the diagram by the *x* symbol. At time 6, the output messages are sent and the system is inactive. Between these events, the state of the data does not change; this state is indicated in the diagram by the = symbol.

If a failure occurs on the system (for example, a loss of power to the computer on which the broker is running), the changes to the state of external resources that were made before the failure have been implemented, but no more changes take place after the failure. This situation is unacceptable in certain circumstances; for example, if a system failure occurs when making a payment from a current account to a mortgage account, the payment might be taken from the current account, but it is not added to the mortgage account.

Transactions: To avoid the problem that is described previously, the broker and the external resource managers with which it works, have a *transactional model*. The broker starts a transaction when data is received by an input node in the message flow, and completes when the processing on that data is finished. For more details about message flow transactions, see “Message flow transactions” on page 1281.

As processing proceeds in a transaction, additional data is recorded that allows the original state to be restored in the event of a failure. The following diagram illustrates the state of this extra data:

```
-----x=========x===x=======x=============x====x-----
     1         2   3       4             5    6
```

The line in the diagram represents the extra data in the system as time passes. At time 1, input data arrives from the input source; for example, a queue. Before time 1, no extra data exists in the system; this state is indicated in the diagram by the - symbol. After time 1, the state represents the fact that data has been received from the input source, so that it can be restored, if necessary. At times 2, 3, 4, and 5, data is used to update external resources such as databases or files. Again, the state of the extra data changes so that the changes to those external resources can be undone, if necessary. At time 6, the output messages are sent, the system is inactive, and extra data in the system no longer exists.

Between these events, the state of the extra data does not change; this state is indicated by the = symbol. If a failure occurs between time 1 and time 6, the extra data is used to restore the original state of the data held by the external resources. Therefore, effectively, no output data has been written to the output target, none of the external resources have been updated, and the input data has not been received from the input source. If no failure occurs, the changes become permanent at time 6 (an undo operation that follows a subsequent failure will not undo the changes).

This mode of operation is known as *coordinated transaction mode*. The successful completion of a transaction is known as its *commit*. Unsuccessful completion is known as *rollback*.

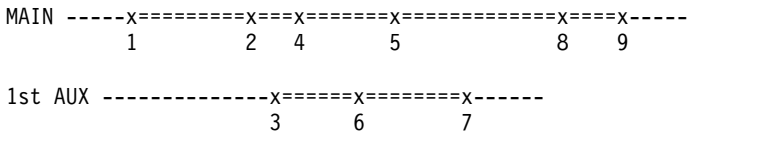
Uncoordinated auxiliary transactions: The key feature of the coordinated transaction mode of operation is that, regardless of where or when the failure appears, either all of the changes to external resources that are associated with one input message are made, or none of the changes are made. However, this behavior is not always suitable, as the following examples illustrate:

- You want to create an audit log of all attempts at processing. The log entries must be committed, even when updates to other resources are rolled back.
- You want to send an acknowledgment or non-acknowledgment message back to the originator of the messages that you are processing, according to whether the message processing succeeds or fails. These messages must be sent even when the updates to other resources are rolled back.

If your message flows have requirements like these, you can configure message flows to change one or more resources in a separate, or auxiliary, transaction. Not all resource managers support this type of transaction.

For some resources, an auxiliary transaction is automatically started; for example, each database connection starts a transaction that is specific to that database, and all updates made in that transaction can be committed or rolled back.

The behavior of an auxiliary transaction is shown in the following diagram:



The *MAIN* line represents the main transaction, which includes the extra data that is recorded to restore the original state if necessary. The *1st AUX* line represents an auxiliary transaction. At time 3, an external resource is updated, and another update is made at time 6. At time 7, the message flow determines that all the changes that must be made under the auxiliary transaction are complete, and it commits the changes.

If the message flow fails before time 7, the state of the system would be unchanged because both transactions would be rolled back. If failure occurs after time 7 but before time 9, the auxiliary transaction would already have been committed. However, the main transaction would be rolled back. If a failure has not occurred by time 9, both transactions are committed.

Database auxiliary transactions: You can use more than one auxiliary transaction, and make a number of updates to database tables that can be committed or rolled back. You can then make additional changes to the same database tables, or to different tables, then commit or rollback these changes.

Each database that you use has its own auxiliary transaction; therefore, if the message flow updates tables that belong to different database instances (different data source names), an auxiliary transaction exists for each database. You can optionally commit or roll back these auxiliary transactions individually. Updates that have not been committed or rolled back when the message flow completes (at time 9 in the example shown previously) are committed or rolled back automatically by the broker, according to whether the processing succeeded or failed.

Use the ESQL COMMIT and ROLLBACK statements to commit and roll back auxiliary database transactions. Obtain operations outside the main transaction by specifying the UNCOORDINATED keyword on the individual database statements (for example, the INSERT and UPDATE statements).

Queue auxiliary transactions: Not all queuing systems have the database capability that is described in the previous section. With WebSphere MQ, each individual uncoordinated read or write operation to a queue has an implied commit action. Therefore, you cannot put two messages, then decide to commit both or roll back both. The COMMIT and ROLLBACK statements therefore operate only on databases.

Nodes: The previous sections refer to message flows, but not to nodes. The way in which a message flow is divided into nodes has no effect on transactions. For operations on databases, an unlimited number of nodes can make updates to the main transaction, and to an unlimited number of auxiliary transactions, without restriction.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Message flow transactions" on page 1281
A transaction describes a set of updates that are made by an application program, which must be managed together. The updates might be made to one or more systems. The updates made by the program are controlled by the environment in which the program executes, and either all are completed, or none. This property of a transaction is known as *consistency*: transactions might have other properties of *atomicity*, *isolation*, and *durability*.

If the message flow processing includes interaction with an external database, you can coordinate the transaction by using XA technology.

Changing message flow behavior

You can change the behavior taken by your message flows to process messages in different ways and at different times.

About this task

If one or more of the default behaviors described in "Default message flow behavior" on page 1278 is not sufficient or appropriate for your message processing, you can change some characteristics of that behavior at different times during the design, development, and production cycles:

- "Behavior you can change when you design your message flows"
- "Behavior you can change when you deploy your message flows" on page 1289
- "Behavior you can change during message flow processing" on page 1289

Behavior you can change when you design your message flows:
About this task

You can influence the behavior of your message flows when you set message node properties, and when you connect together the nodes that you select to run in that flow.

Transactional support

You can configure your message flows to handle your messages, and other data, in transactions. These options are described in "Configuring transactionality for message flows" on page 1290.

Error handling

The broker provides an initial level of error processing for all message flows. If you require further support in your message flows, you can add your own processing. You can learn more about these options in "Handling errors in message flows" on page 2823.

The nodes that support some protocols provide additional default error handling; this support is described, where relevant, in the sections in "Connecting client applications" on page 1537.

Data conversion

If you are exchanging messages between unlike systems, you can update broker or WebSphere MQ configuration, or design and supply your own conversion procedures. Options are described in "Configuring message flows for data conversion" on page 1293.

User-defined properties

You can create user-defined properties for your message flows to associate values with those message flows. You can then configure the nodes in your message flows to access those properties and their values by coding ESQL or Java programs. Read more about user-defined properties, and see how to create them in the "Message Flow editor" on page 6810.

Promoted properties

You can promote some message node properties to the level of the message flow in which the node is included. The advantages of this technique are described in "Promoted properties" on page 1145; see "Defining a promoted property" on page 1297 for details of how to use these properties.

Behavior you can change when you deploy your message flows: About this task

After you have decided on the message flow content, you can change some aspects of its operation before or after deployment.

Configurable properties and BAR overrides

Some of the properties on message flow nodes are configurable; that is, you can change their values when you deploy the message flow. By using this option, you can change some characteristics of a deployed message flow without changing the message flow definitions. For example, you can update queue manager and data source information in the BAR file when you deploy it.

You can change these values by using the WebSphere Message Broker Explorer, the WebSphere Message Broker Toolkit, or the **mqsiapplybaroverride** command.

The execution and threading model

You can increase the number of threads that your message flows use to reduce the time in which your messages are handled. You can also deploy multiple copies of a message flow to one or more brokers. For further information, see "Optimizing message flow throughput" on page 587.

Behavior you can change during message flow processing: About this task

If you want to change the behavior of your message flows in a more dynamic way, you can use the techniques described here. However, you must design your message flows so that they can take advantage of these additional services.

Configurable services

By using a configurable service, you can create and configure properties that relate to external services called by the broker from your message flows. A number of configurable services are supplied with the broker; you can modify or add to these default services, and you can create your own services.

Learn more about this option in “Configurable services” on page 1296. You can use the WebSphere Message Broker Explorer to work with configurable services; several commands are also supplied to create, view, and modify these services.

Local environment overrides

You can configure some nodes to include your own processing; by coding ESQL, Java, PHP, or maps, you can modify the contents of the local environment tree within a message. Some fields in the local environment are used by nodes to determine how the message is processed, therefore by changing the tree contents, you can influence the behavior of subsequent nodes in the message flow. For more details about this option, see “Transforming and enriching messages” on page 2227.

Related concepts:

“The broker environment” on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

“Execution groups” on page 53
An execution group is a named grouping of message flows that have been assigned to a broker. The broker enforces a degree of isolation between message flows in distinct execution groups by ensuring that they run in separate address spaces, or as unique processes.

“Message flows overview” on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

“Default message flow behavior” on page 1278
The broker controls the behavior of your message flows, and defines what actions are taken if you do not change that behavior.

Configuring transactionality for message flows:

A message flow runs in a single transaction, which is started when data is received by an input node, and can be committed or rolled back when all processing has completed.

Before you begin

Before you start:

Ensure that you have completed the following tasks.

- To ensure that you understand how the broker handles transactions, read “Message flow transactions” on page 1281.
- Create a message flow by following the instructions in “Creating a message flow” on page 1431.

About this task

How individual nodes, and the message flow itself, participate in transactions depends on the way you design and develop the message flow, and the level of additional configuration you perform:

1. Configure the node properties in your message flow to set the required level of participation in transactions.
2. If you want the updates made by the message flow to be globally coordinated by an external transaction manager, configure the message flow properties.

What to do next

When you have finished message flow design and development, you can deploy the BAR file to the broker or brokers on which you want the message flow to run. However, if you have configured your message flows for globally coordinated transactions, additional configuration might be required. You, or your system administrator, must ensure that your broker environment, the transaction manager, and the participating resource managers are all correctly configured to support coordinated transactions, before you run the message flow. For details of what might be required, see "Configuring global coordination of transactions (two-phase commit)" on page 697.

If the broker environment, the transaction manager, and the external resource managers are not correctly configured for global coordination, the message flow transactions will not be globally coordinated.

Configuring node properties:
About this task

You can configure the nodes in your message flow to determine how the work taken by each node participates in the message flow transaction. Most nodes for which transactionality is relevant have one or more properties that you can configure to dictate behavior. Therefore, you can decide for each individual node whether it participates in the message flow transaction, or operates independently. Typically, these properties include an option of Automatic, so that subsequent nodes in the flow assume the characteristics set by the input node.

Nodes that support transports that cannot participate in transactions might have other properties to determine what the broker does when a message flow failure occurs. For example, the FileInput node has a set of Retry properties that you can set to determine failure behavior.

A few nodes that interact with external resources do not provide properties; typically, these nodes are included in the message flow transactions, but some exceptions exist; you must check the section that describes properties and how to set them, for each node that you include in your flow to ensure that you understand what action is taken.

If you configure a node not to participate in the message flow transaction, the actions that it takes are committed, or rolled back, when the node exits. No further action is taken when the flow itself completes.

To configure message flow behavior by setting node properties:

Procedure

1. Open the message flow that you want to configure.
2. Set the `Transaction mode` property for the input nodes in this message flow. The value that you set determines the behavior of the input node, and sets the default behavior for the rest of the message flow. Typically, you can choose the value Yes or No;
   - Yes means that the input node completes its own operation under sync point, and the default behavior in the message flow is for actions to be taken under sync point.

- No means that the input node completes its own operation out of sync point, and the default behavior in the message flow is for actions to be taken out of sync point.

Some nodes have additional or alternative values; for example, you can set the property on the MQInput node to Automatic, which means that the node gets the message under sync point if the message is persistent, and out of sync point if it is non-persistent.

For details of the specific options for and actions taken by each node, see the relevant node description; the properties, the tabs they are defined on, and the resulting behavior are not identical across all input nodes.

3. If your message flow includes nodes that interact with external resources, including output, request, and reply nodes, you can set a transaction property on most of these nodes.

   Set the property only if you want to change the behavior of the individual node from the default behavior for the message flow, which you set on the input node. The value that you set on this node has no effect on subsequent nodes in the message flow. If the node does not have a transactional property, its behavior is governed by the default behavior for the message flow, which you set in the input node.

   If your message flow is updating a database from multiple nodes in a single message flow, read the conceptual information about message flow transactions to understand the possible interactions.

   a. Set the `Transaction` property for each node, if supported.
   b. Set the properties that define how errors are handled, if supported. For example, for nodes like the Compute node that can access databases, set the `Treat warnings as errors` and `Throw exception on database error` properties to define how that node handles database warnings and errors. Whether you select these properties, and how you connect the failure terminals of the nodes, also affect the way in which database updates are committed or rolled back.

Configuring message flow properties:
About this task

When you have configured your message flow, you must add it to a BAR file before you can deploy it. When you add it to a BAR file, the message flow is compiled, and additional properties are available for configuration.

The most important property concerned with transactions on distributed systems is Coordinated Transaction. By default, this property is cleared (not selected), which means the message flow is partially coordinated and the broker commits or rolls back the message flow transaction. If you select this property, the input node calls the external transaction manager WebSphere MQ for commit and rollback processing.

This property is ignored when the message flow is deployed to a broker that is running on a z/OS system.

To configure message flow properties:

Procedure

1. Add the message flow to a broker archive.

2. Select the **Manage and Configure** tab below the broker archive editor view, and select the message flow. The configurable properties for the message flow in the broker archive are displayed in the **Properties** view.

   Select `coordinatedTransaction` to configure the message flow as globally coordinated; when you set this property, the external transaction manager (WebSphere MQ) coordinates the transaction with all the resource managers that you have defined to the queue manager.

   z/OS On z/OS, transactions are always globally coordinated. The setting of the `coordinatedTransaction` property for a message flow is ignored. Coordination is provided by the transaction manager RRS.

Related concepts:

"Message flow transactions" on page 1281
A transaction describes a set of updates that are made by an application program, which must be managed together. The updates might be made to one or more systems. The updates made by the program are controlled by the environment in which the program executes, and either all are completed, or none. This property of a transaction is known as *consistency*: transactions might have other properties of *atomicity*, *isolation*, and *durability*.

Configuring message flows for data conversion:

If you exchange messages between applications that run on systems that are incompatible in some way, you can configure your system to provide data conversion as the message passes through the broker.

About this task

Data conversion might be necessary if either of the following two values are different on the sending and receiving systems:

1. CCSID. The Coded Character Set Identifier refers to a set of coded characters and their code point assignments. WebSphere Message Broker can process and construct application messages in any code page for which WebSphere MQ provides conversion to and from Unicode, on all operating systems. For more information about code page support, see the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.

   This behavior might be affected by the use of other products in conjunction with WebSphere Message Broker. Check the documentation for other products, including any databases that you use, for further code page support information.
2. Encoding. This setting defines the way in which a machine encodes numbers; that is, binary integers, packed-decimal integers, and floating point numbers. Numbers that are represented as characters are handled in the same way as all other string data.

If the native CCSID and encoding on the sending and receiving systems are the same, you do not need to call data conversion processes.

WebSphere Message Broker and WebSphere MQ provide data conversion facilities to support message exchange between unlike systems. Your choice of which facilities to use depends on the characteristics of the messages that are processed by your message flows:

- Messages that contain text only
- Message that include numerics
- Messages that are self-defining

Messages that contain text only

Read this section if your messages are WebSphere MQ messages that contain all text (character data or string).

If WebSphere MQ supports the systems on which both sending and receiving applications are running for data conversion, use WebSphere MQ facilities which provide the most efficient data conversion option.

The default behavior of WebSphere MQ is to put messages to queues specifying the local system CCSID and encoding. Applications issuing MQGET can request that the queue manager provides conversion to their local CCSID and encoding as part of get processing.

To use this option:

1. Design messages to be text-only. If you are using COBOL, move numeric fields to USAGE DISPLAY to put them into string form.
2. Set the Format field in the MQMD to MQFMT_STRING (value MQSTR).
3. Call MQGET with MQGMO_CONVERT in the receiving application. If you prefer, you can convert when the message is received by the broker, by setting the Convert property of the MQInput node to yes (by selecting the check box).

If you require more sophisticated data conversion than WebSphere MQ provides in this way (for example, to an unsupported code page), use WebSphere MQ data conversion exits. For more information about these, see the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.

Messages that include numerics

Read this section if your messages include numeric data, or are text only but are not WebSphere MQ messages.

If these messages can be predefined (that is, their content and structure is known and predictable), use the facilities provided by WebSphere Message Broker and the MRM.

All application messages are handled by the broker in Unicode, to which they are converted on input, and from which they are converted on output. You can configure message flows to influence the way in which output messages are constructed.

To use this option:

1. Define the output message in the MRM domain. You can create this definition in one of the following ways:
   - Import an external message definition (for example a C header or COBOL copybook).
   - Create the message model in the message definition editor.
2. Configure a message flow to receive and process this message:
   a. If you include an MQInput node, do not request conversion by this node.
   b. Include a Compute node in the message flow to create the output message with the required content:
      - If the output message is a WebSphere MQ message, code ESQL in the Compute node to set the CCSID and encoding for the target system in the MQMD.

        For example, to set values for a target z/OS system running with CCSID of 37 and encoding of 785:

        ```
        SET OutputRoot.MQMD.CodedCharSetId = 37;
        SET OutputRoot.MQMD.Encoding = 785;
        ```

      - If the output message is not a WebSphere MQ message, code ESQL in the Compute node to set the CCSID and encoding for the target system in the Properties folder.

Messages that are self-defining

Read this section if your messages are self-defining.

Self-defining messages are supported in the XML and JMS domains. These messages are all text and can be handled by WebSphere MQ, if they originate from, or are destined for, WebSphere MQ applications. If not, use WebSphere Message Broker facilities by setting the CCSID and Encoding fields in the Properties folder in the message when it passes through a Compute node.

WebSphere MQ Version 7 Information Center online

Configurable services:

Configurable services are typically runtime properties. You can use them to define properties that are related to external services on which the broker relies; for example, an SMTP server or a JMS provider.

Instead of defining properties on the node or message flow, you can create configurable services so that nodes and message flows can refer to them to find properties at run time. If you use this method, you can change the values of attributes for a configurable service on the broker, which then affects the behavior of a node or message flow without the need for redeployment.

Unless it is explicitly stated by the function that is using the configurable service, you need to stop and start the execution group for the change of property value to take effect.

You can use the WebSphere Message Broker Explorer to view, add, modify and delete configurable services, see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644.

Alternatively, use the following commands to work with configurable services:

- Use the **mqsicreateconfigurableservice** command to create configurable services.
- Use the **mqsideleteconfigurableservice** command to delete configurable services.

- Use the **mqsichangeproperties** command to set attributes after you have created the configurable services.
- Use the **mqsireportproperties** command to report attributes.

For a full list of configurable services and their properties, see "Configurable services properties" on page 3766.

Related concepts:

"Using the WebSphere Message Broker Explorer to work with configurable services" on page 644
Configurable services are used to define properties that are related to external services on which the broker relies. Use the WebSphere Message Broker Explorer to view, add, modify and delete configurable services.

The supplied configurable services, and the configurable services that you create, are defined by their names and properties. You can use the supplied services.

Defining a promoted property:

When you create a message flow, you can promote properties from individual nodes in that message flow to the message flow level. Properties promoted in this way override the property values that you have set for the individual nodes.

Before you begin

Before you start:

Read the concept topic about promoted properties.

About this task

You can perform the following tasks related to promoting properties:
- "Promoting a property" on page 1298
- "Renaming a promoted property" on page 1302
- "Removing a promoted property" on page 1304
- "Converging multiple properties" on page 1306

Some of the properties that you can promote to the message flow are also configurable; you can modify them when you deploy the broker archive file in which you have stored the message flow to each broker. If you set values for configurable properties when you deploy a broker archive file, the values that you

set override values set in the individual nodes, and those that you have promoted.

Related concepts:

"Promoted properties" on page 1145
A promoted property is a message flow node property that has been promoted to the level of the message flow in which it is included.

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

"Editing configurable properties" on page 3227
You can edit configurable properties in the deployment descriptor file (`broker.xml`) of your broker archive.

Chapter 9, "Developing message flow applications," on page 1019
Develop message flows to process your business messages and data.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Promoting a property:

You can promote a node property to the message flow level to simplify the maintenance of the message flow and its nodes, and to provide common values for multiple nodes in the flow by converging promoted properties.

Before you begin

Before you start:
- Create a message flow, as described by "Creating a message flow" on page 1431
- Read the concept topic about promoted properties

About this task

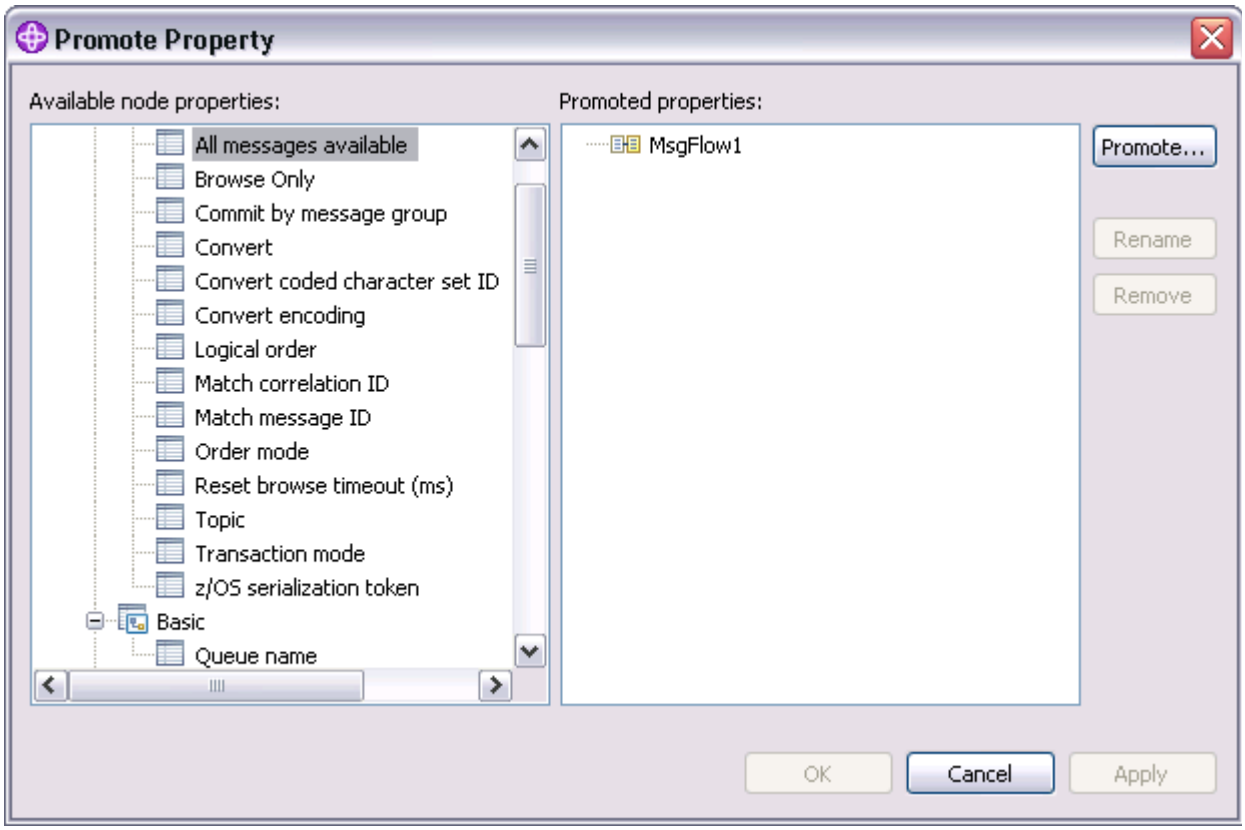
The majority of message flow node properties are available for promotion, but you cannot promote the following properties:
- Properties that name mapping modules
- A property group (but you can promote an individual property)
- A property that you cannot edit (for example, the `Fix` property of the MQInput node)
- The description properties (`Short Description` and `Long Description`)
- Complex properties (for example, the `Query elements` property of the DatabaseRoute node, or the `Opaque elements` property of the MQInput and several other nodes)

To promote message flow node properties to the message flow level, complete the following steps.

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the message flow for which you want to promote properties.
3. Right-click the appropriate node and click **Promote Property**.

The Promote Property dialog box is displayed.



The Available node properties pane lists all available properties for all the nodes in the message flow. The properties for the node that you clicked are expanded. You can expand the properties for all the nodes in the open message flow, regardless of the node that you clicked initially.

The Promoted properties pane displays the name of the open message flow and all the properties that are currently promoted to the message flow. If you have not yet promoted any properties, only the message flow name is displayed as the root of the promoted property tree, as shown in the previous example. If you have already promoted properties from this node, the properties appear in the Promoted properties pane, but not in the Available node properties pane.

4. Select the property or properties that you want to promote to the message flow. You can select multiple properties by holding down Ctrl and selecting the properties.
5. Click **Promote**. The Target Selection dialog box opens and displays valid targets for the promotion.
6. Select the destination group or property for the properties that you want to promote. You can group together related properties from the same or different nodes in the message flow by dropping the selected properties onto a group or property that already exists, or you can create a new target for the promotion by clicking **New Group** or **New Property**. You can rename groups and properties by selecting them and clicking **Rename**.
7. Click **OK** to confirm your selections and close the Target Selection dialog box.

   If you create a new group or property by using the Target Selection dialog box, the changes persist even if you select **Cancel** in the dialog box. When the dialog box closes, groups or properties that you have created by using the

Target Selection dialog box appear in the Promote Property dialog box. You can remove any of these properties from the Promote Property dialog box by selecting them and clicking **Remove**.

8. Click **OK** to commit your changes and close the Promoted Property dialog box. If you click **Apply**, the changes are committed but the dialog box remains open.

Results

The message flow node properties are promoted to the message flow. When you have promoted a property, you can no longer make any changes to that property at the node level; you can update its value only at the message flow level. To view the message flow's properties, click the message flow (not the individual nodes) in the Message Flow editor to display the properties in the Properties view. The properties that you have promoted are organized in the groups that you created. If you now set a value for one of these properties, that value appears as the default value for the property whenever the message flow is included in other message flows.

When you select an embedded message flow in another message flow (a subflow) and view its properties, you see the promoted property values. If you look inside the embedded flow (by selecting **Open Subflow**), you see the original values for the properties. The value of a promoted property does not replace the original property, but it takes precedence when you deploy the message flow.

Promoting properties by dragging:
About this task

You can also promote properties from the Promote Property dialog box by dragging the selected property or properties from the Available node properties pane of the Promote Property dialog box to the Promoted properties pane, as described in the following steps.

Procedure

1. Select the property that you want to promote. You can select multiple properties by holding down Ctrl, and selecting the properties.
2. You can promote the selected properties using the following methods:
   - Drop the selected property or properties in an empty space.

     A new group is created automatically for the message flow, and the property is placed in it, with the original name of the property and the name of the message flow node from which it came displayed beneath the property entry.

     The name of the first group that is created is Group1 by default. If a group called Group1 already exists, the group is given the name Group2, and so on. You can rename the group by double-clicking it and entering new text, or by selecting the group in the Promoted properties pane and clicking **Rename**.

     When you create a new promoted property, the name that you enter is the name by which the property is known within the system, and must meet certain Java and XML naming restrictions. These restrictions are enforced by the dialog box, and a message is displayed if you enter a name that includes a non-valid character. For example, you cannot include a space or quotation marks (").

     If you are developing a message flow in a user-defined project that will be delivered as an Eclipse plug-in, you can add translations for the promoted properties that you have added. Translated names can contain characters,

such as space, that are restricted for system names. The option to provide translated strings for promoted properties is not available if you are working with a message flow in a message flow project.

- Drop the selected property or properties onto a group that already exists, to group together related properties from the same or different nodes in the message flow.

  For example, you might want to group all promoted properties that relate to database interactions. You can change the groups to which promoted properties belong at any time by selecting a property in the Promoted properties pane and dragging it onto a different group.
- Drop the selected property or properties onto a property that already exists, to converge related properties from the same or different nodes in the message flow.

  For example, you might want to create a single promoted property that overrides the property on each node that defines a data source.

  For more information on converging properties, see "Converging multiple properties" on page 1306.

Promoting mandatory properties:
About this task

If you promote a property that is mandatory (that is, an asterisk appears beside the name in the Properties view), the mandatory characteristic of the property is preserved. When a mandatory property is promoted, its value does not need to be set at the node level. If the flow that contains the mandatory promoted property is included as a subflow in another flow, the property must be populated for the subflow node.

Promoting properties through a hierarchy of message flows:
About this task

You can repeat the process of promoting message flow node properties through several levels of message flow. You can promote properties from any level in the hierarchy to the next level above, and so on through the hierarchy to the top level. The value of a property is propagated from the highest point in the hierarchy at which it is set down to the original message flow node when the message flow is deployed to a broker. The value of that property on the original message flow node is overridden.

Related concepts:

"Promoted properties" on page 1145
A promoted property is a message flow node property that has been promoted to the level of the message flow in which it is included.

"Broker properties" on page 1144
For each broker, WebSphere Message Broker maintains a set of properties. You can access some of these properties from your ESQL programs. A subset of the properties is also accessible from Java programs. It can be useful, at run time, to have real-time access to details of a specific node, flow, or broker.

"Packaging and deployment overview" on page 3210
Deployment is the process of transferring data to an execution group on a broker so that it can take effect in the broker. Message flows and associated resources are packaged in broker archive (BAR) files for deployment.

Renaming a promoted property:

If you have promoted a property from the node to the message flow level, it is initially assigned the same name that it has at the node level. You can rename the property to have a more meaningful name in the context of the message flow.

Before you begin

Before you start:
- Promote a property
- Read the concept topic about promoted properties

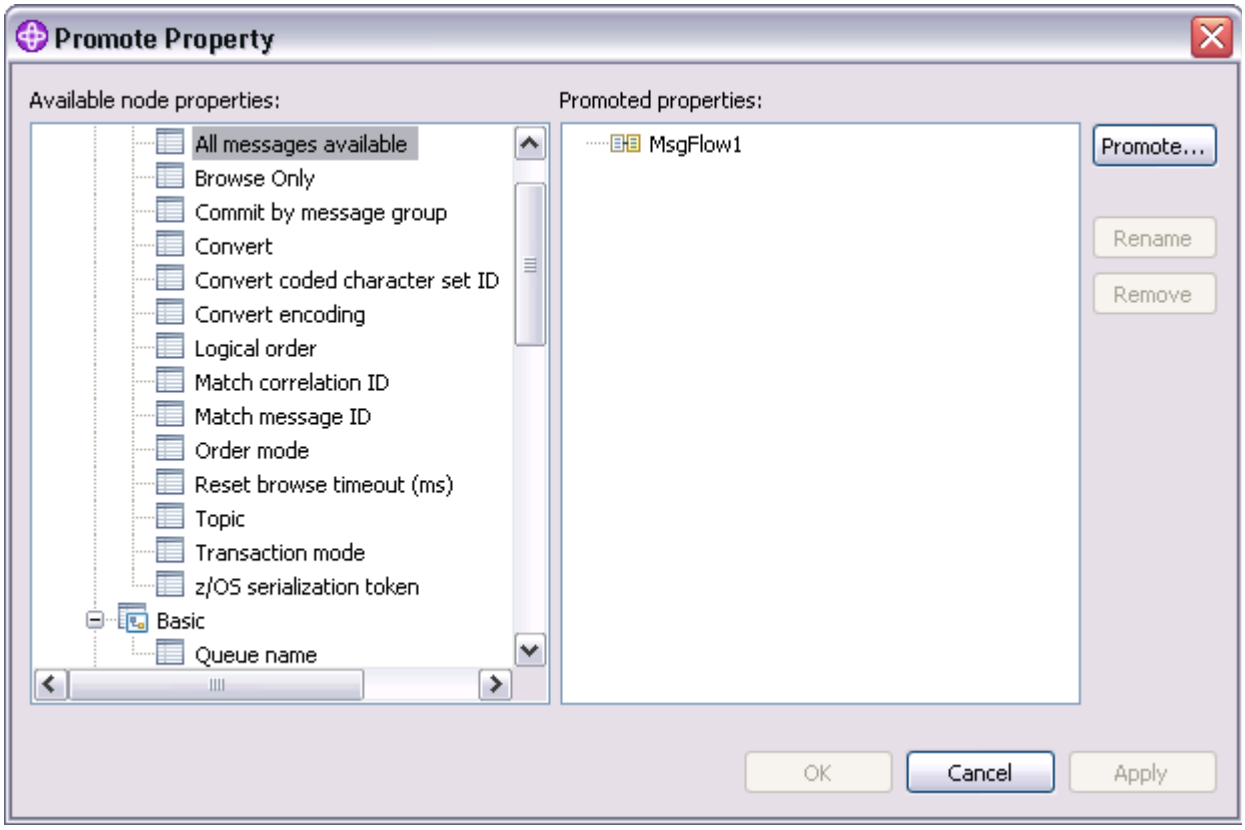
About this task

To rename a promoted property :

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the message flow for which you want to promote properties by double-clicking the message flow in the Broker Development view. You can also open the message flow by right-clicking it in the Broker Development view and clicking **Open** The message flow contents are displayed in the editor view.
3. In the editor view, right-click the symbol of the message flow node for which you want to promote properties.
4. Select **Promote Property**.

   The Promote Property dialog box is displayed.



5. Promoted properties are shown in the Promoted properties pane on the right of the Promote Property dialog box. Double-click the promoted property in the list of properties that are currently promoted to the message flow level, or select the property that you want to rename and click **Rename**. The name is highlighted, and you can edit it. Modify the existing text or enter new text to give the property a new name, and press Enter.
6. Click **Apply** to commit this change without closing the Promote Property dialog box. Click **OK** to complete your updates and close the dialog box.

- Read the concept topic about promoted properties

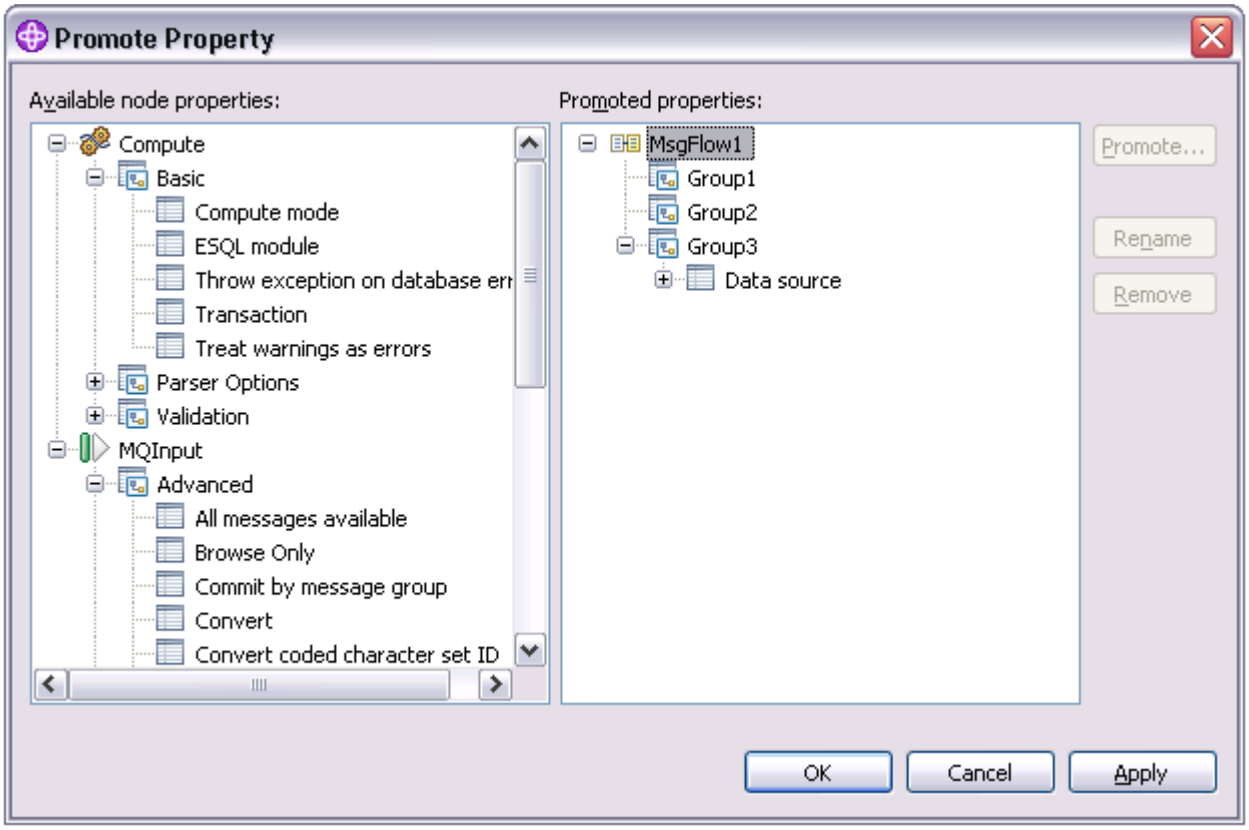
About this task

If you have promoted one or more message flow node properties, and want to delete them:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the message flow for which you want to promote properties by double-clicking the message flow in the Broker Development view. You can also open the message flow by right-clicking it in the Broker Development view and clicking **Open** The message flow contents are displayed in the editor view.
3. In the Editor view, right-click the symbol of the message flow node whose properties you want to promote.
4. Select **Promote Property**.

   The Promote Property dialog is displayed.



5. Select the promoted property that you want to remove from the list of properties in the Promoted properties pane, and click **Remove**. The property is removed from the Promoted properties pane and is restored to the list in the Available node properties pane, in the appropriate place in the tree of properties for the node from which you promoted it. You can promote this property again.
6. To delete all the promoted properties in a single group, select the group in the Promoted properties pane and click **Remove**. The group and all the properties it contains are deleted from this list: the individual properties that you promoted are restored to the nodes from which you promoted them.
7. Click **Apply** to commit this change without closing the Promote Property dialog box. Click **OK** to complete your updates and close the dialog box.

Results

If you have included this message flow in a higher-level message flow, and have set a value for a promoted property that you have now deleted, the embedding flow is not automatically updated to reflect the deletion. However, when you deploy that embedding message flow in the broker domain, the deleted property is ignored.

WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Converging multiple properties:

You can promote properties from several nodes in a message flow to define a single promoted property, which applies to all those nodes.

Before you begin

Before you start:

- Create a message flow, as described in "Creating a message flow" on page 1431
- Read the concept topic about promoted properties

About this task

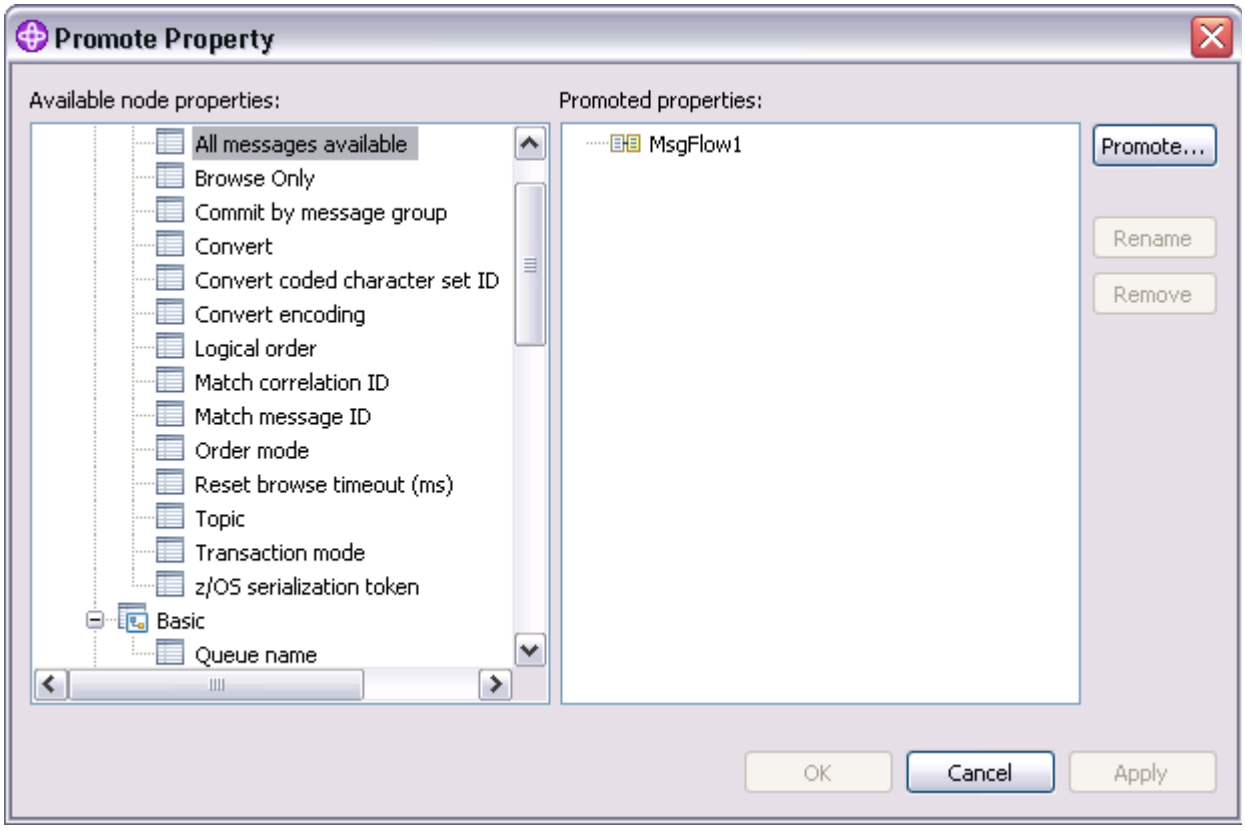
One example for the use of promoting properties is for database access. If a message flow contains two Database nodes that each refer to the same physical database, you can define the physical database just once on the message flow by promoting the `Data Source` property of each Database node to the message flow, and setting the property at the message flow (promoted) level.

To converge multiple node properties to a single promoted property:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the message flow in the Message Flow editor.
3. Right-click the node for which you want to promote the properties, then click **Promote Property**.

   The Promote Property dialog box is displayed.



4. Select the property that you want to converge. The list in the Available node properties pane initially shows the expanded list of all available properties for the selected node. If you have already promoted properties from this node, they do not appear in this pane, but they appear in the Promoted properties pane.

   The Available node properties pane also includes the other nodes in the open message flow. You can expand the properties that are listed under each node and work with all these properties at the same time. You do not have to close the dialog box and select another node from the Message Flow editor to continue promoting properties.

   You can select multiple properties to promote by selecting a property, holding down Ctrl, and selecting one or more other properties.

   If you have you selected multiple properties to converge, all the properties that you have selected must be available for promotion. If one or more of the selected properties is not available for promotion, the entire selection becomes unavailable for promotion, and the **Promote** button is disabled.

5. Click **Promote** to promote the property or properties

   The Target Selection dialog box opens:

   The Target Selection dialog box displays only the valid targets for the promotion of the previously selected property or properties and allows you to create a new target for the promotion, such as to a new group or to a new property.

6. To converge properties from the same or different nodes in the message flow, expand the tree and click a property that already exists. You can rename the properties by selecting them and clicking **Rename**, or by double-clicking the group or property.

7. Click **OK** to confirm your selections.

Note: If you create a new group or property by using the Target Selection dialog box, the changes persist even if you click **Cancel**. When the dialog box closes, groups or properties that you have created by using the Target Selection dialog box appear in the Promote Property dialog box.

8. Expand the property trees for all the nodes for which you want to promote properties.
9. Drag the first instance of the property that you want to converge from the Available node properties pane, and drop it onto the appropriate group in the Promoted properties pane.
   - If the group already contains one or more promoted properties, the new property is added at the end of the group. You can rename the new property by double-clicking the property, or by selecting the property and clicking **Rename**.
   - If you want the promoted property to appear in a new group, drag the property into an empty space below the existing groups to create a new group. Alternatively:
     a. Select the property that you want to promote, and click **Promote**. The Target Selection dialog box opens.
     b. Click **New Group**, and enter the name of the new group.
     c. Click **OK** to confirm your changes.
   - If you drag the property onto an existing promoted property of a different type, a no-entry icon is displayed and you cannot drop the property. You must create this property as a new promoted property, or drop it onto a compatible existing promoted property. Properties must be associated with the same property editor to be compatible. For example, if you are using built-in nodes, you can converge only properties of the same type (string with string, Boolean with Boolean).

   If you are using user-defined nodes, you must check the compatibility of the property editors for the properties that you want to converge. If you have written compiler classes for a node, you must also ensure that converged properties have the same compiler class.
10. Drag all remaining instances of the property from each of the nodes in the Available node properties pane onto the existing promoted property. The new property is added under the existing promoted property, and is not created as a new promoted property.
11. Click **Apply** to commit this change without closing the Promote Property dialog box. Click **OK** to complete your updates and close the dialog box.

    You can also converge properties from the Promote Property dialog box by dragging the selected property or properties from the Available node properties pane to the Promoted properties pane:
    a. Select the property that you want to promote. You can select multiple properties to promote by selecting a property, holding down Ctrl, and selecting one or more other properties.
    b. Drop the selected property or properties onto a property in the Promoted properties pane to converge related properties from the same or different nodes in the message flow.

       For example, you might want to create a single promoted property that overrides the property on each node that defines a data source.

Results

You have promoted properties from several nodes to define a single promoted property, which is used for all those nodes.

Related concepts:

"Promoted properties" on page 1145

Developing message flow applications by using patterns

Create resources that are used to solve a specific business problem by using patterns.

Before you begin

Before you start: If you are not familiar with message flow concepts, message model concepts, and common tasks to manage message flow resources, see "Processing messages" on page 1021.

This section describes one of the four methods that you can use to create message flow applications. The other three methods are described in the following sections:

- "Developing message flow applications by using samples" on page 1406
- "Developing message flow applications from a wizard" on page 1408
- "Developing message flow applications from scratch" on page 1423

If you are unsure which method to use, see Chapter 9, "Developing message flow applications," on page 1019 for a discussion of the advantages of each one.

About this task

The following areas are included:
- "Patterns"
- "Using patterns" on page 1312
- "Pattern categories" on page 1331
- "Built-in patterns" on page 1332
- "User-defined patterns" on page 1334

Related tasks:

Use the samples to learn more about the features that are available in WebSphere Message Broker, and how to use them.

"Developing message flow applications from a wizard" on page 1408
A Quick Start wizard sets up the basic resources that are required to develop a message flow application. The wizard sets up and gives names to containers for the resources in which you then develop your message flow.

"Developing message flow applications from scratch" on page 1423
Design, create, and configure message flows by using the WebSphere Message Broker Toolkit.

"Connecting client applications" on page 1537
Connect your client applications to the broker by using one or more of the supported protocols from other resources and software servers in your network.

"Routing messages" on page 2209
Route messages through your message flow or the broker by using one or more of the techniques described in this section.

"Transforming and enriching messages" on page 2227
Transform and enrich messages by using one or more of the techniques described in this section.

Patterns

A *pattern* is a reusable solution that encapsulates a tested approach to solving a common architecture, design, or deployment task in a particular context.

A pattern captures a tested solution to a commonly recurring problem, addressing the objectives that you want to achieve. The specification of a pattern describes the problem that is being addressed, why the problem is important (the value statement), and any constraints for the solution. Patterns typically emerge from common usage and the application of a particular product or technology.

A WebSphere Message Broker pattern can be used to generate customized solutions to a recurring problem in an efficient way. WebSphere Message Broker patterns are provided to encourage the adoption of preferred techniques in message flow design, to produce efficient and reliable flows. Patterns provide the following benefits:

- Give you guidance for the implementation of solutions
- Increase development efficiency, because resources are generated from a set of predefined templates
- Result in higher quality solutions, through reuse of assets and common implementation of programming approaches, such as error handling and logging

A catalog of WebSphere Message Broker patterns is provided in the WebSphere Message Broker Toolkit in the Patterns Explorer view. The WebSphere Message Broker patterns are divided into pattern categories. *Pattern categories* are categories

that are based on the pattern classification and structure the display in the Patterns Explorer. The catalog provides detailed help that guides you toward a suitable WebSphere Message Broker pattern to create resources that are used to solve a specific business problem.

The catalog of WebSphere Message Broker patterns contains built-in patterns and might also contain user-defined patterns. *Built-in patterns* cover a set of commonly encountered message flow scenarios and are packaged and released with WebSphere Message Broker. You can also create your own *user-defined patterns*.

Each pattern has values that are known as pattern parameters. *Pattern parameters* are parameters that customize and configure a WebSphere Message Broker pattern. The pattern parameters that you configure depend on the particular pattern, and on the options that you enable for that pattern. An example of a pattern parameter is a queue name from where messages are read.

The WebSphere Message Broker patterns provide defaults for most pattern parameters, and help is provided to explain them. After you have configured the pattern parameters, you generate a *pattern instance project*, which contains references to all other projects in the workspace that relate to your pattern instance. A pattern instance project also contains a pattern instance configuration file that stores the pattern parameter values. This configuration file stores the pattern parameters that you configured. Generating a pattern instance project also creates one or more additional WebSphere Message Broker projects that typically contain message flows and other WebSphere Message Broker resources that implement the pattern.

You can open the pattern instance configuration file at any time to see the values of the pattern parameters. When a pattern configuration file has been reopened, you can regenerate the WebSphere Message Broker projects. Regeneration deletes the generated WebSphere Message Broker projects and re-creates them from scratch. The pattern instance project contains an HTML summary file and a pattern instance configuration file. The summary file has a section that explains additional tasks that might be required, such as creating queues.

You can create resources from each WebSphere Message Broker pattern more than once to give you unique pattern instances, each with a different configuration. The pattern parameters that you can configure depend on the particular pattern, and also the options that you enable for that pattern.

Some of the pattern parameter settings can affect the resources that are generated. For example, if you enable logging and error handling, the generated projects contain additional message flows and ESQL scripts.

In all cases, the specification of both the problem and the solution are indispensable parts of the pattern definition.

Related concepts:

A *user-defined pattern* extends the function of WebSphere Message Broker so that you are able to create patterns that you can reuse within your organization.

Related tasks:

"Choosing a pattern" on page 1313
Select a pattern in the Patterns Explorer view to create resources to solve a specific business problem.

Using patterns

Use patterns that are supplied with the WebSphere Message Broker Toolkit to create resources that are used to solve a specific business problem.

Each *WebSphere Message Broker pattern* is designed to address a specific business problem. To find out about the patterns that are supplied in the WebSphere Message Broker Toolkit, see "Built-in patterns" on page 1332. You might also have *user-defined patterns* available to use that are created by a *pattern author*, see "User-defined patterns" on page 1334.

Each pattern has values known as *pattern parameters* that you use to create the pattern resources for use in your environment. The pattern parameters that you can configure depend on the specific pattern, and also the options that you enable for that pattern; for example, logging.

When you select a pattern from the Patterns Explorer, the **Pattern Specification** tab gives details about the purpose and configuration of each pattern parameter associated with a pattern, the effects and consequences of changing them, and any postrequisite tasks. All patterns have pattern parameter properties that distinguish one application of a pattern template from another.

All patterns are either abstract or implementations and as you move down the tree the patterns become more specific. At any level in a tree a pattern can be an implementation.

You can apply pattern implementations only. Pattern implementations map to a complete specification with prerequisite and postrequisite tasks, and pattern parameter details. Pattern implementations have a **Create New Instance** button in the **Pattern Specification** tab. *Abstract* patterns, which cannot be applied, do not have a **Create New Instance** button in the **Pattern Specification** tab.

You can create resources from each pattern more than once to give unique *pattern instances* with different configurations. The configuration for each pattern instance is contained within a single *pattern instance project*. The pattern instance project contains links to all projects containing the resources that are created as a result of generating a pattern instance from your configuration, such as message flows, Java classes for JavaCompute nodes, ESQL modules, message maps, test client, XML files, and style sheet files.

Related concepts:

Related reference:

"Pattern instance projects" on page 6827
A pattern instance project contains project references to all the other projects in the workspace that relate to a specific pattern instance.

Choosing a pattern

Select a pattern in the Patterns Explorer view to create resources to solve a specific business problem.

Before you begin

Before you start:

Before completing this task, read the following overview topics about patterns:
- "Patterns" on page 1310
- "Using patterns" on page 1312

About this task

To create resources by using a patter, complete the following steps.

Procedure

1. Open the Patterns Explorer view by using one of the following methods.
   - In the Broker Development view, click **New pattern instance** in the Pattern Instances section.
   - Click the **Patterns Explorer** tab.
   - Click the **Open Patterns Explorer** icon in the task bar.

   The Patterns Explorer view is displayed.
2. Click **Patterns** in the Patterns Explorer view. The **Pattern Specification** tab displays information about the patterns. For example, to find out about message-based integration patterns, complete the following steps:
   a. Click **Message-based Integration**. The **Pattern Specification** tab displays information about the selected pattern, and because it is an abstract pattern the **Create New Instance** button is not displayed.
   b. Under **Message-based Integration** click another pattern, for example **Message Correlator**. The **Pattern Specification** tab displays information about the selected pattern, and because it is an abstract pattern the **Create New Instance** button is not displayed.
   c. Under **Message Correlator** click another pattern, for example **MQ request-response with persistence**. The **Pattern Specification** tab displays information about the selected pattern, and because it is a pattern implementation the **Create New Instance** button is displayed.
3. Ensure that you look at "Tasks to complete before applying the pattern" and "Constraints on the use of the pattern" for your chosen pattern before you use it.

4. To use a pattern implementation from the **Pattern Specification** tab, click **Create New Instance**. The **Create New Instance** window opens.
5. Enter a new pattern instance name.

   You cannot use the following names:

   - The name of an existing project in the current workspace.
   - On Windows only: MS-DOS device driver names. For more information, see the article on the Microsoft support site: MS-DOS device driver names cannot be used as file names.
6. Click **OK**. If you click **Cancel**, no changes are made to the workspace. The Configure Pattern Parameters page is displayed.
7. On the Configure Pattern Parameters page, complete all the pattern parameter fields as required. Configure pattern parameters by entering the appropriate values. If you do not want to generate the pattern immediately, you can save the parameters to work with later. Before you apply a pattern, you must enter a value for each pattern parameter. You can accept a default value, if one is offered. Empty strings are permitted for some fields.

   If you have already saved a configuration, you can reuse that configuration by editing the parameters, see "Editing and regenerating a pattern" on page 1327.

   Parameter groups might be marked with error markers. You can click the error marker to move to the first field that has an error.

What to do next

Next: Now complete the following task:

- "Generating a pattern instance" on page 1326

Related concepts:

Working with patterns in the Broker Development view

Using the Broker Development view to create patterns.

Before you begin

Before you start:

Before completing this task, read the following overview topics about patterns:

- "Patterns" on page 1310
- "Using patterns" on page 1312

About this task

The Broker Development view has three sections: the working set selection list (<all resources>), Pattern Instances (initially collapsed), and Projects (initially expanded). Pattern instance projects are shown only in the Pattern Instances section, and all other project types are shown in the Projects section. If no projects exist, the Projects section contains a list of Quick Starts links. Use the following instructions to alter the layout of these three sections.

When the workspace contains both pattern instance projects and projects, the Pattern Instances section and the Projects section each have their own resource tree. Each section also has its own scroll bar.

- To open the Pattern Instances or the Projects section to its default or last known size, click the **Restore** icon in the relevant section. If no pattern instance projects exist in the workspace, the Pattern Instances section contains a hyperlink sentence, **New pattern instance**, click this hyperlink to start working with patterns:
  - To maximize the Pattern Instances section, click its **Maximize** icon. This action automatically collapses the Projects section.
  - To maximize the Projects section, click its **Maximize** icon. This action automatically collapses the Pattern Instances section.
- To use a Quick Starts link, use either of the following options:
  - In the Quick Starts list in the Projects section, click the link that you want to use. However, when the Projects section contains projects, the Quick Starts list is not shown in the Projects section, you must, therefore, use the other option.
  - In the toolbar of the Projects section, click the **Quick Starts** link.

What to do next

Next: Now complete the following task:

- "Choosing a pattern" on page 1313

Related concepts:

"Patterns" on page 1310
A *pattern* is a reusable solution that encapsulates a tested approach to solving a common architecture, design, or deployment task in a particular context.

"Using patterns" on page 1312
Use patterns that are supplied with the WebSphere Message Broker Toolkit to create resources that are used to solve a specific business problem.

Related tasks:

Adding or removing project references in a pattern instance project:

A pattern instance project contains references to regular projects and they are listed in the Project References category of a pattern instance project.

About this task

The Project References category under a pattern instance project in the Broker Development view shows the same project references as the Project References page in the Properties window.

To add another project to the list of project references for your pattern instance project, complete the following steps:

Procedure

1. Open the Pattern Instances section of the Broker Development view.
2. Right-click the pattern instance project name, select **Add or Remove Project References** from the menu. The Add or Remove Project References window for the pattern instance project opens, which shows a list of all regular projects, but not pattern instance projects, in the workspace.
3. To add another project to the list of project references, select the project name and click **OK**. The Broker Development view shows the selected project name under the pattern instance Project References category.
4. To remove a project from the list of project references, right-click the project name, select **Add or Remove Project References**, clear the project name check box, and click **OK**. The project name is removed from the Project References category.

Showing a working set for a pattern instance project:

When a pattern instance project is created by the Patterns Explorer, a working set of the same name is generated, and all projects that are part of that pattern instance are placed inside it.

About this task

To view all of the projects in your pattern instance:

Procedure

1. In the Broker Development view, select your pattern instance project in the Working Sets section. The Pattern Instances section displays all of the projects, and the Projects section displays all of the message flow details that are associated with that pattern instance.
2. Select **<all resources>** in the Working Set section, the navigator shows all of the projects in the workspace.

Related concepts:

"Patterns" on page 1310
A *pattern* is a reusable solution that encapsulates a tested approach to solving a common architecture, design, or deployment task in a particular context.

"Using patterns" on page 1312
Use patterns that are supplied with the WebSphere Message Broker Toolkit to create resources that are used to solve a specific business problem.

"Resources" on page 36
The projects, folders, and files that you work with in the WebSphere Message Broker Toolkit workspace are called *resources*. By default, these resources are stored with their metadata in the workspace directory in your local file system. The workspace directory is created the first time that you start the WebSphere Message

Broker Toolkit.

A pattern instance project contains project references to all the other projects in the workspace that relate to a specific pattern instance.

Focusing on a pattern instance:

Several ways are available for you to focus on a particular pattern instance.

Procedure

To focus on your pattern you can use one of the following methods:

- In the **<all resources>** section, click the down arrow icon to open the menu, and select the pattern instance name.
- In the Pattern Instances section, right-click your pattern instance project, select **Focus on Pattern Instance**.
- In the toolbar of the Broker Development view, click the down arrow and select your pattern instance name from the menu.

The navigator refreshes to show the currently selected working set and its associated projects.
To confirm that your pattern instance project is currently in focus, right-click your pattern instance project, ensure that the check box to the left of the **Focus on Pattern Instance** menu item is selected. If you clear this check box, the navigator reverts to the **<all resources>** working set, and shows all of the projects.
If the navigator has focus on your working set, if you click the down arrow in the WebSphere Message Broker Development toolbar, your working set menu item is selected in the menu. You cannot clear a working set from this menu to return to the **<all resources>** section, but you can select a different working set, if one is available.

Creating a working set and focus on a pattern instance:

Creating a working set for an imported project interchange file that contains a pattern instance project and its associated projects.

About this task

If you import a project interchange file that contains a pattern instance project and its associated projects, a working set is not automatically created for the pattern instance project. Therefore, you must create a working set.

Procedure

In the Pattern Instances section of the Broker Development view, right-click the pattern instance project, and select **Create Working Set and Focus on Pattern Instance** in the menu. When this item is selected, a working set is created with the same name as the pattern instance project, the pattern instance project and its associated projects are added to that working set, and the working set is given focus in the navigator.

Related concepts:

Deleting a pattern instance project with project references:

Pattern instance projects typically contain references to regular projects. Therefore, when you select a pattern instance project for deletion you must decide whether to delete all of the referenced projects from the file system.

About this task

Use the following steps to delete a pattern instance project that has project references:

Procedure

1. In the Broker Development view, open the Pattern Instances section.
2. Right-click the pattern instance project, or projects, that you want to delete, click **Delete**. The Confirm Project Delete window opens, displaying any projects that are referenced by the pattern instance project. The **Also delete the projects referenced by this pattern instance project** check box is selected and the **Also delete contents in the file system** check box is cleared by default.
3. Choose one of the following options:
   - To delete the pattern instance project, or projects, and the project references, but leave the contents in the file system, keep the default settings, click **Yes**. The working set section of the Broker Development view switches to **<all resources>**. The pattern instance project, or projects, and the project references still exist in the file system.
   - To delete the pattern instance project, or projects, and the project references from the workspace and the file system, ensure that **Also delete the projects referenced by this pattern instance project** and **Also delete contents in the file system** are both selected, click **Yes**. The working set is deleted. The working set section of the Broker Development view switches to **<all resources>**.
   - To delete your pattern instance project, or projects, from the workspace but not from the file system and to keep the project references in the workspace and file system, ensure that **Also delete the projects referenced by this pattern instance project** and **Also delete contents in the file system** are both cleared. The working set is deleted. The working set section of the Broker Development view switches to **<all resources>**.
   - If you decide not to delete the pattern instance project, or projects, click **No**.

Deleting projects that are referenced by a pattern instance project:

If you want to delete a project, you must take into account whether it is referenced by a pattern instance project.

About this task

Complete the following steps to delete your project if it is referenced by a pattern instance project.

Procedure

1. In the Broker Development view, select the project that you want to delete, then click **Delete**. The Confirm Project Delete window opens with a warning that the project is referenced by a pattern instance project. The default action is to delete the selected project from the workspace, not to delete the project from the file system, and to update the project references of all pattern instance projects that reference it. Therefore, by default **Also remove references from all pattern instance projects** is selected, and **Also delete content under *project_name*** is cleared.
2. Choose one of the following options:
   - To delete the projects from the workspace but leave the contents in the file system, and delete the project reference from the pattern instance projects list of project references, keep the default settings and click **Yes**.
   - To delete the projects from the workspace and remove the contents in the file system, and delete the project reference from the pattern instance projects list of project references, ensure that both **Also remove references from all pattern instance projects** and **Also delete content under *project_name*** are selected, and click **Yes**.
   - To delete the projects from the workspace and remove the contents in the file system, and leave the project reference in the pattern instance projects list of project references, ensure that **Also remove references from all pattern instance projects** is cleared and that **Also delete content under *project_name*** is selected, and click **Yes**. The icon for this project reference changes to reflect that the project no longer exists.
   - To delete the projects from the workspace but leave the contents in the file system, and leave the project reference in the pattern instance projects list of

project references, ensure that both **Also remove references from all pattern instance projects** and **Also delete content under *project_name*** are cleared, and click **Yes**. The icon for this project reference changes to reflect that the project no longer exists.

- If you decide not to delete the projects, click **No**.

Generating a pattern instance

Generate resources from the pattern.

Before you begin

Before you start:

You must have chosen pattern. For more details, see "Choosing a pattern" on page 1313.

About this task

The **Generate** button is unavailable until all required parameters are complete.

To generate the WebSphere Message Broker Toolkit resources for the pattern, complete the following steps.

Procedure

On the Configuration page, click **Generate**. Focus is automatically moved to the Broker Development view, which lists all the new resources that have been generated.
All of the other resources are filtered out in this view.

Results

Following a successful **Generate** action:

- A pattern instance project is created in your workspace and is displayed in the Broker Development view. The pattern instance project contains a pattern instance configuration file and a summary file. The summary file describes the tasks that have been generated, and the tasks that are still required.
- All the resources generated for a pattern instance are packaged into their own working set and the Broker Development view displays only the resources in this working set. The name of the working set is always the same as the pattern instance name provided. This name must always be unique within the workspace.
- You can regenerate the pattern by using the same instance name, but, if you confirm the regeneration, existing projects are deleted, see "Editing and regenerating a pattern."

What to do next

Next: Now complete the following task:

- "Reviewing the pattern instance summary and tasks" on page 1328

Related concepts:

"Using patterns" on page 1312
Use patterns that are supplied with the WebSphere Message Broker Toolkit to create resources that are used to solve a specific business problem.

Related tasks:

"Editing and regenerating a pattern"
You can regenerate a pattern instance after you have edited a saved configuration in a pattern instance project.

Create a working set to limit the number of resources that are displayed in the Broker Development view.

Related reference:

"Pattern instance projects" on page 6827
A pattern instance project contains project references to all the other projects in the workspace that relate to a specific pattern instance.

Editing and regenerating a pattern:

You can regenerate a pattern instance after you have edited a saved configuration in a pattern instance project.

About this task

Before you begin:

You must be in the WebSphere Message Broker Toolkit and have an existing pattern configuration file in a pattern instance project.

Procedure

1. Open an existing pattern configuration by double-clicking the configuration XML file in a pattern instance project. The Configure Pattern Parameters page of the editor displays parameter values for that configuration instance. The

Broker navigation pane is in focus. The title of the Configure Pattern Parameters page for the parameter reflects the pattern instance name (not the pattern name).

2. View and edit the pattern parameters. You can now choose either of the following options:
   - Close the editor without saving the changes.
   - Select **Generate**. Resources, such as projects, already exist in the workspace. You are warned that these resources will be deleted and you can choose whether to continue. If you continue, the resources are regenerated; the existing resources are deleted and re-created. If you decide not to continue, the pattern configuration remains open and no changes are made to the pattern resources.

     When you make changes in the Pattern Configuration editor, the summary file and configuration XML file might be out of date because the *instance_name*_configuration.xml and the *instance_name*_summary.html files do not match the generated resources. The Problems view displays any warning messages. Double-click the warning message to open the relevant editor for the resource.

What to do next

Next: Now complete the following task:

- "Reviewing the pattern instance summary and tasks"

Related concepts:

Reviewing the pattern instance summary and tasks

Showing the summary page for your pattern instance project.

Before you begin

Before you start:

You must have completed the following tasks:

- "Generating a pattern instance" on page 1326

About this task

After generating the pattern instance, you might have to do additional tasks to complete your solution and to support its operation following instance. These tasks are located in a summary file that is created in the pattern reference project, which has the same name as the instance name.

The summary file lists the resources that were created for the pattern instance, based on the pattern parameter values that you entered in the Configure Pattern Parameters page. The summary also lists any outstanding tasks that you must complete to make the solution operational. For example, you might have to configure the message set details that are required by one or more input nodes that form part of the overall solution, or create WebSphere MQ queues for the nodes.

When a pattern has been configured and generated once, it contains both a configuration file and a summary file. If you edit and save the configuration file, both the configuration and the summary files display a warning symbol and a warning also shows in the Problems window indicating that the two files are out of sync. To get the files back in sync, regenerate the pattern.

To view the summary and tasks:

Procedure

1. Click **Windows** > **Show view** > **Tasks** to open the Task view.
2. In the **Path** column, find your pattern instance project name, which includes the pattern instance name that you used when you created the pattern instance.
3. To open the Summary page, double-click anywhere on the task, or right-click and select **Go To**.
4. Complete the tasks that are shown in the summary file.

What to do next

Next: Now complete the following task:

- "Adding files to a broker archive" on page 3223

Related concepts:

"Using patterns" on page 1312
Use patterns that are supplied with the WebSphere Message Broker Toolkit to create resources that are used to solve a specific business problem.

Related tasks:

"Choosing a pattern" on page 1313
Select a pattern in the Patterns Explorer view to create resources to solve a specific business problem.

"Generating a pattern instance" on page 1326
Generate resources from the pattern.

Related reference:

"Pattern instance projects" on page 6827
A pattern instance project contains project references to all the other projects in the workspace that relate to a specific pattern instance.

Importing an existing configuration

You can import a pattern configuration XML file from the workspace or file system and populate your current pattern instance with its values.

Before you begin

Before you start:

Before completing this task, you must have a compatible pattern configuration.

You must be in the WebSphere Message Broker Toolkit and have a pattern instance open.

Procedure

1. Open your current configuration. On the Configure Pattern Parameters page, click the **Open existing configuration** icon. The Open Pattern Configuration window opens.
2. You can select an existing pattern XML configuration file either from a workspace or file system location. Only configuration files created by the same pattern can be imported.
   - To select from a list of compatible XML configuration files that are already in the workspace, click **Workspace**. If you select a valid XML configuration file, the editor is configured with the values from the existing configuration file. You can then choose one of the following options:
     – Save the changes by clicking **OK**.
     – Return to the Configure Pattern Parameters page and discard the changes by clicking **Cancel**.
   - To select an XML configuration file from the file system by using a standard file system window, click **File System**. Select the file that you want to use, click **Open**.

   The configuration XML is validated against the corresponding pattern schema, if you select a configuration that is not valid, for example, from a different pattern, you receive notification. You can then either select the correct file, or cancel the action.
3. Share the pattern instance projects. To share pattern instance projects between WebSphere Message Broker Toolkit workspaces, you can export the pattern instance project into a directory in the file system or into a Project Interchange File (PIF). You can then import the pattern instance project into another workspace. For more information, see “Importing and exporting resources in a Project Interchange file” on page 1452.

What to do next

Next: Now complete the following task:

- “Generating a pattern instance” on page 1326

Related concepts:

“Patterns” on page 1310
A *pattern* is a reusable solution that encapsulates a tested approach to solving a common architecture, design, or deployment task in a particular context.

“Using patterns” on page 1312
Use patterns that are supplied with the WebSphere Message Broker Toolkit to create resources that are used to solve a specific business problem.

Related tasks:

“Generating a pattern instance” on page 1326
Generate resources from the pattern.

"Editing and regenerating a pattern" on page 1327
You can regenerate a pattern instance after you have edited a saved configuration in a pattern instance project.

"Creating a working set and focus on a pattern instance" on page 1319
Creating a working set for an imported project interchange file that contains a pattern instance project and its associated projects.

Pattern categories

Pattern categories are used to structure the display in the Patterns Explorer. A number of categories are provided, and you can also create your own.

A number of pattern categories are available in WebSphere Message Broker, from which you can choose the WebSphere Message Broker pattern that you want to use.

WebSphere Message Broker includes the following categories for built-in patterns. You can also use these pattern categories for your user-defined patterns, or you can create your own categories.

Message-based Integration
An Enterprise Service Bus can extend an existing messaging infrastructure by providing an environment for building and deploying infrastructure level message-based applications. Examples of these applications include routing and transformation services, and logging services. This environment can extend a single underlying messaging infrastructure or provide a bridge between different products and technologies.

Service Enablement
These patterns encapsulate functionality that does not have a service interface, and present this functionality through a service-oriented interface. These patterns represent the move from traditional enterprise application integration into service-oriented architectures, allowing existing assets to be reused in the new style without requiring radical change.

Service Virtualization
These patterns provide loose coupling between services by providing additional levels of direction through an Enterprise Service Bus. These patterns also address the requirements of mediation (for example, routing, protocol conversion, data transformation, and logging) between services, when addressing connectivity requirements in a service-oriented architecture.

Gateway
A Gateway is a part of a message or service bus that provides boundary functions that apply to all incoming messages, and are not format-dependent. Boundary functions typically use data from standard headers (at transport, SOAP, or data level) to determine what action to take, but are not required to understand the complete format of the message data or body. A Gateway pattern can then call a service directly, or call another pattern.

File Processing
An Enterprise Service Bus can provide a managed runtime environment for processing files locally or by using an FTP protocol. Typically this

processing involves activities including the transformation or translation of data held in the files, the shredding of files into multiple individual transaction records, the routing of records, the accumulation of records into target files, and the routing of files or records to specified locations.

Event-driven Integration
Event-driven architecture covers different application scenarios in which an Enterprise Service Bus plays a key role. These scenarios include integration with complex event processing engines that include the ability to filter information or event streams, distribute events in real time, and process events from physical devices, for example, detectors and sensors.

Application Integration
Application Integration is a collection of technologies and services that form a middleware to enable the integration of systems and applications across the enterprise.

For more information about individual built-in patterns, see "Built-in patterns."

Related concepts:

"Patterns" on page 1310
A *pattern* is a reusable solution that encapsulates a tested approach to solving a common architecture, design, or deployment task in a particular context.

"Using patterns" on page 1312
Use patterns that are supplied with the WebSphere Message Broker Toolkit to create resources that are used to solve a specific business problem.

"Built-in patterns"
A *built-in pattern* is a pattern that covers a set of commonly encountered message flow scenarios and that is packaged and released with WebSphere Message Broker.

"User-defined patterns" on page 1334
A *user-defined pattern* extends the function of WebSphere Message Broker so that you are able to create patterns that you can reuse within your organization.

Built-in patterns

A *built-in pattern* is a pattern that covers a set of commonly encountered message flow scenarios and that is packaged and released with WebSphere Message Broker.

The built-in patterns that are supplied in WebSphere Message Broker are shown in the following tables.

You can view patterns in the information center by using the links only when you use the information center that is integrated with the WebSphere Message Broker Toolkit, or when you use the online information center.

Message-based Integration patterns

Pattern name	Description
Message Correlator for WebSphere MQ: request-response with persistence	Use this pattern to accept requests from many client applications on a single queue, and to return responses to the correct client by using transactional flows and persistent WebSphere MQ messages.

Pattern name	Description
Message Correlator for WebSphere MQ: request-response without persistence	Use this pattern to accept requests from many client applications on a single queue, and to return responses to the correct client by using non-transactional flows and non-persistent WebSphere MQ messages.
Message Splitter for WebSphere MQ: one-way (for XML)	Use this pattern to split a large XML message into smaller elements for processing by one or more targets by using transactional flows and persistent WebSphere MQ messages.

Service Enablement patterns

Pattern name	Description
Service Facade to WebSphere MQ: one-way with acknowledgment	Use this pattern to present a Web service interface to clients and to fulfill the service requests by using a WebSphere MQ enabled application.
Service Facade to WebSphere MQ: request-response	Use this pattern to provide a Web service facade to functions that are accessible only through WebSphere MQ. This pattern creates a bridge between the synchronous HTTP protocol, which is typically used with Web services, and existing applications with WebSphere MQ interfaces that cannot be easily upgraded.
Service Access from WebSphere MQ: one-way	Use this pattern to process WebSphere MQ XML messages by using the data that the pattern contains to call a Web service. Use this pattern to bridge from the reliable WebSphere MQ messaging protocols of client application with the synchronous requests, to services to handle updates with an assurance that service failures, including timeouts, are reliably reported. This pattern provides loose coupling between client applications and service providers in timing, protocols, and transport. It is appropriate for service interfaces to existing systems.

Service Virtualization patterns

Pattern name	Description
Service Proxy: static endpoint	Use this pattern to provide decoupling between Web service requesters and Web service providers by routing through a virtual service that is bound directly to the target service provider.

File Processing patterns

Pattern name	Description
Record Distribution to WebSphere MQ: one-way	Use this pattern to bridge between two styles of integration, file based and transaction based.

Application Integration patterns

Pattern name	Description
Data distribution SAP to WebSphere MQ: one-way (for IDoc)	Use this pattern to process various types of IDocs that have a single program identifier without you being required to redeploy or rediscover existing message sets and adapters, even when you are adding different types of IDocs.

Related concepts:

"Patterns" on page 1310
A *pattern* is a reusable solution that encapsulates a tested approach to solving a common architecture, design, or deployment task in a particular context.

Pattern categories are used to structure the display in the Patterns Explorer. A number of categories are provided, and you can also create your own.

"Using patterns" on page 1312
Use patterns that are supplied with the WebSphere Message Broker Toolkit to create resources that are used to solve a specific business problem.

"User-defined patterns"
A *user-defined pattern* extends the function of WebSphere Message Broker so that you are able to create patterns that you can reuse within your organization.

User-defined patterns

A *user-defined pattern* extends the function of WebSphere Message Broker so that you are able to create patterns that you can reuse within your organization.

The *pattern author* creates a user-defined pattern to meet a business or technical requirement, and the *pattern user* configures a user-defined pattern that the pattern author has created. The user-defined pattern is available to a pattern user in the Patterns Explorer view in the Broker Application Development perspective of the WebSphere Message Broker Toolkit.

To create user-defined patterns, you must provide the implementation of the solution that reflects good practice in your organization. This implementation is known as an *exemplar*. An exemplar is a project that holds content for a pattern. An exemplar contains message flows and other resources, such as source code, Java classes for JavaCompute nodes, ESQL modules, message maps, test client, XML files, and style sheet files. Exemplars are used to create pattern plug-ins by configuring a *pattern authoring project*.

You can use the Pattern Authoring editor to configure a pattern and create the pattern plug-ins that implement the pattern. You can distribute the pattern plug-ins so that other people can use your pattern. Your pattern is displayed in the Patterns Explorer view and can be used in the same way as the built-in patterns.

To create a user-defined pattern, see "Creating a user-defined pattern" on page 1336.

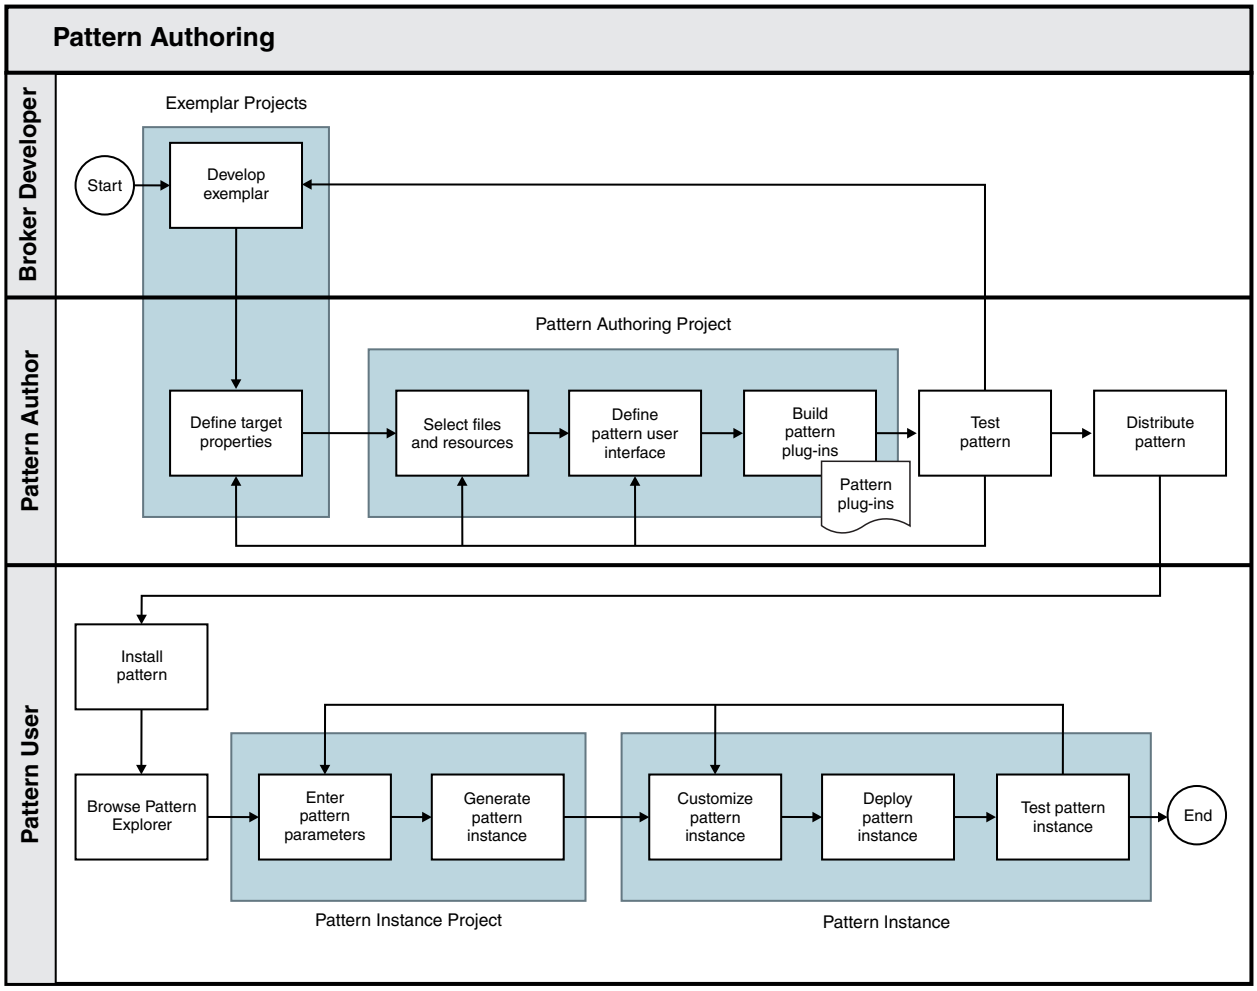
Package the plug-ins for your user-defined pattern into a pattern archive so that pattern users can download and install the pattern on their own system.

Creating a user-defined pattern

The workflow showing the actions required for pattern authoring.



The three stages of creating a user-defined pattern are performed by the WebSphere Message Broker developer, the pattern author, and the pattern user.

1. The WebSphere Message Broker developer develops the exemplar. The exemplar is fundamental to the pattern authoring process. It assumes that the exemplar is the starting point for a pattern. Some modifications might be required to the exemplar to prepare it for pattern authoring.
2. The pattern author creates a pattern plug-in from the exemplar. Authoring a pattern is a design activity. Some of the pattern authoring focuses on the resources in WebSphere Message Broker, for example, defining the target properties for the pattern and configuring the user interface that is presented to the pattern user.

   The pattern author then shares the user-defined pattern with the pattern user. Patterns are most useful when they are shared with a user base. This user base can be within an organization, or a broader community, for example, open source licensing.
3. The pattern user receives a user-defined pattern, and uses it in accordance with the requirements of the organization.

Pattern authoring

The following sample shows how to build a WebSphere Message Broker pattern. The sample provides an example message flow project that calculates the sunrise and sunset times in a PHPCompute node. The sample also provides a pattern authoring project that configures a pattern.

- Solar Pattern Authoring

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

To create a user-defined pattern, complete the following tasks. "Extending a user-defined pattern" is an optional set of tasks that you can use to add features to your user-defined pattern. For example, by extending a user-defined pattern you can create user-defined patterns that include parameters that pattern users can modify.

1. "Creating a pattern authoring project"
2. "Selecting the source files to use for a user-defined pattern" on page 1338
3. Optional: "Adding and removing the project references for a user-defined pattern" on page 1339
4. Optional: "Extending a user-defined pattern" on page 1340
5. "Building pattern plug-ins" on page 1395
6. "Testing a user-defined pattern" on page 1396
7. "Packaging and distributing pattern plug-ins" on page 1397

When you have created pattern plug-ins for your user-defined pattern, pattern users can install them to use in WebSphere Message Broker projects, see "Downloading and installing a pattern archive" on page 1400.

Related concepts:

A *built-in pattern* is a pattern that covers a set of commonly encountered message flow scenarios and that is packaged and released with WebSphere Message Broker.

"User-defined patterns" on page 1334
A *user-defined pattern* extends the function of WebSphere Message Broker so that you are able to create patterns that you can reuse within your organization.

Creating a pattern authoring project:

Create a pattern authoring project and choose an exemplar for the project.

About this task

Procedure

To create a pattern authoring project:

1. Click **File** > **New** > **Other**. A window opens in which you can select a wizard.
2. Expand **Message Broker - Flow Development**, select **Pattern Authoring Project**, click **Next**. The New Pattern Authoring Project wizard opens.
3. Enter a pattern name and a project name for your pattern, then click **Next**.
4. Select the project references that you require. These references are the exemplars for the user-defined pattern.
5. Click **Finish**.

Results

Your pattern folder is displayed in the Projects section of the **Broker Development** view and in the Pattern Authoring editor.

What to do next

Next:

Select the source files. For more information, see "Selecting the source files to use for a user-defined pattern."

Related concepts:

"User-defined patterns" on page 1334
A *user-defined pattern* extends the function of WebSphere Message Broker so that you are able to create patterns that you can reuse within your organization.

"Creating a user-defined pattern" on page 1336
The workflow showing the actions required for pattern authoring.

Selecting the source files to use for a user-defined pattern:

Select the source files to include in your pattern.

Before you begin

Before you start:

Complete the following task:

- "Creating a pattern authoring project" on page 1337

Procedure

To select the source files to use in the user-defined pattern:

1. In the Pattern Authoring editor, click the **Source Files** tab.
2. In the **Select Source Files** section, select the source files in the referenced projects that you want to include in your pattern.

What to do next

Next:

- Extend the pattern, see "Extending a user-defined pattern" on page 1340.

- Change the project references, see “Adding and removing the project references for a user-defined pattern.”
- Build the pattern, see “Building pattern plug-ins” on page 1395.

Related concepts:

“User-defined patterns” on page 1334
A *user-defined pattern* extends the function of WebSphere Message Broker so that you are able to create patterns that you can reuse within your organization.

“Creating a user-defined pattern” on page 1336
The workflow showing the actions required for pattern authoring.

Related tasks:

“Creating a pattern authoring project” on page 1337
Create a pattern authoring project and choose an exemplar for the project.

Adding and removing the project references for a user-defined pattern:

Change the project references for a user-defined pattern so that you can change the source files in the user-defined pattern.

Before you begin

Before you start:

Complete the following task:

- “Creating a pattern authoring project” on page 1337

Procedure

To add or remove project references:

1. In the Pattern Authoring editor, click the **Source Files** tab. Click **Change Project References**.
2. To add a new project reference, select the project reference that you want to add and click **OK**. If you add a new project reference, none of the source files within the project reference are selected. To select source files for the new project reference, see “Selecting the source files to use for a user-defined pattern” on page 1338. If your user-defined pattern requires referenced projects but they are not included as source files in the pattern, you must distribute the referenced projects to pattern users to ensure the user-defined pattern works.
3. To remove a project reference, clear the project reference that you want to remove and click **OK**. If you remove a referenced project from the workspace, the source files are removed from the pattern authoring project but the project reference remains. If you later add the project back into the workspace, the source files are added to the pattern authoring project.

What to do next

Next:

- You can extend the pattern; see “Extending a user-defined pattern” on page 1340.
- If the pattern is complete, you can now build the pattern; see “Building pattern plug-ins” on page 1395.

Related concepts:

“User-defined patterns” on page 1334
A *user-defined pattern* extends the function of WebSphere Message Broker so that

you are able to create patterns that you can reuse within your organization.

"Creating a user-defined pattern" on page 1336
The workflow showing the actions required for pattern authoring.

Related tasks:

Select the source files to include in your pattern.

Extending a user-defined pattern

Extend a user-defined pattern to customize its behavior so that it is easier to use or to provide guidance to pattern users.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338

About this task

A basic user-defined pattern is a copy of an existing message flow, but by extending a user-defined pattern you can allow the pattern user to customize the pattern.

Procedure

You can extend a user-defined pattern in the following ways:

- Create documentation for the pattern. Creating documentation provides guidance to your pattern users. To update the pattern documentation, see "Creating documentation for a pattern" on page 1342.
- Define the target properties. A user-defined pattern can change the value of user-defined properties, promoted node properties, and node properties in a message flow. A property that is changed by a pattern is called a target property. Pattern users create a pattern instance by configuring pattern parameters. The values of the pattern parameters that are configured by a pattern user can be used to configure the target properties in the pattern instance. To define target properties, see "Defining the target properties" on page 1342.
- Define the user interface. You can customize how the pattern parameters are displayed to pattern users by defining the user interface. For example, you can rename or group pattern parameters, and you can define default values for pattern parameters. To define the user interface, see "Defining the user interface" on page 1343, "Adding and editing parameter groups" on page 1345, and "Enabling parameter groups" on page 1347.
- Configure the categories in the Patterns Explorer view. When a pattern user imports a user-defined pattern, it is shown in the Patterns Explorer view. You can select which category the user-defined pattern is assigned to in the Patterns Explorer view and create new categories. To configure the categories, see "Creating and configuring categories" on page 1350.
- Configure the SOAP nodes. To use SOAP nodes in user-defined patterns, see "Configuring SOAP nodes for user-defined patterns" on page 1351.

- Change pattern parameter IDs. Pattern parameter IDs are used to refer to pattern parameters in XPath, Java, and PHP code. You can write the code to modify pattern parameters or pattern instances. Default parameter IDs are assigned, but you can change them to custom IDs. To change parameter IDs, see "Changing pattern parameter IDs" on page 1352.
- Transform the pattern parameters. You can calculate values for pattern parameters from other pattern parameters by using XPath expressions. To set up transformations for pattern parameters and then test the transformations, see "Transforming pattern parameters" on page 1353 and "Testing a transformation expression" on page 1355.
- Enable or disable the pattern parameters. You can use XPath expressions to control whether a pattern parameter can be modified by a pattern user based on the values of other pattern parameters. To set up enabling expressions for pattern parameters and then test the expressions, see "Enabling pattern parameters" on page 1357 and "Testing an enabling expression" on page 1358.
- Use enumerated values for the pattern parameters. You can set up enumerated types for pattern parameters so that pattern users have a predefined list of values for the pattern parameters. If a target property has a list of possible values, the pattern authoring tool generates an enumerated type for that target property. You can modify the enumerated type that is automatically created. To use enumerated types see "Using enumerated values for pattern parameters" on page 1360 and "Creating enumerated types for pattern parameters" on page 1361.
- Modify pattern instances by using Java or PHP. You can write code in Java or PHP that modifies pattern instances when a pattern user generates an instance of a user-defined pattern. For example, you can write code to modify the structure of a message flow based on the values of pattern parameters. To use Java or PHP in user-defined patterns, see "Modifying pattern instances by using Java or PHP" on page 1364.

What to do next

Next:

After extending your user-defined pattern, you must build the pattern plug-in, see "Building pattern plug-ins" on page 1395.

Related concepts:

"User-defined patterns" on page 1334
A *user-defined pattern* extends the function of WebSphere Message Broker so that you are able to create patterns that you can reuse within your organization.

Generate resources from the pattern.

Creating documentation for a pattern:

When you create a pattern authoring project, a default HTML pattern specification is created as part of the project. You can edit this pattern specification to document your user-defined pattern.

Before you begin

Before you start:

Complete the following task:

- "Creating a pattern authoring project" on page 1337

About this task

Procedure

To edit the pattern specification, complete the following steps.

1. Open the Projects section of the Broker Development view.
2. Expand your pattern authoring project, and expand **Pattern Specification**.
3. Right-click `overview.htm` and select **Open With** > **HTML Editor**. The default user-defined pattern specification is shown in the HTML editor.
4. Edit the content of the pattern specification in the HTML editor. The default specification contains example links to suggested HTML files. To ensure that these links work correctly, you must create the required files and edit the links in the default specification. If you do not require these additional pages, delete the example links from the default specification.
5. To save the changes, click **File** > **Save**.
6. To view the updated pattern specification, click the **Categories** tab of the Pattern Authoring editor.

Related concepts:

"User-defined patterns" on page 1334
A *user-defined pattern* extends the function of WebSphere Message Broker so that you are able to create patterns that you can reuse within your organization.

"Creating a user-defined pattern" on page 1336
The workflow showing the actions required for pattern authoring.

Defining the target properties:

Identify the target properties in the workspace project so that you can define the pattern interface and pattern users can modify the pattern parameters.

Before you begin

Before you start:

Create the pattern authoring project and select the source files. For information about creating a pattern authoring project, see "Creating a pattern authoring project" on page 1337. For information about selecting the source files, see "Selecting the source files to use for a user-defined pattern" on page 1338.

Procedure

To identify the target properties that you want to use in the workspace project:

1. In the Broker Development view, double-click the message flow that you want to use.
2. Open the Select Target Properties window by completing one of the following steps:
   - To select a node property as a target property, in the Message Flow editor, right-click the node that you want to use and click **Pattern** > **Select Target Properties**.
   - To select a user-defined property as a target property, in the Message Flow editor, right-click the canvas and click **Pattern** > **Select Target Properties**.
3. In the Select Target Properties window, select the target properties that you want to use in the pattern.
4. Close the Select Target Properties window.
5. Save the message flow.

Results

The selected target properties are displayed in the Target Properties panel of the **Source Files** tab in the Pattern Authoring editor.

What to do next

Next:

Define the user interface; see "Defining the user interface."

Related concepts:

"User-defined patterns" on page 1334
A *user-defined pattern* extends the function of WebSphere Message Broker so that you are able to create patterns that you can reuse within your organization.

"Creating a user-defined pattern" on page 1336
The workflow showing the actions required for pattern authoring.

Related tasks:

"Extending a user-defined pattern" on page 1340
Extend a user-defined pattern to customize its behavior so that it is easier to use or to provide guidance to pattern users.

Defining the user interface:

To control how pattern users view and edit pattern parameters in the Pattern Instance editor after the pattern user has created an instance of a user-defined pattern, you must define the user interface.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338
- "Defining the target properties" on page 1342

About this task

When a pattern user creates an instance of a user-defined pattern, the parameter groups and pattern parameters that are defined in the **Pattern Configuration** tab of the Pattern Authoring editor are displayed in the Pattern Instance editor. If the **Pattern Configuration** tab displays groups or parameters that you do not want in the final pattern, you must delete them from the **Pattern Configuration** tab before building the pattern plug-ins.

To define the user interface, open the **Pattern Configuration** tab of the Pattern Authoring editor. In the **Groups and Parameters** list, entries are shown in a hierarchy in which groups contain pattern parameters, and pattern parameters contain target properties.

Procedure

To define the user interface, choose one or more of the following options:

1. You can define the groups in which pattern parameters are displayed and assign target properties to pattern parameters:
   a. To define the groups in which pattern parameters are displayed in the Pattern Instance editor, drag pattern parameters to groups. To add new groups or edit existing groups, see "Adding and editing parameter groups" on page 1345. To control whether parameter groups are enabled by using XPath expressions, see "Enabling parameter groups" on page 1347.
   b. To assign target properties to pattern parameters, drag target properties to pattern parameters. If the target property and pattern parameter do not use a compatible editor, an error message is displayed; see step 5 on page 1345 to change the parameter editor. If you drag multiple target properties to one pattern parameter, all target properties in that pattern parameter are populated with the same value that is entered for the pattern parameter by the pattern user.
2. To add a new pattern parameter, click **Add Parameter**, and click **OK**. To configure the new parameter, see steps 4 and 5 on page 1345.
3. To remove a pattern parameter or parameter group, select the pattern parameter or parameter group to remove and click **Delete**.
   - To remove a parameter group it must have no pattern parameters assigned to it.
   - To remove a pattern parameter it must have no target properties assigned to it. To remove a target property so that you can remove a pattern parameter, clear the target property in the Message Flow editor of the Broker Development view. For more information about defining target properties, see "Defining the target properties" on page 1342. When you remove a target property in the Message Flow editor, the associated pattern parameter and parameter group are not automatically deleted in the **Pattern Configuration** tab of the Pattern Authoring editor.
4. You can change the name of a pattern parameter, create help text, create a field prompt, and configure parameter options in the **Basic** tab. In the **Groups and Parameters** list, select the pattern parameter and click **Edit**, or double-click the pattern parameter. The Edit Parameter window opens.
   - To change the name of the pattern parameter, enter a name for the pattern parameter in the **Display Name** field and click **OK**. The name for the pattern parameter is changed to the new name.

- To change parameter options, select or clear the **Hide the parameter**, **Configure during deployment**, and **Mandatory parameter** check boxes, as required.
- To enter a field prompt, type a text into the **Field prompt** field.
- To provide help text for the pattern parameter, type the text in the **Help Text (HTML)** field.
- To close the Edit Parameter window after you have completed your changes, click **OK**.

5. You can change the parameter editor, and set a default value for a pattern parameter in the **Editor** tab. In the **Groups and Parameters** list, select the pattern parameter and click **Edit**, or double-click the pattern parameter. The Edit Parameter window opens. Click the **Editor** tab.
   - To change the parameter editor, select the required editor in the **Parameter editor** list.

     To use an enumerated type for the parameter, select **Drop Down Selection** in the **Parameter editor** list, then select an enumerated type for the parameter in the **Type selection** field. For more information, see "Using enumerated values for pattern parameters" on page 1360.
   - To enter a default value for a pattern parameter, if **Parameter editor** is `Drop Down Selection` or `Check Box`, select a value from the **Default value** list. Otherwise, enter a value in the **Default value** field.
   - To close the Edit Parameter window after you have completed your changes, click **OK**.

What to do next

Next:

You can build the pattern plug-ins, see "Building pattern plug-ins" on page 1395.

Related concepts:

Select the source files to include in your pattern.

"Extending a user-defined pattern" on page 1340
Extend a user-defined pattern to customize its behavior so that it is easier to use or to provide guidance to pattern users.

"Defining the target properties" on page 1342
Identify the target properties in the workspace project so that you can define the pattern interface and pattern users can modify the pattern parameters.

Adding and editing parameter groups:

Edit parameter groups to control how pattern parameters are displayed to pattern users when they create pattern instances from a user-defined pattern.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338
- "Defining the target properties" on page 1342

About this task

After defining target properties, a default list of parameter groups is created. You can edit the default groups or add new groups.

Procedure

- To add a new group:
  1. In the **Pattern Configuration** tab of the Pattern Authoring editor, click **Add Group**. The Add Group window opens.
  2. Enter a display name for the group in the **Display name** field.
  3. Enter a description for the group in the **Description** field.
  4. The **Generate help documentation** check box is selected by default. If you do not want to show the help documentation for the parameters in the group, clear the **Generate help documentation** check box. To add help documentation for pattern parameters, see "Defining the user interface" on page 1343.
  5. If you do not want the group to display with a surrounding box in the Configure Pattern Parameters page, clear the **Display parameters in a group box** check box. If a group is displayed in a group box, pattern users can expand or collapse the group box to display or hide the parameters in that group. Parameters in a group that is not shown in a group box are always visible.
  6. Click **OK**. The new group is shown in the Groups and Parameters list.
- To edit an existing group:
  1. In the **Pattern Configuration** tab of the Pattern Authoring editor, double-click the group name that you want to edit, or select the group name and click **Edit**. The Edit Group window opens.
  2. To change the display name, enter a display name for the group in the **Display name** field.
  3. To change the description, enter a description for the group in the **Description** field.
  4. If you want to show help documentation for the parameters in the group, ensure the **Generate help documentation** check box is selected. To add help documentation for pattern parameters, see "Defining the user interface" on page 1343.
  5. If you want the group to display with a surrounding box in the Configure Pattern Parameters page, ensure the **Display parameters in a group box** check box is selected. If a group is displayed in a group box, pattern users can expand or collapse the group box to display or hide the parameters in that group. Parameters in a group that is not shown in a group box are always visible.
  6. Click **OK**. The modified group is shown in the Groups and Parameters list.

What to do next

Next:

You can choose whether a parameter group is enabled based on the value of pattern parameters; see "Enabling parameter groups."

"Extending a user-defined pattern" on page 1340
Extend a user-defined pattern to customize its behavior so that it is easier to use or to provide guidance to pattern users.

Enabling parameter groups:

In a user-defined pattern, control whether parameter groups are enabled based on the values of pattern parameters.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338
- "Defining the target properties" on page 1342

About this task

By default, when pattern users configure an instance of a user-defined pattern, all the parameter groups that are defined in the user-defined pattern are enabled. Enabled parameter groups and pattern parameters within those groups are visible to pattern users in the Configure Parameters page. You can control whether a parameter group in an instance of a user-defined pattern is enabled by using an XPath expression:

- If the expression evaluates to Boolean true, the parameter group is enabled. When a pattern user configures an instance of a user-defined pattern, the parameter group and pattern parameters within that group are visible to pattern users in the Configure Parameters page. The values of pattern parameters within enabled parameter groups populate the target properties of the user-defined pattern.

- If the expression evaluates to Boolean `false`, the parameter group is disabled. When a pattern user configures an instance of a user-defined pattern, the parameter group is not shown to pattern users in the Configure Parameters page. Pattern parameters within disabled groups are not shown to pattern users and the values of those parameters do not populate the target properties in an instance of the user-defined pattern.

If no XPath expression is entered for a parameter group, the parameter group is enabled. For XPath reference information, including information about XPath functions, see W3C XPath 1.0 Specification.

The `pp:getValue()` function is included, in addition to the functions in the XPath 1.0 Specification. The `pp:getValue()` function takes the parameter ID of a pattern parameter and returns the value of that pattern parameter. To see the parameter ID for a pattern parameter:

1. In the **Pattern Configuration** tab of the Pattern Authoring editor, double-click a parameter group, or select a parameter group and click **Edit**. The Edit Group window opens.
2. Click the **Visibility** tab. The parameter IDs for pattern parameters are shown in the **Parameter ID** column of the Pattern Parameters table. To change parameter IDs, see "Changing pattern parameter IDs" on page 1352.

Procedure

To control whether a pattern parameter group is enabled by using an XPath expression:

1. In the **Pattern Configuration** tab of the Pattern Authoring editor, double-click the parameter group that you want to control, or select the parameter group and click **Edit**. The Edit Group window opens.
2. Click the **Enable** tab. Create an XPath expression for your chosen parameter group:
   - To select a function:
     a. Expand **Boolean**, **Number**, **Pattern**, or **String** in the Functions section, then click a function. The function is displayed in the **Function name** field.
     b. Click **Use**. The function is inserted into the **Expression** field at the cursor.
   - To select an operator:
     a. Click an operator in the Operators section. The operator is displayed in the **Operator** field.
     b. Click **Use**. The operator is inserted into the **Expression** field at the cursor.
   - To select a pattern parameter:
     a. Click a pattern parameter in the Pattern Parameters table. The parameter ID shown in the **Parameter ID** column of the Pattern Parameters table for the chosen parameter is displayed in the **Parameter ID** field.
     b. Click **Use**. The parameter ID is inserted into the **Expression** field at the cursor. To change parameter IDs, see "Changing pattern parameter IDs" on page 1352.
   - You can also edit the expression directly in the **Expression** field.
3. Repeat the actions in step 2, as required, to create your XPath expression.
4. You can now choose whether to test your expression:
   - To test your expression, see "Testing a group enabling expression" on page 1349.

- To accept the expression without testing it, click **OK**. The Edit Group window closes.

Related concepts:

"Testing a group enabling expression"
In a user-defined pattern, test an XPath expression that is used for enabling parameter groups.

"Changing pattern parameter IDs" on page 1352
Change default pattern parameter IDs to make it easier to write XPath, Java, and PHP code that uses parameter IDs.

Testing a group enabling expression:

In a user-defined pattern, test an XPath expression that is used for enabling parameter groups.

Before you begin

Before you can complete this task, you must have completed the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338
- "Defining the target properties" on page 1342
- "Enabling parameter groups" on page 1347

Procedure

To test your XPath expression:

1. If the **Enable** tab in the Edit Group window is not already open, complete the following steps to open the tab:
   a. In the **Pattern Configuration** tab of the Pattern Authoring editor, select the parameter group containing the XPath expression that you want to test and click **Edit**. The Edit Group window opens.
   b. Click the **Enable** tab.
2. To test the expression, click **Evaluate**. The expression is evaluated by using the values in the **Test Values** column of the Pattern Parameters section, and the result is shown in the **Result** field. The result shows whether the parameter group is enabled or disabled, and the value of the expression is shown in

parentheses. If the value is `true`, the associated group is enabled; if the value is `false`, the group is disabled. Use the following table to determine the value of your XPath expression.

Result data type	Evaluates to true	Evaluates to false
Boolean	`true`	`false`
Numeric	Any non-zero value	`0` or `0.0`
String	Any string that returns `true` with a match that is not case-sensitive	Any string that does not return `true` with a match that is not case-sensitive

3. To change the test value for a parameter, select the parameter in the Pattern Parameters section and enter the required test value in the **Test value** field. Click **Set**. The new test value is shown in the Pattern Parameters section.
4. Repeat steps 2 on page 1349 and 3, as required, to test the XPath expression. If you want to modify the expression, see "Enabling parameter groups" on page 1347.
5. When you have finished testing the expression, click **OK**. The Edit Group window closes.

Related concepts:

Creating and configuring categories:

Configure categories to which to assign user-defined patterns in the Patterns Explorer view.

Before you begin

Before you start:

Complete the following task:

- "Creating a pattern authoring project" on page 1337

About this task

You can drag your user-defined pattern into any existing category, or you can create a new category. If you create a category, you can write a category specification that provides information about the category for other users. User-defined patterns are shown within these categories in the Patterns Explorer view.

Procedure

To create a new category, update the category specification, assign your pattern to a category, rename a category, or remove a category, begin by opening the **Categories** tab of the Pattern Authoring editor. You can now choose one or more of the following options:

- To create a new category as a subcategory of an existing category:
  1. Select an existing category.
  2. Click **Add Category**. The Add Category window opens.
  3. Enter the name of your new category and click **OK**. The new category is added to the category list under the category previously selected. The Save Your Pattern File window opens, asking you to confirm whether you want to save your patterns file. Click **Yes**.
- To edit the category specification for a category:
  1. Double-click the category. The HTML editor opens containing the default category specification.
  2. Update the category specification to describe the category, and click **File** > **Save** to save any changes.
- To assign your user-defined pattern to a category, drag your user-defined pattern to your chosen category.
- To rename a category:
  1. Click **Rename Category**. The Edit Category window opens.
  2. Enter the new name, click **OK**. The Save Your Pattern File window opens, asking you to confirm whether you want to save your patterns file.
- To remove a category, click **Remove category**. The Save Your Pattern File window opens, asking you to confirm whether you want to save your patterns file. Click **Yes**.

Configuring SOAP nodes for user-defined patterns:

Configure the target properties on SOAPInput, SOAPRequest, and SOAPAsyncRequest nodes by using a WSDL file.

Before you begin

Before you can complete this task, you must have completed the following tasks:

- "Creating a pattern authoring project" on page 1337

Procedure

To configure target properties on SOAP nodes by using a WSDL file:

1. Select an exemplar that uses a SOAPInput, SOAPRequest, or SOAPAsyncRequest node. See "Selecting the source files to use for a user-defined pattern" on page 1338.
2. Define the target properties and ensure that the `WSDL file name` target property is selected as a target property in the SOAPInput, SOAPRequest, or SOAPAsyncRequest node. See "Defining the target properties" on page 1342.

What to do next

When the pattern user generates an instance of the user-defined pattern, the WSDL file name is presented as a pattern parameter. After the pattern user inputs the WSDL file name, the properties in the WSDL file are used to configure the SOAP node target properties. Examples of WSDL properties are the port type, binding, and service port values.

The target properties are configured with the first occurrence of each WSDL property.

Extend a user-defined pattern to customize its behavior so that it is easier to use or to provide guidance to pattern users.

Changing pattern parameter IDs:

Change default pattern parameter IDs to make it easier to write XPath, Java, and PHP code that uses parameter IDs.

Before you begin

Before you can complete this task, you must have completed the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338
- "Defining the target properties" on page 1342

About this task

Pattern parameter IDs uniquely identify pattern parameters. As a pattern author, you use pattern parameter IDs when writing XPath expressions to transform or enable pattern parameters, or when writing Java or PHP code to modify pattern instances. Every pattern parameter in a user-defined pattern has a default pattern parameter ID assigned, but you can change pattern parameter IDs from the default values so that they are easier to identify in your code.

Procedure

To change pattern parameter IDs from the default values:

1. In the **Pattern Configuration** tab of the Pattern Authoring editor, double-click the parameter for which you want to change the parameter ID, or select the parameter and click **Edit**. The Edit Parameter window opens.
2. In the **Parameter ID** field of the **Basic** tab, enter your new parameter ID. The new parameter ID can be made up of ASCII characters, but must start with a non-numeric character.
3. Click **OK**. The Edit Parameter window closes.

What to do next

- To use the new parameter ID in an XPath expression to transform pattern parameters, see "Transforming pattern parameters."
- To use the new parameter ID in an XPath expression to enable pattern parameters, see "Enabling pattern parameters" on page 1357.
- To use the new parameter ID in Java or PHP code to modify pattern instances, see "Modifying pattern instances by using Java or PHP" on page 1364.

Related concepts:

Transforming pattern parameters:

Calculate a pattern parameter value from the values entered for other pattern parameters.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338
- "Defining the target properties" on page 1342

About this task

You can transform pattern parameters by using XPath expressions; for example, to calculate a pattern parameter value from the values entered for other pattern parameters. WebSphere Message Broker supports XPath 1.0. For XPath reference information, including information about XPath functions, see W3C XPath 1.0 Specification.

- The `pp:getValue()` function is included, in addition to the functions in the XPath 1.0 Specification. The `pp:getValue()` function takes the parameter ID of a pattern parameter and returns the value of that pattern parameter. To see the parameter ID for a pattern parameter:
  1. In the **Pattern Configuration** tab of the Pattern Authoring editor, double-click a parameter, or select a parameter and click **Edit**. The Edit Parameter window opens.
  2. Click the **Transform** tab. The parameter IDs for pattern parameters are shown in the **Parameter ID** column of the Pattern Parameters table.
- When a pattern instance is generated by a pattern user, transformation expressions are processed before any Java and PHP code that has been added to modify pattern instances. Transformation of pattern parameters is processed in the following sequence:
  1. Every parameter that has an XPath transformation expression is evaluated.
  2. The value of each parameter that has an XPath transformation expression is updated with the result of its evaluation, overwriting the value entered by the pattern user.
  3. The parameters are evaluated in top to bottom order, as they are listed in the **Pattern Configuration** tab of the Pattern Authoring editor.

Procedure

To transform a pattern parameter by using an XPath expression:

1. In the **Pattern Configuration** tab of the Pattern Authoring editor, double-click the parameter that you want to transform, or select the parameter and click **Edit**. The Edit Parameter window opens.
2. Click the **Transform** tab. Create an XPath expression for your chosen parameter:
   - To select a function:
     a. Expand **Boolean**, **Number**, **Pattern**, or **String** in the Functions section, then click a function. The function is displayed in the **Function name** field.
     b. Click **Use**. The function is inserted into the **Expression** field at the cursor.
   - To select an operator:
     a. Click an operator in the Operators section. The operator is displayed in the **Operator** field.
     b. Click **Use**. The operator is inserted into the **Expression** field at the cursor.
   - To select a pattern parameter:

a. Click a pattern parameter in the Pattern Parameters table. The parameter ID shown in the **Parameter ID** column of the Pattern Parameters table for the chosen parameter is displayed in the **Parameter ID** field.
b. Click **Use**. The parameter ID is inserted into the **Expression** field at the cursor.

- You can also edit the expression directly in the **Expression** field.

3. Repeat the actions in step 2 on page 1354, as required, to create your XPath expression.
4. You can now choose whether to test your expression:
   - To test your expression, see "Testing a transformation expression."
   - To accept the expression without testing it, click **OK**. The Edit Parameter window closes.

Testing a transformation expression:

Test your XPath transformation expression created in a user-defined pattern to check that it works correctly.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338
- "Defining the target properties" on page 1342
- "Transforming pattern parameters" on page 1353

Procedure

To test your XPath expression:

1. If the **Transform** tab in the Edit Parameter window is not already open, complete the following steps to open the tab:
   a. In the **Pattern Configuration** tab of the Pattern Authoring editor, double-click the parameter containing the XPath expression that you want to test, or select the parameter and click **Edit**. The Edit Parameter window opens.
   b. Click the **Transform** tab.
2. To change the test value for a parameter, select the parameter in the Pattern Parameters section and enter the required test value in the **Test value** field. Click **Set**. The new test value is shown in the Pattern Parameters section.
3. To test the expression, click **Evaluate**. The expression is evaluated by using the values in the **Test Values** column of the Pattern Parameters section and the result is shown in the **Result** field. If the expression is not valid an error message is displayed in the **Result** field.
4. Repeat steps 2 and 3, as required, to test the XPath expression. If you want to modify the expression, see "Transforming pattern parameters" on page 1353.
5. When you have finished testing the expression, click **OK**. The Edit Parameter window closes.

Extend a user-defined pattern to customize its behavior so that it is easier to use or to provide guidance to pattern users.

Enabling pattern parameters:

You can control whether pattern parameters can be edited by pattern users based on the values of other pattern parameters.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338
- "Defining the target properties" on page 1342

About this task

By using XPath expressions you can control whether pattern users can edit pattern parameters in the Pattern Instance editor . If an expression evaluates to Boolean true, the pattern user can configure the parameter in the Configure Pattern Parameters page; if an expression evaluates to Boolean `false`, the parameter is read-only, and the pattern user cannot configure it. When the pattern user configures pattern parameters, expressions are evaluated whenever any of the pattern parameters used in an expression change.

WebSphere Message Broker supports XPath 1.0. For XPath reference information, including information about XPath functions, see W3C XPath 1.0 Specification.

The `pp:getValue()` function is included, in addition to the functions in the XPath 1.0 Specification. The `pp:getValue()` function takes the parameter ID of a pattern parameter and returns the value of that pattern parameter. To see the parameter ID for a pattern parameter:

1. In the **Pattern Configuration** tab of the Pattern Authoring editor, double-click a parameter, or select a parameter and click **Edit**. The Edit Parameter window opens.
2. Click the **Enable** tab. The parameter IDs for pattern parameters are shown in the **Parameter ID** column of the Pattern Parameters table.

Procedure

To define an XPath expression to control whether a pattern parameter can be edited:

1. In the **Pattern Configuration** tab of the Pattern Authoring editor, select the parameter that you want to configure. Click **Edit**. The Edit Parameter window opens.
2. Click the **Enable** tab. Create an XPath expression for your selected parameter by applying the following operations as required:
   - To select a function:
     a. Click a function in the Functions section. The function is displayed in the **Function name** field.
     b. Click **Use**. The function is inserted into the **Expression** field at the cursor.
   - To select an operator:
     a. Click an operator in the Operators section. The operator is displayed in the **Operator** field.

b. Click **Use**. The operator is inserted into the **Expression** field at the cursor.

- To select a pattern parameter:
  a. Click a pattern parameter in the Pattern Parameters table. The ID shown in the **Parameter ID** column of the Pattern Parameters table for the selected parameter is displayed in the **Parameter ID** field.
  b. Click **Use**. The parameter ID is inserted into the **Expression** field at the cursor.
- You can also edit the expression directly in the **Expression** field.

A common requirement is for a pattern parameter to be read-only. To ensure that a pattern parameter is read-only, set the XPath expression for the pattern parameter to `false()`.

3. You can now choose whether to test your expression:
   - To test your expression, see "Testing an enabling expression."
   - To accept the expression without testing it, click **OK**. The Edit Parameter window closes.

Testing an enabling expression:

Test an XPath enabling expression that you created in a user-defined pattern to check that it works correctly.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338
- "Defining the target properties" on page 1342
- "Enabling pattern parameters" on page 1357

Procedure

To test your XPath expression:

1. If the **Enable** tab in the Edit Parameter window is not already open, complete the following steps to open the tab:
   a. In the **Pattern Configuration** tab of the Pattern Authoring editor, select the parameter containing the XPath expression that you want to test and click **Edit**. The Edit Parameter window opens.
   b. Click the **Enable** tab.
2. To test the expression, click **Evaluate**. The expression is evaluated by using the values in the **Test Values** column of the Pattern Parameters section, and the result is shown in the **Result** field. The result shows whether the parameter is enabled or disabled, and the value of the expression is shown in parentheses. If the value is `true`, the associated parameter is enabled; if the value is `false`, the parameter is disabled. Use the following table to determine the value of your XPath expression.

Result data type	Evaluates to True	Evaluates to False
Boolean	`true`	`false`
Numeric	Any non-zero value	`0` or `0.0`
String	Any string that returns `true` with a match that is not case-sensitive	Any string that does not return `true` with a match that is not case-sensitive

3. To change the test value for a parameter, select the parameter in the Pattern Parameters section and enter the required test value in the **Test value** field. Click **Set**. The new test value is shown in the Pattern Parameters section.
4. Repeat steps 2 and 3, as required, to test the XPath expression. If you want to modify the expression, see "Enabling pattern parameters" on page 1357.
5. When you have finished testing the expression, click **OK**. The Edit Parameter window closes.

Using enumerated values for pattern parameters:

Use enumerated types to provide predefined values for the pattern parameters in your user-defined patterns.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338
- "Defining the target properties" on page 1342

About this task

You can use enumerated types to provide pattern users with a predefined list of pattern parameter values to select from. For enumerated types that you create, you can add, remove, and edit values. As part of the pattern authoring process, any target properties that use a list of values have enumerated types created for them automatically. You can remove values from this automatically generated list, but you cannot add new values or change existing values.

Procedure

- Create your own enumerated types. See "Creating enumerated types for pattern parameters" on page 1361.
- Edit enumerated types. See "Editing enumerated types for pattern parameters" on page 1362.
- Assign enumerated types to pattern parameters. See "Defining the user interface" on page 1343.

Related concepts:

"User-defined patterns" on page 1334

Identify the target properties in the workspace project so that you can define the

pattern interface and pattern users can modify the pattern parameters.

Creating enumerated types for pattern parameters:

Define enumerated types to provide predefined values for pattern parameters in your user-defined patterns.

Before you begin

Before you start:

Complete the following tasks:
- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338
- "Defining the target properties" on page 1342

About this task

Enumerated types give pattern users a predefined list of values to select from when they choose values for pattern parameters after generating a new pattern instance.

Procedure

To create a new enumerated type:
1. In the Pattern Authoring editor, click the **Pattern Configuration** tab. Click **Enumerated Types**. The Configure Enumerated Types window opens.
2. Click the **Add** button that is under the **Enumerated type** field. The Enter New Enumeration window opens.
3. Enter a name for the enumeration in the **Enter a name for the enumeration** field. Click **OK**. The new enumeration is displayed in the table of values, and a display name and default value are entered in the table.
4. For manipulating values, either adding or editing, use the following options:
   - To add a new value, click the **Add** button that is next to the table of values. A new display name and value are added to the table.
   - To edit a display name or value, double-click the display name or value in the table. Type a new entry and then press Enter to save the new display name or value.
5. When you have finished adding values and editing display names and values, click **OK**. The Configure Enumerated Types window closes.

What to do next

Next:

You can now assign your enumerated type to a pattern parameter, see "Defining the user interface" on page 1343.

Related concepts:

"User-defined patterns" on page 1334
A *user-defined pattern* extends the function of WebSphere Message Broker so that you are able to create patterns that you can reuse within your organization.

Related tasks:

"Creating a pattern authoring project" on page 1337
Create a pattern authoring project and choose an exemplar for the project.

Select the source files to include in your pattern.

"Defining the target properties" on page 1342
Identify the target properties in the workspace project so that you can define the pattern interface and pattern users can modify the pattern parameters.

"Extending a user-defined pattern" on page 1340
Extend a user-defined pattern to customize its behavior so that it is easier to use or to provide guidance to pattern users.

Editing enumerated types for pattern parameters:

Edit enumerated types to add, remove or rename values in existing enumerated types, or to rename an enumerated type. You can edit an existing user-generated enumerated type to add, remove, or change values and display names within the enumerated type, or to change the name of the enumerated type.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338
- "Defining the target properties" on page 1342
- "Creating enumerated types for pattern parameters" on page 1361

About this task

As part of the pattern authoring process, target properties that use a list of values have enumerated types automatically created for them. You can remove values from this automatically generated list or regenerate the original list of values, but you cannot add new values or edit existing values.

You can duplicate or remove user-generated enumerated types and enumerated types created from target properties.

For enumerated types that you create, you can add, remove, and edit values.

Procedure

To edit enumerated types:

1. In the Pattern Authoring editor, click the **Pattern Configuration** tab. Click **Enumerated Types**. The Configure Enumerated Types window opens.
2. In the **Enumerated type** field, select the enumerated type to edit.
3. You can make the following changes to user-generated enumerated types:
   - Rename the enumerated type. To rename the enumerated type, click **Rename**. The Rename Enumeration window opens. Enter a name for the enumeration and click **OK**. The Rename Enumeration window closes.
   - Add new values. To add a new value, click the **Add** button that is next to the table of values. A new value and display name are added to the table.

- Remove values. To remove a value, select the value to remove and click the **Remove** button that is next to the table of values. The value is removed from the table.

  If a value is the only entry in the table, you cannot remove it.
- Change existing values and display names. To edit a value or display name, double-click the value or display name in the table. Type a new entry and then press Enter to save the new display name or value.
- Duplicate the enumerated type. To duplicate an enumerated type, click **Duplicate**. The duplicate enumerated type is displayed. The name of the duplicate enumerated type is the same as the original, but with _1 added to the end.
- Remove the enumerated type. To remove an enumerated type, click **Remove**. The enumerated type is removed.

  If an enumerated type is being used by a pattern parameter it cannot be removed. You can check if an enumerated type is being used by a parameter in the **This enumerated type is used by the following parameter** field. To modify a parameter so that it does not use an enumerated type, see "Defining the user interface" on page 1343.

4. You can make the following changes to enumerated types that are created from target properties:
   - Rename the enumerated type. To rename the enumerated type, click **Rename**. The Rename Enumeration window opens. Enter a name for the enumeration and click **OK**. The Rename Enumeration window closes.
   - Remove values. To remove a value, select the value to remove and click the **Remove** button that is next to the table of values. The value is removed from the table.

     If a value is the only entry in the table, you cannot remove it.
   - Reset the original values. To restore values you have removed from the list, click **Reset Values**. The original list is displayed.
   - Duplicate the enumerated type. To duplicate an enumerated type, click **Duplicate**. The duplicate enumerated type is displayed. The name of the duplicate enumerated type is the same as the original, but with _1 added to the end.
   - Remove the enumerated type. To remove an enumerated type, click **Remove**. The enumerated type is removed.

     If an enumerated type is being used by a pattern parameter it cannot be removed. You can see if an enumerated type is being used by a parameter in the **This enumerated type is used by the following parameter** field. To modify a parameter so that it does not use an enumerated type, see "Defining the user interface" on page 1343.
5. Repeat the tasks in steps 3 on page 1362 and 4 until your changes are complete. Click **OK**. The Configure Enumerated Types window closes.

What to do next

Next:

You can now build your pattern; see "Building pattern plug-ins" on page 1395.

Related concepts:

"User-defined patterns" on page 1334
A *user-defined pattern* extends the function of WebSphere Message Broker so that you are able to create patterns that you can reuse within your organization.

Related tasks:

"Extending a user-defined pattern" on page 1340
Extend a user-defined pattern to customize its behavior so that it is easier to use or to provide guidance to pattern users.

Modifying pattern instances by using Java or PHP:

Use Java or PHP code to modify pattern instances when the pattern user generates an instance of a user-defined pattern. For example, you can use Java or PHP code to modify the structure of a message flow based on the values of pattern parameters.

When you author user-defined patterns, you can include Java or PHP code to modify pattern instances. This code is run when the pattern user generates an instance of a user-defined pattern and can be used to carry out a number of actions on the pattern.

By using the Java API, you can access all the nodes, connections, and pattern parameters in a user-defined pattern. Examples of changes that you can make by using Java code are:

- Adding, removing, and copying nodes
- Changing connections between nodes
- Renaming nodes
- Changing pattern parameter values and user-defined property values
- Renaming message flows

By using the PHP API for user-defined patterns, you can access the pattern parameters and the pattern instance name of a user-defined pattern. Examples of changes that you can make by using PHP code are:

- Marking up ESQL files to change the operation of the ESQL file depending on the value of pattern parameters
- Taking values from an XML file and using them as pattern parameters
- Changing pattern parameter values
- Renaming message flows
- Running other PHP scripts or Java code

Do not use Java or PHP API code to set the `WSDL file name` property, or any of the properties set by the WSDL file, on a SOAPInput, SOAPRequest, or SOAPAsyncRequest node in your user-defined pattern. To set the `WSDL file name` property, see "Configuring SOAP nodes for user-defined patterns" on page 1351. To modify other properties on these nodes, select the properties as target properties when you create your user-defined pattern. To select target properties, see "Defining the target properties" on page 1342.

Choosing between Java and PHP

WebSphere Message Broker contains a Java to PHP bridge, therefore you can complete some pattern authoring tasks by using either Java or PHP. You can choose which language to use based on the existing skills, assets, or libraries within your organization. The WebSphere Message Broker Toolkit includes code completion and a debugger for Java, which make Java a good choice for longer or more complex code. PHP written in the WebSphere Message Broker Toolkit can be changed and tested without relaunching the workbench, which makes PHP a good choice if you want to change your code and view the results quickly. If you do not have a preference between Java and PHP after considering the skills and assets of your organization and the testing approach, use Java for changes to the structure of the message flow and use PHP to modify text files.

Plug-in packaging

The code you write to modify pattern instances is contained in a separate plug-in from the user-defined pattern. When you create a pattern archive, your code plug-ins are automatically packaged with the generated pattern plug-ins. For more information about packaging user-defined patterns, see "Packaging and distributing pattern plug-ins" on page 1397.

Sequence of actions when a pattern user generates a pattern instance

When a pattern user generates an instance of a user-defined pattern, the following actions occur in sequence:

1. The pattern instance projects are created and all non-message flow files are copied into the workspace.
2. The message flows in the pattern plug-ins are loaded into memory.
3. Pattern parameters that are transformed by using XPath expressions are evaluated. If a pattern parameter is disabled by using an XPath expression, its parameter values are not changed. All target properties are set in all message flows within the user-defined pattern based on pattern parameter values.
4. The Java and PHP code targets are run in top-to-bottom order as they are listed in the Pattern Authoring editor.
5. The message flows are saved into the pattern instance projects.

Creating a code plug-in project:

Create a Java and PHP plug-in project to contain pattern instance modification code.

Before you begin

Before you can complete this task, you must have completed the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338

About this task

You must create a code plug-in project to contain the Java and PHP pattern instance modification code that you write. You can distribute the Java and PHP code plug-in project in the pattern archive for the associated user-defined pattern to pattern users. See "Packaging and distributing pattern plug-ins" on page 1397.

Procedure

To create a Java and PHP code plug-in project:

1. Open the **Pattern Configuration** tab of the Pattern Authoring editor.
2. Click **Add**. The Add Java or PHP Code window opens.
3. Click **New Project**. The New Pattern Authoring Java and PHP Project window opens.
4. Enter a plug-in ID for the new code plug-in. After the plug-in is created, the plug-in ID is shown in the Projects section of the Broker Development view. The plug-in ID is also used to identify the plug-in when you distribute it to pattern users.
5. Optional: If you want to include PHP code in the code plug-in, select **Add PHP support to the project**. If you select this option a `main.php` template and example PHP scripts are added to the code plug-in.
6. Optional: If you want to include a Java class in the code plug-in, complete the following steps:
   a. Select **Add an example pattern authoring Java class to the project**.
   b. Enter a package name for the Java class in the **Package name** field.
   c. Enter a class name for the Java class in the **Class name** field.
7. Click **Finish**. The New Pattern Authoring Java and PHP Project window closes.
8. You can now add Java or PHP code to a user-defined pattern:
   - To add Java code to a user-defined pattern, see "Modifying pattern instances by using the Java API" on page 1367.
   - To add PHP code to a user-defined pattern, see "Modifying pattern instances by using PHP" on page 1389.
   - To return to pattern authoring without adding code, in the Add Java or PHP Code window, click **Cancel**.

Modifying pattern instances by using the Java API:

Add Java code to a code plug-in project to modify a pattern instance when the pattern instance is generated by a pattern user.

Before you begin

Before you can complete this task, you must have completed the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338
- "Creating a code plug-in project" on page 1366

About this task

You can add Java code to a code plug-in project so that it runs when a pattern instance is generated. To add the Java code, select the Java class that you want to run.

The Java class you select can be created in the following ways:

- If you added a Java class when you created the code plug-in, then a template Java class is created and added to the project. This class is based on the Pattern Authoring Class template and contains the basic structure required to function correctly.
- When you follow the steps in this topic to select a Java class, you can optionally create a new Java class. A class created in this way is based on the Pattern Authoring Class template and contains the basic structure required to function correctly.
- You can write your own Java class. This class must implement the `GeneratePatternInstanceTransform` interface.

Regardless of how the class is created, you must add your own code within the class to complete the steps you require when the pattern instance is generated. For examples of Java API code for completing common tasks, see "Examples of Java API code" on page 1369. For reference information about the Java API, see "Java API for user-defined patterns" on page 5345.

Procedure

To select a Java class to run when a pattern instance is generated:

1. If the Add Java or PHP Code window is not open, in the **Pattern Configuration** tab of the Pattern Authoring editor, click **Add**. The Add Java or PHP Code window opens.
2. In the **Type of code** list, select Java.
3. In the **Class name** list, select the name of the class that you want to run when a pattern instance is generated. A class is shown in the **Class name** list if it is in the current workspace and if it implements the `GeneratePatternInstanceTransform` interface.
4. Optional: You can create a new Java class:
   a. Click **New Java Class**. The New Pattern Authoring Java Class window opens.
   b. In the **Source folder** field, click **Browse** and select the folder in which to store the new Java class file.
   c. Optional: In the **Package** field, enter the name of the Java package for the new class. If you leave this field blank, the default package is used.
   d. Optional: Select **Enclosing type** and enter an enclosing type in the **Enclosing type** field.
   e. Enter a name for the new Java class in the **Name** field.
   f. Optional: Change the Superclass for the new Java class in the **Superclass** field.
   g. Optional: To add an interface for the new Java class, click **Add**. The Implemented Interfaces Selection window opens. In the **Choose interfaces** field, enter the name of the interface that you want to add, select the interface in the **Matching items** list and click **OK**. The Implemented Interfaces Selection window closes.
   h. Optional: To remove an interface for the Java class, select the interface in the **Interfaces** list and click **Remove**.
   i. Optional: Click **Next** to view information about the Pattern Authoring Class template, which is used to create the Java class.
   j. Click **Finish**.
5. Click **OK**. The Add Java or PHP Code window closes and the Java class is shown in the Java and PHP Code section of the **Pattern Configuration** tab.
6. Optional: The Java and PHP code listed in the Java and PHP Code section of the **Pattern Configuration** tab runs from top to bottom when a pattern instance is generated. To change the order in which the code is run, select the entry you want to move in the **Java and PHP Code** section and click the **Up** or **Down** button to change the position of the entry in the list.

What to do next

In the Java class that you selected to run when the pattern instance is generated, you must now write the code to perform the steps you require. For examples of Java API code for completing common tasks, see "Examples of Java API code" on page 1369

page 1367 For reference information about the Java API, see "Java API for user-defined patterns" on page 5345. For information about the Java development views and editors within the WebSphere Message Broker Toolkit, see Java Development User Guide plug-in - Views and Editors.

Loading an existing message flow into memory:

Use the Java API to modify a pattern instance to load a message flow into memory and make it available to other Java API methods.

About this task

You must load a message flow into memory to use it with Java API methods within your Java code. To load a message flow into memory, use the getMessageFlow() method of the PatternInstanceManager object, which is automatically passed to your Java code. The getMessageFlow() method takes the message flow project containing the required message flow file and the relative path to the message flow file from this project.

Procedure

- For example, to load a message flow that is in the default schema:

```
public class MyJava implements GeneratePatternInstanceTransform {
    public void onGeneratePatternInstance(PatternInstanceManager patternInstanceManager) {
        MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
        if (mf1 != null) {
           // Message flow was found
        }
        else {
```

```
            // Message flow was not found
        }
    }
}
```

- The following example shows how to load a message flow that is in the mqsi schema:

```
public class MyJava implements GeneratePatternInstanceTransform {
    public void onGeneratePatternInstance(PatternInstanceManager patternInstanceManager) {
        MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "mqsi/main.msg
        if (mf1 != null) {
            // Message flow was found
        }
        else {
            // Message flow was not found
        }
    }
}
```

Results

Result:

You can now refer to the instance of the MessageFlow object in your Java code.

Renaming a node:

Use Java API code to modify a pattern instance to rename a node in a message flow.

About this task

To rename a node, you must first access the required node. You can access the node by using the existing name of the node and the getNodeByName() method. You can then rename the node by using the setNodeName() method, which takes the new node name as a parameter. For example:

Example

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
Node mqinNode = mf1.getNodeByName("My Input Node");
mqinNode.setNodeName("New Input Node");
```

Adding a node and a subflow node:

Use the Java API to modify a pattern instance to add a new node or subflow node to a message flow.

About this task

You can add a new built-in node, or a new subflow node to a message flow.

- When you add a subflow node by using the Java API, you must link the subflow node with the subflow message flow by using the setSubFlow() method of the subflow node object. For example, if you have assigned your subflow message flow to message flow instance *sub1* and you have assigned your subflow node to subflow node instance *sfNode*, you must use the following statement to link the subflow node with the subflow message flow:

  ```
  sfNode.setSubFlow(sub1);
  ```

Procedure

- The following example shows you how to add a new built-in node:

  ```
  MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
  MQInputNode mqinNode = new MQInputNode();
  mqinNode.setNodeName("My Input Node");
  mqinNode.setQueueName("INPUTQ");
  mf1.addNode(mqinNode);
  ```

- The following example shows you how to add a new subflow node to a message flow:

  1. A new subflow node is created and assigned to object *sfNode*.
  2. The subflow node name is set to *My Sub Flow Node*.

3. The subflow node is linked to the subflow message flow by using the setSubFlow() method.
4. The new subflow node is added to the message flow held in object *mf1*.

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
MessageFlow sub1 = patternInstanceManager.getMessageFlow("MyFlowProject", "subflow.msgflow");
SubFlowNode sfNode = new SubFlowNode();
sfNode.setNodeName("My Sub Flow Node");
sfNode.setSubFlow(sub1);
mf1.addNode(sfNode);
```

Setting the position of a node:

Use the Java API to modify a pattern instance to set the position of a node on the canvas in the Broker Development view.

About this task

You can set the position of a node on the canvas by using the setLocation() method of the node object. The following example sets the position of a new MQOutput node to coordinates x=300 pixels, y=100 pixels:

Example

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
MQOutputNode mqoutNode = new MQOutputNode();
mqoutNode.setLocation(300, 100);
```

Copying a node:

Use the Java API to modify a pattern instance to copy a node or subflow node to a message flow.

About this task

You can copy a built-in or subflow node by using the clone() method. In the following example, a new MQInput node *mqinNode* is created and properties on the node are set. A new MQInput node *mqinNode1* is then created by copying *mqinNode* by using the clone() method. When the node is copied, the node properties are also copied:

Example

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
MQInputNode mqinNode = new MQInputNode();
mqinNode.setNodeName("My Input Node");
mqinNode.setQueueName("INPUTQ");
MQInputNode mqinNode1 = (MQInputNode) mqinNode.clone();
mqinNode1.setNodeName("Copy of My Input Node");
mf1.addNode(mqinNode1);
```

Removing a node:

Use the Java API to modify a pattern instance to remove a node from a message flow.

About this task

To remove a node you must first get the required node from the message flow object. In the following example, the getNodeByName() method is used to get the required node from message flow object *mf1*. The node is then removed by using the removeNode() method. When a node is removed, any connections to or from the node are also removed:

Example

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
Node mqinNode = mf1.getNodeByName("My Input Node");
mf1.removeNode(mqinNode);
```

Adding connections between nodes:

Use the Java API to modify a pattern instance to add connections between nodes.

About this task

You can connect both subflow and built-in nodes using the Java API. The first example shows you how to connect two built-in nodes. The second example shows you how to connect a built-in node to a subflow node.

To use the terminals of a subflow node, you must link the subflow node with the subflow message flow by using the setSubFlow() method of the subflow node object. For example, if you have assigned your subflow message flow to message flow instance *sub1* and you have assigned your subflow node to subflow node instance *sfNode*, you must use the following statement to link the subflow node with the subflow message flow:

```
sfNode.setSubFlow(sub1);
```

Procedure

- The following example shows you how to connect two built-in nodes:
  1. A MQInput node and a Collector node are created.
  2. The getInputTerminal() method is used to create a dynamic Input terminal called *NEWIN* on the Collector node.
  3. The Input terminal is connected to the Output terminal of the MQInput node by using the connect() method of the message flow object *mf1*.

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
MQInputNode mqinNode = new MQInputNode();
mqinNode.setNodeName("My Input Node");
mqinNode.setQueueName("INPUTQ");
CollectorNode colNode = new CollectorNode();
colNode.getInputTerminal("NEWIN");
mf1.connect(mqinNode.OUTPUT_TERMINAL_OUT, colNode.getInputTerminal("NEWIN"));
```

  To use a static terminal on a node you must use the appropriate constant defined for it in the API. These constants are listed in the Java API reference, see "Java API for user-defined patterns" on page 5345.

- The following example shows you how to connect a subflow node to a built-in node. You must load the subflow message flow and link it to a subflow node. You must use the getInputTerminal(), getInputTerminals(), getOutputTerminal() or getOutputTerminals() method to access the terminal on the subflow node to which you want to connect. The example code completes the following steps:
  1. The main message flow, `main.msgflow`, and a Compute node in the main message flow are loaded into memory.
  2. The subflow message flow, `subflow.msgflow`, and the subflow node in the main message flow are loaded into memory.
  3. The setSubFlow() method of the subflow node is used to link the subflow message flow *sub1* to the subflow node *sfNode*.
  4. The getOutputTerminal() method is used to get the Process terminal of the subflow node. The connect() method of the message flow object is used to connect this terminal to the Input terminal of the Compute node.

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
ComputeNode compNode = (ComputeNode)mf1.getNodeByName("My Compute Node");
MessageFlow sub1 = patternInstanceManager.getMessageFlow("MyFlowProject", "subflow.msgflow");
SubFlowNode sfNode = (SubFlowNode)mf1.getNodeByName("My Subflow Node");
sfNode.setSubFlow(sub1);
mf1.connect(sfNode.getOutputTerminal("Process"), compNode.INPUT_TERMINAL_IN);
```

WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Adding and connecting user-defined nodes:

Use the Java API to modify a pattern instance to add user-defined nodes and to connect user-defined nodes to other nodes.

About this task

The code required to add and connect user-defined node is different to the code required for built-in nodes and subflow nodes.

When you write Java code for user-defined nodes you must be aware of the following information:

- User-defined nodes are supported by instances of the GenericNode class. To add user-defined nodes to message flows, create instances of GenericNode and add them to the message flow instance.
- To retrieve existing instances of a user-defined node, call getNodeByName() and cast the returned object to a GenericNode object.
- The terminals defined on your user-defined nodes are not automatically available in the Java API. If you create an instance of a GenericNode class, it does not have any input or output terminals listed. The methods getInputTerminals() and getOutputTerminals() return empty lists.
- To get an input terminal for a GenericNode, call getInputTerminal() and pass the terminal name that exists on the generic node. This method returns the input terminal and makes it available in the message flow object that contains your generic node. After you have used getInputTerminal() with a known terminal name, this input terminal is returned if getInputTerminals() is used.
- To get an output terminal for a GenericNode, call getOutputTerminal() and pass the terminal name that exists on the generic node. This method returns the output terminal and makes it available in the message flow object that contains your generic node. After you have used getOutputTerminal() with a known terminal name, this output terminal is returned if getOutputTerminals() is used.

Example

The following example shows how you can add a user-defined node to a message flow and connect it to a built-in node:

1. An MQInput node is created and added to the message flow.
2. A user-defined node is created by using the GenericNode class and is added to the message flow object.
3. The static output terminal of the MQInput is assigned to the variable *outputTerminal*.
4. The input terminal of the user-defined node is assigned to the variable *inputTerminal* by using the getInputTerminal() method with the known terminal name *In*.
5. The nodes are connected by using the connect() method.
6. The final section of code shows that the input node is now available for use in the message flow, by using the getInputTerminals() method of the user-defined node instance.

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");

MQInputNode mqinNode = new MQInputNode();
mqinNode.setNodeName("My Input Node");
mqinNode.setQueueName("IN");
mf1.addNode(mqinNode);

GenericNode myNode = new GenericNode("MyUserDefinedNode");
myNode.setNodeName("MyNode");
mf1.addNode(myNode);

OutputTerminal outputTerminal = mqinNode.OUTPUT_TERMINAL_OUT;
InputTerminal inputTerminal = myNode.getInputTerminal("In");
mf1.connect(outputTerminal, inputTerminal);

InputTerminal[] inputTerminals = myNode.getInputTerminals();
System.out.println("Input terminals on my node:");
for (int i = 0; i < inputTerminals.length; i++) {
   InputTerminal inputTerminal = inputTerminals[i];
   System.out.println(inputTerminal.getName());
}
```

Creating or changing user-defined properties:

Use the Java API to modify a pattern instance to create or change user-defined properties (UDPs).

About this task

You can create new UDPs and add them to the message flow, or you can discover existing UDPs and modify them.

Procedure

- The following example shows you how to create a UDP and add it to a message flow:
  1. A UDP called `Property1` is created in parameter group `Group1`. The data type of the UDP is defined as a string and the UDP is given the default value `Hello World!`
  2. The UDP is then added to the message flow by using the addFlowProperty() method.

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
UserDefinedProperty udp = new UserDefinedProperty("Group1", "Property1", UserDefinedProperty.Usage
mf1.addFlowProperty(udp);
```

- In the following example, the existing UDPs in a message flow are discovered by using the getFlowProperties() method on the message flow. The setName() method is then used to set the name of the first UDP to `Property3`:

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
Vector<FlowProperty> flowProperties = mf1.getFlowProperties();
flowProperties.get(0).setName("Property3");
```

Creating ESQL modules:

Use the Java API to modify a pattern instance to create ESQL modules. You can then associate ESQL modules with nodes that use ESQL. For example, if you create a Compute node, you can use the Java API to create an ESQL module and then associate that module with the node.

About this task

Examples of nodes that use ESQL are Compute, Database, DatabaseInput, and Filter nodes. If you are using a non-default broker schema, you must set the

schema by using the setBrokerSchema() method.

Procedure

- The following example shows you how to create an ESQL module in the mqsi schema. The module is then assigned to a new Compute node by using the setComputeExpression() method:

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
ESQLModule module = new ESQLModule();
module.setBrokerSchema("mqsi");
module.setEsqlMain("MyESQLMain");
ComputeNode compNode = new ComputeNode();
compNode.setNodeName("My Compute Node");
compNode.setComputeExpression(module);
mf1.addNode(compNode);
```

- The following example shows you how to create an ESQL module in the default schema. The setBrokerSchema() method is not required.

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
ESQLModule module = new ESQLModule();
module.setEsqlMain("MyESQLMain");
ComputeNode compNode = new ComputeNode();
compNode.setNodeName("My Compute Node");
compNode.setComputeExpression(module);
mf1.addNode(compNode);
```

- The following example shows you how to discover an ESQL module from within an ESQL file by using the getEsqlModules() method. You can then use the ESQL module to set the compute expression on a Compute node by using the setComputeExpression() method.

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
File esql = new File("FileBatchProcessingSample_Branch.esql");
ESQLFile esqlFile = new ESQLFile(esql);
Vector<ESQLModule> esqlModules = esqlFile.getEsqlModules();
ComputeNode compNode = new ComputeNode();
compNode.setNodeName("My Compute Node");
compNode.setComputeExpression(esqlModules.get(0));
mf1.addNode(compNode);
```

Renaming a message flow:

Use the Java API to modify a pattern instance to rename message flows.

About this task

You can write code to rename a message flow by using the setName() method. In the following example, a message flow file called `main.msgflow` is renamed to `mainGenerated.msgflow`:

Example

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
mf1.setName(mf1.getName()+"Generated");
```

Running PHP code using the Java API:

Use the Java API to modify a pattern instance to run PHP scripts from within your Java code.

About this task

You can run PHP scripts from within the Java API by using the runScript() method of the PatternInstanceManager object. In the following example, the Java API runs a PHP script in the `com.your.company.domain.code` plug-in, `templates/script.php`:

Example

```
@Override
public void onGeneratePatternInstance (PatternInstanceManager patternInstanceManager) {
 patternInstanceManager.runScript("com.your.company.domain.code", "templates/script.php");
}
```

Related concepts:

Updating filter tables on Route nodes:

Use the Java API to modify a pattern instance to update filter tables on Route nodes.

About this task

You can add and update rows on the filter table of a Route node.

Adding a new row

The following example shows you how to add a new row to a filter table by using the createRow() method:

1. The message flow and the Route node are loaded into memory.
2. The filter table of the Route node is loaded into memory by using the getFilterTable() method of the RouteNode object.
3. A new filter table row is created by using the createRow() method.
4. The value of the `filter pattern` property on this new row is set to `value="123"` by using the setFilterPattern() method.
5. The `routing output terminal` property is set to `NEWOUT` by using the setRoutingOutputTerminal() method.
6. The new row is then added to the filter table by using the addRow() method.

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
RouteNode routeNode = (RouteNode)mf1.getNodeByName("My Route Node");
RouteNode.FilterTable filterTable = (RouteNode.FilterTable)routeNode.getFilterTable();
RouteNode.FilterTableRow newRow = filterTable.createRow();
newRow.setFilterPattern("value=\"123\"");
newRow.setRoutingOutputTerminal("NEWOUT");
filterTable.addRow(newRow);
```

Updating a row

The following example shows you how to update rows on the filter table of a Route node.

1. The message flow, Route node, and filter table of the Route node are loaded into memory.
2. The rows of the filter table are loaded into memory by using the getRows() method.
3. The `filter pattern` property of the first row of the filter table is set to `value2="456"`.
4. The `routing output terminal` property of the first row of the filter table is set to `NEWOUT2`.

```
MessageFlow mf1 = patternInstanceManager.getMessageFlow("MyFlowProject", "main.msgflow");
RouteNode routeNode = (RouteNode)mf1.getNodeByName("My Route Node");
RouteNode.FilterTable filterTable = (RouteNode.FilterTable)routeNode.getFilterTable();
Vector<RouteNode.FilterTableRow> filterTableRows = filterTable.getRows();
filterTableRows.get(0).setFilterPattern("value2=\"456\"");
filterTableRows.get(0).setRoutingOutputTerminal("NEWOUT2");
```

"Java API for user-defined patterns" on page 5345
Use the Java API to write Java code to modify user-defined pattern instances.

Testing Java code:

After writing Java code to modify pattern instances, test the code to check that it works correctly.

Before you begin

Before you test your Java code, you must build the pattern plug-ins; see "Building pattern plug-ins" on page 1395.

About this task

You can test your Java code either by creating an instance of a pattern and checking that it is modified as you expect or by using the Java debugger to step through the code.

Procedure

- To test your user-defined pattern by creating an instance of the pattern, see "Testing a user-defined pattern" on page 1396.
- To use the Java debugger, you must open a temporary workspace to generate an instance of your user-defined pattern, then return to the original workspace to step through the code. To use the Java debugger, complete the following steps:
  1. In your Java code file, add a breakpoint to the required line of code. To add a breakpoint, right-click the marker bar (vertical ruler) to the left of the required code and click **Toggle Breakpoint**.
  2. In the Pattern Authoring editor, click the **Create Pattern** tab.
  3. Click **Debug Pattern**. The Workspace Launcher window opens.
  4. Select the temporary workspace in which to generate an instance of your user-defined pattern. Click **Browse** and select a workspace or enter a workspace in the **Workspace** field. Click **OK**. The selected workspace opens.
  5. In the temporary workspace, you must generate an instance of your user-defined pattern. In the Broker Development view, click the **Patterns Explorer** tab and select your user-defined pattern.
  6. In the **Pattern Specification** tab, click **Create New Instance**. Enter a name for the instance of your user-defined pattern and click **OK**.
  7. Enter any mandatory pattern parameters and click **Generate**. The generation of the pattern instance stops when it reaches the breakpoint in your Java code.

8. In the original workspace, in the Confirm Perspective Switch window, click **Yes**. The original workspace switches to debug mode and shows the code paused at your breakpoint.
9. You can now use the Java debugger to test your code; see "Java Debugger" on page 6723.
10. When you have finished testing the code in the Java debugger, close the temporary workspace and switch back to the Broker Application Development perspective in the original workspace; see "WebSphere Message Broker Toolkit perspectives" on page 34.

What to do next

Next:

You can either change your Java code and retest it or you can package and distribute your user-defined pattern:

- To change and retest your Java code, edit the code file and then repeat the steps in this topic.
- To package and distribute your user-defined pattern, see "Packaging and distributing pattern plug-ins" on page 1397

To ensure that changes in your Java code are included in your generated pattern, change the version number of the Java plug-in, as described in the following steps.

1. Update the version number of the Java plug-in in `manifest.mf`.
2. Update the version number of the pattern on the **Create Pattern** tab.
3. Re-create the pattern plug-ins and pattern archive, as described in "Building pattern plug-ins" on page 1395.

   To check that the pattern archive contains the correct versions of the plug-ins, you can look at the `feature.xml` file.
4. Install the pattern.

Modifying pattern instances by using PHP:

Add PHP code to a code plug-in project to modify a pattern instance when the pattern instance is generated by a pattern user.

Before you begin

Before you can complete this task, you must have completed the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338
- "Creating a code plug-in project" on page 1366

About this task

You can add PHP code to a code plug-in project by selecting a PHP script, which runs when a pattern instance is generated. You can choose whether to write the output of this script to a file. For example, you can write a PHP script that creates an ESQL file that is used in your user-defined pattern.

If you added PHP support when you created the code plug-in, a PHP template and example scripts are created and added to the project. Alternatively, you can write your own PHP script. Regardless of how the script is created, you must add your own code within the script to complete the steps you require when the pattern instance is generated. For examples of PHP code for completing common tasks, see "Examples of PHP API code" on page 1390. For reference information about the PHP pattern authoring API, see "PHP API for user-defined patterns" on page 5345.

Procedure

To select a PHP script to run when a pattern instance is generated:

1. If the Add Java or PHP Code window is not open, in the **Pattern Configuration** tab of the Pattern Authoring editor, click **Add**. The Add Java or PHP Code window opens.
2. In the **Type of code** list, select PHP.
3. In the **Project name** list, select the project or plug-in that contains the PHP script that you want to run when a pattern instance is generated. If the required plug-in is installed, but is not in your workspace, click **Browse** and select the required plug-in.
4. In the **PHP file name** list, select the name of the script you want to run when a pattern instance is generated. The **PHP file name** list shows all the PHP scripts in the project or plug-in that you selected.
5. Optional: To write the output of the PHP script to a file, select **Write the output from the PHP file into an output file**.
   a. In the **Pattern instance project** list, select the pattern instance project in which you want to include the output file.
   b. In the **Output file name** field, enter a name for the output file. You can include a path in this field, for example `scripts/example.mqsc` to write the output to the `scripts` folder.
6. Click **OK**. The Add Java or PHP Code window closes and the PHP script that you selected is shown in the **Java and PHP Code** section of the **Pattern Configuration** tab.

7. Optional: The Java and PHP code listed in the Java and PHP Code section of the **Pattern Configuration** tab runs from top to bottom when a pattern instance is generated. To change the order in which the code runs, select the entry you want to move in the Java and PHP Code section and click the **Up** or **Down** button to change the position of the entry in the list.

What to do next

Next:

In the PHP script that you selected to run when the pattern instance is generated, you must now write the code to perform the steps you require. For examples of PHP code for completing common tasks, see "Modifying pattern instances by using PHP" on page 1389. Related reference:

"PHP API for user-defined patterns" on page 5345
Use the PHP API to write PHP code to develop user-defined pattern applications.

Examples of PHP API code:

Use the following examples of PHP API code for common tasks to help you write your own PHP code to modify pattern instances.

About this task

The following examples show PHP code that you can use to complete common tasks when you are creating user-defined patterns:

Procedure

- Running additional PHP scripts. The following example shows how to use a PHP script to run another PHP script, by using the mb_pattern_run_template() function. The mb_pattern_run_template() function uses the following parameters:
  1. The first parameter required by mb_pattern_run_template() is the name of the project containing the PHP template; `Transform` in this example.
  2. The second parameter required by mb_pattern_run_template() is the name of the PHP script to run; in this example `example.esql.php`, which is in a subfolder called `mqsi`.
  3. The third parameter required by mb_pattern_run_template() is the name of the file to which the output is written; in this example `example.esql`, in subfolder `mqsi`.

  The user-defined pattern in this example contains a Boolean pattern parameter called `includeErrorHandling`. This pattern parameter is used to create a check box in the pattern:

```
<?php
    if ($_MB['PP']['includeErrorHandling'] == 'true') {
        mb_pattern_run_template("Transform", "mqsi/example.esql.php", "mqsi/example.esql");
    }
?>
```

- Using PHP scripts with markup for ESQL. In the following example, the user-defined pattern contains a pattern parameter called `errorQueue`, which can contain the values `none` or `errorAction`:

```
BROKER SCHEMA mqsi
<?php
    if ($_MB['PP']['errorAction'] == 'errorQueue') {
        echo "DECLARE ErrorAction EXTERNAL CHARACTER '".$_MB['PP']['errorAction']."';";

        echo <<<ESQL

        CREATE FILTER MODULE CheckErrorAction
            CREATE FUNCTION Main() RETURNS BOOLEAN
            BEGIN
                IF ErrorAction = 'errorQueue' THEN
                    RETURN TRUE;
                ELSE
                    RETURN FALSE;
                END IF;
            END;
        END MODULE;

        ESQL;
    }
?>
```

- Using PHP scripts to remove files from a project. In the following example, the script first checks the value of the check box pattern parameter, which has the pattern parameter ID `pp1`. If this parameter is set to `false`, the script deletes the `Log.msgflow` and `Log.esql` files from the pattern instance project. Message flow files must be deleted by using the removeMessageFlow() function. Non-message flow files can be deleted by using the standard PHP function unlink():

```
if ($_MB['PP']['pp1'] == 'false') {

    $pim = $_MB["PATTERN_INSTANCE_MANAGER"];

    $logmsgflow = $pim->getMessageFlow("Example_Flows", "mqsi/Log.msgflow");
    $pim->removeMessageFlow($logmsgflow);

    $piworkspace = $pim->getWorkspaceLocation();
```

```
    $piname = $pim->getPatternInstanceName();
    $logesql = $piworkspace . "/" . $piname . "_Example_Flows/mqsi/Log.esql";
    unlink($logesql);
}
```

- Running Java code from PHP by using a static Java method. The following example shows a Java class, *MyClass*, that can be run from within a PHP script. The class contains a static method:

```
package com.your.company.domain.code;

import com.ibm.broker.config.appdev.MessageFlow;
import com.ibm.broker.config.appdev.patterns.GeneratePatternInstanceTransform;
import com.ibm.broker.config.appdev.patterns.PatternInstanceManager;

public class MyClass implements GeneratePatternInstanceTransform {

    public static void doSomethingUseful(String message) {
        System.out.println("Message received [" + message + "]");
    }

    @Override
    public void onGeneratePatternInstance(PatternInstanceManager patternInstanceManager) { }
}
```

  You can run the *MyClass* class from PHP as shown in the following example. In the line `$class = $pim->getPluginClass("com.your.company.domain.code", "com.your.company.domain.code.MyClass")`, the first argument, `com.your.company.domain.code`, is the ID of the plug-in that contains the Java class. The second argument, `com.your.company.domain.code.MyClass`, is the name of the class.

```
<?php
    $pim = $_MB["PATTERN_INSTANCE_MANAGER"];
    $class = $pim->getPluginClass("com.your.company.domain.code", "com.your.company.domain.code.My
    java_import("com.your.company.domain.code.MyClass");
    MyClass::doSomethingUseful("Hello!");
?>
```

- Running Java code from PHP by using a non-static Java method. The following example shows a Java class, *MyClass*, that can be run from within a PHP script. The class contains a method that is not static:

```
package com.your.company.domain.code;

import com.ibm.broker.config.appdev.MessageFlow;
import com.ibm.broker.config.appdev.patterns.GeneratePatternInstanceTransform;
import com.ibm.broker.config.appdev.patterns.PatternInstanceManager;

public class MyClass implements GeneratePatternInstanceTransform {

   public void doSomethingUseful(String message) {
      System.out.println("Message received [" + message + "]");
   }

   @Override
   public void onGeneratePatternInstance(PatternInstanceManager patternInstanceManager) { }
}
```

  You can run the *MyClass* class from PHP as shown in the following example. In the line `$class = $pim->getPluginClass("com.your.company.domain.code", "com.your.company.domain.code.MyClass")`, the first argument, `com.your.company.domain.code`, is the ID of the plug-in that contains the Java class. The second argument, `com.your.company.domain.code.MyClass`, is the name of the class. A new instance of the class is created in the line `$obj = $class->newInstance()`. In the last line of the example, the `doSomethingUseful()` method of the class is run.

```
<?php
    $pim = $_MB["PATTERN_INSTANCE_MANAGER"];
    $class = $pim->getPluginClass("com.your.company.domain.code", "com.your.company.domain.code
    $obj = $class->newInstance();
    $obj->doSomethingUseful("Hello!");
?>
```

- Using PHP scripts to read table values. In the following example, the PHP script extracts the values from an array stored in the superglobal variable *$_MB*. First the script searches inside the array for any values stored in the *event* and *response* variables, and then returns the values:

```
<?php
 $pim = $_MB["PATTERN_INSTANCE_MANAGER"];
 $table = $pim->getParameterTable("table1");
 $count = $table->getRowCount();
 for ($j=0;$j<$count ;$j++ ) {
  echo "".$_MB['PP']['table1'][$j]['event']."';\n";
  echo "".$_MB['PP']['table1'][$j]['response']."';\n";
 }
?>
```

  The array has the following structure:

```
array(4) {
 ["PATTERN_INSTANCE_MANAGER"]=>
 object(Java)#1 (0) {
 }
 ["PP"]=>
  array(10) {
   ["queueName"]=>string(11) "QP.QUEUE.QS"
   ["configurePrefixSuffix"]=>string(5) "false"
   ["queuePrefix"]=>string(3) "QP."
   ["queueSuffix"]=>string(3) ".QS"
   ["logging"]=>string(5) "queue"
   ["generateMessageSet"]=>string(4) "true"
   ["table1"]=>
   array(2) {
     [0]=>
      array(2) {
     ["event"]=>string(6) "event1"
     ["response"]=>string(9) "response1"
      }
     [1]=>
      array(2) {
     ["event"]=>string(6) "event2"
     ["response"]=>string(9) "response2"
      }
   }
 }
```

After writing PHP code to modify pattern instances, test the code to check that it works correctly.

Related reference:

"PHP API for user-defined patterns" on page 5345
Use the PHP API to write PHP code to develop user-defined pattern applications.

Testing PHP API code:

After writing PHP code to modify pattern instances, test the code to check that it works correctly.

Before you begin

Before you test your PHP code, you must build the pattern plug-ins; see "Building pattern plug-ins" on page 1395.

About this task

You can check that your PHP scripts work correctly by creating an instance of your user-defined pattern. When you test your user-defined pattern, a new workspace is opened in which to create the instance of your pattern. If you want to change your PHP code and retest it, you are not required to open a new workspace after each change. If you make any other changes to the pattern authoring project, you must rebuild the pattern plug-ins and launch a new workspace.

Procedure

To test your user-defined pattern, see "Testing a user-defined pattern" on page 1396. A new workspace is opened in which you generate an instance of your user-defined pattern. After the pattern instance is generated, check that your PHP code has worked correctly. For example, if you write PHP code to remove files from a pattern instance project, check that the files are deleted.

What to do next

Next:

You can either change your PHP code and retest it or you can package and distribute your user-defined pattern:

- To change and retest your PHP code, repeat the following steps until all your changes are complete. You can keep the test workspace open and continue to change your code and generate pattern instances without closing and relaunching the test workspace after each change:
  1. Edit the PHP code file in your main workspace and save the file.
  2. In the test workspace, generate a new instance of your user-defined pattern and check the results.
- To package and distribute your user-defined pattern, see "Packaging and distributing pattern plug-ins" on page 1397.

Extend a user-defined pattern to customize its behavior so that it is easier to use or to provide guidance to pattern users.

"Modifying pattern instances by using PHP" on page 1389
Add PHP code to a code plug-in project to modify a pattern instance when the pattern instance is generated by a pattern user.

"Building pattern plug-ins"
You must build the pattern plug-ins before you can distribute user-defined patterns to pattern users.

"Testing a user-defined pattern" on page 1396
Ensure that you test your user-defined pattern before you share it with your pattern users.

Building pattern plug-ins

You must build the pattern plug-ins before you can distribute user-defined patterns to pattern users.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338

About this task

Procedure

To build the pattern plug-ins:

1. In the Pattern Authoring editor, click the **Create Pattern** tab.
2. Enter values in the **Plug-in ID** and **Version** fields for your plug-in according to the naming and version numbering conventions within your organization. For more information about naming conventions for Eclipse plug-ins, see http://wiki.eclipse.org/Naming_Conventions. For more information about version numbering conventions for Eclipse plug-ins, see http://wiki.eclipse.org/Version_Numbering.
3. Optional: Select **Create translation plug-ins**, if required.
4. Click **Create Pattern Plug-ins**.

   The plug-ins for your user-defined pattern are created and displayed in the Projects section of the Broker Development view. The plug-ins are named *PluginID*, and *PluginID*.doc, where *PluginID* is the value entered in the **Plug-in ID** field in the **Create Pattern** tab. If **Create translation plug-ins** is selected, two additional plug-ins are created, named *PluginID*.nl1 and *PluginID*.nl1.doc.

What to do next

Next:

You must now test the pattern, see "Testing a user-defined pattern" on page 1396.

Related concepts:

"User-defined patterns" on page 1334
A *user-defined pattern* extends the function of WebSphere Message Broker so that you are able to create patterns that you can reuse within your organization.

The workflow showing the actions required for pattern authoring.

Related tasks:

"Creating a pattern authoring project" on page 1337
Create a pattern authoring project and choose an exemplar for the project.

"Selecting the source files to use for a user-defined pattern" on page 1338
Select the source files to include in your pattern.

Testing a user-defined pattern

Ensure that you test your user-defined pattern before you share it with your pattern users.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a pattern authoring project" on page 1337
- "Selecting the source files to use for a user-defined pattern" on page 1338
- "Building pattern plug-ins" on page 1395

About this task

Before you distribute your user-defined pattern, you can test it to ensure that it works correctly. To test your user-defined pattern, the Pattern Authoring editor opens a temporary workspace in which you can generate an instance of your user-defined pattern. You can then check that your user-defined pattern works correctly. If your user-defined pattern contains Java pattern authoring API code, see "Testing Java code" on page 1387. If your user-defined pattern contains PHP pattern authoring API code, see "Testing PHP API code" on page 1394.

Procedure

To test your user-defined pattern:

1. In the Pattern Authoring editor, click the **Create Pattern** tab.
2. Click **Test Pattern**. The Workspace Launcher window opens.
3. Select the temporary workspace in which to generate an instance of your user-defined pattern. Click **Browse**. Select a workspace or enter a workspace in the **Workspace** field. Click **OK**. The selected workspace opens.
4. Click the **Patterns Explorer** tab in the Broker Development view. Your new user-defined pattern is shown in the Patterns Explorer view.
5. Test your pattern by generating a new pattern instance. See "Using patterns" on page 1312.
6. If you want to change your pattern, change the pattern authoring project and then rebuild the pattern plug-ins. If you are changing only Java or PHP pattern authoring API code, you do not have to rebuild the pattern plug-ins; see "Testing Java code" on page 1387 and "Testing PHP API code" on page 1394.

What to do next

Next:

After you have tested the pattern, you can share it with the pattern users, see "Packaging and distributing pattern plug-ins."

Use Java or PHP code to modify pattern instances when the pattern user generates an instance of a user-defined pattern. For example, you can use Java or PHP code to modify the structure of a message flow based on the values of pattern parameters.

Related tasks:

"Creating a pattern authoring project" on page 1337
Create a pattern authoring project and choose an exemplar for the project.

"Selecting the source files to use for a user-defined pattern" on page 1338
Select the source files to include in your pattern.

"Building pattern plug-ins" on page 1395
You must build the pattern plug-ins before you can distribute user-defined patterns to pattern users.

Packaging and distributing pattern plug-ins

Package the plug-ins for your user-defined pattern into a pattern archive so that pattern users can download and install the pattern on their own system.

Before you begin

Before you start:

Before you can complete this task, you must have completed the following tasks for your user-defined pattern:

1. "Creating a pattern authoring project" on page 1337
2. "Selecting the source files to use for a user-defined pattern" on page 1338
3. "Building pattern plug-ins" on page 1395
4. "Testing a user-defined pattern" on page 1396

About this task

To enable pattern users to use your user-defined pattern, you must create a pattern archive from the pattern plug-ins. The pattern archive is published to a pattern community site, which is either a website or shared file system directory. The pattern user can download and install the pattern archive from the pattern community site. The following tasks describe this process:

- The pattern author creates a pattern archive, see "Creating a pattern archive" on page 1398.
- The pattern author uploads the pattern archive to a patterns community site, see "Uploading a pattern archive" on page 1399.

- The pattern user downloads and installs the pattern archive, see “Downloading and installing a pattern archive” on page 1400.

If you want to uninstall a user-defined pattern, see “Uninstalling a pattern archive” on page 1405.

Related concepts:

“User-defined patterns” on page 1334
A *user-defined pattern* extends the function of WebSphere Message Broker so that you are able to create patterns that you can reuse within your organization.

“Creating a user-defined pattern” on page 1336
The workflow showing the actions required for pattern authoring.

Creating a pattern archive:

Package your user-defined pattern as a pattern archive so that you can distribute it to pattern users.

Before you begin

Before you start:

Before you can complete this task, you must have completed the following tasks:

- “Creating a pattern authoring project” on page 1337
- “Selecting the source files to use for a user-defined pattern” on page 1338
- “Building pattern plug-ins” on page 1395
- “Testing a user-defined pattern” on page 1396

About this task

When you have tested your user-defined pattern and you are satisfied with its content and quality, package it into a pattern archive so that you can distribute it to your pattern users.

Procedure

To package your user-defined pattern into a pattern archive, complete the following tasks:

1. Open your pattern instance project, click the **Create Pattern** tab.
2. In the Pattern Distribution section, click **Create Pattern Archive**. The "Create a Pattern Archive" window opens.

   The **File name** defaults to the first segment of the pattern project name appended by `.patternzip`
3. To select a location, click **Browse**, and navigate to the required location. The **Location** is the file system location to which the pattern archive is saved. If you want to publish the pattern archive directly to a pattern community shared file system location to which you have write access, select that location.
4. Click **Finish**. A progress monitor is displayed at the bottom of the window.
   - If you click **Cancel** while the creation process is being run, the progress monitor stops and a warning message is displayed saying that the operation has stopped and the pattern archive will not be created. You can choose to restart the creation process by clicking **Finish**, or cancel the creation process by clicking **Cancel**. If the pattern archive has already been created, it is

removed from the target location and its resources are deleted from the workspace. If you click **Cancel** again, the window is closed.

- If an error occurs during the creation process, for example, the disk is full, or a write access permissions problem has occurred, an error message is displayed. You can correct the problem without exiting the window, and try again.

If the process completes successfully, the window closes.

Results

The pattern plug-ins and features are generated in the workspace. If the plug-ins already exist in the workspace, you are asked if you want to overwrite them; if you have already created the `.doc` plug-in or your translated files, you might choose not to overwrite the plug-ins. The pattern is temporarily displayed in the Patterns Explorer view. A pattern archive with the extension `.patternzip` is created in the target location.

What to do next

Next:

- If you published the pattern archive directly to a pattern community shared file system location, pattern users can now download the pattern archive, see "Downloading from a shared file system" on page 1404.
- If you did not publish the pattern archive directly to a pattern community shared file system location, you can upload the pattern archive to a pattern community site to distribute the pattern archive to pattern users, see "Uploading a pattern archive."

Related concepts:

Uninstall the pattern archive to remove a user-defined pattern from the Patterns Explorer view.

Uploading a pattern archive:

The pattern author can upload a pattern archive to a pattern community site so that it can be distributed to pattern users.

Before you begin

Before you start:

Before you can complete this task, the pattern author must have completed the following task:

- "Creating a pattern archive" on page 1398

About this task

To publish a user-defined pattern, the pattern author must upload the pattern archive to a pattern community site, which is either a pattern community website or a pattern community shared file system location. To upload to a pattern community website, the pattern author must have write access to the website.

Procedure

- To upload to a pattern community website:
  - If the pattern community website supports the upload interface, the pattern author can specify the pattern metadata, for example, category, icon, and description, and then upload the pattern archive to the pattern community website.
  - If the pattern community website does not support the upload interface, the pattern archive must be passed to the administrator of the pattern community website so that it can be published.
- To upload to a pattern community shared file system location:
  - If the pattern author has write access to the shared file location, that location can be selected when the pattern archive is created. See "Creating a pattern archive" on page 1398.
  - If the pattern author does not have write access to the shared file location, the pattern archive must be passed to the administrator of the shared file location so that it can be published.

What to do next

Next:

The pattern user can now download and install the pattern archive, see "Downloading and installing a pattern archive."

Related concepts:

"User-defined patterns" on page 1334

To use a user-defined pattern, download and install the pattern archive for the user-defined pattern.

"Uninstalling a pattern archive" on page 1405
Uninstall the pattern archive to remove a user-defined pattern from the Patterns Explorer view.

Downloading and installing a pattern archive:

To use a user-defined pattern, download and install the pattern archive for the user-defined pattern.

Before you begin

Before you start:

Before you can complete this task, you must decide which user-defined pattern you want to use from a pattern community site.

About this task

Before you can update a pattern archive to a newer version of an installed pattern archive, you must uninstall the current version of the pattern archive, see "Uninstalling a pattern archive" on page 1405.

When you have chosen a user-defined pattern that you want to use from a pattern community site, download and install the pattern archive for that user-defined pattern to your local system by using one of the following methods:

- "Downloading from a pattern community website"
- "Downloading from a pattern community website by using a helper application" on page 1402
- "Downloading from a shared file system" on page 1404

What to do next

Next:

You can now use the user-defined pattern in your projects, see "Using patterns" on page 1312.

Related concepts:

"User-defined patterns" on page 1334

Related tasks:

"Uninstalling a pattern archive" on page 1405
Uninstall the pattern archive to remove a user-defined pattern from the Patterns Explorer view.

Downloading from a pattern community website:

To use a user-defined pattern in your WebSphere Message Broker projects, download and install the pattern archive for the user-defined pattern from a pattern community website.

Before you begin

Before you start:

Before you can complete this task, you must have the URL of the user-defined pattern that you want to download.

In this installation use case, only HTTP URLs that have no security are supported.

About this task

If you want to stop the download process, click **Cancel**, the pattern is not installed and the tasks are rolled back. If you click **Cancel** again, the Download Pattern window closes.

Procedure

1. In the Patterns Explorer view, click **Download**. The Download and Install Pattern window opens.
2. Type in, or copy and paste, the complete URL for the pattern archive into the **File Location** field, click **Download**. The progress monitor starts to run and the status line shows the individual tasks that are being performed.

Results

The new user-defined pattern is displayed in the Patterns Explorer view.

What to do next

Next:

You can now use the user-defined pattern in your projects. See "Using patterns" on page 1312.

Related concepts:

"User-defined patterns" on page 1334
A *user-defined pattern* extends the function of WebSphere Message Broker so that you are able to create patterns that you can reuse within your organization.

Related tasks:

"Downloading from a pattern community website by using a helper application"
To use a user-defined pattern in your WebSphere Message Broker projects, download and install the pattern archive for the user-defined pattern from a pattern community website by using a helper application.

"Downloading from a shared file system" on page 1404
To use a user-defined pattern in your WebSphere Message Broker projects, download and install the pattern archive for the user-defined pattern from a pattern community site that is a shared file system by using the file URL or by browsing for a file.

"Uninstalling a pattern archive" on page 1405
Uninstall the pattern archive to remove a user-defined pattern from the Patterns Explorer view.

Downloading from a pattern community website by using a helper application:

To use a user-defined pattern in your WebSphere Message Broker projects, download and install the pattern archive for the user-defined pattern from a pattern community website by using a helper application.

Before you begin

Before you start:

Before you can complete this task, you must be on the pattern community website that contains the pattern archive that you want to download.

About this task

You can install a pattern archive directly from a pattern community website by using a helper application.

Procedure

1. Navigate to the pattern archive that you want to download.
2. Click the link for the required pattern archive. A new window opens. The content of the window depends on your browser, but the typical options are to either open the file or save the file.
3. Install the pattern archive:
   - Windows On Windows:

     Select the option to open the pattern archive. The Install Pattern Archive window opens and shows a progress monitor.

     If you have more than one WebSphere Message Broker Toolkit installed on your workstation, the helper application is for the WebSphere Message Broker Toolkit that you most recently installed. If you want to control which WebSphere Message Broker Toolkit is extended with your pattern, download the file to disk, follow the instructions in "Downloading from a shared file system" on page 1404, then start the WebSphere Message Broker Toolkit that you want to extend.
   - Linux On Linux:

     The exact steps you must complete to install the pattern archive depend on your Linux distribution and the file explorer and browser you use. Use the following steps as a guide.

     a. Save the pattern archive to your local file system. Select the option in your browser window to save the pattern archive to your local file system. Choose a location for the file and start the download.

     b. After the download completes, open the pattern archive with the **MBPatternInstaller** helper application. Open a file explorer and navigate to the pattern archive. Use the **Open with** menu option on the pattern archive and select `MBPatternInstaller.bin`. The MBPatternInstaller application is located in the WebSphere Message Broker Toolkit installation directory, for example, `/opt/IBM/WMBT700`. The Install Pattern Archive window opens and shows a progress monitor.
4. Close and relaunch the WebSphere Message Broker Toolkit.

Results

The new user-defined pattern is displayed in the Patterns Explorer view.

What to do next

Next:

You can now use the user-defined pattern in your projects. See "Using patterns" on page 1312.

Uninstall the pattern archive to remove a user-defined pattern from the Patterns Explorer view.

Downloading from a shared file system:

To use a user-defined pattern in your WebSphere Message Broker projects, download and install the pattern archive for the user-defined pattern from a pattern community site that is a shared file system by using the file URL or by browsing for a file.

Before you begin

Before you start:

Before you can complete this task, you must have access to the pattern community site that contains the pattern archive that you want to download.

About this task

- If you want to download and install the pattern archive for the user-defined pattern from a pattern community website by using a helper application and you have more than one WebSphere Message Broker Toolkit installed on your workstation, the helper application is for the WebSphere Message Broker Toolkit that you most recently installed. If you want to control which WebSphere Message Broker Toolkit is extended with your pattern, download the file to disk, complete the following instructions, then start the WebSphere Message Broker Toolkit that you want to extend.
- If you want to stop the download process, click **Cancel**, the pattern is not installed and the tasks are rolled back. If you click **Cancel** again, the Download and Install Pattern window closes.

Procedure

In the Patterns Explorer view, click **Download**. The Download and Install Pattern window opens.

- If you want to download the pattern by using the file URL, type in, or copy and paste, the complete URL for the pattern archive into the **File Location** field, click **Download**. The progress monitor starts to run and the status line shows the individual tasks that are being performed.
- If you want to download the pattern by browsing your local file system:
  1. Click **Browse**. The Select The Pattern Archive To Install window opens.
  2. Navigate to the pattern archive that you want to use, click **Open**.
  3. Click **Download**. The progress monitor starts to run and the status line shows the individual tasks that are being performed.

Results

The new user-defined pattern is displayed in the Patterns Explorer view.

What to do next

Next:

You can now use the user-defined pattern in your projects; see "Using patterns" on page 1312.

Related concepts:

"User-defined patterns" on page 1334

"Uninstalling a pattern archive"
Uninstall the pattern archive to remove a user-defined pattern from the Patterns Explorer view.

Uninstalling a pattern archive:

Uninstall the pattern archive to remove a user-defined pattern from the Patterns Explorer view.

Before you begin

Before you start:

Before you can complete this task, you must have completed the following task:

- "Downloading and installing a pattern archive" on page 1400

Each user-defined pattern archive has one pattern feature, the name of which is based on the name of the main pattern plug-in. If the name of the plug-in is *com.your.company.Test*, the name of the pattern feature is *com.your.company.Test.Feature_<plug-in version>*. If translation was selected by the pattern author, the pattern archive has a second pattern feature, *com.your.company.Test.Feature_NL.<plug-in version>*. To uninstall a pattern archive you must know the feature name of the pattern archive to ensure that the correct user-defined pattern is removed.

About this task

You can uninstall a pattern archive for a user-defined pattern that you have previously installed. Uninstalling a pattern archive removes the associated user-defined pattern from the Patterns Explorer view.

Procedure

To uninstall the pattern archive:

1. Click **Help** > **Software Updates**. The "Software Updates and Add-ons" window opens.
2. Click the **Installed Software** tab.
3. Browse to and select the pattern feature. If translation was selected by the pattern author, two pattern features exist and both must be selected.
4. Click **Uninstall**. The Eclipse Update window opens.
5. You can either restart the workspace, or click **Apply Changes**.

Results

The pattern archive is removed and the user-defined pattern is removed from the Patterns Explorer view.

Related concepts:

Developing message flow applications by using samples

Use the samples to learn more about the features that are available in WebSphere Message Broker, and how to use them.

Before you begin

Before you start:

If you are not familiar with message flow concepts, message model concepts, and common tasks to manage message flow resources, see "Processing messages" on page 1021.

This section describes one of the four methods that you can use to create message flow applications. The other three methods are described in the following sections:

- "Developing message flow applications by using patterns" on page 1309
- "Developing message flow applications from a wizard" on page 1408
- "Developing message flow applications from scratch" on page 1423

If you are unsure which method to use, see Chapter 9, "Developing message flow applications," on page 1019 for a discussion of the advantages of each option.

About this task

The supplied samples provide tested message flows that focus on a particular feature or function supported by WebSphere Message Broker. Samples are more limited in scope than patterns, but provide comprehensive examples of typical

message processing in particular scenarios. These samples are stand-alone; you can use them without having to create and configure additional resources.

Because they are created to demonstrate a particular facet of the product, the samples are not always designed to use the preferred techniques for a particular task. Therefore, use them as examples to learn how particular functions work, not as complete production-level solutions. You might find them helpful as a starting point to developing your own message flows, or as part of a larger solution.

To access the samples, complete the following steps.

Procedure

1. Open the samples gallery in the WebSphere Message Broker Toolkit by clicking **Help** > **Samples and Tutorials** > **WebSphere Message Broker Toolkit - Message Broker**.
2. Expand the available categories and click a sample to open it.

   The following categories of sample are available:

   Application samples
   The application samples are small end-to-end WebSphere Message Broker applications that were created by using the WebSphere Message Broker Toolkit. The Application samples demonstrate how to transform and route messages through message flows.

   Control and Routing samples
   The control and routing samples demonstrate how to use WebSphere Message Broker to control and route messages.

   File Processing samples
   The file processing samples demonstrate how to process files by using WebSphere Message Broker.

   Industry samples
   The Industry samples demonstrate how you can use WebSphere Message Broker in the retail and healthcare industries.

   Message Formats samples
   The message formats samples demonstrate how to process messages with different formats by using WebSphere Message Broker.

   Message Transformation samples
   The message transformation samples demonstrate alternative ways to develop WebSphere Message Broker applications to transform messages.

   Monitoring samples
   The monitoring samples demonstrate how to monitor your WebSphere Message Broker flows, including how to use WebSphere Business Monitor.

   Security samples
   The security samples demonstrate how to use Identity Security features in WebSphere Message Broker.

   Transports and Connectivity samples
   The transports and connectivity samples demonstrate the many ways of connecting WebSphere Message Broker to other applications, including EIS systems.

Web Service samples
The Web Service samples demonstrate how you can use WebSphere Message Broker as both a consumer and provider of web services.

For a full list of the available samples, see "Samples" on page 98.

3. Follow the instructions to import, deploy, and run the samples. The samples documentation also describes how to remove the samples when you have finished with them.

Developing message flow applications from a wizard

A Quick Start wizard sets up the basic resources that are required to develop a message flow application. The wizard sets up and gives names to containers for the resources in which you then develop your message flow.

Before you begin

Before you start: If you are not familiar with message flow concepts, message model concepts, and common tasks to manage message flow resources, see "Processing messages" on page 1021.

This section describes one of the four methods that you can use to create message flow applications. The other three methods are described in the following sections:

- "Developing message flow applications by using patterns" on page 1309
- "Developing message flow applications by using samples" on page 1406
- "Developing message flow applications from scratch" on page 1423

If you are unsure which method to use, see Chapter 9, "Developing message flow applications," on page 1019 for a discussion of the advantages of each one.

To learn about the wizards that you use to start developing message flows, see "Quick Start wizards overview."

About this task

Procedure

- "Creating an application from scratch" on page 1411
- "Creating an application based on WSDL or XSD files" on page 1413
- "Creating an application based on an existing message set" on page 1415
- "Creating an application that uses WebSphere Adapters" on page 1416
- "Creating an application by using the Configure New Web Service Usage wizard" on page 1417
- "Creating an application based on SCA import or export files" on page 1422

What to do next

After you have created a message flow, the next step is to develop it. For more information about how to start, see "Designing a message flow" on page 1455.

Transform and enrich messages by using one or more of the techniques described in this section.

Quick Start wizards overview

You can use a Quick Start wizard to set up the basic resources that are required to develop a message flow application. The wizard sets up and gives names to containers for the resources that you need when you develop a message flow.

The resources that you can set up are described in the following list.

Message flow project
A specialized container in which you create and maintain all the resources that are associated with one or more message flows.

Message set project
A specialized container in which you create and maintain all the resources that are associated with a message set.

Message set
A container for grouping messages and associated message resources (elements, types, groups).

Message flow
A container for a sequence of processing steps that run in the broker when an input message is received.

Working set
A specialized container in which you can group related projects so that you limit the number of resources that are displayed in the Broker Development view.

The following Quick Start wizards and links are available.

- **Start from scratch**, described in "Creating an application from scratch" on page 1411
- **Start from existing message set**, described in "Creating an application based on an existing message set" on page 1415
- **Start from adapter connection**, described in "Creating an application that uses WebSphere Adapters" on page 1416
- **Start from SCA Import or Export**, described in "Creating an application based on SCA import or export files" on page 1422
- **Start from patterns** link which opens the Patterns Explorer view, described in "Developing message flow applications by using patterns" on page 1309
- **Start from samples** link which opens the **Samples and Tutorials** tab, described in "Developing message flow applications by using samples" on page 1406

Related concepts:

"Message flow projects" on page 1035
A message flow project is a specialized container in which you create and maintain all the resources associated with one or more message flows.

"Message set projects" on page 1161
A *message set project* is a specialized container in which you create and maintain all the resources associated with one message set.

"Message sets overview" on page 1162
A message set is a container for grouping messages and associated message resources (elements, types, groups).

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Resources" on page 36
The projects, folders, and files that you work with in the WebSphere Message Broker Toolkit workspace are called *resources*. By default, these resources are stored with their metadata in the workspace directory in your local file system. The workspace directory is created the first time that you start the WebSphere Message Broker Toolkit.

Creating an application from scratch

Use the "Start from scratch" wizard to create the basic resources that are required to develop a broker application.

About this task

The "Start from scratch" wizard creates the following resources:

- A message flow project
- A message set project, and sets up the project dependency
- A message set
- Optional: A message flow
- Optional: A working set

To create these resources, complete the following steps:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the "Start from scratch" wizard by using one of the following methods:
   - In the Projects section of the Broker Development view, if no projects are listed, the Quick Starts links are displayed. Click **Start from scratch**.
   - In the Projects section toolbar, click **Quick Starts**, the Quick Starts links are displayed. Click **Start from scratch**.

   The New Message Broker Application panel of the wizard is displayed. In this panel, you can type the names of the basic resources that are required to develop a broker application.
3. Type into the appropriate fields, the names of the message flow project, the message set project, the message set, the message flow, and the name of the working set that contains the two new projects. Default names of the message flow project, the message flow, and the working set are already displayed in the appropriate fields, but you can edit these fields by typing your own names for these resources.

   You can change any of the names that are displayed by typing into the appropriate field the name that you want. You can also clear either of the check boxes that relate to the creation of a new message flow or a new working set; if you clear either of the check boxes, you cannot enter text into the associated name field, and the associated resource file is not created.

4. Click **Next**. The Message Set Physical Formats panel is displayed. The panel lists three physical formats: **XML documents**, **Binary data** (Custom Wire Format), and **Text data** (TDS Format).
5. Select one or more of the check boxes to describe the type of message data that you want to process. If you do not select a check box, **XML documents** is selected by default.
6. Click **Finish** to complete the task. The "Start from scratch" wizard closes.

Results

The wizard creates a message flow project, message set project, message set, and, optionally, a message flow, with the names that you have specified. It also creates, optionally, a new working set, with the name that you have specified. The working set contains all the resources you have created, and the Broker Development view shows the new working set as the active working set. If you have chosen not to create a new working set, the projects are created in the active working set currently shown in the Broker Development view.

The XML, CWF, or TDS formats are created with default names for the message set.

The message flow, if created, is opened in the message flow editor.

What to do next

Next: If you have created a message flow, you can now go on to "Defining message flow content" on page 1488.

"Rules for naming workspace objects" on page 6827

Creating an application based on WSDL or XSD files

You can use existing WSDL or XSD files as the basis for your solution.

Procedure

1. Open the New Message Broker Application wizard.
   a. Click **File** > **New** > **Project**, or right-click anywhere in the Broker Development view, and click **New> Project**. The New Project window opens.
   b. Double-click **Message Brokers**. A list of wizards is displayed.
   c. Select **Start from WSDL and/or XSD files**, and click **Next**.

   The first panel of the New Message Broker Application wizard is displayed.
2. Set up the basic resources that are required to develop a broker application that uses existing WSDL and XSD files as a starting point.
   - Type the name of your new application in the **Message flow project name** field.

     The name that you type is also displayed in the **Message set project name** and **Message set name** fields, but with 'MessageSet' appended.

     Similarly, the name that you type is also displayed in the **Message flow name** field (with 'Flow' appended), and in the **Working set name** field.
   - Click **Next**.

     You can change any of the names that are displayed by typing into the appropriate field the name that you want. You can also clear either of the check boxes that relate to the creation of a new message flow or a new working set; if you do this, you cannot enter text into the associated name field.

3. Select the WSDL or XSD files that you want to use as the initial contents of the message set.
   - To choose WSDL or XSD files that exist in your workspace, click **Use resources from the workspace**.

     You are presented with a list of resources from which you can choose. Resources are filtered to show resources only in the active working set.
   - To choose WSDL or XSD files that exist outside your workspace, click **Use external resources** and type a directory name in the **From directory** field. Click **Browse**.

     You are presented with a list of the items in that directory. Make your choice from this list.

   In both cases, a two-pane view is displayed. On the left side, containers (for example, projects, folders, and message sets) are displayed. On the right side, the contents of these containers are shown. Depending on which button you clicked, either a workspace view or a file system view of the resources is displayed.

   If the only use of the XSD file is from the WSDL bindings, you do not have to select an XSD file that a selected WSDL files depends on.

   The view incorporates an option that allows you to copy the source file into the `importFiles` directory of the message set.

   You can use this option as follows:
   - If you choose only WSDL files, you can select the check box.
   - If you choose only XSD files, the option is automatically selected and the check box is greyed out. If you subsequently select a WSDL file, the check box is enabled but the selection state is not changed; that is, the check box remains selected.
   - Regardless of what you select, if the `importFiles` folder exists in the message set project after the import, it is collapsed.
   - If you import only WSDL files, the wizard sets the default message domain to SOAP.
4. Click **Next**. If you selected one or more WSDL files, the WSDL files that you selected are shown in a check box tree, with the acceptable bindings for each file shown as children.
5. Select one or more bindings for each of the WSDL files that you selected. If you do not select at least one binding for each WSDL file, an error message is displayed and the **Next** and **Finish** buttons are disabled.
6. Click **Next**. If you selected one or more XSD files, the XSD files that you selected are displayed in the next pane, with the global elements for each file shown as children.
7. (Optional) Select the global elements from which you want to create message definitions. Click **Next**.
8. (Optional) If any errors or warnings are listed, either click **Finish**, if you want the import to be attempted regardless of the errors or warnings listed, or click **Cancel** to terminate the import. You can then correct any errors and attempt the import again.
9. Click **Finish**.

What to do next

After a WSDL file has been imported into a message set, you can drag the WSDL file onto the message flow editor. The next step is to develop the message flow. For

more information about how to start, see “Designing a message flow” on page 1455.

Creating an application based on an existing message set

Create a new application that is based on an existing message set.

Before you begin

Before you start:

You must have created a message set by following the instructions in “Creating a message set” on page 2842.

About this task

To create a new application, complete the following steps.

Procedure

1. Click **File** > **New** > **Project**, or right-click anywhere in the Broker Development view and click **New** > **Project**. The New Project wizard opens.
2. Click **Message Brokers**. A list of wizards is displayed.
3. Click **Start from existing message set**, then click **Next**. The first panel of the New Message Broker Application wizard opens.

   The **Start from existing message set** wizard can also be found in the Project section toolbar. Click **Quick Starts** and select the **Start from existing message set** wizard.
4. Set up the basic resources that are required to develop a broker application from an existing message set, then click **Next**.
   - If the message set that you want to use is in a compressed (`.zip`) file, select **Import a message set from a .zip file**, and either type the location of the message set in the **.zip file** and **Compressed message set** fields, or click **Browse** and select, and open, the `.zip` file from the list that is displayed. Then select the required message set.

     If the `.zip` file that you specify does not contain a message set, you receive a message. You can then type a different location for the message set in the **.zip file** field. Otherwise, click **Cancel**.

- If the message set that you want to use is not in a compressed file, click **Create a new message set by copying an existing message set** and type into the **Message set to copy** field the name of the message set file that you want to copy.

  A list is displayed of the message set names from which you can choose. Message sets are filtered to show resources in the active working set only.

5. Enter the names of the projects, the message flow, the message set, and the working set that contains the two new projects. Default names of the message flow project, the message flow, and the working set are already supplied, but you can replace these names. However, if the message set is copied from a `.zip` file that is a project interchange file, you cannot edit the names of the message set project and the message set; the names are imported from the `.zip` file.
6. Click **Finish**.

   The new message set project, message set, message flow project, and message flow are created. A new working set is also created, if required. The new projects are displayed in the specified working set. The contents of the message set project and the message flow project are displayed in the Broker Development view. The message flow is opened in the message flow editor.

What to do next

The next step is to develop the message flow. For more information about how to start, see "Designing a message flow" on page 1455.

Related concepts:

Creating an application that uses WebSphere Adapters

Use the **Start from adapter connection** quick start wizard to create an application that uses WebSphere Adapters.

Before you begin

Before you start:

- Before you run the Adapter Connection wizard, you must gather some information from the Enterprise Information System (EIS). For more information about these prerequisite steps, as well as steps to complete after you have run the wizard, see "Connecting to an EIS by using the Adapter Connection wizard" on page 2037.

Procedure

1. In the Projects section of the Broker Development view, click **Quick Starts**, then click **Start from adapter connection**. The Adapter Connection wizard opens.
2. Follow the on-screen instructions.
3. Click **Finish**.

Results

When you have completed the steps in the wizard, the specified message set project contains a message set with a message type for each business object, and the specified message flow project references the message set project.

Creating an application by using the Configure New Web Service Usage wizard

Use these instructions to generate a message flow by using the Configure New Web Service Usage wizard.

About this task

This task topic describes how to create a new application by using the Configure New Web Service Usage wizard.

Procedure

1. Open a message set project that contains a WSDL file.
2. Select a WSDL file from either the message set or the `ImportFiles` folder and drag the WSDL file onto the Message Flow editor canvas. Validation occurs and if any of the following errors occurs, a message appears.

- The WSDL file does not come from either a message set or `ImportFiles` folder of the message set project.

  For a multiple-file WSDL, the process also checks that either imports inside the main WSDL have been properly imported into the message set, or imports are available in the `ImportFiles` folder.
- The message set that contains the WSDL file does not support any of the SOAP, XMLNSC, XMLNS, or MRM domains.

  However, if the message set that contains the WSDL file does not support only the SOAP domain, you can generate a flow based on the HTTP nodes, and the process continues.
- No HTTP bindings exist in the WSDL file.
- No port types exist in the WSDL file.

For the flow and subflows to be created correctly, the WSDL file that you are dropping onto the Message Flow editor canvas must be WS-I compliant. If no errors occur, the first page of the **Configure New Web Service Usage** wizard appears. For further information about the fields in the wizard, see Configure Web Service Usage details.

3. In Web service usage, select **Expose message flow as a Web service** or **Invoke Web service from message flow**. If you select **Expose message flow as a Web service**, you can use WebSphere Message Broker with other applications on the Web. If you select **Invoke Web service from message flow**, you use WebSphere Message Broker to start the Web service.
4. Select the **Port type** that you are going to use. By default, the initially selected port type is the first one that has at least one HTTP binding associated with it.

   You receive an error message in the following circumstances:
   - The selected port type does not contain at least one operation.
   - No SOAP bindings (with HTTP transport) in the WSDL document are associated with the port type.
5. Select the **Binding** that you are going to use. You receive an error message in the following circumstances:
   - The selected binding has no operations associated with it.
   - The selected binding has no ports associated with it.

   The **Service Port** field lists all the WSDL ports that point to a selected binding.
6. Select the **Binding operations** that you require. By default, only those operations that are implemented by the binding that you choose are selected.

   If you select one of the operations that is not implemented by the selected binding, you receive a warning message, but you can continue.
7. Click **Next**. For further information on the following fields, see File generation details.
8. Select **HTTP nodes** if you have imported the WSDL file from a message set and do not want the default value of **SOAP nodes**. If you select **HTTP nodes**, you see a message that explains the advantages of using the SOAP nodes. By using SOAP nodes, you can use features such as WS_Security and WS_Addressing. However, if the message set does not support the SOAP domain, you receive an error message.

   If you import the WSDL file from the `ImportFiles` folder, you cannot select **SOAP nodes**.

   All the file names that are generated, together with their location, are listed on this page.

A Details pane appears if any warnings occur about the subflow that is generated.

9. Click **Finish** to complete the wizard, create the subflow, and add appropriate nodes to the main flow. For details about the subflow and nodes that generated by the wizard if you select **Expose message flow as a Web service** as the initial step, see "Web service provider message flow generated."

   For details about the subflow and nodes that are generated by the wizard if you select **Invoke Web service from message flow** as the initial step, see "Web service consumer message flow generated" on page 1420.

What to do next

The next step is to develop the message flow. For more information about how to start, see "Designing a message flow" on page 1455.

Related concepts:

"Generate WSDL" on page 1274
A *Web Services Description Language* (WSDL) document specifies the interface to a web service, and enables a web service client to start it. A WSDL document that is generated from a message model defines web service requests and responses in terms of the messages that you have defined in that message model.

Web service provider message flow generated

This provides additional information in relation to the Configure New Web Service Usage wizard about the message flow generated when the flow is a web service provider.

Note that the default name for the generated subflow is prefixed by the name of the WSDL file you selected.

Generated message flow

The message flow generated consists of a:

SoapInput node

This `SOAPInput` node completes the `LocalEnvironment` destination tree with the SOAP operation so that it can be followed either by a:

- `SOAPExtract` node, or by a
- `RouteToLabel` node. In this case, appropriate `Label` nodes need to be in place.

The `out` terminal of the `SOAPInput` node is connected to the `in` terminal of the `SOAPExtract` node.

Subflow node
The subflow node name reflects the name of the WSDL file.

SOAPReply node
This node sends the response message back to the originating client.

Typically, you connect the output of your node, or nodes, that handle your operation, or operations, to the `in` terminal of the `SOAPReply` node.

Generated message subflow

The generated subflow is constructed as follows:

- The input node is connected to the `SOAPExtract` node, which removes the SOAP envelope.

  The `SOAPExtract` node also allows for routing of the SOAP messages, based on the operation being performed. In particular, the SOAP message is routed to a `Label` node within the message flow as identified by the SOAP operation within the message.
- The `Failure` output terminal of the `SOAPExtract` node is connected to the `Output` node used when a process fails named, for example, `failure`.
- A `Label` node is generated for each SOAP operation and each `Label` node is connected to the corresponding `Output` node.
- Each `Output` node in the subflow corresponds to an output terminal for the `SOAPExtract` node in the main message flow.

  Therefore, there is one `failure` output terminal, plus one output terminal for each operation.

  Typically, you connect the output terminal corresponding to the operation you require to the node, or nodes, that handle this operation, for example, `Compute` node.

Web service consumer message flow generated

This provides additional information in relation to the Configure New Web Service Usage wizard about the message flow generated when the flow is a web service consumer.

Note that the default name for the generated subflow is prefixed by the name of the WSDL file you selected.

Generated message flow

The low generated consists of a single node that has a number of output terminals:

- `Failure`
- `Error`

- `Fault`
- One more, corresponding to the name of the selected operation.

Typically, your message flow feeds an input message to the in terminal of the generated subflow node, and handles various outcomes of the web service invocation.

The default name of the subflow node is a combination of selected operation and WSDL file name. You can change the name of the corresponding `.msgflow` file on the second page of the wizard; see "Configure New Web Service Usage wizard: File generation details" on page 6393.

The generated `.msgflow` file is placed into the `gen` folder of the message set project; see "Generated message subflow" for details of this subflow.

Generated message subflow

The generated subflow is constructed as follows:

- A `SOAPRequest` node immediately follows an `Input` node. This is a synchronous request and response node that blocks after sending the request, until the response is received. The `SOAPRequest` node parses the response message.
- The `Failure` and `Error` terminals are connected to the `Output` nodes for failure and error respectively.
- The `Out` terminal is connected to the `SOAPExtract` node.

  The `SOAPExtract` node removes the SOAP envelope so that the body of a SOAP message is extracted.

  The `SOAPExtract` node also allows for routing of the SOAP messages, based on the operation being performed. Note that only the selected operation and fault are handled.

  In particular, the SOAP message is routed to a `Label` node within the message flow as identified by the SOAP operation or a `ws__Fault` label, if fault is returned from the web service.

  Each `Label` node is connected to the corresponding `Output` node.

  The `Failure` terminal of the `SOAPExtract` node is connected to the `Output` node for failure.
- Each `Output` node in the subflow corresponds to an output terminal for the subflow node.

  Therefore, there are three output terminals:

  – `Failure`
  – `Fault`
  – One for the selected operation.

Creating an application based on SCA import or export files

You can create a new application that is based on existing SCA import or export files.

Procedure

1. Open the New Message Broker Application wizard by using either of the following methods:
   - In the Projects section of the Broker Development view, click **Quick Starts**, then click **Start from SCA Import or Export**.
   - Click **File** > **New** > **Project**, double-click **Message Brokers**, then click **Start from SCA Import or Export**.

   The first panel of the New Message Broker Application wizard is shown.
2. Enter names for the projects, message set and message flow, then click **Next**.

   You can change any of the names that are displayed by typing into the appropriate field the name that you want. You can also clear either of the check boxes that relate to the creation of a new message flow or a new working set, but you cannot enter text into the associated name field.
3. Select the project interchange file that contains the SCA import or export files that you want to use as the initial contents of the message set.
   - To choose SCA import or export files that exist in your workspace, click **Use resources from the workspace**.

     A list of available resources is displayed.
   - To choose SCA import or export files that exist outside your workspace, click **Use external resources** and enter a directory name, or click **Browse** to browse for a directory.

     A list of the items in that directory is displayed.

   In both cases, a two-pane view is displayed. On the left side, containers (for example, projects, folders, and message sets) are displayed. On the right side, the contents of these containers are shown. Depending on which option you selected, either a workspace view or a file system view of the resources is displayed.
4. To copy the imported files into the `ImportFiles` folder, select **Copy source file into the 'ImportFiles' directory of the message set project**.
5. To show all resources in the workspace. select **Apply working set filtering to artifact selection(s) on this page**; if you clear the check box, only resources in the current active working set are shown. If no working set is selected, this check box is not displayed.
6. Click **Next**. If you selected one or more files, the files that you selected are shown in a check box tree.
7. Select the project interchange file that contains the SCA components that you want to import into the message set. The project interchange file contains the SCA import components that you want to implement in WebSphere Message Broker, or the SCA export components that you want to invoke from WebSphere Message Broker.
8. Click **Finish**. The SCA components that you have selected are added to the message set that you have specified.

9. Drag an SCA component from the message set in the tree structure in the left pane onto the message flow editor pane.

   Dragging a `.outsca` file:

   - If the `.outsca` file contains either a single request-response operation, or more than one operation (one-way or request-response), you are prompted to select the operation. If the chosen operation is request-response, you can also choose whether to invoke the service synchronously or asynchronously. Synchronous invocation is the default value, and creates a SCARequest node. Choosing the asynchronous option creates a pair of SCAAsyncRequest and SCAAsyncResponse nodes.
   - If the chosen operation is one-way, synchronous invocation is the only option, and a SCARequest node is created.

   Dragging a `.insca` file:

   - If the `.insca` file contains only one-way operations, dragging a `.insca` file onto the canvas creates an SCAInput node.
   - Otherwise, a pair of SCAInput and SCAReply nodes is created.

What to do next

Next: Develop the message flow. For more information about how to start, see "Designing a message flow" on page 1455.

Related concepts:

"Service Component Architecture (SCA) overview" on page 2096
Service Component Architecture (SCA) is a specification that describes a model for building applications and systems using a service-oriented architecture (SOA).

Developing message flow applications from scratch

Design, create, and configure message flows by using the WebSphere Message Broker Toolkit.

Before you begin

Before you start: If you are not familiar with message flow concepts, message model concepts, and common tasks to manage message flow resources, see "Processing messages" on page 1021.

This section describes one of the four methods that you can use to create message flow applications. The other three methods are described in the following sections:

- "Developing message flow applications by using patterns" on page 1309
- "Developing message flow applications by using samples" on page 1406
- "Developing message flow applications from a wizard" on page 1408

If you are unsure which method to use, see Chapter 9, "Developing message flow applications," on page 1019 for a discussion of the advantages of each one.

About this task

To develop a message flow from scratch follow these activities in order.

1. For information about managing message flows, see "Managing message flow resources" on page 1424.

2. To learn about the choices that you have when designing the content of your message flows to provide the processing that your applications require, see “Designing a message flow” on page 1455.
3. To learn about constructing and configuring the content of your message flows, see “Defining message flow content” on page 1488.

Related tasks:

“Developing message flow applications by using patterns” on page 1309
Create resources that are used to solve a specific business problem by using patterns.

“Developing message flow applications by using samples” on page 1406
Use the samples to learn more about the features that are available in WebSphere Message Broker, and how to use them.

“Developing message flow applications from a wizard” on page 1408
A Quick Start wizard sets up the basic resources that are required to develop a message flow application. The wizard sets up and gives names to containers for the resources in which you then develop your message flow.

“Connecting client applications” on page 1537
Connect your client applications to the broker by using one or more of the supported protocols from other resources and software servers in your network.

“Routing messages” on page 2209
Route messages through your message flow or the broker by using one or more of the techniques described in this section.

“Transforming and enriching messages” on page 2227
Transform and enrich messages by using one or more of the techniques described in this section.

Managing message flow resources

Manage your message flows and associated resources in the WebSphere Message Broker Toolkit.

Before you start: Read “Message flows overview” on page 1022.

- “Creating a message flow project” on page 1425
- “Deleting a message flow project” on page 1427
- “Creating a broker schema” on page 1429
- “Creating a message flow” on page 1431
- “Opening an existing message flow” on page 1433
- “Copying a message flow by using copy” on page 1435
- “Analyzing planned changes to message flows” on page 1436
- “Renaming a message flow” on page 1438
- “Moving a message flow” on page 1439
- “Deleting a message flow” on page 1441
- “Deleting a broker schema” on page 1442
- “Version and keyword information for deployable objects” on page 1443
- “Showing resource references” on page 1447
- “Saving a message flow” on page 1448
- “Importing and exporting resources in a Project Interchange file” on page 1452

To learn more about message flows look at the following sample:

- Airline Reservations

In this sample, you can explore message flow resources, and learn how to create, delete, and rename the resources.

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Related tasks:

Transform and enrich messages by using one or more of the techniques described in this section.

Creating a message flow project

A message flow project is a container for message flows; you must create a project before you can create a message flow.

Before you begin

Before you start:

Read the concept topic about "Message flow projects" on page 1035.

About this task

The project and its resources are stored in a file system or in a shared repository. If you are using a file system, you can use the local file system or a shared drive. If you store files in a repository, you can use all the available repositories that are supported by Eclipse; for example, CVS.

To create a message flow project and other resource files that you need to start developing applications, you can use a Quick Start wizard (as described in "Quick Start wizards overview" on page 1409).

To create only a message flow project, perform the following actions:

Procedure

1. Switch to the Broker Application Development perspective.
2. Click **File** > **New** > **Message Flow Project** or right-click any resource in the Broker Development view and click **New** > **Message Flow Project**.

   You can also press Ctrl+N to display a dialog box, from which you select the wizard to create a new object. Click **Message Brokers** in the left view; the right view displays a list of objects that you can create for WebSphere Message Broker. Click **Message Flow Project** in the right view, then click **Next**. The New Message Flow Project wizard opens.
3. Enter a name for the project. Choose a project name that reflects the message flows that it contains. For example, if you want to use this project for financial processing message flows, you might give it the name Finance_Flows.
4. To use the default location for the new message project directory (the `\workspace` subdirectory of your current installation), leave the **Use default** check box selected (it is selected when the dialog box opens). When you choose this option, you cannot edit the **Directory** field.

   If you do not want to use the default location, clear the **Use default** check box and specify a location for the new message flow project files in **Directory**.
5. If this message flow project depends on other message flow projects or message set projects, click **Next**.

   A list of current projects is displayed. Select one or more message flow projects, one or more message set projects, or both, from the list to indicate the dependencies of this new message flow project. Message flow projects and message set projects are filtered to show only resources in the active working set.

   This message flow project depends on another message flow project if you intend to use common resources in it. Common resources that you can share between message flow projects are:
   a. ESQL subroutines (defined in broker schemas)
   b. Mappings
   c. Message sets
   d. Subflows

   For example, you might want to reuse a subflow that provides standard error processing, such as writing the message to a database, or recording a trace entry.

   This message flow project depends on a message set project if you intend to refer to the message it defines in ESQL in the message flow nodes.

   You can add dependencies after you have created the message flow project by right-clicking the project in the Broker Development view and clicking **Properties**. Click **Project References** and select the dependent message flow or message set project from the list of projects displayed.
6. Click **Finish** to complete the task.

Results

The project file is created in a directory that has the same name as your message flow project in the specified location. All other files that you create that are related to this message flow project are created in this same directory.

A default broker schema (`default`) is also created in the project. You can create and use different schemas in a single project to organize message flow resources and to provide the scope of resource names to ensure uniqueness.

What to do next

Next: create a message flow.

Related concepts:

"Project references" on page 44
When a projects refers to other projects in the workspace, this is called a *project reference*. When one project references another, the files in the referenced project are available for use by the referring project. For example to configure certain nodes, to create libraries of reusable message flows, and to enable Content Assist in the ESQL editor.

"Development repository" on page 45
Use a development repository to benefit from features such as version control and access control of files, which make it easier for teams to work on shared resources.

Deleting a message flow project

A message flow project is the container in which you create and maintain all the resources associated with one or more message flows. These resources are created as files, and are displayed in the project in the Broker Development view. If you do not want to retain a message flow project, you can delete it.

Before you begin

Before you start:

Complete the following steps.

- "Creating a message flow project" on page 1425
- Read the concept topic about "Message flow projects" on page 1035

About this task

When you delete a message flow project in the WebSphere Message Broker Toolkit, you delete the project and its resources. If you are using a shared repository, the repository might retain a copy of a deleted resource.

To delete a message flow project, complete the following steps.

Procedure

1. Select the message flow project that you want to delete, and click **Edit** > **Delete**. You can also press Delete, or right-click the project in the Broker Development view and click **Delete**.
2. You must choose if you want the contents of the message flow project folder to be deleted with this action in the displayed confirmation dialog box. The dialog box contains two buttons:
   - The first button confirms that all contents are to be deleted.
   - The second button requests that the directory contents are not deleted. The default action is not to delete the contents; therefore, the second button is selected by default when the dialog box is initially displayed.

   a. Select the appropriate button. If you choose not to delete the contents of the message flow project directory, all the files and the directory itself are retained.

      If you later create another project with the same name, and specify the same location for the project (or accept the location as the default value), you can access the files previously created.

      If you choose to delete all the contents, all files and the directory itself are deleted.
3. Click **Yes** to complete the delete request, or **No** to terminate the delete request.

Results

When you click **Yes**, the requested objects are deleted.

If you maintain resources in a shared repository, a copy is retained in that repository. You can follow the instructions provided by the repository supplier to retrieve the resource, if required.

If you are using the local drive or a shared drive to store your resources, no copy of the resource is retained. Be careful to select the correct resource when you complete this task.

Related concepts:

"By name linking" on page 43
You identify objects using a combination of a *namespace* and a name, referred to as a *fully qualified name*. The use of fully qualified names, called *by name linking*, makes it easy to identify and locate objects, and to correct broken references.

"Development repository" on page 45
Use a development repository to benefit from features such as version control and access control of files, which make it easier for teams to work on shared resources.

"Broker Application Development perspective" on page 6784
The Broker Application Development perspective is the default perspective that is displayed when you start the WebSphere Message Broker Toolkit.

Creating a broker schema

To organize your message flow project resources, and to define the scope of resource names to ensure uniqueness, you can create broker schemas. A default schema is created when you create the message flow project, but you can create additional schemas.

Before you begin

Before you start:

Complete the following steps.

- "Creating a message flow project" on page 1425
- Read the concept topic about broker schemas

About this task

To create a broker schema:

Procedure

1. Switch to the Broker Application Development perspective.
2. Click **File** > **New** > **Broker Schema** or right-click any resource in the Broker Development view and click **New** > **Broker Schema**.

   You can also press Ctrl+N. This displays a dialog that allows you to select the wizard to create a new object. Click Message Brokers in the left view. The right view displays a list of objects that you can create for WebSphere Message Broker. Click **Broker Schema** in the right view, then click **Next**. The New Broker Schema wizard displays.
3. Enter the message flow project in which you want the new schema to be created. If a message flow project or one of its resources is highlighted when you start the wizard, that project name appears in the dialog box. If a name does not appear in this field, or if you want to create the schema in another project, click **Browse** and select the correct project from the displayed list. The message flow project list is filtered to show projects in the active working set.

   You can type the project name in, but you must enter a valid name. The dialog box displays a red cross and the error message `The specified project does`

not exist if your entry is not a valid project. You must specify a message flow project; if you select a message set project, you cannot complete the operation.

4. Enter a name for the schema. Choose a name that reflects the resources that it contains. For example, if you want to use this schema for message flows for retail applications, you might give it the name Retail.

   A broker schema name must be a character string that starts with a Unicode character followed by zero or more Unicode characters or digits, and the underscore symbol (_). You can use the period to provide a structure to the name, for example Stock.Common.

5. Click **Finish** to complete the task.

   If category view is selected in the Broker Development view when you create the schema, you see a message to say that the schema has been created, but it might not be visible in the Broker Development view when it is empty. To show the new schema in the Broker Development view, click **Hide Categories**

    on the Broker Development view toolbar.

Results

The schema directory is created in the project directory. If the schema name is structured by using periods, further subdirectories are defined. For example, the broker schema Stock.Common results in a directory Common, in directory Stock, in the message flow project directory.

Related concepts:

"Broker schemas" on page 1036
A broker schema is a symbol space that defines the scope of uniqueness of the names of resources defined within it. The resources include message flows and other optional resources such as ESQL files, Java files, and mapping files.

The Broker Application Development perspective is the default perspective that is displayed when you start the WebSphere Message Broker Toolkit.

"Rules for naming workspace objects" on page 6827

Creating a message flow

Create a message flow to specify how to process messages in the broker. You can create one or more message flows and deploy them to one or more brokers.

Before you begin

Before you start:

- Complete the following task: "Creating a message flow project" on page 1425.
- Read the concept topic about "Broker schemas" on page 1036.

About this task

The mode that your broker is working in can affect the number of message flows that you can use; see "Restrictions that apply in each operation mode" on page 3657.

The message flow and its resources are stored in a file system or in a shared repository. If you are using a file system, it can be on the local drive, or a shared drive. If you store files in a repository, you can use all the available repositories that are supported by Eclipse; for example, CVS.

Use this process to create a complete message flow that you can deploy, or a subflow that provides a subset of function (for example, a reusable error processing routine), that you cannot deploy on its own.

To create a message flow and other resource files that you need to start developing applications, you can use a Quick Start wizard.

To create only a message flow, perform the following actions:

Procedure

1. If you have not already created the message flow project in which you want to create the message flow, you can either create it now, or you can create the message flow project as an optional step in creating the message flow (in step 4). If you want to create the message flow project first, see "Creating a message flow project" on page 1425. The project can be empty, or can have message flows defined in it.
2. Complete one of the following actions to open a message flow:
   - Click **File** > **New** > **Message Flow**.
   - Right-click a resource in the Broker Development view and click **New** > **Message Flow**.
   - Press Ctrl+N. This action displays a dialog box in which you can select the wizard to create an object:
     a. Click **Message Brokers** in the left view. The right view displays a list of objects that you can create for WebSphere Message Broker.
     b. Click **Message Flow** in the right view, then click **Next**. The New Message Flow wizard displays.

3. Identify the project in which you want to define the message flow. This field is filtered to show only resources in the active working set.
   - If you have a resource selected in the Broker Development view, the name of the corresponding project is displayed in the Message Flow Project field.
   - If you do not have a resource selected, the first field is blank.
     - If you have already created the message flow project for this message flow, you can perform either of the following actions:
       - Type the name of the project into the field.
       - Click the down-arrow and select the appropriate project from the list displayed.
     - If you have not already created the message flow project, select **New**. The New Message Flow Project wizard starts, and you can use it to create the message flow project for your new message flow, as described in "Creating a message flow project" on page 1425.

       When you have finished creating the message flow project, the New Message Flow Project wizard closes, and the name of your new message flow project is displayed in the Message Flow Project field of the New Message Flow window.

   If your entry is not a valid project name, the window displays a red cross, and the error message `The specified project does not exist`.
4. In the Message flow **Name** field, enter the name of the new message flow. You can use all valid characters for the name, but it is helpful to choose a name that reflects its function, for example, OrderProcessing.
5. Decide whether you want to use the default broker schema. When you create a message flow project, a default schema is created in it, and this default value is assumed unless you clear it. You can create and use different schemas in a single project to organize message flow resources, and to provide the scope of resource names to ensure uniqueness.
   - If you want the message flow to be created in the default broker schema, ensure that you select **Use default** in the Flow organization section.
   - If you want to use a different broker schema, clear **Use default**. You can now perform either of the following actions:
     - Enter the name of the broker schema into the **Schema** field.
     - Click **Browse** to select from the broker schemas in the message flow project.
6. Click **Finish**.

Results

The new message flow (`<message_flow_name>.msgflow`) is displayed in its project in the Broker Development view. The Editor view is empty, and ready to populate.

What to do next

WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Opening an existing message flow

Open an existing message flow to change or update its contents, or to add or remove nodes.

Before you begin

Before you start

You must have completed the following task:
- "Creating a message flow" on page 1431

About this task

To open an existing message flow:

Procedure

1. Switch to the Broker Application Development perspective. The Broker Development view is populated with all the message flow and message set projects that you have access to. A message flow is contained in a file called `<message_flow_name>.msgflow`.
2. Right-click the message flow that you want to work with, and click **Open**. Alternatively you can double-click the message flow in the Broker Development view.

   The graphical view of the message flow is displayed in the editor view. You can now work with this message flow; for example, you can add or remove nodes, change connections between nodes, or modify node properties.
3. Click **Open ESQL** for any node in the flow that requires ESQL, or double-click the ESQL file (the .esql file) in the Broker Development view to open it, if you want to work with the ESQL file for this message flow.
4. Click **Open Mappings** for any node in the flow that requires mappings, or double-click the mappings file (the `.msgmap` file) in the Broker Development view to open it, if you want to work with the mappings file for this message flow.
5. Click **Open Java** for any JavaCompute node in the flow, or double-click the Java file in the Broker Development view to open it, if you want to work with the Java file for this message flow.

Related reference:

"Broker Application Development perspective" on page 6784
The Broker Application Development perspective is the default perspective that is displayed when you start the WebSphere Message Broker Toolkit.

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Copying a message flow by using copy

You might find it useful to copy a message flow as a starting point for a new message flow that has similar function. For example, you might want to replace or remove one or two nodes to process messages in a different way.

Before you begin

Before you start:

To complete this task, you must have created a message flow, as described in "Creating a message flow" on page 1431.

About this task

To copy a message flow:

Procedure

1. Switch to the Broker Application Development perspective.
2. Select the message flow (`<message_flow_name>.msgflow`) that you want to copy in the Broker Development view.
   a. Right-click the file and click **Copy** from the menu.
3. Right-click the broker schema in the message flow project to which you want to copy the message flow and click **Paste**. You can copy the message flow in the same broker schema in the same message flow, or to a different broker schema in the same message flow project, or to a broker schema in a different message flow project.

   When you copy a message flow, the associated files (ESQL and mapping, if present) are not automatically copied to the same target message flow project. If you want these files copied as well, you must do this explicitly following this procedure.

   You might also need to update nodes that have associated ESQL or mappings, to ensure that modules are unique.

   For example, if you have created a message flow Test1 that contains a single Compute node, and you copy message flow Test1 and its associated `.esql` file to the same broker schema in the same message flow project (and give the new copy a different name, for example Test2), two modules named Test1_Compute now exist in the single schema. One is in `Test1.esql`, the second in `Test2.esql`.

   This duplication is not supported, and an error message is written to the Problems view when you have completed the copy action. You must rename the associated ESQL modules in the `.esql` file and update the matching node properties to ensure that every module in a broker schema is unique.

Results

The message flow is copied with all property settings intact. If you intend to use this copy of the message flow for another purpose, for example to retrieve messages from a different input queue, you might have to modify its properties.

You can also use **File** > **Save As** to copy a message flow. This task is described in "Saving a message flow" on page 1448.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an

input message is received.

Analyzing planned changes to message flows

Use impact analysis to analyze the effect of renaming or moving message flows, including subflows.

Before you begin

Before you start:

You must have completed the following tasks:

- “Creating a message flow project” on page 1425.
- “Creating a message flow” on page 1431.
- Ensure that you have enabled indexing, by following the instructions in “Enabling and disabling indexing” on page 1454.

About this task

This information covers the following tasks:

- “Renaming message flows” on page 1437
- “Moving the message flow file” on page 1437

If a node in the message flow contains either an ESQL path expression, or an XPath expression, it might not be possible to unambiguously determine which structure in the message set the expression refers to. Ambiguity occurs when multiple constructs have the same name, and the parent of the construct cannot be determined. For example, consider a message definition that has the following constructs:

Global element declaration with name G1

Global element declaration with name G2

Global element declaration with name G3

G2 contains an element reference to global element G1

G3 contains a local element declaration with name G1

The message flow might contain the following ESQL path:

```
InputRoot.MRM.ns1:G1
```

Or the following XPath path:

```
$InputRoot/MRM/ns1:G1
```

The construct G1 cannot be unambiguously determined. It can refer to G2/G1 or G3/G1. In this case, impact analysis reports both G2/G1 and G3/G1 as potential impacts. The list of secondary impacts might contain references to elements that are not in fact affected by the primary change.

Renaming message flows:
About this task

Use this procedure to analyze the impact of renaming a message flow.

Procedure

1. In the Broker Development view, right-click the flow or subflow that you want to rename, then click **Impact Analysis** > **Rename**.
2. In the Impact Analysis - Rename Artifact window, type the new name of the object, then click **Analyze Impact**.

   The Rename Artifact dialog box shows the results of impact analysis, listing primary and secondary impacts.

   You can view the results of impact analysis in the Impact Analysis dialog box, or the Impact Analysis view of the WebSphere Message Broker Toolkit. For more information about how to view information about selected resources, mark changes as complete, copy results to an external application, and view previous results, see "Impact Analysis view" on page 6801.

Moving the message flow file:
About this task

You can analyze the effects of moving a message flow file.

Procedure

1. Right-click the message flow file, then click **Impact Analysis** > **Move**.
2. Select the new container for the object, then click **Analyze Impact**.

   The Impact Analysis - Move Artifact dialog box shows the results of impact analysis, listing primary and secondary impacts.

   You can view the results of impact analysis in the Impact Analysis dialog box, or the Impact Analysis view of the WebSphere Message Broker Toolkit. For more information about how to view information about selected resources, mark changes as complete, copy results to an external application, and view previous results, see "Impact Analysis view" on page 6801.

Renaming a message flow

You can rename a message flow. You might want to rename a flow if you have modified it to provide a different function, and you want the name of the flow to reflect this new function.

Before you begin

Before you start

This task assumes that you have created a message flow. For more information, see "Creating a message flow" on page 1431.

About this task

You can use impact analysis to analyze the effect of renaming message flows. For more information about impact analysis, see "Analyzing planned changes to message flows" on page 1436.

To rename a message flow, complete the following steps.

Procedure

1. To open the Rename Resource dialog box, select the flow that you want to rename (*message_flow_name*.msgflow), then click **File** > **Rename**.
2. Enter a new name for the file.
3. Click **OK** to rename the file, or **Cancel** to cancel the request. If you click **OK**, the file is renamed.

   After you have renamed the flow, any references that you have to this flow (for example, if it is embedded in another message flow) are no longer valid.
4. You must open the affected message flows and correct the references if you are not sure where you have embedded this message flow.
   a. Click **File** > **Save All** The save action saves and validates all resources. Unresolved references are displayed in the Problems view; click each error listed to open the message flow that makes a non-valid reference in the editor view.

b. Right-click the subflow icon and click **Locate Subflow**. The Locate Subflow dialog box opens, listing the available message flow projects.
c. Expand the list and explore the resources available to locate the required subflow.
d. Select the correct subflow, and click **OK**. All references in the current message flow are updated for you. All related errors are removed from the Problems view.

WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Moving a message flow

You can move a message flow from one broker schema to another in the same project or to a broker schema in another project. You might want to move a flow, for example, if you are reorganizing the resources in your projects.

Before you begin

Before you start:

Complete the following task:

- "Creating a message flow" on page 1431

You can use impact analysis to analyze the effect of moving message flows and subflows; for more information, see "Analyzing planned changes to message flows" on page 1436.

About this task

To move a message flow:

Procedure

1. Drag the message flow that you want to move from its current location to a broker schema in the same or another message flow project.

   If the target location that you have chosen is not valid, a black no-entry icon appears over the target, an error dialog box is displayed, and the message flow

is not moved. You can move a message flow to another schema in the same project or to a schema in another message flow project. If you have created an empty broker schema for this purpose, it might not be visible in the Broker Development view if category mode is selected. To see an empty schema in the Broker Development view, click Hide Categories  .

Alternatively, you can use the following method:

a. Right-click the message flow that you want to move (*message_flow_name*.msgflow) in the Broker Development view and click **Move**, or **File** > **Move**. The Move dialog box is displayed, and contains a list of all valid projects to which you can move this message flow.

b. Select the project and the broker schema in the project to which you want to move the message flow. You can move a message flow to another schema in the same project or to a schema in another message flow project.

c. Click **OK** to complete the move, or **Cancel** to cancel the move. If you click **OK**, the message flow is moved to its new location.

2. Check the Problems view for errors or warnings that are generated by the move. Errors are indicated by the error icon , warnings are indicated by the warning icon . The errors in this view include those that are caused by broker references. When the move is complete, all references to this message flow (for example, if this message flow is a reusable error routine that you have embedded in another message flow) are checked.

   If you have moved the message flow in the same broker schema (in the same or another project), all references are still valid. However, if you move the message flow from one broker schema to another (in the same or a different project), the references are broken because the resources are linked by a fully-qualified name of which the broker schema is a part. Information about broken references is written to the Problems view; for example, `Linked or nested flow mflow1 cannot be located`.

3. Double-click each error or warning to correct it. The message flow that contains the error is opened in the editor view and the node in error is highlighted.

Results

When you move a message flow, the associated files (for example, all ESQL or mapping files) are not automatically moved to the target broker schema. If you want to move these files as well, you must do so explicitly by following the procedure in this topic.

Related concepts:

"By name linking" on page 43
You identify objects using a combination of a *namespace* and a name, referred to as a *fully qualified name*. The use of fully qualified names, called *by name linking*, makes it easy to identify and locate objects, and to correct broken references.

WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Deleting a message flow

Delete message flows from your message flow project when you no longer need them.

Before you begin

Deleting a message flow in the WebSphere Message Broker Toolkit deletes the project and its resources. If you are using a shared repository, the repository might retain a copy of a deleted resource.

Before you start:

This task assumes that you have created a message flow. For more information, see "Creating a message flow" on page 1431.

Before you delete a message flow, you can list resources that refer to that flow and would therefore be affected by the deletion; for more information, see "Showing resource references" on page 1447.

About this task

To delete a message flow, complete the following steps.

Procedure

1. Select the message flow that you want to delete, then click **Edit** > **Delete**. A confirmation dialog box is displayed.
2. Click **Yes** to delete the message flow, or **No** to cancel the delete request. When you click **Yes**, the requested objects are deleted.

   If you maintain resources in a shared repository, a copy is retained in that repository. You can follow the instructions provided by the repository supplier to retrieve the resource if required.

   If you are using the local file system or a shared file system to store your resources, no copy of the resource is retained. Be careful to select the correct resource when you complete this task.
3. Check the Problems view to see if errors have been returned to the delete request. Errors are generated if you delete a message flow that is embedded in another flow, because the reference is no longer valid.
   a. Click the error in the Problems view. The flow that now has a non-valid reference is displayed.

b. Either remove the node that represents the deleted flow from the parent flow, or create another message flow with the same name to provide whatever processing is required.

Results

When you delete the message flow, the files that are associated with the flow (the ESQL and mapping files, if present) are not deleted by this action. If you want to delete these files also, you must do so explicitly.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Deleting a broker schema

You can delete a broker schema that you have created in a message flow project if you no longer need it.

Before you begin

Before you start:

This topic assumes that you have already created a broker schema, as described in "Creating a broker schema" on page 1429. For more information about schemas, see "Broker schemas" on page 1036.

About this task

To delete a broker schema, complete the following steps.

Procedure

1. If the schema contains resources, delete them. To delete the schema, it must be empty. The schema might not be visible in the Broker Development view when it is empty. To show the new schema in the Broker Development view, click **Hide Categories**  on the Broker Development view toolbar.
2. Select the broker schema, then click **Edit** > **Delete**. A confirmation dialog box is displayed.
3. Click **Yes** to delete the broker schema directory or **No** to cancel the delete request. When you click **Yes**, the requested objects are deleted.

   If you maintain resources in a shared repository, a copy is retained in that repository. You can follow the instructions provided by the repository supplier to retrieve the resource, if required.

If you are using the local file system or a shared file system to store your resources, no copy of the resource is retained. Be careful to select the correct resource when you complete this task.

Results

Version and keyword information for deployable objects

Use the Broker Archive editor to view the version and keyword information of deployable objects.

You can display properties of deployed objects, and can modify associated comments:

- "Object version in the Broker Archive editor"
- "Version, deployment time, and keywords of deployed objects"
- "Path and Comment columns" on page 1444

Object version in the Broker Archive editor

The Version column on the Manage page of the Broker Archive editor displays the version tag for the following objects that have a defined version.

- `.dictionary` files
- `.cmf` files
- Embedded JAR files with a version defined in a `META-INF/keywords.txt` file

You cannot edit the Version column.

You can use the **mqsireadbar** command to list the keywords that are defined for each deployable file within a deployable archive file. For more information, see "**mqsireadbar** command" on page 3697.

Version, deployment time, and keywords of deployed objects

In the WebSphere Message Broker Explorer, the Properties QuickView displays the following properties for all deployed objects:

- Version
- Deployment time

- All defined keywords

For example, you deploy a message flow with the following literal strings:

- `$MQSI_VERSION=v1.0 MQSI$`
- `$MQSI Author=fred MQSI$`
- `$MQSI Subflow 1 Version=v1.3.2 MQSI$`

The Properties view displays these properties:

Property	Description
Deployment Time	Date and time of deployment
Modification Time	Date and time of modification. **Note:** This property has no concept of time zone, therefore it is only meaningful if you know in which time zone it was last modified.
Version	`v1.0`
Author	`fred`
Subflow 1 Version	`v1.3.2`

If the keyword information is not available, a message is displayed in the Properties view to indicate the reason; for example, if keyword resolution has not been enabled at deployment time, the Properties view displays the message `Deployed with keyword search disabled`.

Path and Comment columns

If you add source files, the Path column on the Manage tab is populated automatically.

To add a comment, double-click the Comment column and type the text that you require.

Embedded keywords in an XSL style sheet; their location is not restricted. You can also add a keyword as an XML comment.

"Broker Archive editor" on page 6794
Use the Broker Archive editor to create and manage broker archive (BAR) files.

"Guidance for defining keywords" on page 4017
You can add extra information to an object in the form of one or more keywords.

Message flow version and keywords:

When you are developing a message flow, you can define the version of the message flow as well as other key information that you want to be associated with it.

After the message flow has been deployed, you can view the properties of the message flow in the WebSphere Message Broker Toolkit. These properties include the deployment and modification dates and times (the default information that is displayed) as well as any additional version or keyword information that you have set.

You can define information to give details of the message flow that has been deployed; therefore, you can check that it is the message flow that you expect.

Version

You can set the version of the message flow in the `Version` property.

You can also define a default message flow version in the `Default version tag` of the message flow preferences. All new message flows that are created after this value has been set have this default applied to the `Version` property at the message flow level.

Keywords

Keywords are extracted from the compiled message flow (the `.cmf` file) rather than the message flow source (the `.msgflow` file). Not all the source properties are added to the compiled file. Therefore, add message flow keywords in only these places:

- The `label` property of a Passthrough node
- ESQL comments or string literals
- The `Long Description` property of the message flow

Any keywords that you define must follow certain rules to ensure that the information can be parsed. The following example shows some values that you might want to define in the `Long Description` property:

```
$MQSI Author=John Smith MQSI$
$MQSI Subflow 1 Version=v1.3.2 MQSI$
```

The following table contains the information that the WebSphere Message Broker Toolkit shows.

Message flow name	Example
Deployment Time	28-Aug-2004 15:04
Modification Time	28-Aug-2004 14:27
Version	v1.0
Author	John Smith
Subflow 1 Version	v1.3.2

In this display, the version information has also been defined using the `Version` property of the object. If the version information has not been defined using the property, it is omitted from this display.

If message flows contain subflows, you can embed keywords in each subflow.

Restrictions within keywords

Do not use the following characters within keywords because they cause unpredictable behavior:

```
^ $ . | \ < > ? + * = & [ ] ( )
```

You can use these characters in the values that are associated with keywords; for example:

- `$MQSI RCSVER=$id$ MQSI$` is acceptable
- `$MQSI $name=Fred MQSI$` is not acceptable

Related concepts:

"Version and keyword information for deployable objects" on page 1443
Use the Broker Archive editor to view the version and keyword information of deployable objects.

"Subflows" on page 1030
You can include subflows in your message flows in the same way as you include built-in or user-defined nodes. You can also connect subflows to other nodes in the same way.

Showing resource references

If you are considering changing a resource, you can see a list of other resources that would be affected by that change.

Before you begin

Before you start:

Before you can search for affected resources, you must enable indexing by following the instructions in "Enabling and disabling indexing" on page 1454.

About this task

To search for affected resources, complete the following steps.

Procedure

1. Right-click a resource in the Broker Development view and click **Show all references**.

   The search results view shows all affected references in a tree format, including the location of that resource, such as a node property or the line number of an ESQL file.

2. Optional: To open a resource in the appropriate editor, double-click a resource. Alternatively, to choose the editor in which to open a resource, right-click the resource and click **Open with**.

What to do next

If you are considering renaming or moving a resource, and you know the new name or location, you can run impact analysis; for more information, see "Impact analysis: analyzing the effects of planned changes to your applications" on page 1150.

Related concepts:

"Resources" on page 36
The projects, folders, and files that you work with in the WebSphere Message Broker Toolkit workspace are called *resources*. By default, these resources are stored with their metadata in the workspace directory in your local file system. The workspace directory is created the first time that you start the WebSphere Message Broker Toolkit.

"Impact analysis: analyzing the effects of planned changes to your applications" on page 1150
When developing an application, you might want to change the names of some artifacts, or move them. Impact analysis reports the artifacts that are likely to be affected by a particular change.

Enable indexing to support impact analysis.

Related reference:

"Impact analysis: reference" on page 4174
Some artifacts are excluded from secondary analysis.

Saving a message flow

You might want to save your message flow when you close the WebSphere Message Broker Toolkit, work with another resource, or validate the contents of the flow.

Before you begin

Before you start:

This topic assumes that you have created or opened a message flow, as described in the following topics:

- "Creating a message flow" on page 1431
- "Opening an existing message flow" on page 1433

About this task

To save a message flow, complete the following steps.

Procedure

1. To save the flow without closing it, click **File** > **Save**. You can also save everything by clicking **File** > **Save All**.

   The message flow is saved and the message flow validator validates the contents of the flow. The validator reports all errors that it finds in the Problems view. The flow remains open in the editor view. For example, if you save a message flow and have not set a mandatory property, an error message

appears in the Problems view and the editor marks the node with the error icon  . The message flow in the Broker Development view is also marked with the error icon. This error can occur if you have not edited the properties of an MQInput node to define the queue from which the input node retrieves its input messages.

You might also get warnings when you save a message flow; warnings are also shown in the Problems view. Warnings indicate that, although the configuration of the message flow does not contain an explicit error, the configuration might result in unexpected results when the flow completes. For example, if you have included an input node in your message flow that you have not connected to another node, you get a warning.

2. If you save a message flow that includes a subflow, and the embedded subflow is no longer available, three error messages are added to the Problems view. These errors indicate that the input and output terminals and the embedded subflow itself cannot be located. This error can occur if the embedded subflow has been moved or renamed.

   To resolve this situation, right-click the subflow node in error and click **Locate Subflow**. The Locate Subflow dialog box is displayed, listing the available message flow projects. Expand the list and explore the resources available to locate the required subflow. Select the correct subflow and click **OK**. All references in the current message flow are updated and the errors are removed from the Problems view.

3. You can also save a message flow when you close it. When you click **File** > **Close**, you are asked if you want to save the flow. Click **Yes** to save and close. Validation occurs and all errors and warnings are written to the Problems view.

What to do next

For information about using the **File** > **Save As** option to take a copy of the current flow, see "Copying a message flow by using the save option" on page 1450.

For information about handling errors that occur when you save, see "Correcting errors from saving a message flow" on page 1451.

WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Copying a message flow by using the save option:

You can copy a message flow by using the **File** > **Save As** option.

Before you begin

Before you start:

This topic assumes that you have created or opened a message flow, as described in the following topics:
- "Creating a message flow" on page 1431
- "Opening an existing message flow" on page 1433

Procedure

1. Click **File** > **Save As**.
2. Specify the message flow project in which you want to save a copy of the message flow. By default, the current project is selected; you can accept this name, or choose another name from the list.
3. Specify the name for the new copy of the flow. To save this message flow in the same project, you must either give it another name, or confirm that you want to overwrite the current copy.

   To save the message flow in another project, the project must already exist. You can save the flow with the same name or another name in another project.
4. Click **OK**.

   The message flow is saved and its contents are validated. The editor provides a report of errors and warnings in the Problems view.

What to do next

For information about handling errors that occur when you save a message flow, see "Correcting errors from saving a message flow" on page 1451.

WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Correcting errors from saving a message flow:

Correct the errors that are reported when you save a message flow.

About this task

When you save a message flow, as described in "Saving a message flow" on page 1448, the flow is validated. Errors and warnings are shown in the Problems view. The following steps describe how to correct errors that occur when you save a flow.

Procedure

1. Examine the list of errors and warnings in the Problems view.
2. Double-click each entry in turn.

   The message flow is opened in the editor view (if it is not already open), and the editor selects the node in which the error was detected. If the error has been generated because you have not set a mandatory property, the editor also opens the Properties view, or dialog box, for that node.

   If you have included a user-defined node in your message flow, and have defined one or more of its properties as configurable, you might get a warning about a custom property editor. If you define a property as a configurable property, and you have specified that it uses a custom property editor, the Broker Archive editor cannot handle the custom property editor, and handles the property as if it is type string. This action restricts your ability change this property at deployment time.
3. Correct the error that is indicated by the message. For example, provide a value for a mandatory property.

4. When you have corrected all the errors, save the message flow again.

   The editor validates all the resources that you have changed, and removes the corresponding graphical indication from the nodes that you have modified successfully. Corrected errors are also removed from the Problems view.

Results

You do not have to correct every error to save your work. The editor saves your resources even if it detects errors or warnings, so that you can continue to work with them at a later date. However, you cannot deploy a resource that has a validation error. You must correct every error before you deploy a resource. Warnings do not prevent successful deployment.

Importing and exporting resources in a Project Interchange file

You can import resources to, or export resources from, WebSphere Message Broker by using a Project Interchange file.

About this task

You can work with resources created by other products by importing them into WebSphere Message Broker in a Project Interchange file. For example, you can define a WebSphere Message Broker message set from WebSphere Process Server resource files. In this case, you would export the resources from WebSphere Process Server in the Project Interchange file, then import the file into WebSphere Message Broker.

Similarly, you can share pattern instance projects between WebSphere Message Broker Toolkit workspaces. You can export the pattern instance project into a Project Interchange file, then import the pattern instance project into another workspace.

Procedure

To import or export a Project Interchange file, complete the following steps.

- To import a Project Interchange file:
  1. Click **File** > **Import**. The Import wizard opens.
  2. Expand **Other**, click **Project Interchange**, then click **Next**.
  3. Specify the location of the Project Interchange file that you want to import.
  4. Specify the location to which you want to import the resources. By default, your current workspace is selected.
  5. Select the projects that you want to import, then click **Finish**.
- To export a Project Interchange file:
  1. Click **File** > **Export**. The Export wizard opens.
  2. Expand **Other**, click **Project Interchange**, then click **Next**.
  3. Select the projects that you want to export, and specify the location for the compressed file that is created. You can save the file to a folder on your file system, or to a disk drive.
  4. Click **Finish**. The Project Interchange file is created in the specified location.

Enabling and disabling indexing

Enable indexing to support impact analysis.

About this task

Indexing must be enabled to support impact analysis. The act of indexing determines what definitions and relationships exist in WebSphere Message Broker artifacts. These definitions and relationships are used to perform impact analysis. By default, indexing is disabled, for performance reasons.

Procedure

1. Click **Window** > **Preferences**, then click **Broker Development** > **Impact Analysis** in the left pane.
2. Optional: To enable indexing, select **Enable the indexing of Message Broker artifacts**.
   - When indexing is enabled, a full build of all artifacts in the workspace occurs once. Indexing of artifacts occurs on further incremental and full builds. Only artifacts participating in the builds are indexed.
   - Indexes for these artifacts are stored in memory, and written to disk when the WebSphere Message Broker Toolkit is shut down.
3. Optional: To disable indexing, clear the **Enable the indexing of Message Broker artifacts** check box.
   - Indexes of artifacts are removed from memory.
   - When the WebSphere Message Broker Toolkit is shut down, an index of items in memory is written to disk. This index is smaller, because the indexes of artifacts have been removed.
   - Artifacts are not indexed during builds, resulting in better performance.

Designing a message flow

A message flow can perform a wide range of operations, depending on your business and operational requirements. For best performance and capability, you must design it to include the most appropriate nodes.

Before you begin

Before you start:

Read the following concept topic: "Message flow nodes" on page 1024.

About this task

When you design a message flow, consider the following questions and options:

- The mode that your broker is working in can affect the types of node that you can use and the number of message flows you can deploy. For more information, see "Restrictions that apply in each operation mode" on page 3657.
- Which nodes provide the function that you require. In many cases, you can choose between several nodes that provide a suitable function. You might have to consider other factors listed here to determine which node is best for your overall needs. You can include built-in nodes, user-defined nodes, and subflow nodes. For more information, see "Deciding which nodes to use" on page 1457.
- Whether it is appropriate to include more than one input node. For more information, see "Using more than one input node" on page 1473.
- How to specify the characteristics of the input message. For more information, see "Defining input message characteristics" on page 1475.
- Whether to determine the path that a message follows through the message flow, based on the content or the characteristics of the message. Several nodes provide checks or examination of the message, and have output terminals that can be connected to direct certain messages to different nodes. For more information, see "Using nodes for decision making" on page 2209.
- Whether you can use subflows that provide a well-defined subset of processing. You might be able to reuse subflows that were created for another project (for example, an error processing routine), or you might create a subflow in your current project, and reuse it in several places in the same message flow. For more information, see "Subflows" on page 1030.
- What response times your applications expect from the message flow. This factor is influenced by several aspects of how you configure your nodes and the message flow. For more information, see "Optimizing message flow response times" on page 3264.
- Whether your message flow processing makes demands on system resources such as stack size. For more information, see "System resources for message flow development" on page 3267.
- Whether you can use the destination list in the local environment that is associated with the message to determine the processing in the message flow (for example, by using RouteToLabel and Label nodes), or the target for the

output messages (for example, by setting the `Destination Mode` property of the MQOutput node to Destination List). For more information, see “Creating destination lists” on page 1477.

- Whether to use WebSphere MQ cluster queues. For more information, see “Using WebSphere MQ cluster queues for input and output” on page 1544.
- Whether to use WebSphere MQ shared queues on z/OS . For more information, see “Using WebSphere MQ shared queues for input and output (z/OS)” on page 1546.
- Whether to validate input messages that are received by the input node, or output messages that are generated by the Compute node, or both. For more information, see “Validating messages” on page 1478.
- Whether to view or record message structure in Trace node output. For more information, see “Viewing the logical message tree in trace output” on page 1481.
- Whether your message flows access data in databases. You must configure brokers, databases, and database connections to enable this function, as described in “Working with databases” on page 2109. You must also configure your message flows; see “Accessing databases from message flows” on page 2112.

  If you include nodes that use ESQL, for information about how to code the appropriate statements, see “Accessing databases from ESQL” on page 2115. If you want to access databases from Java nodes by using JDBC, see “Interacting with databases by using the JavaCompute node” on page 2661 or “Extending the capability of a Java message processing or output node” on page 3069.

  You can also access databases through the Broker Application Development perspective in the WebSphere Message Broker Toolkit; see “Adding database definitions to the WebSphere Message Broker Toolkit” on page 2278.
- Whether your message flows access data in files. By using the FileInput and FileOutput nodes, your message flows can read messages from files and write messages to files in the local file system, or on a network file system that appears local to the broker. For more information, see “Connecting client applications” on page 1537.
- Whether your messages must be handled in a transaction. You can set the properties of some built-in nodes to control how transactions are managed, and how messages are processed in a transaction. For more information, see “Configuring transactionality for message flows” on page 1290.

  If you want to include JMSInput and JMSOutput nodes in your message flow transactions, you must consider the additional information in “Configuring JMS and SOAP nodes to support global transactions” on page 1716.
- Whether you want your messages to go through data conversion. For information about the available options, see “Configuring message flows for data conversion” on page 1293.
- Whether you want to use the MQGet node. For more information about how messages are processed by the MQGet node, and a description of a request-reply scenario that uses this node, see “Using MQGet nodes” on page 1564.
- How your message flows can benefit from user exits. For more information, see “Exploiting user exits” on page 2985.
- What steps to take to ensure that messages are not lost. For more information, see “Ensuring that messages are not lost” on page 1561.
- How errors are handled in the message flow. You can use the facilities provided by the broker to handle any errors that arise during message flow execution (for example, if the input node fails to retrieve an input message, or if writing to a

database results in an error). However, you might prefer to design your message flow to handle errors in a specific way. For more information, see "Handling errors in message flows" on page 2823.

- Whether you want a systems monitoring tool to be able to query, discover, and set certain user-defined properties at run time. For more information, see "Setting message flow user-defined properties at run time in a CMP application" on page 985.

For a basic introduction to developing message flows, see the IBM Redbooks publication WebSphere Message Broker Basics. (This link works only if you are connected to the Internet.)

You can define your own nodes to use in WebSphere Message Broker message flows.

Deciding which nodes to use

WebSphere Message Broker includes many message processing nodes that you can use in your message flows.

Before you begin

Before you start:

Read the concept topic, "Message flow nodes" on page 1024.

About this task

WebSphere Message Broker also provides an interface that you can use to define your own nodes, known as user-defined nodes.

The mode that your broker is working in can affect the types of node that you can use; see "Restrictions that apply in each operation mode" on page 3657.

Your decision about which nodes to use depends on the processing that you want to perform on your messages.

Input, output, and request nodes

Input and output nodes define points in the message flow to which client applications send messages (input nodes, such as MQInput), and from which client applications receive messages (output nodes, such as

MQOutput). Client applications interact with these nodes by putting messages to, or getting messages from, the I/O resource that is specified by the node as the source or target of the messages. Although a message flow must include at least one input node, it does not have to include an output or request node.

An input node is different from other nodes, because it controls when the rest of the message flow is triggered to do its processing. The input node is designed to check when there is data for the message flow to process, read that data from the transport or server, and present that data to the rest of the flow for processing. The other nodes do processing, but do not control when the flow gets invoked.

You can also use reply, request, and response nodes to interact with other applications from within a message flow; these types of node are supplied for a subset of protocols only.

- If you are creating a message flow for deployment to a broker, you must include at least one input node to receive messages. The input node that you select depends on the source of the input messages, and where in the flow you want to receive the messages.
- If you want to send the messages that are produced by the message flow to a target application, you can include one or more output nodes. The output node that you select depends on the transport across which the target application expects to receive those messages.
- If you want to make a request, in the middle of your flow, to an external system, and put the result into the message tree, use a request node.

Nodes for manipulating, enhancing, and transforming messages

Most enterprises have applications that have been developed over many years, on different systems, using different programming languages, and different methods of communication. WebSphere Message Broker removes the need for applications to understand these differences by providing the ability to configure message flows that transform messages from one format to another.

For example, personal names are held in many forms in different applications. Family name first or last, with or without middle initials, uppercase or lowercase, are just some of the permutations. Because you can configure your message flow to know the requirements of each application, each message can be transformed to the correct format without modifying the sending or receiving application.

You can work with the content of the message to update it in several ways. Your choices here might depend on whether the message flow must handle predefined (modeled) messages, self-defining messages (for example, XML), or both.

A message flow can completely rebuild a message, convert it from one format to another (for example, changing order of fields, byte order, or language), remove content from the message, or introduce specific data into it. For example, a node can interact with a database to retrieve additional information, or to store a copy of the message (whole or part) in the database for offline processing.

The following examples show the importance of message transformation:

- An order entry application has a part ID in the body of the message, but its associated stock application expects it in the message header. The

message is directed to a message flow that knows the two different formats, and can therefore reformat the information as it is needed.

- A data-entry application creates messages containing stock trade information. Some applications that receive this message need the information as provided, but others need additional information added to the message about the price to earnings (PE) ratio. The stock trade messages are directed to a message flow that passes the message unchanged to some output nodes, but calculates and adds the extra information for the others. The message flow does this calculation by looking up the current stock price in a database, and uses this value and the trade information in the original message to calculate the PE value before passing on the updated message.

You can also create message flows that use these nodes to interact with each other. Although the default operation of one message flow does not influence the operation of another message flow, you can force this action by configuring your message flows to store and retrieve information in an external source, such as a database.

These nodes are supplied to transform messages.

Nodes for making decisions

You can use nodes that determine the order and flow of control in the message flow in various ways to decide how messages are processed by the flow. You can also use nodes (TimeoutControl and TimeoutNotification) that determine the time, and frequency of occurrence, of events in the message flow. Routing is independent of message transformation, although the route that a message takes might determine exactly what transformation is performed on it.

For example, a money transfer application always sends messages to one other application. You might decide that every message with a transfer value of more than $10,000 must also be sent to a second application, to enable all high-value transactions to be recorded.

In another example, a national auto club offers a premier service to specific members for orders above a threshold value. Most orders are routed through the typical channels, but, if the membership number and order value meet certain criteria, the order gets special treatment.

You can also establish a more dynamic routing option by building additional routing information into the message when it is processed. Optional sets of rules are set up to receive messages according to values (destinations) set into the message. You can establish these rules such that a message is processed by one or more of the optional sets of rules, in an order determined by the added message content.

These nodes are provided to decide about the route that a message follows through the message flow.

Nodes for controlling time-sensitive operations

You might want a batch application process to run every day at a specific time, or you might want information to be processed and published at fixed intervals (for example, currency exchange rates are calculated and sent to banks), or you might want to take a specified recovery action if certain transactions are not completed within a defined time. For all these cases, two timeout nodes (TimeoutControl and TimeoutNotification) are provided; see “Nodes for controlling time-sensitive operations” on page 1471.

Miscellaneous nodes

Other nodes exist to do the following tasks:

- Collate requests
- Create message collections
- Control the sequence of messages
- Handle and report errors
- Invoke the message flow security manager

See "Miscellaneous nodes" on page 1472 for details.

Related concepts:

You can use several built-in nodes in different ways to control the path that a message takes through the message flow.

Chapter 11, "Packaging and deploying," on page 3209
Package resources that you create in the WebSphere Message Broker Toolkit, such as message flows, and deploy them to execution groups on brokers.

Related reference:

"**mqsisetdbparms** command" on page 3954
Use the **mqsisetdbparms** command to associate a specific user ID and password (or SSH identity file) with one or more resources that are accessed by the broker.

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Input nodes:

You must include at least one input node in your message flow.

An input node is different from other nodes, because it controls when the rest of the message flow is triggered to do its processing. The input node is designed to check when there is data for the message flow to process, read that data from the transport or server, and present that data to the rest of the flow for processing. The other nodes do processing, but do not control when the flow gets invoked.

DatabaseInput node
Use the DatabaseInput node to respond to events in a database. For example, the broker can keep an external system synchronized with a database by sending updates to the target system whenever data is changed in the database.

EmailInput node
Use the EmailInput node to retrieve an email, with or without attachments, from an email server that supports Post Office Protocol 3 (POP3) or Internet Message Access Protocol (IMAP).

FileInput node
Use a FileInput node if the messages are contents of files.

FTEInput node
Use the FTEInput node to receive files using WebSphere MQ File Transfer Edition.

HTTP input node
Use an HTTPInput node if the messages are sent by a Web services client.

Input node
If you are creating a message flow that you want to embed in another message flow (a subflow) that you will not deploy as a stand-alone message flow, you must include at least one Input node to receive messages into the subflow.

An instance of the Input node represents an In terminal. For example, if you have included one instance of the Input node, the subflow icon shows one In terminal, which you can connect to other nodes in the main flow in the same way that you connect any other node.

To deploy a message flow, it must have at least one input node. If your message flow does not contain an input node, you are prevented from adding it to the broker archive file. The input node can be in the main flow, or in a message flow that is embedded in the main flow.

You can use more than one input node in a message flow. For more information, see "Using more than one input node" on page 1473.

JMSInput node
Use a JMSInput node if the messages are sent by a JMS application.

MQInput node
Use an MQInput node if the messages arrive at the broker on a WebSphere MQ queue, and the node is to be at the start of a message flow.

SCAInput node
Use the SCAInput node with the SCAReply node to process messages from WebSphere Process Server.

SOAP input node
Use the SOAPInput node to process client SOAP messages and to configure the message flow to behave like a SOAP Web Services provider.

TCPIPClientInput or TCPIPServerInput node
Use a TCPIPClientInput node or a TCPIPServerInput node to create a TCP/IP connection when messages are sent through raw TCP/IP sockets.

TCPIPClientReceive or TCPIPServerReceive node
Use a TCPIPClientReceive node or a TCPIPServerReceive node to read the messages that arrive in the message flow through a TCP/IP connection.

User-defined input node
Use a user-defined input node if the message source is a client or application that uses a different protocol or transport.

WebSphere Adapters nodes
Use the WebSphere Adapters nodes to interact with Enterprise Information Systems (EIS) such as SAP, Siebel, and PeopleSoft. The following input nodes are available:

- SAPInput node
- SiebelInput node
- PeopleSoftInput node
- JDEdwardsInput
- TwineballInput node

The WebSphere Adapters input nodes monitor an EIS for a particular event. When that event occurs, business objects are sent to the input node. The node constructs a tree representation of the business objects and propagates it to the Out terminal so that the data can be used by the rest of the message flow.

The WebSphere Adapters request nodes can send and receive business data. They request information from an EIS and propagate the data to the rest of the message flow.

Related tasks:

"Deciding which nodes to use" on page 1457
WebSphere Message Broker includes many message processing nodes that you can use in your message flows.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Output nodes:

If you want to send the messages that are produced by the message flow to a target application, include one or more output nodes in the flow.

EmailOutput node
Use the EmailOutput node to send an email message to one or more recipients.

FileOutput node
Use a FileOutput node if a file is the target of the output messages.

FTEOutput node
Use the FTEOutput node to write messages to files using the WebSphere MQ File Transfer Edition.

HTTPReply node
Use an HTTPReply node if the messages are in response to a Web services client request.

JMSOutput and JMSReply nodes
Use a JMSOutput node if the messages are for a JMS destination.

The JMSReply node has a similar function to the JMSOutput node, but the JMSReply node sends JMS messages only to the reply destination that is supplied in the JMSReplyTo header field of the JMS message tree. Use the JMSReply node to treat a JMS message that is produced from a message flow as a reply to a JMS input message, and when you have no other routing requirements.

MQOutput and MQReply nodes
Use an MQOutput node if the target application expects to receive messages on a WebSphere MQ queue, or on the WebSphere MQ reply-to queue that is specified in the input message MQMD.

Use an MQReply node if the target application expects to receive messages on the WebSphere MQ reply-to queue that is specified in the input message MQMD.

Output node
If you are creating a message flow that you want to embed in another message flow (a subflow) that you will not deploy as a stand-alone message flow, you must include at least one Output node to propagate messages to subsequent nodes that you connect to the subflow.

An instance of the Output node represents an Out terminal. For example, if you have included two instances of the Output node, the subflow icon shows two Out terminals, which you can connect to other nodes in the main flow in the same way that you connect any other node.

Publication node
Use a Publication node to distribute the messages using the publish/subscribe network for applications that subscribe to the broker across all supported protocols. A Publication node is an output node that uses output destinations that are identified by subscribers whose subscriptions match the characteristics of the current message.

SAPReply node
Use this node with the SAPInput node to respond to an incoming SAP event.

SOAPReply node
Use a SOAPReply node if the target application expects to receive SOAP messages in response to a message sent to the SOAPInput node.

SCAReply node
Use the SCAReply node to send a message from the broker to the originating client in response to a message received by a SCAInput node.

TCPIPClientOutput or TCPIPServerOutput node
Use a TCPIPClientOutput node or a TCPIPServerOutput node if the messages are to be sent to the target application through raw TCP/IP sockets.

User-defined output node
Use a user-defined output node if the target is a client or application that uses a different protocol or transport.

Related tasks:

"Deciding which nodes to use" on page 1457
WebSphere Message Broker includes many message processing nodes that you can use in your message flows.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Request nodes:

If you want to make a request, in the middle of your flow, to an external system, and put the result into the message tree, use a request node.

MQGet node
Use an MQGet node to retrieve a message from a WebSphere MQ queue, if you want to get the message later in the message flow.

HTTPRequest node
Use an HTTPRequest node if your message flow interacts with a web service after it has started.

FileRead node
Use the FileRead node to read a file from the middle of a message flow. The node can:

- Read the entire contents of the file.
- Read a single record.
- Rename or delete the file without reading any data.

WebSphere Adapters nodes
Use the WebSphere Adapters nodes to interact with Enterprise Information Systems (EIS) such as SAP, Siebel, and PeopleSoft. The following request nodes are available:

- SAPRequest node
- SiebelRequest node
- PeopleSoftRequest node
- JDEdwardsRequest node
- TwineballRequest node

SOAP nodes
Use the SOAP nodes to process client SOAP messages and to configure the message flow to behave like a SOAP web Services provider:

- SOAPRequest
- SOAPAsyncRequest
- SOAPAsyncResponse

WebSphere Service Registry and Repository (WSRR) nodes
Use the WebSphere Service Registry and Repository nodes to retrieve web services information:

- Use the EndpointLookup node to retrieve service endpoint information held in the WebSphere Service Registry and Repository.
- Use the RegistryLookup node to retrieve any type of entity held in the WebSphere Service Registry and Repository.

IMSRequest node
Use the IMSRequest node to send a request to run a transaction on a local or remote IBM Information Management System (IMS) system, and wait for a response. IMS Connect must be configured and running on the IMS system.

CORBARequest node

Use the CORBARequest node to call an external CORBA application over Internet Inter-Orb Protocol (IIOP). You can create a message flow that contains a CORBARequest node, which calls a CORBA server. The message flow uses an IDL file to call methods on a remote CORBA object. You can then give existing CORBA applications a new external interface; for example, a SOAP interface.

CICSRequest node

Use the CICSRequest node to call an external CICS Transaction Server for z/OS application over TCP/IP-based IP InterCommunications (IPIC) protocol. You can create a message flow that contains a CICSRequest node, which calls an application on CICS. By using the CICS support that is provided in WebSphere Message Broker you can deploy CICS applications into a service-oriented architecture (SOA).

Database node

Use the Database node to interact with a database that is identified by the node properties. The Database node handles both predefined and self-defining messages. Use the ESQL editor to code ESQL functions to update database content from the message, insert new information into the database, and delete information from the database, using information in the message. Do not use the ESQL code that you develop for use in a Database node in any other type of node.

This node provides a flexible interface with a wide range of functions. It also has properties that you can use to control the way in which the interaction participates in transactions.

You can control the way in which the database is accessed by this node by specifying user and password information for the data source that you specify in the node properties. Use the **mqsisetdbparms** command to initialize and maintain these values.

You can update only databases from this node; you cannot update message content. If you want to update message content, use the Compute or Mapping node.

DataDelete, DataInsert, DataUpdate nodes

The DataDelete, DataInsert, and DataUpdate nodes are specialized forms of the Database node that provide a single mode of interaction (deletion of one or more rows, insertion of one or more rows, or update of one or more existing rows).

The DataDelete, DataInsert, and DataUpdate nodes handle only predefined messages. Use a mapping editor to develop mappings to perform these functions. Do not use the mappings that you develop for these nodes in any other type of node. You can use these nodes to control the transactional characteristics of the updates that they perform.

You can control the way in which the database is accessed by these nodes by specifying user and password information for the data source that you specify in the node property. Use the **mqsisetdbparms** command to initialize and maintain these values.

You can update only databases from these nodes; you cannot update message content. If you want to update message content, use the Compute or Mapping node.

DatabaseRetrieve node

Use the DatabaseRetrieve node to ensure that information in a message is

up to date. Use the node to modify a message using information from a database. For example, you can add information to a message using a key, such as an account number, that is contained in a message. Use the DatabaseRetrieve node to implement message routing with minimal programming logic. For more advanced routing scenarios, use a Compute node or a JavaCompute node.

Warehouse node

The Warehouse node provides a store interface that you can use to store all or part of the message in a database, for example, for audit reasons. The Warehouse node handles only predefined messages. Use the Mapping editor to develop mappings to perform this action. Do not use the mappings that you develop for a Warehouse node in any other type of node.

You can control the way in which the database is accessed by this node by specifying user and password information for the data source that you specify in the node property. Use the **mqsisetdbparms** command to initialize and maintain these values.

You can update only a database from this node; you cannot update message content. If you want to update message content, use the Compute or Mapping node.

SCARequest, SCAAsyncRequest, and SCAAsyncResponse nodes

- The SCARequest node is used to send a request to WebSphere Process Server. The node is configured using a Broker SCA Definition (`.outsca`) file; depending on the contents of the `.outsca` file, requests are either:
  - Two-way, synchronous; the node sends the request, then blocks until it receives a response, or the timeout period is exceeded.
  - One-way; the node sends a request only.
- The SCAAsyncRequest and SCAAsyncResponse nodes are used to construct a pair of message flows that call a WebSphere Process Server service component asynchronously.

  The SCAAsyncRequest node sends an SCA outbound request to a service component that runs in WebSphere Process Server.

  The SCAAsyncResponse node receives the response from a business process that is running in WebSphere Process Server and to which the previous asynchronous request was made. The SCAAsyncResponse node can be in the same message flow or in a separate message flow.

  Calling a WebSphere Process Server service component asynchronously means that the SCAAsyncRequest node sends a request but does not wait for the associated response to be received, although it might wait for an acknowledgment of the request.

  The nodes are used as a pair, and correlate responses and requests. See "SCAAsyncRequest node" on page 4690 and "SCAAsyncResponse node" on page 4698.

WebSphere Message Broker includes many message processing nodes that you can use in your message flows.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Nodes for manipulating, enhancing, and transforming messages:

Optionally, include nodes to change messages.

Compute node

Use the Compute node to:

- Manipulate message content
- Transform the message in some way
- Interact with a database to modify the content of the message or the database and pass on one or more new messages

You can use this node to manipulate predefined and self-defining messages.

Use the ESQL editor to create an ESQL module, specific to this node, that contains the statements that define the actions to perform against the message or database. Do not use the ESQL code that you develop for use in a Compute node in any other type of node.

You can control the way in which the database is accessed by this node by specifying user and password information for the data source that you specify in the node property. Use the **mqsisetdbparms** command to initialize and maintain these values.

If possible, perform your message manipulation requirements in a single Compute node. Fewer, more complex Compute nodes perform better than a larger number of simpler nodes because the broker parses the message on entry to each Compute node.

JavaCompute node

Use the JavaCompute node to:

- Examine an incoming message and, depending on its content, propagate it unchanged to one of the node's output terminals. The node behaves in a similar way to a Filter node, but uses Java instead of ESQL to determine which output terminal to use.
- Change part of an incoming message and propagate the changed message to one of the output terminals.
- Interact with a database through a JDBC type 4 connection to modify the content of the message or the database and pass on one or more new messages
- Create and build a new output message that is independent of the input message.

PHPCompute node

Use the PHPCompute node to route and transform an incoming message, using the PHP scripting language. The node functions in a similar way to the JavaCompute node, but uses PHP instead of Java for message transformation and routing.

Mapping node

Use the Mapping node to create a message from the input message by mapping the content of elements of the output message from elements of the input message, or from database content. You can also extract parts of the message, and optionally change their content, to create an output message that is a partial copy of the message that is received by the node. The Mapping node handles only predefined messages.

You can control the way in which the database is accessed by this node by specifying user and password information for the data source that you specify in the node property. Use the **mqsisetdbparms** command to initialize and maintain these values.

Use the Mapping editor to develop mappings to perform simple manipulations on predefined messages. Do not use the mappings that you develop for use in a Mapping node in any other type of node.

Extract node

The Extract node is deprecated in WebSphere Message Broker . Although message flows that contain an Extract node remain valid in WebSphere Message Broker , where possible, redesign your message flows so that any Extract node is replaced by a Mapping node.

With an Extract node, you can create an output message from specified elements of the input message. You can extract parts of the message, and optionally change their content, to create an output message that is a partial copy of the message received by the node. The Extract node handles only predefined messages.

Use the Mapping editor to develop mappings to perform simple manipulations on predefined messages in the Extract node. Do not use the mappings that you develop for use in an Extract node in any other type of node.

XSLTransform node

Use the XSLTransform node (formerly known as the XMLTransformation node) to transform an input XML message into another format using XSLT style sheets and to set the message domain, message set, message type, and message format for the generated message. It is imperative that the data can be parsed into an XML message. The style sheet, using the rules that are defined in it, can perform the following actions:

- Sort the data
- Select data elements to include or exclude based on some criteria
- Transform the data into another format

The Xalan-Java transformation engine (Apache Xalan-java XSLT processor) is used as the underlying transformation engine. For more information about XML Transformations, the W3C specification of the syntax, and semantics of the XSL Transformations language for transforming XML documents into other XML documents, see W3C XSL Transformations.

You can deploy style sheets and XML files to broker execution groups, to help with style sheet and XML file maintenance.

JMSMQTransform node

Use the JMSMQTransform node to transform a message with a JMS message tree into a message that has a tree structure that is compatible with the format of messages that are produced by the WebSphere MQ JMS provider.

The JMSMQTransform node can be used to send messages to existing message flows and to interoperate with WebSphere MQ JMS and WebSphere MQ Publish/Subscribe.

MQJMSTransform node

Use the MQJMSTransform node to receive messages that have a

WebSphere MQ JMS provider message tree format, and transform them into a format that is compatible with messages that are to be sent to JMS destinations.

You can use the MQJMSTransform node to send messages to existing message flows and to interoperate with WebSphere MQ JMS and WebSphere MQ Publish/Subscribe.

SOAPEnvelope and SOAPExtract nodes
Use the SOAPEnvelope and SOAPExtract nodes to add or remove SOAP envelopes from the SOAP message body. You can use the SOAPExtract node both to extract the envelope, and to route the message based on the message content to a Label node.

Header nodes
Use the HTTPHeader, JMSHeader, or MQHeader nodes to manipulate HTTP, JMS, and WebSphere MQ transport headers and their properties without writing compute nodes. You cannot use these nodes to change the message body.

- Use the HTTPHeader node to add, modify, or delete HTTP headers such as HTTPInput, HTTPResponse, HTTPRequest and HTTPReply.
- Use the JMSHeader node to modify contents of the JMS Header_Values and Application properties so that you can control the node's output without programming.
- Use the MQHeader node to add, modify, or delete MQ Message Descriptor (MQMD) and MQ Dead Letter Header (MQDLH) headers.

User-defined processing node
Use a user-defined node processing node to handle specific requirements that are not met by the built-in nodes.

For example, if your node accesses a database, include a user-defined node to interact with the database. You can control the way in which the database is accessed by this node by specifying user and password information for the data source that you specify in the node property. Use the **mqsisetdbparms** command to initialize and maintain these values.

Related tasks:

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Nodes for making decisions:

Optionally, use nodes that determine the order and flow of control in the message flow in various ways to make decisions about how messages are processed by the flow.

Nodes for making decisions

Validate node
Use the Validate node to check that the message that arrives on its input terminal is as expected. You can check that the message has the expected message template properties (that is, the message domain, message set and message type) and that the content of the

message is correct. You can check the message against one or more of message domain, message set, or message type.

The Validate node replaces the Check node, which is deprecated in WebSphere Message Broker . The Validate node works in the same way as the Check node, but it has additional Validation properties to enable the validation of message content by parsers that support that capability.

Filter node

Use the Filter node with an ESQL statement to determine the next node to which the message is sent by this node. Do not use the ESQL code that you develop for use in a Filter node in any other type of node.

The node's terminals are True, False, Unknown, and Failure; the message is propagated to the True terminal if the test succeeds, and to the False terminal if it fails. If the statement cannot be resolved (for example, it tests the value of a field that is not in the input message), the message is propagated to the Unknown terminal. If any other error is detected, the message is propagated to the Failure terminal.

The test in the ESQL statement can depend on message content, database content, or a combination of the two.

If you refer to a database, you can control the way in which it is accessed by this node by specifying user and password information for each data source defined in the registry on the broker system. Use the **mqsisetdbparms** command to initialize and maintain these values.

Use this node in preference to the Compute node to provide message selection and routing; the Filter node is more efficient for this task.

FlowOrder node

You can connect the terminals of this node to force the message to be processed by one sequence of nodes, followed by a second sequence of nodes.

Passthrough node

Use the Passthrough node to enable version control of a subflow at run time. Use this node to add a label to your subflow. By combining this label with a reserved word replacement from your version control system, you can identify which version of a subflow is included in a deployed message flow. You can use this label for your own purposes. If you have included the correct version keywords in the label, you can see the value of the label:

- Stored in the broker archive (BAR) file, using the **mqsireadbar** command
- As last deployed to a particular broker, on the properties of a deployed message flow in the WebSphere Message Broker Toolkit
- In the broker, if you enable user trace for that message flow

Route node

Use the Route node to direct messages that meet certain criteria down different paths of a message flow. For example, you can forward a message to different service providers, based on the

request details. You can also use the Route node to bypass unnecessary steps. For example, you can check to see if certain data is in a message, and perform a database lookup operation only if the data is missing. If you set the `Distribution Mode` property to `All`, you can trigger multiple events that each require different conditions. For example, you can log requests that relate to a particular account identifier, and send requests that relate to a particular product to be audited.

Use the Route node to implement message routing with minimal programming logic. For more advanced routing scenarios, use a Compute node or a JavaCompute node.

RouteToLabel node
Use the RouteToLabel node following a Compute node or a JavaCompute node for complex routing. Define a list of destinations in a Compute or JavaCompute node that are acted on by the RouteToLabel node, which interrogates the destinations and passes the message on to the corresponding Label node.

DatabaseRoute node
Use the DatabaseRoute node to route a message using information from a database in conjunction with applied XPath routing expressions. The node looks up a collection of named column values from a located database row and synchronously applies one or more XPath expressions to these acquired values. Use the DatabaseRoute node to implement message routing with minimal programming logic. For more advanced routing scenarios, use a Compute node or a JavaCompute node.

Label node
Use the Label node as a target for the next sequence of one or more nodes that are to process a message. Use this node in combination with the RouteToLabel node for all types of messages, or with the SOAPExtract node for SOAP messages.

The Label node only routes the message to the next node in the flow and performs no processing.

ResetContentDescriptor node
Use the ResetContentDescriptor node to set new message properties that are used when the message bit stream is next parsed by a subsequent node in the message flow.

Related tasks:

"Deciding which nodes to use" on page 1457
WebSphere Message Broker includes many message processing nodes that you can use in your message flows.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Nodes for controlling time-sensitive operations:

Run processes at specific times, or at fixed intervals, and take action if transactions are not completed within a defined time.

TimeoutControl node
Use a TimeoutControl node and a TimeoutNotification node together in a

message flow to control events that occur at a specific time or at defined time intervals. The TimeoutControl node receives an input message that contains a timeout request. All or part of this input message is validated and stored to be propagated by an associated TimeoutNotification node in the message flow. The input message is also propagated unchanged to the next node in the message flow.

More than one TimeoutControl node can be associated with each TimeoutNotification node.

TimeoutNotification node
Use a stand-alone TimeoutNotification node to generate messages that are propagated at configured times or time intervals to the next node in the message flow for further processing.

Related tasks:

"Deciding which nodes to use" on page 1457
WebSphere Message Broker includes many message processing nodes that you can use in your message flows.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Miscellaneous nodes:

Nodes to perform a variety of tasks.

Nodes for collating requests

Use the AggregateControl, AggregateReply, and AggregateRequest nodes to collate related requests and responses. Use these nodes to generate several requests in response to one input message, to control and coordinate the responses that are received in response to those requests, and to combine the information that is provided by the responses to continue processing.

Node for creating message collections

Use the Collector node to generate collections of messages and make multiple synchronous or asynchronous requests in parallel. The Collector node does not need an initial fan-out stage, and can group unrelated input messages by correlating their content. You can configure dynamic input terminals on a Collector node to receive messages from different sources. You can also configure properties on the Collector node, known as event handlers, to determine how messages are added to a message collection, and when a message collection has completed.

Nodes for controlling the sequence of messages
Use the Sequence node to apply a sequence number to a message received from an input source, and the Resequence node to change the sequence of messages that contain a sequence number. You can divide messages into sequence groups and use the Sequence and Resequence nodes to control the sequences in groups of messages that arrive at the nodes.

Nodes for handling and reporting errors

Use the following nodes to affect error handling and reporting:

Trace node
Include a Trace node to generate one or more trace entries to record what is happening in the message flow at this point.

TryCatch node
Include a TryCatch node to control the error processing when exceptions are thrown.

Throw node
Include a Throw node to force an exception to be thrown, and specify the identity of the exception, to make it easier to diagnose the problem.

Node for invoking the message flow security manager
Use the SecurityPEP node to invoke the message flow security manager at any point in the message flow between an input node and an output (or request) node. The SecurityPEP node enables you to invoke the security manager even if your input nodes do not support message flow security. You can also use the SecurityPEP node to invoke different aspects of security (for example, authentication and authorization) at different points in the message flow.

Related tasks:

"Deciding which nodes to use" on page 1457
WebSphere Message Broker includes many message processing nodes that you can use in your message flows.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Using more than one input node

You can include more than one input node in a single message flow.

Before you begin

Before you start:

Read the following concept topic:

- "Message flow nodes" on page 1024

About this task

You might find this useful in the following situations:

- The message flow provides common processing for messages that are received from multiple transports. For example, a single message flow might handle:
  - Data in messages received from WebSphere MQ, and therefore through a WebSphere MQ queue and an MQInput node
  - Messages that are received from native IP connections (a Real-timeInput node)
- You need to set standard properties on the MQInput node if input messages:
  - are predefined, and
  - are all received from WebSphere MQ, and
  - do not include an MQRFH2 header.

If the required standard properties are not always the same for every message, you can include more than one input node and configure each to handle a particular set of properties.

This requirement is not necessary for self-defining messages.

- Each input node in a message flow causes the broker to start a separate thread of execution. Including more than one input node might improve the message flow performance. However, if you include multiple input nodes that access the same input source (for example, a WebSphere MQ queue), the order in which the messages are processed cannot be guaranteed. If you want the message flow to process messages in the order in which they are received, this option is not appropriate.

  If you are not concerned about message order, consider using additional instances of the same message flow rather than multiple input nodes. If you set the `Additional Instances` property of the message flow when you deploy it to the broker, multiple copies of the message flow are started in the execution group. This is the most efficient way of handling multiple instances.

Look at the following sample :

- Scribble

This sample uses two input nodes: an MQInput node and a Real-timeInput node. You can use these two input nodes to enable the sample's message flow to accept input from both WebSphere MQ transport and native IP connections. You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Defining input message characteristics

When a message is received by an input node in a message flow, the node detects how to interpret that message by determining the domain in which the message is defined and starting the appropriate parser.

Before you begin

Before you start:

Read the following concept topic:

- "Parsers" on page 1072

About this task

You can provide message domain information to the input node in one of two ways:

1. You can configure the built-in input nodes to indicate the message domain, and therefore the parser to be started, for each message that is received.
2. You can set values in the input message itself that specify this information. Include an MQRFH2 header, which contains a folder that defines the message characteristics. This approach is more flexible because it means that the input node can start the appropriate parser based on the content of each message.

If the input message is defined in the MRM domain, and is therefore interpreted by the MRM parser, you must specify the following additional properties:

- The `Message set` within which the message is defined
- The `Message type`, which is defined by the message model
- The `Message format`, which defines the physical characteristics of the message

The way that these properties are set depends upon the type of message, or node, that you want to use:

- If the message is a WebSphere MQ message, these properties can be set either in the input node or in the MQRFH2 header of the incoming message. If the properties are set in both, the properties of the MQRFH2 header take precedence. If the properties are not found in either the node or the MQRFH2 header, the default value is empty and the `BLOB` parser is used.
- If the message is a JMS message, the property that is set on the node takes precedence. If the `Message domain` is empty, the `Message domain` is, by default, derived according to certain criteria following a predetermined order of precedence; see "JMS message payload and appropriate parser" on page 1698.
- If the input message belongs to a `Message domain` other than those for which a parser is supplied, you must provide a user-defined parser to handle it, and a user-defined input node to accept it for processing in the message flow. Check the documentation provided with the user-defined parser and node for further information.
- If the `Message domain` is in a TimeoutControl node, an empty `Message domain` has either of the following results:
  - If the `Stored message location` property is also empty, the full message is stored. When the message comes back at TimeoutNotification, it is parsed in the same way as the original message.
  - If the `Stored message location` property is not empty, a partial message is stored and no parser is associated, therefore, by default, it is treated as `BLOB`.

- If the `Message domain` is in a ResetContentDescriptor node, an empty `Message domain` has either of the following results:
  - If `Reset message domain` is cleared, the domain is not reset.
  - If `Reset message domain` is selected, the default is `BLOB`.
- If the input node cannot determine the message characteristics, the default value is empty and the message is considered to be in the `BLOB` domain, and the `BLOB` parser is started.

Import either of the following samples, or another sample that uses a `Message set`, and look at the values on the **Input Message Parsing** properties tab of the input node in the sample's message flow.

- Video Rental
- Comma Separated Value (CSV)

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Parsers" on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

"Logical tree structure" on page 1042
The logical tree structure is the internal (broker) representation of a message. It is also known as the message assembly.

"Message modeling" on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

"How the message tree is populated" on page 1047
The message tree is initially populated by the input node of the message flow.

Related tasks:

"Designing a message flow" on page 1455
A message flow can perform a wide range of operations, depending on your business and operational requirements. For best performance and capability, you must design it to include the most appropriate nodes.

Creating destination lists

Create a list of destinations to indicate where a message is sent.

Before you begin

Before you start:

Read the concept topic "Message flow nodes" on page 1024.

About this task

You can include a Compute node in your message flow, and configure it to create a destination list in the local environment subtree. You can then use the destination list in the following nodes:

- The MQOutput and JMSOutput nodes, to put output messages to a specified list of destinations.
- The RouteToLabel node, to pass messages to Label nodes.

  For details about how this technique is used, look at the following sample:

  – Airline Reservations

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

For more information about accessing the LocalEnvironment subtree, destination list contents, and example procedures for setting values for each of these scenarios, see "Accessing the local environment tree" on page 2463.

For more information about how to populate destination in the LocalEnvironment subtree, and how to build JMS destination lists, see "Populating Destination in the local environment tree" on page 2467.

You might find it useful to create the contents of the destination list from an external database that is accessed by the Compute node. You can then update the destinations without needing to update and redeploy the message flow.

The use of the destination list to define which applications receive the output messages is in contrast to the publish/subscribe application model, in which the recipients of the publications are those subscribers that are currently registered with the broker. The processing that is completed by the message flow does not have any effect on the current list of subscribers.

Related concepts:

"Local environment tree structure" on page 1056
The local environment tree is a part of the logical message tree in which you can store information while the message flow processes the message.

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Validating messages

The broker provides validation based on the message model for predefined messages.

Before you begin

Before you start:

Read the concept topics about message flows and parsers, especially "MRM parser and domain" on page 1111 and "XMLNSC parser" on page 1090.

About this task

Validation applies only to messages that you have modeled and deployed to the broker. Specifically, the message domains that support validation are MRM, XMLNSC, SOAP, and IDOC.

The broker does not provide any validation for self-defining messages. The XMLNSC, and SOAP domains validate predefined messages directly against message model schema filesXML Schema files. The MRM and IDOC parsers validate predefined messages against the message dictionary generated from a message set.

Message flows are designed to transform and route messages that conform to certain rules. By default, parsers perform some validity checking on a message, but only to ensure the integrity of the parsing operation. However, you can validate a message more stringently against the message model contained in the message set by specifying validation options on certain nodes in your message flow.

You can use validation options to validate the following messages:
- Input messages that are received by an input node
- Output messages that are created, for example, by a Compute, Mapping, or JavaCompute node

These validation options can ensure the validity of data entering and leaving the message flow. The options provide you with some degree of control over the validation performed to:

- Maintain a balance between performance requirements and security requirements

- Validate at different stages of message flow completion; for example, on input of a message, before a message is propagated, or at any point in between
- Cope with messages that your message model does not fully describe

You can also specify what action to take when validation fails.

Message validation involves navigating a message tree, and checking the validity of the tree. Message validation is an extension of tree creation when the input message is parsed, and of bit stream creation when the output message is written.

Validation options are available on the following nodes:

Node type	Nodes with validation options
Input node	FileInput, FTEInput, HTTPInput, JMSInput, MQInput, SCAInput, , SOAPInput,TimeoutNotification,
Output node	FileOutput, FTEOutput, HTTPReply, JMSOutput, JMSReply, MQOutput, MQReply, SCAReply, SOAPReply
Other nodes	Compute, CICSRequest, DatabaseRetrieve, HTTPRequest, JavaCompute, Mapping, MQGet, ResetContentDescriptor, SCAAsyncResponse, SCARequest, SOAPRequest, SOAPAsyncResponse, Validate, XSLTransform

Validation options can also be specified on the ESQL CREATE statement and the ASBITSTREAM function.

To validate input messages that are received on an input node, you can specify validation properties on the input node. The input message is then validated when the message bit stream is parsed to form the message tree.

You can also use the `Parse Timing` property of the input node to control whether the entire message is parsed and validated at this time, or whether individual fields in the message are parsed and validated only when referenced.

To validate output messages that are created by a transformation node, specify validation properties either on the node itself, or on the output node that sends the message. The validation takes place when the message bit stream is created from the message tree by the output node.

Alternatively, use a Validate node to validate a message tree at a particular place in your message flow, or use the ESQL ASBITSTREAM function in a Compute, Filter, or Database node.

A limited amount of validation occurs by default if you leave the validation settings unaltered. At this default level, an exception is thrown if one of the following statements is true:

- A data mismatch occurs; for example, the parser cannot interpret the data that is provided for the field type specified.
- The order of elements in the output message does not match the order of elements in the logical message tree (MRM CWF, and MRM TDS fixed-length models only).

Additionally, the MRM parser performs limited remedial action under the following circumstances:

- Extraneous fields are discarded on output for fixed formats (CWF and TDS fixed-length models only).

- If mandatory content is missing, default values are supplied, if available, on output for fixed formats (CWF and TDS fixed-length models only).
- If the data type of an element in the tree does not match that specified in the dictionary, the data type is converted on output to match the dictionary definition, if possible, for all formats.

However, by using validation options you can request more thorough validation of messages. For example, you might want to validate one or more of the following conditions, and throw an exception, or log the errors:

- The whole message at the start of the message flow
- That complex elements have the correct `Composition` and `Content Validation`
- That all data fields contain the correct type of data
- That data fields conform to the value constraints in the message model
- That all mandatory fields are present in the message
- That only the expected fields are present in the message
- That message elements are in the correct order

The samples illustrate some of these validation options.

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

When using validation options, it is important to understand the following behavior.

- The `Parse Timing` property, which controls whether *on-demand* parsing (sometimes called partial parsing) takes place, affects the timing of the validation of input messages, including message headers.

  For more information about the `Parse Timing` property, see "Parsing on demand" on page 4173.
- If a message tree is passed to an output node, by default the output node inherits the validation options in force for the message tree. You can override these options by specifying a new set of validation options on the output node.
- If a message tree is passed as input to a Compute, Mapping, XSLTransform, DatabaseRetrieve, or JavaCompute node, any new output message trees that the node creates have the validation options specified by the node itself (even if the whole message is copied). You can override this behavior and specify that the messages that are created by the node inherit the validation options of the input message tree.
- (MRM domain only) When the bit stream is written, and validation options are applied, the entire message is validated. The message tree might contain an unresolved type (for example, if a Compute node copied an unresolved type from an input message to an output message without resolving it). If such a type is encountered, a validation error occurs because it is not possible to validate the type. To prevent this error, ensure that all unresolved types are resolved before they are copied to output messages.
- (MRM domain only) Do not select the `Truncate fixed length strings` check box because validation is done before truncation, and a fixed-length field fails validation if its length exceeds the length that is defined in the message set. For

more information about the `Truncate fixed length strings` property, see "Custom Wire Format message set properties" on page 5375 and "TDS Format message set properties" on page 5381.

For information about how you can control validation by using different properties, see "Validation properties" on page 4169.

Related concepts:

"Parsers" on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

"MRM parser and domain" on page 1111
You can use the MRM domain to parse and write a wide range of message formats.

"SOAP parser and domain" on page 1082
You can use the SOAP parser to create a common WSDL-based logical tree format for working with Web services, independent of the physical bitstream format.

"XML parsers and domains" on page 1084
You can use XML domains to parse and write messages that conform to the W3C XML standard.

"XMLNSC parser" on page 1090
The XMLNSC parser is a flexible, general-purpose XML parser that offers high performance XML parsing and optional XML Schema validation.

"Message modeling" on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

"Predefined and self-defining messages" on page 1076
Both predefined and self-defining messages are supported.

Related reference:

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

"CREATE statement" on page 5082
The CREATE statement creates a new message field.

"ASBITSTREAM function" on page 5224
The ASBITSTREAM field function generates a bit stream for the subtree of a given field according to the rules of the parser that owns the field.

Viewing the logical message tree in trace output

To view the structure of the logical message tree at any point in the message flow, include a Trace node and write some or all the message (including headers and all four message trees) to the trace output destination.

About this task

You might find trace output useful to check or record the content of a message before and after a node has changed it, or on its receipt by the input node. For example, if you include a Compute node that builds a destination list in the local environment tree, you might want a record of the structure that it has created as part of an audit trail, or you might want to check that the Compute node is working as you expect it to.

UNIX On UNIX, syslog entries are restricted in length and messages that are sent to the syslog are truncated by the newline character. To record a large amount of data in a log on UNIX, set the `Destination` property on the Trace node to `File` or `User Trace` instead of `Local Error Log`.

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the message flow for which you want to view messages. Open an existing message flow, or create a message flow.
3. Include a Trace node wherever you want to view part or all the message tree structure. You can include as many Trace nodes as you choose; however, each node that you introduce can affect the performance of message flow processing.
4. Set the Trace node properties to trace the message, or parts of the message, that you want to view. Specify the parts of the message by using ESQL field references. Several examples are included later in this topic.
5. If you have added a Trace node to investigate a particular behavior of your message flow, and have now resolved your concerns or checked that the message flow is working correctly, remove the Trace node or nodes, and redeploy the message flow.

Example

Assume that you have configured a message flow that receives an XML message on a WebSphere MQ queue in an MQInput node. The input message includes an MQRFH2 header. The message has the following content:

```
<Trade type='buy'
 Company='IBM'
 Price='200.20'
 Date='2000-01-01'
 Quantity='1000'/>
```

You can include and configure a Trace node to produce output that shows one or more of the trees created from this message: the message body, environment, local environment, and exception trees. If you choose to record the content of the message body, the Properties tree and the contents of all headers (in this example, at least an MQMD and an MQRFH2) are included. You specify what you want to be recorded when you set the Trace node property `Pattern`. You can use most of the correlation names to define this pattern (you cannot use those names that are specific to the Compute node).

Message body

If you want the Trace node to write the message body tree including Properties and all headers, set `Pattern` to $Root. If you want only the message data, set `Pattern` to ${Body}.

The trace output generated for the message tree of the preceding message with Pattern set to $Root would look like the following example:

```
Root
      Properties
         CreationTime=GMTTIMESTAMP '1999-11-24 13:10:00'          (a GMT timestamp field)

  ... and other fields ...

      MQMD
         PutDate=DATE '19991124'                                  (a date field)

         PutTime=GMTTIME '131000'                                 (a GMTTIME field)

  ... and other fields ...

      MQRFH
          mcd
          msd='xml'                                              (a character string field)

         .. and other fields ...

      XML
         Trade
          type='buy'                                             (a character string field)

         Company='IBM'                                           (a character string field)

         Price='200'                                             (a character string field)

         Date='2000-01-01'                                       (a character string field)

         Quantity='1000'                                         (a character string field)
```

Environment

To trace any data in the environment tree, set Pattern to ${Environment}. This setting produces output like the following example:

```
(0x1000000)Environment = (
     (0x1000000)Variables = (
       (0x1000000)MyVariable1 = (
         (0x2000000) = '3'
       )
       (0x1000000)MyVariable2 = (
         (0x2000000) = 'Hello'
       )
     )
 )
```

To trace particular variables in the variables folder of the environment tree, you can use a more specific pattern, for example ${Environment.Variables.MyVariable1}. This setting returns the value only (for example, it returns just the value 3).

LocalEnvironment

To trace data in the local environment tree, set Pattern to ${LocalEnvironment}. The output you get is like the following example, which shows that a destination list has been created in the local environment tree:

```
(0x1000000)Destination = (
    (0x1000000)MQ               = (
      (0x1000000)DestinationData = (
        (0x3000000)queuename = 'MQOUT'
      )
    )
     (0x1000000)MQDestinationList = (
      (0x1000000)DestinationData = (
        (0x3000000)queuename = 'OLDMQOUT'
      )
    )
    (0x1000000)RouterList       = (
      (0x1000000)DestinationData = (
        (0x3000000)labelname = 'continue'
      )
      (0x1000000)DestinationData = (
        (0x3000000)labelname = 'custdetails'
      )
      (0x1000000)DestinationData = (
        (0x3000000)labelname = 'trade'
      )
    )
  )
```

Another example, shown here, includes a WrittenDestination folder. This example represents a trace that has been written by a Trace node that is included after an MQOutput node, where the Out terminal of the MQOutput node is connected to a sequence of nodes including the Trace node. When an Out terminal is connected, the local environment is augmented with information about the action that the output node has performed.

```
(0x1000000)Destination       = (
    (0x1000000)MQ               = (
      (0x1000000)DestinationData = (
        (0x3000000)queuename = 'MQOUT'
      )
    )
  (0x1000000)WrittenDestination = (
    (0x1000000)MQ = (
      (0x1000000)DestinationData = (
        (0x3000000)queueName        = 'MQOUT'
        (0x3000000)queueManagerName = 'MQSI_SAMPLE_QM'
        (0x3000000)replyIdentfier   = X'414d51204d5153495f53414d504c455f1f442f3b12600100'
        (0x3000000)msgId            = X'414d51204d5153495f53414d504c455f1f442f3b12600100'
        (0x3000000)correlId         = X'000000000000000000000000000000000000000000000000'
 (0x03000000):GroupId          = X'414d512042524f4b45523220202020203f59934620001803'
      )
    )
  )
)
```

ExceptionList

To trace data in the exception list, set `Pattern` to ${ExceptionList}.

You can also view message structure in the message flow, and other information, when you use the flow debugger.

Use the MQOutput node to send messages to clients that connect to the broker using the WebSphere MQ Enterprise Transport and that use the MQI and AMI application programming interfaces.

"Exception list structure" on page 4224
An exception list contains information about exceptions, such as error numbers, the name of the node that generated the exception, and the reason for the exception.

Changing the parser used in a message flow

If you need to change the parser that is used in a message flow, use the ResetContentDescriptor node to request that the message is reparsed by a different parser.

About this task

Use the ResetContentDescriptor node to set new message properties that are used when the message bit stream is next parsed by a subsequent node in the message flow.

For example, if the format of an incoming message is unknown when it enters a message flow, the BLOB parser is started. Later on in the message flow, you might decide that the message is predefined as a message in the MRM domain, and you can use the ResetContentDescriptor node to set the correct values to use when the message is parsed by a subsequent node in the message flow.

You can select from the following parsers:
- MRM
- XMLNSC
- DataObject
- XMLNS
- JMSMap
- JMSStream
- MIME
- BLOB
- XML (this domain is deprecated; use XMLNSC)
- IDOC (this domain is deprecated; use MRM)
- JSON

If you specify MRM, XMLNSC, DataObject, or IDOC as the new parser, you can also specify a different message template (message set, message type, and message format).

Whether or not the node reparses the message straight away depends on the settings of the `Parse timing` option in the node properties. `Parse timing` is, by default, set to `On Demand`, which causes parsing of the message to be delayed. For more details on controlling when the message is parsed, see "Parsing on demand" on page 4173.

Related concepts:

"Specifying namespaces in the Message Type property" on page 1208
When using the MRM domain, the *Message Type* property is used to specify the name of the message.

"Multipart messages" on page 1191
A *multipart message* contains one or more other messages within its structure. The contained message is sometimes referred to as an *embedded message*.

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Parsers" on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

"ResetContentDescriptor node" on page 4663
Use the ResetContentDescriptor node to request that the message is reparsed by a different parser.

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

Providing user-defined properties to control behavior

User-defined properties can be set at design time, deployment time, or run time.

About this task

For example, user-defined properties can be queried, discovered, and set at run time to dynamically change the behavior of a message flow. You can use the Administration API for WebSphere Message Broker (also known as the CMP API) to manipulate these properties, which can be used by a systems monitoring tool to perform automated actions in response to situations that it detects in the monitored systems.

Procedure

- You can use the Message Flow editor to define a user-defined property when you construct a message flow. For more information, see "Message Flow editor" on page 6810.
- You can set user-defined properties at deployment time to configure a message flow, as described in "Configuring a message flow at deployment time with user-defined properties" on page 2626.
- You can use the CMP API to manipulate user-defined properties on a message flow dynamically at run time, as described in "Setting message flow user-defined properties at run time in a CMP application" on page 985.

Related concepts:

"User-defined properties" on page 1147
A user-defined property (UDP) is a property that is defined when you construct a message flow by using the Message Flow editor. This property can be used by the ESQL or Java program inside message flow nodes, such as a Compute node.

"User-defined properties in ESQL" on page 2376
Access user-defined properties (UDPs) as variables in your ESQL program by specifying the EXTERNAL keyword on a DECLARE statement. For example, the ESQL statement `DECLARE today EXTERNAL CHARACTER 'monday'` defines a user-defined property called today with an initial value monday.

Related tasks:

"Accessing message flow user-defined properties from a JavaCompute node" on page 2659
Customize a JavaCompute node to access properties that you have associated with the message flow in which the node is included.

Related reference:

"Message Flow editor" on page 6810
The Message Flow editor is the default editor provided by the Broker Application Development perspective for defining a graphical representation of a message flow in the WebSphere Message Broker Toolkit, and for setting properties for individual message flow nodes.

Defining message flow content

You can define message flow content by adding and configuring message flow nodes and connecting them to form flows.

About this task

When you create a message flow, the editor view is initially empty. You must create the contents of the message flow by using a combination of the following tasks:

- "Adding a message flow node" on page 1494
- "Adding a subflow" on page 1501
- "Renaming a message flow node" on page 1502
-
- "Connecting message flow nodes" on page 1520
- "Inserting nodes into existing message flows" on page 1525
- "Adding a bend point" on page 1527
- "Aligning and arranging nodes" on page 1530

While you are developing message flows, you might want to record notes about flow development or particular nodes in the flow:

- "Adding annotations to a message flow or node" on page 1531
- "Editing annotations on a message flow or node" on page 1533
- "Copying annotations on a message flow or node" on page 1534
- "Showing and hiding annotations on a message flow or node" on page 1535
- "Deleting annotations from a message flow or node" on page 1536

When you finalize the contents of the message flow, you might also need to complete the following tasks:

- "Removing a message flow node" on page 1519
- "Removing a node connection" on page 1526
- "Removing a bend point" on page 1528

To learn more about message flow content, you can import either of the following samples:

- Airline Reservations
- Error Handler

Follow the supplied instructions to build the sample yourself. You can also try adding and deleting nodes, adding subflows, and connecting nodes together.

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

For a basic introduction to developing message flows, see the IBM Redbooks publication WebSphere Message Broker Basics.

Related concepts:

A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related reference:

"Broker Application Development perspective" on page 6784
The Broker Application Development perspective is the default perspective that is displayed when you start the WebSphere Message Broker Toolkit.

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Using the node palette

The node palette contains all the built-in nodes, which are organized into categories.

Before you begin

Before you start:

Read the following concept topic "Message flow node palette" on page 1027.

About this task

You can add the nodes that you use most often to the Favorites category by following the instructions in "Adding nodes to the Favorites category on the palette" on page 1492.

You can change the palette preferences in the WebSphere Message Broker Toolkit. The changes that you can make are described in the following topics.

Procedure

- "Changing the palette layout" on page 1490
- "Changing the palette settings" on page 1490
- "Customizing the palette" on page 1491

Related concepts:

"Message flow node palette" on page 1027
The palette in the Message Flow editor contains all the built-in nodes, which are organized into categories, or drawers. A drawer is a container for a list of icons, such as the **Favorites** drawer.

Related tasks:

The Message Flow editor is the default editor provided by the Broker Application Development perspective for defining a graphical representation of a message flow in the WebSphere Message Broker Toolkit, and for setting properties for individual message flow nodes.

Changing the palette settings:

How to use the **Palette Settings** dialog box.

About this task

Change the palette settings in the Message Flow editor using the **Palette Settings** dialog box.

Procedure

1. Switch to the Broker Application Development perspective.
2. Right-click the palette to display the pop-up menu.
3. Click **Settings**. The **Palette Settings** dialog box opens.
4. Use the dialog to change the appropriate setting:

- Click **Change** to change the font on the palette.
- Click **Restore Default** to restore the default palette settings.
- In the **Layout** list, click the appropriate radio button to change the palette layout. (See "Changing the palette layout" on page 1490 for more information.)
- Select **User large icons** to toggle between large and small icons in the palette.
- In the **Drawer options** list, click the appropriate radio button to change the way that drawers are handled in the palette. A drawer is a container for a list of icons, such as the **Favorites** drawer on the Message Flow editor's palette, or the **Entity** drawer on the Broker Topology editor's palette.

Related tasks:

You can change the layout of the palette in the Message Flow editor.

"Customizing the palette"
If you customize the message flow node palette, you can make it easier to find the nodes that you use most often.

Related reference:

"Message Flow editor" on page 6810
The Message Flow editor is the default editor provided by the Broker Application Development perspective for defining a graphical representation of a message flow in the WebSphere Message Broker Toolkit, and for setting properties for individual message flow nodes.

Customizing the palette:

If you customize the message flow node palette, you can make it easier to find the nodes that you use most often.

About this task

This saves time and on-screen space. For example:

- Change the order of the drawers in the palette so that the ones that you use most often are at the top.
- Hide any drawers that you do not use, to save on-screen space.
- Pin open the drawers that contain the nodes that you use most often.
- Create your own drawers to hold user-defined nodes that you create.

Customize the palette for the Message Flow editor using the Customize Palette dialog box:

Procedure

1. Switch to the Broker Application Development perspective.
2. Right-click the palette, then click **Customize**. The Customize Palette dialog box opens.
   - To change the order of entries and drawers in the palette, click the appropriate item in the list to highlight it, then click **Move Down** or **Move Up**. You cannot move any category above the Favorites category.
   - To hide an entry or drawer, click the appropriate item in the list to highlight it, then select the **Hide** check box.
   - To create a new separator, click **New** > **Separator**.
   - To create a new drawer:
     a. Click **New** > **Drawer**.

b. Type a name and description for the drawer.
c. If required, select the **Open drawer at start-up** check box.
d. If required, select the **Pin drawer open at start-up** check box.

3. Click **OK** or **Apply** to save your changes.

Results

You have customized the message flow node palette.

Related tasks:

Adding nodes to the Favorites category on the palette:

The nodes on the palette are organized in categories. The first category is Favorites, which is usually empty. You can drag the nodes that you use most often to the Favorites category.

Before you begin

Before you start:

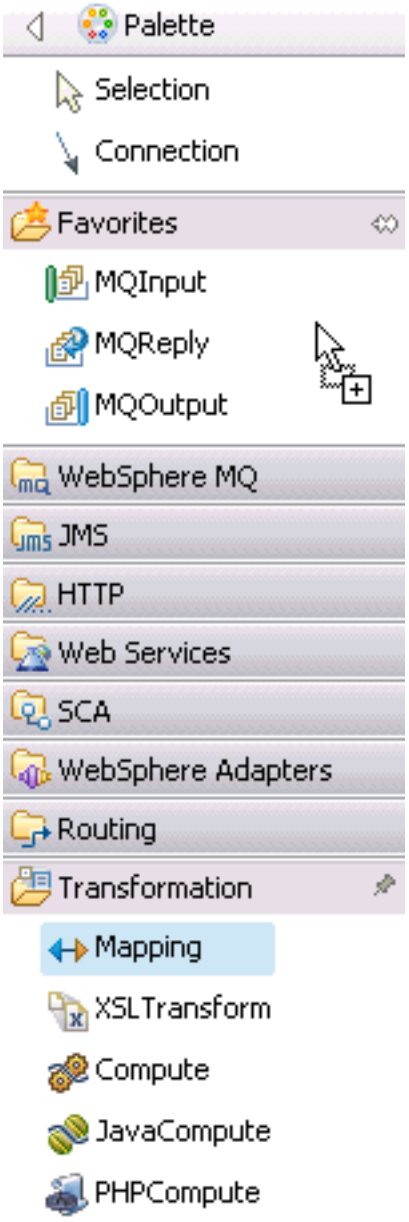
Read the concept topic about the message flow node palette.

About this task

The following steps describe how to drag nodes into the Favorites category.

Procedure

1. Switch to the Broker Application Development perspective.
2. On the palette, open the Favorites category.
3. On the palette, open the category that contains the node that you want to add to the Favorites category.
4. Use the mouse to drag the node into the Favorites category, as shown in the following example:



Results

Alternatively, right-click the palette and choose the appropriate option to add or remove nodes from the Favorites category.

Adding a message flow node

When you have created a message flow, add nodes to define its function.

Before you begin

Before you start:

- Create a message flow or open an existing message flow; see "Creating a message flow" on page 1431 and "Opening an existing message flow" on page 1433.
- Read the concept topic about message flow nodes, see "Message flow nodes" on page 1024.

About this task

To add a node to a message flow:

Procedure

1. Open the message flow with which you want to work.
2. Open the Palette.
   - Hold the mouse pointer over the palette bar while it is in collapsed mode. The palette bar expands. When you move the mouse pointer away from the palette bar, it collapses again.
   - Click the **Show Palette** icon at the top of the palette bar. The palette bar expands and it remains expanded when the mouse is moved away from the palette bar. To collapse the palette bar again, click the **Hide Palette** icon at the top of the palette bar while it is in expanded mode.
3. Click **Selection** above the palette of nodes.
4. Decide which node you want to add: a built-in node or a user-defined node. You can select any of the nodes that are displayed in the node palette, but you can add only one node at a time.

   Nodes are grouped in categories according to the function that they provide. To see descriptions of the nodes in the palette, either hold the mouse pointer over a node in the palette, or switch to the Details view by following the instructions in "Changing the palette layout" on page 1490.
5. Drag the node from the node palette onto the canvas.

   When you add a node to the canvas, the editor automatically assigns a name to the node, but the name is highlighted and you can change it by entering a name of your choice. If you rename the node, the name that you choose must be unique in the message flow. If you do not change the default name at this time, you can change it later, see "Renaming a message flow node" on page 1502. The default name is set to the type of node for the first instance. For

example, if you add an MQInput node to the canvas, it is given the name MQInput; if you add a second MQInput node, the default name is MQInput1; the third is MQInput2, and so on.

6. Repeat steps 4 on page 1494 and 5 on page 1494 to add further nodes.
7. You can also add nodes from other flows into this flow:
   a. Open the other message flow.
   b. Select the node or nodes that you want to copy from the editor or outline views, and press Ctrl+C or click **Edit** > **Copy**.
   c. Return to the flow with which you are currently working.
   d. Press Ctrl+V or click **Edit** > **Paste**. This action copies the node or nodes into your current flow. The node names and properties are preserved in the new copy.

Results

When you have added the nodes that you want in this message flow, you can connect them to specify the flow of control through the message flow, and you can configure their properties.

You can also add user-defined nodes to your message flow. To find out about user-defined nodes, see "User-defined nodes" on page 2989.

What to do next

Now you can configure the nodes, see "Configuring a message flow node" on page 1503.

Related concepts:

Installing a user-defined node:

Develop message flows that use a user-defined node.

About this task

You can develop message flows by using the user-defined node in the same way as the built-in nodes. Before you can use a user-defined node, you must install it into your WebSphere Message Broker Toolkit. A user-defined node is installed differently depending on how it was packaged.

Procedure

1. Install the user-defined node project:
   - If the user-defined node was packaged as plug-in JAR files, copy your JAR files into the dropins folder in your WebSphere Message Broker Toolkit installation location, and run the **mb -clean -initialize** command to pick up the new files.

     Note: For some WebSphere Message Broker Toolkit installations, the dropins folder (for example `C:\Program Files (x86)\IBM\WMBT700`) is not created. In this case, you can create the dropins folder manually.
   - If the user-defined node was packaged as an update site, install the plug-ins from the update site, see "Installing from an update site" on page 3124.
2. Stop and restart your WebSphere Message Broker Toolkit. The user-defined nodes are displayed in the palette in the Message Flow editor under the category that you specified for the user-defined node project.

Related concepts:

If you have packaged your user-defined nodes into an update site, use the software update mechanism to install the user-defined nodes.

"Testing a subflow user-defined node project" on page 3097
Test how the user-defined node is displayed, and how it behaves in your environment.

Message sets packaged with a user-defined node:

Adding message sets to an update site.

About this task

Message sets are automatically packaged into user-defined node JAR files and update sites. If you drag a user-defined node from the palette onto the canvas, the WebSphere Message Broker Toolkit detects whether the required message sets are available in the current workspace.

Procedure

1. If the required message sets are unavailable in the current workspace, a warning is displayed in the **Problems** tab, and the **Import Required Message Sets** window opens.
2. To import the message set from the user-defined node plug-in, click **Import selected message sets**, or you can import the message sets from another source.

   If the message set is available in the same execution group at execution time, you do not have to import the message sets.

Related concepts:

"User-defined nodes" on page 2989
User-defined nodes are the main mechanism for extending the functions of WebSphere Message Broker.

Export the user-defined node project to make it available for other users.

Adding a node by using the keyboard:

You can use the keyboard to perform tasks in the Message Flow editor, such as adding a node to the canvas.

Before you begin

Before you start:
- Ensure that you have created or opened a message flow. For more information, see "Creating a message flow" on page 1431 or "Opening an existing message flow" on page 1433.
- Read the concept topic, "Message flow nodes" on page 1024.

Procedure

1. Open the message flow to which you want to add a node.
2. Open the Palette view or the Palette bar.
3. Select a node in the Palette view or Palette bar by using the up and down arrows to highlight the node that you want to add to the canvas.
4. Add the node to the canvas by using one of the following methods:
   - Press **Alt + L**, then press **N**.
   - Press **Shift + F10** to open the pop-up menu for the Palette, and press **N**.

   The node that you selected in the Palette bar or Palette view is placed on the canvas in the Editor view.

   When you add a node to the canvas, the editor automatically assigns a name to the node, but the name is highlighted and you can change it by entering a name of your choice. If you do not change the default name at this time, you can change it later by following the instructions in "Renaming a message flow node" on page 1502. The default name is set to the type of node for the first instance. For example, if you add an MQInput node to the canvas, it is given the name MQInput. If you add a second MQInput node, the default name is MQInput1; the third is MQInput2, and so on.

Results

You can move the node that you have placed on the canvas by using the keyboard controls described in "WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit keyboard shortcuts" on page 6828.

Related concepts:

“Message Flow editor” on page 6810
The Message Flow editor is the default editor provided by the Broker Application Development perspective for defining a graphical representation of a message flow in the WebSphere Message Broker Toolkit, and for setting properties for individual message flow nodes.

“Message Flow editor menus” on page 6813

“Accessibility features for WebSphere Message Broker” on page 135
Accessibility features help users who have a physical disability, such as restricted mobility or limited vision, to use information technology products successfully.

Dragging a resource from the Broker Development view:

Drag a node or a related resource into the Message Flow editor.

Before you begin

Before you start:

Complete the following tasks:
- Create or open a message flow, as described in “Creating a message flow” on page 1431 and “Opening an existing message flow” on page 1433.
- Read concept information in “Message flow nodes” on page 1024.

About this task

To create a node, drag a resource from the Broker Development view to an empty canvas. To modify an existing node, drag a resource onto that node. The following resources are supported:
- An Adapter file
- An ESQL file
- A Java file
- A subflow
- A WSDL file
- An XSL file

Procedure
1. Open the message flow with which you want to work.
2. Drag one of the supported resources from the Broker Development view onto the canvas.
   - If you drop the resource on an empty canvas, a node is created and configured automatically.

     The following table shows the results when you drag a resource from the Broker Development view onto an empty canvas:

Resource	Node created	Property set
Adapter file	A “PeopleSoftInput node” on page 4630, “SAPInput node” on page 4676, or “SiebelInput node” on page 4740 is created	`Adapter component`
CORBA IDL file	A “CORBARequest node” on page 4349 is created	`IDL file`

Resource	Node created	Property set
ESQL file	A “Compute node” on page 4340 is created	`ESQL Module`
Java file	A “JavaCompute node” on page 4514 is created	`Java Class`
WSDL file	A “SOAPInput node” on page 4795 or “SOAPRequest node” on page 4828 is created	`WSDL file name`
XSL file	An “XSLTransform node” on page 4968 is created	`Stylesheet`

- If you drop the resource onto an existing node, the relevant node property is updated with the name of the resource file. For example, if you drop a Java file onto a JavaCompute node, the `Java Class` property is set to the class name of the Java file that you are dropping. If you drop an ESQL file over any node that uses ESQL, such as a Database node, the `ESQL Module` property is set.

Use the XSLTransform node to transform an XML message to another form of message, according to the rules provided by an XSL (Extensible Stylesheet Language) style sheet, and to set the `Message domain`, `Message set`, `Message type`, and `Message format` for the generated message.

Adding a subflow

In a message flow, you can include an embedded message flow, also known as a *subflow*. For example, you might define a subflow that provides error handling, and include it in a message flow connected to a failure terminal on a node that can generate an error in some situations.

Before you begin

Before you start:

To complete this task, you must have created a message flow to use as a subflow, and a message flow in which to insert the subflow. For more details, see "Creating a message flow" on page 1431.

About this task

You can embed subflows into your message flow if either of the following statements is true:

- The flow that you want to embed is defined in the same message flow project.
- The flow is defined in a different message flow project, and you have specified the dependency of the current message flow project on that other project.

You can embed subflows into other subflows.

Procedure

To add a subflow to a message flow, complete the following steps:

1. Open the message flow in which you want to embed the subflow.
2. To add a subflow, drag the message flow that you want to add from the Broker Development view to the editor. Alternatively, click **Flow** > **Add subflow**, then select the flow that you want to add from the list. The embedded subflow is shown in the Message Flow editor as a single node with the terminals that represent the Input and Output nodes that you have included in the subflow.
3. Connect the subflow node to one or more of the nodes in the main message flow. For more details, see "Connecting message flow nodes" on page 1520.
4. To add and connect further subflow nodes, repeat steps 2 and 3.
5. To work with the contents of the subflow, double-click the subflow icon. The subflow opens in the Message Flow editor.

What to do next

You can also package your subflow as a user-defined node so that you can use it in a message flow; for more information, see "Using a subflow as a user-defined node" on page 3008.

Related concepts:

"Subflows" on page 1030
You can include subflows in your message flows in the same way as you include built-in or user-defined nodes. You can also connect subflows to other nodes in the

Create user-defined nodes either from scratch, or by using an existing subflow.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Renaming a message flow node

You can change the name of any type of node (a built-in node, user-defined node, or subflow node) to reflect its purpose.

Before you begin

Before you start:

Complete the following tasks:

- Create a message flow, as described in "Creating a message flow" on page 1431.
- Read the concept topic, "Message flow nodes" on page 1024.

About this task

When you first add a node to the canvas, the editor automatically assigns a name to the node; the name is highlighted, and you can change it by entering a name of your choice. If you do not change the default name at this time, you can change it later, as described in this topic. For example, you might include a Compute node to calculate the price of a specific part in an order; you could change the name of the node to Calculate_Price.

When you rename a node, use only the supported characters for this entity. The editor prevents you from entering unsupported characters.

To rename a node:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the message flow with which you want to work.
3. You can rename a node in three ways:
   - Right-click the node and click **Rename**. The name is highlighted; enter a name of your choice and press **Enter**.
   - Click the node to select it, then click the name of the node so that it is highlighted; enter a name of your choice and press **Enter**.
   - Click the node to select it, then on the Description tab of the Properties view, enter a name of your choice in the Node name field.

   The name that you enter must be unique in the message flow.

What to do next

If you generate ESQL code for a Compute, Database, or Filter node, the code is contained in a module that is associated with the node. The name of the module in the ESQL file must match the name specified for the module in the *ESQL Module* property of the corresponding node. You can modify the module name, and change it from its default value (which is the name of the message flow, concatenated with the name of the node with which the module is associated). However, ensure that the module in the ESQL file matches the node property.

Configuring a message flow node

When you have included an instance of a node in your message flow, you can configure its properties to customize how it works.

Before you begin

Before you start:

- Read the concept topic about message flow nodes

- Add a node

Viewing the properties of a node:
About this task

To view a node's properties:

Procedure

1. In the Message Flow editor, open the message flow with which you want to work.
2. To open the Properties view, right-click a node and click **Properties**.
   The selected node's properties are displayed. You can edit the properties.

Editing the properties of a node:
About this task

Properties are organized into related groups and displayed on tabs. Each tab is listed on the left of the Properties view. Click each tab to view the properties that you can edit.

Procedure

- Every node has at least one tab, **Description**, where you can change the name of the node and enter short and long descriptions. The description fields are optional because they are used only for documentation purposes.
- If a property is mandatory (that is, one for which you must enter a value), the property name is marked with an asterisk, as shown in the following example:
  `Queue Name*` _____
- Many nodes have properties that require XPath expressions, typically to identify the location of a particular resource. For example, for the MQInput node, you can specify the location of the security token and password by using either ESQL or XPath expressions. For help in constructing an XPath expression, you can open the XPath Expression Builder by clicking **Edit** next to each XPath property. For more information about using XPath expressions, see "Using XPath" on page 1506.

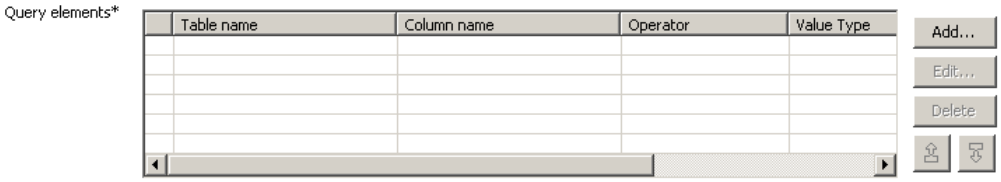
What to do next

For details of how to configure each individual built-in node, see the node description. You can find a list of the nodes, with links to the individual topics, in "Built-in nodes" on page 4293.

If you have included a user-defined node, refer to the documentation that came with the node to understand if, and how, you can configure its properties.

Editing complex properties:
About this task

A complex property is a property to which you can assign multiple values. Complex properties are displayed in a table in the Properties view, where you can add, edit, and delete values, and change the order of the values in the table. This example shows the `Query elements` complex property of the DatabaseRoute node.



Procedure

- To add a value to a complex property, click **Add**, enter the required fields in the dialog box that opens, then click **OK**. The values appear in the table. Repeat this step to enter as many values as are required.
- To edit a value, click any element in a row, click **Edit**, edit any of the values in the dialog box, then click **OK**.
- To delete a value, click any element in a row and click **Delete**. The entire row is deleted.
- To change the order of values in the table, click any element in a row and click the up icon  or down icon  to move the row.

Promoting properties:
About this task

You can promote node properties to their containing message flow; for more information, see “Promoting a property” on page 1298. Use this technique to set some values at the message flow level, without having to change individual nodes. This can be useful, for example, when you embed a message flow in another flow, and want to override some property such as output queue or data source with a value that is correct in this context. You cannot promote complex properties. For a full list of properties that are unavailable for promotion, as well as instructions for how to promote properties, see “Promoting a property” on page 1298.

Overriding properties at deployment time:
About this task

You can override a small number of node property values when you deploy a message flow. These property values are known as configurable properties, and you can use them to modify some characteristics of a deployed message flow without changing the message flow definitions. For example, you can update queue manager and data source information.

Even though you can set values for configurable properties at deployment time, you must set values for these properties within the message flow if they are mandatory. Each built-in node reference topic contains a table of properties, which identifies the configurable and mandatory properties.

What to do next

Next: connect the nodes.

Related concepts:

“Promoted properties” on page 1145
A promoted property is a message flow node property that has been promoted to the level of the message flow in which it is included.

WebSphere Message Broker includes many message processing nodes that you can use in your message flows.

"Creating a message flow" on page 1431
Create a message flow to specify how to process messages in the broker. You can create one or more message flows and deploy them to one or more brokers.

"Adding a message flow node" on page 1494
When you have created a message flow, add nodes to define its function.

"Defining a promoted property" on page 1297
When you create a message flow, you can promote properties from individual nodes in that message flow to the message flow level. Properties promoted in this way override the property values that you have set for the individual nodes.

"Editing configurable properties" on page 3227
You can edit configurable properties in the deployment descriptor file (`broker.xml`) of your broker archive.

Using XPath:

XPath provides an alternative method to ESQL for entering expressions in the property fields of specific built-in nodes.

About this task

In addition to ESQL as a message transformation language, WebSphere Message Broker supports an alternative expression grammar in property fields. For more information, see "ESQL-to-XPath mapping table" on page 5046.

You can use ESQL or XPath expressions in built-in nodes, within your message flows, to query or update message trees that are specified as accessible, and that you expect to be processed by a given node.

This section provides information on:
- "XPath overview" on page 1507
- "Namespace support" on page 1508
- "XPath Expression Builder" on page 1510
- "Creating XPath expressions" on page 1515
- "Selecting the grammar mode" on page 1516

A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

XPath overview:

The XML Path Language (XPath) is used to uniquely identify or address parts of an XML document. An XPath expression can be used to search through an XML document, and extract information from any part of the document, such as an element or attribute (referred to as a *node* in XML) in it. XPath can be used alone or in conjunction with XSLT.

Some of the built-in nodes provided in the WebSphere Message Broker Toolkit can use XPath expressions to specify the part of a message that is processed by the node. For example, you can use an XPath expression to identify fields in a message and determine if they match a specified value, or to set the field value by updating it with the results of a database query.

You can use XPath 1.0 path expressions in your flow to access specific parts of an incoming message, create or locate parts of an outgoing message, and perform complex message processing that might involve values present in message trees accessible by a node so that you can transform, filter, or retrieve values from a message.

For example, the Route node applies XPath 1.0 general expressions to the content of message trees associated with the incoming message assembly for this node. Following evaluation of an expression the result is cast as a Boolean (true or false) result, and this in turn is used to determine if a copy of the incoming message is routed down an output terminal associated with the processed expression.

If you have XML schema definition (`.mxsd`) files present in your workspace, any elements, attributes or data types defined in such definitions can be loaded into the Data types viewer and selected to automatically generate a path expressions mapping to the definition concerned.

Equally, depending on the XPath expressions supported by the property concerned, you can select XPath functions and operators to include in an expression, or you can build your own expressions manually.

The Data types viewer contains a list of variables relating to trees that can be accessed by expressions for the node property concerned.

For example, `$InputRoot` gives access to the incoming message tree. The fixed format of standard folders you can expect to exist under this tree, for example, `Properties` and `MQMD` are described without the need to import an `.mxsd` definition for them. These structures can be navigated in the viewer and, on selection of an

element within them, a path expression that maps to the element in question is built automatically through the XPath 1.0 language.

For further information on XPath 1.0 see W3C XPath 1.0 Specification.

You can use the XPath Expression Builder to visually build XPath expressions to set the relevant properties in your nodes. You launch the XPath Expression Builder from buttons located along side property fields present in the Properties viewer, for those nodes that support the use of XPath expressions as property values.

The XPath files in WebSphere Message Broker are supplied in three property editors; see "XPath property editors" on page 5047 for more details.

The XPath editor supports both content-assist directly on the text field and also an **Edit...** button that launches the XPath builder dialog. The dialog gives you a larger area in which to build your XPath expressions.

The content assist based control contains two different proposal lists in the following order:

1. Nodes and Variables
2. Functions and Operators

The node and variable proposals are displayed the first time that you use the XPath editor. In this view, the status bar reads `Press` **`Ctrl+Space`** `to show Function and Operation Proposals`.

Pressing **`Ctrl+Space`** when you are in the function and operator level proposals selects the Node and Variable proposals.

"ESQL reference" on page 5019
SQL is the industry standard language for accessing and updating database data and ESQL is a language derived from SQL Version 3, particularly suited to manipulating both database and message data.

Namespace support:

The XPath Expression builder provides qualified support for namespaces.

The XPath Expression builder dialog contains a namespace settings table that:

- Supports simplified expressions that enable qualified namespace matching at run time

- Can be auto-generated based on imported schema definitions and generated expressions (based on selections made in the dialog when you build an expression)
- Allows you to add your own entries to the table

The table encapsulates deployable data passed to the runtime environment, as part of the nodes attribute data, and is used by the node to modify expressions through prefix-to-URI substitution. The final expressions support namespace matching, because they are processed against a target tree when employed by their associated message processing engine, that is, the XPath 1.0 runtime engine or ESQL runtime engine.

When you enter an ESQL field reference expression in a read-only or read-write path field, or an XPath 1.0 path expression in a read-only or read-write path field, or a general expression field (general expressions can contain zero or more path expressions), WebSphere Message Broker understands the language from the syntax you use.

XPath is the default for general expression fields that are validated by ensuring they conform to the XPath 1.0 grammar. For path expression fields XPath is assumed if the expression is valid and begins with a $ sign.

The language you can use is dictated by the property editor currently in use for a node's property field.

Namespace prefixes are used in an XPath or ESQL expression to make the statements shorter and easier to understand, while still supporting the ability to qualify an element name match by also matching on its associated namespace URI.

For example, consider the following message, where namespace prefix `b` is overridden through an inner declaration:

```
<b:a xmlns:b='xyz'>
 <!-- the namespace of elements 'a' and 'c' using prefix 'b'  is xyz -->
 <b:c>
  <b:d  xmlns:b='qrs'>
   <!-- the namespace of elements 'd' and 'e' using prefix 'b' is now qrs -->
   <b:e>100</b:e>
  </b:d>
 </b:c>
</b:a>
```

Note that the scope of a namespace declaration declaring a prefix extends from the beginning of the start tag in which it appears to the end of the corresponding end tag, excluding the scope of any inner declarations with the same namespace prefix. In the case of an empty tag, the scope is the tag itself: `>`.

To navigate to element `e` in the above message use the following human-readable XPath expression:

```
/b:a/b:c/b2:d/b2:e
```

Note, that to prevent the auto-generated prefix to the URI map produced in the expression dialog overloading the same prefix (in this case `b`), the inner `b` prefix is appended with a numeric value to distinguish it from the outer `b` prefix. This strategy is repeated for each prefix name clash.

This notation is similar to the equivalent human-readable ESQL expression:

```
Root.b:a.b:c.b2:d.b2:e
```

To support namespace prefixes within expressions, the XPath Expression Builder Dialog automatically generates a prefix to a URI namespace settings table (based on the content of imported schema definitions, through which expressions are generated) .

Without the use of namespace prefixes to URI mapping data in this table, the runtime environment would be forced to take a less efficient approach, where portable but verbose XPath expressions would be required by it to provide namespace matching support.

The previous expression:

```
/b:a/b:c/b2:d/b2:e
```

would take the form:

```
/*[namespace-uri()='xyz' and local-name()='a']/*[namespace-uri()='xyz'
   and local-name()='c']/*[namespace-uri()='qrs' and
   local-name()='d']/*[namespace-uri()='qrs' and local-name()='e']
```

"Predefined XPath mapping functions" on page 5001
Some XPath functions are available for use with message maps.

XPath Expression Builder:

You can launch the XPath Expression Builder from most property fields that support, or expect, XPath expressions as a value that can be entered into the field.

The use of the XPath Expression Builder is optional, in that it is an aid to you in developing message flow applications. The XPath Expression Builder helps you to construct message processing expressions in either XPath or ESQL. You are free to enter expressions by hand, or use the XPath Expression Builder to help construct such expressions.

The XPath Expression Builder does not support use of the `$Body` variable. You can use the `$Body` variable when you enter an expression by hand, but the XPath Expression Builder and associated validation in the WebSphere Message Broker Toolkit do not support it. Use the `$Root` variable instead.

You can populate the fields, regardless of the state of the node; that is, whether the node is detached or connected, or fully, partially, or completely unconfigured.

You launch the XPath Expression Builder from a button in the following locations:

- Table cells, located to the right of the text entry field within the cell.
- **Add** or **Edit** dialog boxes used to construct rows in tables, located to right of the property field concerned.
- Tabs in the property viewer for a node, to the right of a property field.

Variables (or in ESQL terminology, correlation names) provide a list of all message tree start points that are applicable to the property field from which the dialog was launched.

If a field is a read-only or a read-write path field, expressions must start with such a variable to indicate which tree in which message assembly the path expression is mapping to.

XPath variable names map to existing correlation names found in ESQL field reference expressions, but to conform to the ESQL grammar they are designated as variable references by prefixing them with the dollar ($) character.

For example:

ESQL `Root.XMLNSC.CUST_DETAILS.NAME`

XPATH
`$Root/XMLNSC/CUST_DETAILS/NAME`

The variable indicates to which tree and where in that tree the expression is anchored.

The XPath Expression Builder dialog box supports validation, which you can turn off on the XPath preferences page by clearing the **Validate when creating XPath expressions** check box.

If you select the `$Root` or `$Body` variables and create an expression that refers to the body of the message, the XPath expression contains the message element. This expression is correct for message bodies owned by the XMLNSC, XMLNS, XML, and DataObject domains.

For message bodies that are owned by the MRM, MIME, SOAP, and IDOC domains, you must remove the message element from the expression.

For example, the XPath expression `$Body/my_message/my_field` is correct for XMLNSC, but must be changed to `$Body/my_field` to be correct for MRM.

Views

There are three main views when functions are supported.

Whether a view is displayed, and what is displayed in it, depends on what type of property editor you have used to launch the dialog, and its tailored settings; for example, for path type fields you do not see a functions pane. The operators that are supported can change as can the list of applicable variables.

Data Types Viewer
This view shows the different schema types, elements, and attributes that you can use within the XPath expression that you are creating, as well as the allowable variable references.

XPath Function
This view shows four main top level categories, which are:

String This category corresponds to the description in the XPath 1.0 specification of `section-String-Functions`.

Boolean
This category corresponds to the description in the XPath 1.0 specification of `section-Boolean-Functions`.

Numeric
This category corresponds to the description in the XPath 1.0 specification of `section-Number-Functions`.

Nodeset
This category corresponds to the description in the XPath 1.0 specification of `section-Node-Set-Functions`.

For information on the format of XPath 1.0 expressions see the W3C XPath 1.0 Specification.

Operators
This view shows a list of all of the available operators that you can use within the given XPath expression.

Namespace settings

If you expand **Namespace settings** in the XPath Expression Builder dialog you see a table of Prefix and Namespace pair strings. This table is automatically updated when XPath expressions are created. If the default prefix generated is not what you want, you can change it by clicking **Change Prefix**.

To add a prefix and namespace map entry click **Add** and complete the fields in the dialog.

To edit or delete an entry in the table, select the item and click **Edit** or **Delete** respectively.

Edit opens another field dialog allowing you to change the prefix and namespace.

For information about the preferences supplied with the XPath editor, see "XPath editor preferences" on page 1513.

XPath editor preferences:

This topic describes the possible options available to you when you use the XPath editor.

The following lists describe the custom preferences used in the XPath editor.

- Validation option:

  Validation when building XPath expressions
  Default: checked.

  This option is used to perform validation each time you update the XPath expression. As validation requires re-parsing the expression against the XML Schema document you can turn this option off, for example, if you are dealing with very large complex XPath expressions.

- Content Assist display options:

  Show XML Schema model groups
  Default: not checked.

  This option allows you to view XML schema model groups, or not.

  Show type in XML Schema tree
  Default: checked.

  This option allows you to view the `<type name>` in both the Content Assist view and the XPath expression builder, or not.

  Show function parameters
  Default: checked.

  This option allows you to have function parameters shown, or not.

  Show function return type
  Default: checked.

  This option allows you to have function return types shown, or not.

  Show content assist description
  Default: checked.

  This option allows you to view the description of a given selected entry in the Content Assist view, or not..

- Auto-Activation option:

  Enable auto activation
  Default: checked.

  When this option is active, the Content Assist field appears whenever the cursor is after one of the following:

  – / - Forward slash character
  – [- left bracket character
  – (- Left parentheses character
  – , - Comma character

  You set the delay time, before the Content Assist field appears, in the **Auto activation delay** field. The time is in milliseconds and the range is a positive number between zero and 9999.

- Content assist color options:

This preference allows you to customize the background and foreground colors for the Content Assist fields. The default background color is (red, green, blue - 254, 241, 233) and the default foreground color is (red, green, blue - 0, 0, 0) - black.

Related tasks:

"Using XPath" on page 1506
XPath provides an alternative method to ESQL for entering expressions in the property fields of specific built-in nodes.

Related reference:

"XPath Expression Builder" on page 1510
You can launch the XPath Expression Builder from most property fields that support, or expect, XPath expressions as a value that can be entered into the field.

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

XPath expressions supported by default:

XPath supports a number of expressions by default.

The following expressions are supported:

Read-only fields

```
$Root, $Body, $Properties, $LocalEnvironment,  $DestinationList,
$ExceptionList, $InputRoot , $InputBody, $InputProperties,
$InputLocalEnvironment, $InputDestinationList,
$InputExceptionList,$Environment.
```

To exclude variables for a node property from the default list, specify a comma separated string of variables. For example, specifying:

```
"com.ibm.etools.mft.ibmnodes.editors.xpath.XPathReadOnlyPropertyEditor", "InputRoot ,
 InputBody, InputProperties, InputLocalEnvironment, InputDestinationList,
 InputExceptionList"
```

restricts the XPath field to support only:

```
$Root, $Body, $Properties, $LocalEnvironment,  $DestinationList, $ExceptionList'
$Environment
```

Read-write fields

```
$InputRoot , $InputBody, $InputProperties, $InputLocalEnvironment,
$InputDestinationList, $InputExceptionList,  $OutputRoot ,
$OutputLocalEnvironment, $OutputDestinationList,
$OutputExceptionList, $Environment.
```

To exclude variables for a node property from the default list, specify a comma separated string of variables. For example, specifying:

```
"com.ibm.etools.mft.ibmnodes.editors.xpath.XPathReadWritePropertyEditor", "InputRoot ,
 InputBody, InputProperties, InputLocalEnvironment, InputDestinationList,
 InputExceptionList"
```

restricts the XPath field to support only:

```
$OutputRoot, $OutputLocalEnvironment, $OutputDestinationList, $OutputExceptionList,
 $Environment
```

Expression fields

```
$Root, $Body, $Properties, $LocalEnvironment,  $DestinationList,
$ExceptionList, $InputRoot , $InputBody, $InputProperties,
$InputLocalEnvironment, $InputDestinationList, $InputExceptionList,
```

```
$OutputRoot , $OutputLocalEnvironment, $OutputDestinationList,
$OutputExceptionList, $Environment.
```

To exclude variables for a node property from the default list, specify a comma separated string of variables. For example, specifying:

```
"com.ibm.etools.mft.ibmnodes.editors.xpath.XPathPropertyEditor", "InputRoot ,
InputBody, InputProperties, InputLocalEnvironment, InputDestinationList,
InputExceptionList, OutputRoot , OutputLocalEnvironment, OutputDestinationList,
OutputExceptionList"
```

restricts the XPath field to support only:

```
$Root, $Body, $Properties, $LocalEnvironment,  $DestinationList, $ExceptionList,
 $Environment.
```

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

"Predefined XPath mapping functions" on page 5001
Some XPath functions are available for use with message maps.

Creating XPath expressions:

A number of built-in primitive nodes have properties that can be specified using an XPath 1.0 expression; most commonly where this language is used to form a path expression to locate incoming message body elements received by a node.

About this task

Other less common node property fields support the entry of general XPath 1.0 expressions that support a wider range of the language to perform more complex evaluations in the broker's XPath 1.0 runtime engine.

The XPath Expression builder provides a tree view of a message, and supports the automatic generation of an XPath 1.0 path expression, through the selection of an element within the tree.

The Schema Viewer section provides a tree view of the input message. To visually build your XPath expression follow these steps:

Procedure

1. Add the relevant node to your message flow
2. In the Properties viewer, enter the correlation name, or press Ctrl + Space to use content assist, or press Edit to use the Expression editor. Content assist is also invoked by simply typing $ in cell-based property fields. See "Correlation names" on page 1069 for further information on correlation names.
3. Expand the tree, navigate to the field for which you want to build an expression, and click to select it. A field is either an element, or an attribute. Double click the field to add it to the XPath expression. You can also drag fields, functions, and operators to the desired location in the XPath expression when using the XPath Expression builder.
4. To set conditions, enter them as you would a normal XPath Expression.

Results

The complete XPath expression is shown either:

- In the XPath Expression pane if you are using the XPath Expression builder.

  The Expression builder dialog is an optional aid for generating expressions that, when complete, form the value in a node's property field.

  If you do not use the Expression builder dialog, the expressions entered manually are validated using the property editor.
- In the Property field if it is in the node itself.

Messages are displayed at the top of the XPath Editor window to alert you to the fact that a path or expression you have entered is not valid.

Note: The editor does not prevent you from entering, and saving, an expression that is not valid.

Example

Here is the XPath expression built in the XPath Expression Builder to filter the Employee business objects for all employees who are managers: `$Root/XMLNSC/getEmployeeInfo/Emp[isManager=true()]`.

- `$Root/XMLNSC/`: The body section of the message; that is, the last child of root. This example assumes that the XMLNSC domain is being used.
- `/getEmployeeInfo`: The name of the operation in the interface.
- `/Emp`: The name of the input message type.
- `[isManager=true()]`: Checks whether the `isManager` field is set to true.

In this case the same expression works for both request and response flows, because the input and output messages for the operation are identical.

For more information on XPath 1.0, see W3C XPath 1.0 Specification.

"Predefined XPath mapping functions" on page 5001
Some XPath functions are available for use with message maps.

Selecting the grammar mode:

The grammar mode allows you to use only a restricted set of expressions, in either XPath or ESQL, and checks whether the syntax you have entered is valid.

About this task

WebSphere Message Broker supports the following field categories:

- Read-only path field
- Read-write path field
- Expression field

Each of these field types can be either fixed or mixed language, that is, ESQL, XPath, or either.

If you use XPath syntax, and the expressions are not supported for the property you are using, the syntax is rejected during the validation process.

ESQL and XPath have similar restrictions on the syntax that is permitted for the first two of these field types. There are restrictions to the expression fields as well, but as this type of field supports general expressions that can be used in either language, the range of syntax available is greater than in the first two.

WebSphere Message Broker uses code assistance in the grammar management of XPath 1.0 to validate the syntax of expressions you enter. This assistance is always available, regardless of the grammar mode you are using.

By default, you are operating in the restricted grammar mode.

Code assistance enables you to construct syntactically correct expressions but it does not validate those expressions. Validation is performed by property editors in which such expressions are entered.

If you attempt to use an expression that is not valid, the property editor marks it as such, either from a syntax or schema validation perspective.

You receive error or warning messages depending on the preference choices you set in **Windows>Preferences>Broker Development>XPath>Validation** .

If, under the above validation settings, particular checks are to be marked as errors, error markers are shown in the problems viewer. This behavior results in a message flow being marked as broken, and it cannot then be imported into, or compiled in, a deployable broker archive (BAR) file using the Broker Archive editor.

If you want to use the appropriate unrestricted grammar to input a specific field type, property editors do not force restricted forms of ESQL or XPath 1.0 expressions for such fields that expect them. Instead, you can enter the full range of syntax in the context of the field category concerned, namely, path or general expression, without the validation checks being applied. This means that if you need to, you can deploy the full range of syntax supported by the ESQL or XPath 1.0 runtime environment. Note, however, that such expressions might not be in a form that can be converted to the other language.

To use unrestricted grammar, carry out the following procedure:

Procedure

1. Click **Window -> Preferences** and expand **Broker Development**.
2. Expand **XPath** and click **Grammar**.
3. Clear the **Use XPath and ESQL equivalent grammar** check box.

What to do next

Note that expressions are still checked for valid syntax appropriate in the context of the field type, but you can now use the full range of grammar supported by the runtime environment.

Using dynamic terminals

You can add, rename, and remove dynamic terminals on a node in the Message Flow editor.

Before you begin

Before you start:

- Add a node that supports dynamic terminals; for more details, see "Adding a message flow node" on page 1494 and "Message flow node terminals" on page 1034.

About this task

Some message flow nodes support dynamic input or output terminals, including the Collector, Route, and DatabaseRoute nodes. When you have added a node to the flow editor, you can add, remove, or change dynamic terminals.

Procedure

- **Adding a dynamic terminal**
  1. Right-click the node and click **Add Input Terminal** or **Add Output Terminal**.
  2. Enter a name for the new terminal and click **OK**. The name must be unique for the terminal type. For example, if an input terminal called *In* already exists, you cannot create a dynamic input terminal with the name *In*.

     The new terminal is displayed on the node. If a node has five or more terminals, they are displayed as a terminal group. The following example shows a Route node with more than four output terminals.  To connect a particular output terminal, click the terminal group to open the Terminal Selection dialog box, or right-click the node and select **Create Connection**.
- **Renaming a dynamic terminal**
  1. Right-click the node and click **Rename Input Terminal** or **Rename Output Terminal**. These options are available only if you have added one or more appropriate terminals to this node.

2. Select from the list the name of the terminal that you want to change. Only dynamic terminals are listed because you cannot change the name of a static terminal.
3. Enter a new name for the terminal and click **OK**. Do not rename a dynamic terminal if one of the node properties is configured to use that name.

- **Removing a dynamic terminal**
  1. Right-click the node and click **Remove Input Terminal** or **Remove Output Terminal**, These options are available only if you have added one or more appropriate terminals to this node.
  2. Select from the list the name of the terminal that you want to remove and click **OK**. Only dynamic terminals are listed because you cannot remove a static terminal. Do not remove a dynamic terminal if one of the node properties is configured to use that terminal.

What to do next

When you have added dynamic terminals to a node, connect them to other nodes in the message flow; for more information, see "Connecting message flow nodes" on page 1520.

Removing a message flow node

When you have created and populated a message flow, you might need to remove a node to change the function of the flow, or to replace it with another more appropriate node. The node can be a built-in node, a user-defined node, or a subflow node.

Before you begin

Before you start:

This topic assumes that you have completed one or more of the following tasks.

- Create a message flow, or open an existing message flow, as described in "Creating a message flow" on page 1431 and "Opening an existing message flow" on page 1433.
- Add a node to the message flow, as described in "Adding a message flow node" on page 1494.
- Add a subflow, as described in "Adding a subflow" on page 1501.
- Read background information about nodes in "Message flow nodes" on page 1024.

About this task

To remove a node from a message flow, complete the following steps.

Procedure

1. Open the message flow with which you want to work.
2. Highlight the node that you want to remove and click **Edit** > **Delete**.

   The node is removed from the flow. If you have created any connections between that node and any other node, those connections are also deleted when you delete the node.
3. If you delete a node in error, you can restore it by clicking **Edit** > **Undo Delete** or pressing Ctrl+Z. The node and its connections, if any, are restored.
4. If you undo the deletion, but decide that it is correct to delete the node, click **Edit** > **Redo Delete**.

Connecting message flow nodes

When you include more than one node in your message flow, you must connect the nodes to indicate how the flow of control passes from input to output. The nodes can be built-in nodes, user-defined nodes, or subflow nodes.

Before you begin

Before you start:

Complete the following tasks.

- Add a note to your message flow, as described in "Adding a message flow node" on page 1494.
- Add a subflow to your message flow, as described in "Adding a subflow" on page 1501.
- Read the concept topic, "Message flow connections" on page 1032.

About this task

Your message flow might contain just one MQInput node, one Compute node, and one MQOutput node. Or it might involve a large number of nodes, and perhaps embedded message flows, that provide a number of paths through which a message can travel depending on its content. You might also have some error processing routines included in the flow. You might also need to control the order of processing.

You can connect a single output terminal of one node to the input terminal of more than one node (this is known as fan-out). If you do this, the same message is propagated to all target nodes, but you have no control over the order in which the subsequent paths through the message flow are executed (except with the FlowOrder node).

You can also connect the output terminal of several nodes to a single node input terminal (this is known as fan-in). Again, the messages that are received by the target node are not received in any guaranteed order.

When you have completed a connection, it is displayed as a black line, and is drawn as close as possible to a straight line between the connected terminals. This behavior might result in the connection passing across other nodes. To avoid this problem, you can add bend points to the connection.

In the Message Flow editor, you can display node and connection metadata by holding the mouse pointer over a node or subflow in a message flow. To view metadata information for a node, subflow, or connection:

1. Switch to the Broker Application Development perspective.
2. Open a message flow.
3. In the Message Flow editor, hold the mouse pointer over a node, a subflow, or a node connection in the open message flow by placing the mouse over the element.

A custom tooltip is displayed below the element.

- To turn the pop-up window into a scrollable window, press **F2**.
- To hide the pop-up window, either press Esc or move the mouse away from the node.

If you define a complex message flow, you might have to create a large number of connections. The principle is the same for every connection. You create connections either by using the mouse, or by using the Terminal Selection dialog. See "Creating node connections with the mouse" on page 1522 and "Creating node connections with the Terminal Selection dialog box" on page 1523 for more information.

"Adding a bend point" on page 1527
When you are working with a message flow, and connecting your chosen nodes together to determine the flow of control, you might find that a connection that you have made crosses over an intervening node and makes the flow of control difficult to follow. To help you to display the message flow nodes and their connections in a clear way, you can add bend points to the connections that you have made to improve the organization of the display. The addition of bend points has no effect on the execution of the nodes or the operation of the message flow.

"Removing a bend point" on page 1528
When you are working with a message flow in the editor view, you might want to simplify the display of the message flow by removing a bend point that you previously added to a connection between two nodes.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Creating node connections with the mouse:

Use the mouse to connect one node to another.

Before you begin

Before you start:

Read the concept topic about connections.

About this task

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the message flow with which you want to work.
3. Click the terminal from which the connection is to be made; that is, the terminal from which the message is propagated from the current node.

For example, you can click the Failure, Out, or Catch terminal of the MQInput node. Hold the mouse pointer over each terminal to see the name of the terminal. You do not need to keep the mouse button pressed.

Alternatively, click **Connection** on the palette, then click the node from which the connection is to be made. The Terminal Selection dialog box opens for you to choose the terminal from which to make a connection. Click **OK**. If a node has five or more input or output terminals (for example, if you have added dynamic terminals), they are displayed in a group. The following example shows a node with more than four output nodes.  To select a particular output terminal, click the grouped output terminal to open the Terminal Selection dialog box.

4. Click the input terminal of the next node in the message flow (to which the message passes for further processing). The connection is made when you click a valid input terminal. The connection appears as a black line between the two terminals.

Results

In the Message Flow editor, you can display node and connection metadata by holding the mouse pointer over a node or subflow in a message flow. To view metadata information for a node, subflow, or connection:

1. Switch to the Broker Application Development perspective.
2. Open a message flow.
3. In the Message Flow editor, hold the mouse pointer over a node, a subflow, or a node connection in the open message flow by placing the mouse over the element.

A custom tooltip is displayed below the element.

- To turn the pop-up window into a scrollable window, press **F2**.
- To hide the pop-up window, either press Esc or move the mouse away from the node.

What to do next

Next: add a bend point, as described in "Adding a bend point" on page 1527.

Related concepts:

Use the Terminal Selection dialog box to connect one node to another.

Creating node connections with the Terminal Selection dialog box:

Use the Terminal Selection dialog box to connect one node to another.

Before you begin

Before you start:

Read the concept topic about connections.

About this task

1. Switch to the Broker Application Development perspective.
2. Open the message flow with which you want to work.
3. Click **Connection** above the node palette.
4. Click the node from which you want the connection to be made. The Terminal Selection dialog box is displayed.
5. Select the terminal from the list of valid terminals on this node. Click **OK**. The dialog box closes.
6. Click the node to which to make the connection. If this node has only one input terminal, the connection is made immediately. If this node has more than one input terminal, the Terminal Selection dialog box is displayed again, listing the input terminals of the selected node. Click the correct terminal and click **OK**.

Alternatively, you can make a connection in the following way:

Procedure

1. Click **Selection** above the node palette.
2. Right-click the node from which you want to make the connection and click **Create Connection**. The Terminal Selection dialog box is displayed.
3. Select the terminal from the list of valid terminals on this node. Click **OK**. The dialog box closes.
4. Click the node to which to make the connection. If this node has only one input terminal, the connection is made immediately. If this node has more than one input terminal, the Terminal Selection dialog box is displayed again, listing the input terminals of the selected node. Click the correct terminal and click **OK**.

Results

In the Message Flow editor, you can display node and connection metadata by holding the mouse pointer over a node or subflow in a message flow. To view metadata information for a node, subflow, or connection:

1. Switch to the Broker Application Development perspective.
2. Open a message flow.
3. In the Message Flow editor, hold the mouse pointer over a node, a subflow, or a node connection in the open message flow by placing the mouse over the element.

A custom tooltip is displayed below the element.

- To turn the pop-up window into a scrollable window, press **F2**.
- To hide the pop-up window, either press Esc or move the mouse away from the node.

Inserting nodes into existing message flows

You can insert a node into an existing message flow without having to delete existing connections and create connections for the new node.

Before you begin

Before you start:

The following instructions assume that you have created a message flow, as described in “Creating a message flow” on page 1431.

About this task

In earlier versions of WebSphere Message Broker, to insert a new node into a message flow, you had to delete the existing connection between two nodes, insert the new node, then create new connections between the existing nodes and the new node. From WebSphere Message Broker Version 7.0 onwards, you can insert a new node in one step by dropping it onto an existing connection, as described by the following steps.

Procedure

1. In the Message Flow editor, open the message flow into which you want to insert a new node.
2. Choose the node that you want to insert from the message flow node palette.
3. Drag the node onto the connection between the two nodes where you want the new node to be added. When the mouse pointer is over the connection, a label is displayed saying "Add a node here". When you release the mouse button, the node is inserted in the message flow and is automatically connected to the preceding and succeeding nodes.

Related concepts:

“Message flow node palette” on page 1027
The palette in the Message Flow editor contains all the built-in nodes, which are organized into categories, or drawers. A drawer is a container for a list of icons, such as the **Favorites** drawer.

The Message Flow editor is the default editor provided by the Broker Application Development perspective for defining a graphical representation of a message flow in the WebSphere Message Broker Toolkit, and for setting properties for individual message flow nodes.

Removing a node connection

The message flow editor displays the nodes and connections in the editor view. You can remove connections to change the way in which the message flow processes messages.

Before you begin

Before you start:

Complete the following tasks:
- "Connecting message flow nodes" on page 1520.
- Read the concept topic, "Message flow connections" on page 1032.

About this task

To remove a connection that you have created between two nodes:

Procedure

1. Open the message flow that you want to work with.
2. Click **Selection** above the node palette.
3. Select the connection that you want to delete. When you hold the mouse pointer over the connection, the editor highlights the connection that you have selected by thickening its line, adding an arrowhead at the target terminal end, and annotating the connection with the name of the two terminals connected, for example Out->In.

   When you select the connection, the editor appends a small black square at each end and at every bend point of the connection, and a small arrowhead at the target terminal end. The annotation disappears when you select the connection.
4. Check that the selected connection is the one that you want to delete.
5. Right-click the connection and click **Delete**, press the Delete key, or click **Edit** > **Delete**. If you want to delete further connections, repeat these actions from step 3.
6. If you delete a connection in error, you can restore it by right-clicking in the editor view and clicking **Undo Delete**. The connection is restored.
7. If you undo the delete, but decide that it is the correct delete action, you can right-click in the editor view and click **Redo Delete**. You can also delete a connection by selecting it in the Outline view and pressing the Delete key.

Results

If you delete a node, its connections are automatically removed; you do not have to do this as a separate task.

Related concepts:

"Message flows overview" on page 1022

WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Adding a bend point

When you are working with a message flow, and connecting your chosen nodes together to determine the flow of control, you might find that a connection that you have made crosses over an intervening node and makes the flow of control difficult to follow. To help you to display the message flow nodes and their connections in a clear way, you can add bend points to the connections that you have made to improve the organization of the display. The addition of bend points has no effect on the execution of the nodes or the operation of the message flow.

Before you begin

Before you start:

- Connect the nodes
- Read the concept topic about bend points

About this task

To add a bend point:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the message flow that you want to work with.
3. Click **Selection** above the node palette.
4. Select the connection to which you want to add a bend point. The editor appends a small black square to each end of the connection to highlight it.
   a. Check that this is the correct connection. The editor also adds a small point (a handle) in the connection halfway between the in and out terminals that are joined by this connection.
5. Hold the mouse pointer over this point until the editor displays a black cross to indicate that you now have control of this bend point.

a. Hold down the left mouse button and move your mouse to move the black cross and bend point across the editor view.

6. As you drag your mouse, the connection is updated, retaining its start and end points with a bend point at the drag point. You can move the bend point anywhere in the editor view to improve the layout of your message flow.
7. Release the mouse button when the connection is in the correct place. The editor now displays the bend point that you have created with a small square (such as those at the ends of the connection), and displays another two small points in the connection, one between your newly-created bend point and the out terminal, the other between the new bend point and the in terminal.

Results

If you want to add more than one bend point to the same connection, repeat these actions from step 4 on page 1527 using the additional small points inserted into the connection.

What to do next

Next: align and arrange the nodes.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

"Defining message flow content" on page 1488

The message flow editor displays the nodes and connections in the editor view. You can remove connections to change the way in which the message flow processes messages.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Removing a bend point

When you are working with a message flow in the editor view, you might want to simplify the display of the message flow by removing a bend point that you previously added to a connection between two nodes.

Before you begin

Before you start:

- Add a bend point
- Read the concept topic about bend points

About this task

To remove a bend point:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the message flow that you want to work with.
3. Click **Selection** above the node palette.
4. Select the connection from which you want to remove the bend point. The editor highlights the connection and its current bend points by thickening its line and appending a small black square to each end of the connection, and by indicating each bend point with a small black square. Check that this is the correct connection.
5. Right-click over the selected connection, if you added this bend point in the current edit session.
   a. Click **Undo Create Bend Point**.

   The editor removes the selected bend point.

   If you right-click in the editor view without a connection being selected, you can also click **Undo Create Bend Point** from the menu. However, this removes the last bend point that you created in any connection, which might not be the one that you want to remove.
6. Move the bend point to straighten the line if you added this bend point in a previous edit session, because you cannot use the undo action. When the line is straight, the bend point is removed automatically.

   When the bend point has been removed, the connection remains highlighted. Both ends of the connection, and any remaining bend points, remain displayed as small black squares. The editor also inserts small points (handles) into the connection between each bend point and between each terminal and its adjacent bend point, which you can use to add more bend points.
7. If you want to remove another bend point from the same connection, repeat these actions from step 4.

"Adding a bend point" on page 1527
When you are working with a message flow, and connecting your chosen nodes together to determine the flow of control, you might find that a connection that you have made crosses over an intervening node and makes the flow of control difficult to follow. To help you to display the message flow nodes and their connections in a clear way, you can add bend points to the connections that you have made to improve the organization of the display. The addition of bend points has no effect on the execution of the nodes or the operation of the message flow.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Aligning and arranging nodes

When you are working in the Message Flow editor, you can decide how your nodes are aligned in the editor view.

Before you begin

This option is closely linked to the way in which your nodes are arranged. The default for both alignment and arrangement is left to right, which means that the in terminal of a node appears on its left edge, and its out terminals appear on its right edge. You can also change this characteristic of a node by rotating the icon display to right to left, top to bottom, and bottom to top.

Before you start

To complete this task, you must have completed the following task:

- "Adding a message flow node" on page 1494

About this task

To modify the way in which nodes and connections are displayed in the editor:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the message flow that you want to work with.
3. Click **Selection** above the node palette.
4. Right-click in the editor window and select **Manhattan Layout** if you want the connections between the nodes to be displayed in Manhattan style; that is with horizontal and vertical lines joined at right angles.
5. If you want to change the layout of the complete message flow:
   a. Right-click in the editor view and click **Layout**. The default for the alignment is left to right, such that your message flow starts (with an input node) on the left and control passes to the right.
   b. From the four further options displayed, **Left to Right**, **Right to Left**, **Top to Bottom**, and **Bottom to Top**, click the option that you want for this message flow. The message flow display is updated to reflect your choice. As a result of the change in alignment, all the nodes in the message flow are also realigned.

      For example, if you have changed from a left to right display (the default) to a right to left display, each node in the flow has now also changed to right to left (that is, the in terminal now appears on the right edge, the out terminals appear on the left edge).
6. You might want to arrange an individual node in a different direction from that in which the remaining nodes are arranged in the message flow:
   a. Right-click the node that you want to change and click **Rotate**. Four further options are displayed: **Left to Right**, **Right to Left**, **Top to Bottom**, and **Bottom to Top**. The option that represents the current arrangement of the node is not available for selection.
   b. Click the option that you want for this node.

Results

If you change the alignment of the message flow, or the arrangement of an individual node, or both, these settings are saved when you save the message flow. They are applied when another user accesses this same message flow, either through a shared repository or through shared files or import and export. When you reopen the message flow, you see these changed characteristics. The alignment and arrangement that you have selected for this message flow have no effect on the alignment and arrangement of any other message flow.

You can also access the editor toolbar to select other options related to the display and arrangement of nodes, for example, snap to grid. These options are defined in "Message Flow editor" on page 6810.

Adding annotations to a message flow or node

You can add annotations to a message flow, a node, or multiple nodes. You can use these annotations to record reminders, issues arising during the development of a message flow, or informal documentation to facilitate team development.

Before you begin

Before you start:

The following instructions assume that you have created a message flow, as described in "Creating a message flow" on page 1431.

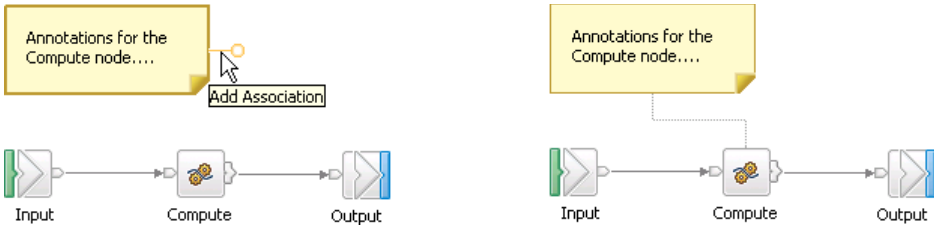
About this task

Procedure

- **Adding an annotation to a message flow**
  1. Open the message flow that you want to annotate in the Message Flow editor.
  2. In the message flow node palette, click **Note**, then click the canvas of the Message Flow editor. A blank note, in editing mode, is added to the canvas.
  3. Enter your comments to the note.
  4. To exit editing mode, click the canvas outside the note. The note resizes according to the amount of text that you enter.
  5. To save the contents of the note, save the message flow.
- **Associating an annotation with a node**
  1. Add a note to the canvas, as described in the preceding steps.
  2. To associate a note with a node in the message flow, move the mouse pointer over the edge of the note until a connector appears.
  3. Click the connector, then click the node with which you want to associate the note. The sticky note is associated with the selected node. This association is shown in the Message Flow editor by a dotted line.

     You can repeat these steps to associate an annotation with more than one node.

     The following diagram shows that a connector appears when you move the mouse cursor over the edge of a note, and that a dotted line represents the association between a node and a note.



What to do next

After you have added an annotation to a message flow or node, you can modify the annotation in the following ways:

- "Editing annotations on a message flow or node" on page 1533
- "Copying annotations on a message flow or node" on page 1534
- "Showing and hiding annotations on a message flow or node" on page 1535
- "Deleting annotations from a message flow or node" on page 1536

Editing annotations on a message flow or node:

After you have added an annotation to a message flow or node, in the form of a sticky note, you can edit the contents of that note.

Before you begin

Before you start:

The following instructions assume that you have added an annotation to a message flow or node, as described in "Adding annotations to a message flow or node" on page 1531.

About this task

You can add annotations to message flows or nodes to create reminders, or record details about message flow development. For example, you might want to add a list of modifications that need to be made to a message flow. As you complete the modifications, you might want to edit the annotation to reflect progress. The following steps describe how to edit an annotation.

Procedure

- **Editing the content of a note**
  1. In the Message Flow editor, open the message flow that contains the note that you want to edit.
  2. To put the note into editing mode, click the text of the note. The note changes color, acquires a blue border, and a cursor appears.
  3. Edit the content of the note. You can use standard cut, copy, and paste operations.
  4. To exit editing mode, click the canvas outside the note. The note resizes according to the amount of text that you enter.
  5. To save the contents of the note, save the message flow.
- **Moving a sticky note**
  - To move a sticky note, click inside the note (not on the text) so that black dots appear at each corner. You can now drag the note to a new position on the canvas. If the note is associated with one or more nodes, the association line also moves.
  - You can also move a sticky note by using cut and paste operations. Right-click the note, click **Cut**, right-click the canvas where you want the note to appear, and click **Paste**.
- **Changing the association of a sticky note**
  - To associate a sticky note with a different node, move the mouse pointer over the old node, click the end of the association line, hold down the mouse button, then drag the association line to the new node. When you release the mouse button, the sticky note is associated with the new node, as indicated by a dotted line.

– To associate a node with a different sticky note, move the mouse pointer over the old sticky note, click the end of the association line, hold down the mouse button, then drag the association line to the new sticky note. When you release the mouse button, the node is associated with the new sticky note, as indicated by a dotted line.

Copying annotations on a message flow or node:

You can copy annotations that you have added to a message flow or node to the same instance of the Message Flow editor, or to a different instance of the editor.

Before you begin

Before you start:

The following instructions assume that you have added an annotation to a message flow or node, as described in "Adding annotations to a message flow or node" on page 1531.

Procedure

- In the Message Flow editor, open the message flow that contains the annotation that you want to copy. A copy of the note appears in the new location. If the original note is associated with one or more message flow nodes, those associations are not copied. You can also cut and paste a note in the same way.
- Right-click the note that you want to copy, then click **Copy**.
- Optional: If you want to copy annotations to a different Message Flow editor, switch to the Message Flow editor to which you want to copy the note.
- Right-click the Message Flow editor canvas where you want the copy of the note to appear, then click **Paste**.

Processing WebSphere MQ messages

WebSphere Message Broker provides a number of nodes for handling messages received from or sent to WebSphere MQ applications.

About this task

WebSphere Message Broker provides the following nodes for working with message received from or sent to WebSphere MQ applications:

MQInput node
Use an MQInput node if the messages arrive at the broker on a WebSphere MQ queue, and the node is to be at the start of a message flow.

MQGet node
Use an MQGet node to retrieve a message from a WebSphere MQ queue, if you want to get the message later in the message flow.

MQReply node
Use an MQReply node if the target application expects to receive messages on the WebSphere MQ reply-to queue that is specified in the input message MD.

MQOutput node
Use an MQOutput node if the target application expects to receive messages on a WebSphere MQ queue, or on the WebSphere MQ reply-to queue that is specified in the input message MD.

MQHeader node
Use the MQHeader nodes to manipulate WebSphere MQ transport headers and their properties without writing compute nodes. Use the MQHeader node to add, modify, or delete Message Descriptor (MD) and Dead Letter Header (DLH) headers.

JMSMQTransform node
Use the JMSMQTransform node to transform a message with a JMS message tree into a message that has a tree structure that is compatible with the format of messages that are produced by the WebSphere MQ JMS provider.

The JMSMQTransform node can be used to send messages to existing message flows and to interoperate with WebSphere MQ JMS and WebSphere MQ Publish/Subscribe.

MQJMSTransform node
Use the MQJMSTransform node to receive messages that have a WebSphere MQ JMS provider message tree format, and transform them into a format that is compatible with messages that are to be sent to JMS destinations.

You can use the MQJMSTransform node to send messages to existing message flows and to interoperate with WebSphere MQ JMS and WebSphere MQ Publish/Subscribe.

Application programming interfaces

WebSphere Message Broker supports several programming interfaces that are in use by WebSphere MQ applications today; it does not provide any unique programming interfaces.

- Message Queue Interface (MQI)

The MQI provides a few calls that allow an application to interact with other applications in a network of WebSphere MQ queue managers. The calls support a large range of parameters that allow a rich choice of processing options for each and every message.

Client applications using the MQI can run on any supported WebSphere MQ operating system, and therefore any limitations that are enforced for language or function are defined by the relevant product for that operating system.

The MQI is described in the *Application Programming Reference* and *Application Programming Guide* sections in the WebSphere MQ Version 7 Information Center online . Details are also provided of the programming language and operating system support available for clients that use this interface.

- Application Messaging Interface (AMI)

  The AMI is designed to simplify the application programmer's task by centralizing the selection of optional parameters outside the application program. It also provides support for the more advanced functions available from the broker. The AMI is designed for general messaging applications with and without a broker.

  The principal functions of the AMI are administrator-defined packets of options known as policies and services. An application specifies a service to determine the underlying messaging support required, and associates a policy with sending or receiving a message to control attributes for message processing, such as priority.

  The policies and services mean that the application does not have to understand details of the MQRFH2 header and the MQI interface.

  Client applications using the AMI are restricted to the operating systems and programming languages supported by this interface. The AMI is defined in the *Publish/Subscribe User's Guide* section in the WebSphere MQ Version 7 Information Center online.

If you have existing end-user applications that are written to these interfaces, they can typically run unchanged in a broker environment. You must create the message flows to interact with these applications from the supported protocols, using the appropriate input and output nodes. WebSphere Message Broker provides built-in input and output nodes for its supported protocols and you can create your own user-defined nodes to support additional protocols.

You can also create new end-user applications to interact with the broker.

Message headers

WebSphere Message Broker provides parsers for many WebSphere MQ headers, and can therefore accept messages that contain these headers from the WebSphere MQ Enterprise Transport protocol.

Messages must include a WebSphere MQ Message Descriptor (MQMD) as the first header, which must precede user or application data in every message. The MQMD contains basic control information that must travel with the message, including:

- The message identifier
- The destination of the reply, if one is to be sent
- Reply and report options (for example, confirm on delivery report)
- The format of any following data in the message

When a message is processed by a WebSphere Message Broker broker, it typically (but not necessarily) has one or more additional headers. The header following the MQMD is always identified in the format field within the MQMD, and itself contains another format field to identify either the header that follows, or the format of the user data.

The additional headers can include:

MQRFH
: The Rules and Formatting header is used by WebSphere MQ Publish/Subscribe.

MQRFH2
: The MQRFH2 is an updated version of MQRFH and allows Unicode strings to be transported without translation, and it can carry numeric data types. The MQRFH2 header carries a description of the message contents, so that WebSphere Message Broker can select the correct message parser when content-based processing is carried out on the message. In addition, this header contains publish/subscribe command messages.

  Use the MQRFH2 header in all new applications written for the WebSphere Message Broker environment that use a supported protocol based on WebSphere MQ technology. The MQRFH2 header must be immediately before the body of the message (that is, the last header).

  If an MQRFH2 header is not included (which is normally the case of the application uses a supported protocol that is not based on WebSphere MQ technology), you must configure the message flow that processes its messages to specify the message characteristics (by setting the input node properties).

Related information:

WebSphere MQ Enterprise Transport

WebSphere MQ Enterprise Transport is a service that connects applications to messaging middleware.

The WebSphere MQ Enterprise Transport is the transport used by WebSphere MQ. The WebSphere MQ Enterprise Transport supports WebSphere MQ applications that connect to WebSphere Message Broker to benefit from message routing and transformation options.

The WebSphere MQ Enterprise Transport provides all the reliable messaging features available in WebSphere MQ. This transport provides persistent and non-persistent messaging and supports transactions. To use the WebSphere MQ Enterprise Transport, you must deploy a message flow that contains an MQInput node to your broker. If this message flow sends output messages to other WebSphere MQ applications, it must also include an MQOutput, MQReply, or Publication node.

The WebSphere MQ Enterprise Transport is a queued transport; applications communicate with the broker by writing data to and reading data from message queues. Use the WebSphere MQ Enterprise Transport when you require assured delivery of messages or need to use transactional support.

WebSphere MQ Enterprise Transport is used by WebSphere MQ clients or application programs that are written to the Application Messaging Interface (AMI) or Message Queue Interface (MQI). The client uses the services provided by the message flows deployed within one or more brokers in the broker network by interacting with the queues serviced by those message flows.

The queue specified in the MQInput node determines the queue on which the broker receives publications from publishing applications. Subscribers connect to the broker by sending a registration request to the broker's SYSTEM.BROKER.CONTROL.QUEUE. The subscriber specifies a queue on which they want to receive any publications on the registered topic in the registration request.

All WebSphere Message Broker applications, like WebSphere MQ applications, can use all the supported WebSphere MQ interfaces to put messages to the message flow queues. In fact, every WebSphere MQ application is a potential WebSphere Message Broker application.

These applications use one of two techniques to gain access to broker services:

- An application can use a WebSphere MQ client connection. You can use all the WebSphere MQ clients supported by Version 6.0 or later. You can therefore connect applications running in a wide variety of environments into your broker network. An application running on the same system as the queue manager to which it connects can also use a client connection.
- An application running on the same system as a broker can use a local connection to the queue manager that hosts that broker. If it uses this method, the client must execute on the same system. It can connect to a queue manager supporting a broker, or to any other queue manager in the WebSphere MQ network that has a defined path to the broker's queue manager. (This option is not possible on z/OS, where clients are not supported.)

Multiple applications can communicate using separate local queue managers by using WebSphere MQ intercommunication (*remote queue definitions*, or *clustering*). For more details, see "Concepts of intercommunication" in the *Intercommunication* section of the WebSphere MQ information center.

WebSphere Message Broker does not impose any particular conditions or restrictions on applications.

Receiving applications can get the messages put to the output queue or queues of a message flow when they have been processed by that message flow. The applications must be connected, either by a client/server connection, or across a local connection, to the queue manager that owns the queue or queues defined as the target for their messages. If the message flow provides a publish/subscribe service, the Publication node puts the messages to the queue specified by the subscriber as its local receiver queue.

Applications that connect using WebSphere MQ Enterprise Transport use a mixture of point-to point and publish/subscribe models.

The following built-in nodes are provided to support this protocol:
- MQInput
- MQOutput
- MQReply
- MQGet
- Publication
- SCA nodes, when communicating with WebSphere Process Server applications.

Related concepts:

"Nodes for connectivity" on page 1028

Use the SCAAsyncResponse node with the SCAAsyncRequest node to construct a pair of message flows that start a component asynchronously.

Using WebSphere MQ cluster queues for input and output

Design your broker network to use WebSphere MQ queues, if appropriate for your business needs.

About this task

The use of queue manager clusters has the following significant benefits:

1. Reduced system administration

   Clusters need fewer definitions to establish a network; you can set up and change your network more quickly and easily.

2. Increased availability and workload balancing

   You can benefit by defining instances of the same queue to more than one queue manager, therefore distributing the workload through the cluster.

If you use clusters with WebSphere Message Broker, consider the following queues:

For SYSTEM.BROKER queues:
The SYSTEM.BROKER queues are defined for you when you create WebSphere Message Broker components, and are not defined as cluster queues. Do not change this attribute.

For message flow input queues:
If you define an input queue as a cluster queue, consider the implications for the order of messages or the segments of a segmented message. The implications are the same as for any WebSphere MQ cluster queue. In particular, the application must ensure that, if it is sending segmented messages, all segments are processed by the same target queue, and therefore by the same instance of the message flow at the same broker.

For message flow output queues:

- WebSphere Message Broker always specifies MQOO_BIND_AS_Q_DEF when it opens a queue for output. If you expect segmented messages to be put to an output queue, or want a series of messages to be handled by the same process, you must specify DEFBIND(OPEN) when you define that queue. This option ensures that all segments of a single message, or all messages in a sequence, are put to the same target queue and are processed by the same instance of the receiving application.
- If you create your own output nodes, specify MQOO_BIND_AS_Q_DEF when you open the output queue, and DEFBIND(OPEN) when you define the queue, if you need to ensure message order, or to ensure a single target for segmented messages.

For publish/subscribe applications:

- If the target queue for a publication is a cluster queue, you must deploy the publish/subscribe message flow to all the brokers on queue managers in the cluster. However, the cluster does not provide any of the failover function to the broker network and function. If a broker to which a message is published, or a subscriber registers, is unavailable, the distribution of the publication or registration is not taken over by another broker.
- When a client registers a subscription with a broker that is running on a queue manager that is a member of a cluster, the broker forwards a proxy registration to its neighbors in the broker domain; the registration details are not advertised to other members of the cluster.
- A client might choose to become a clustered subscriber, so that its subscriber queue is one of a set of clustered queues that receive a particular publication. In this case, when registering a subscription, use the name of an "imaginary" queue manager that is associated with the cluster; this queue manager is not the one to which the publication is sent, but an alias for the broker to use. As an administrative activity, a blank queue manager alias definition is made for this queue manager on the broker that satisfies this subscription for all clustered subscribers. When the broker publishes to a subscriber queue that names this queue manager, resolution of the queue manager name results in the publication being sent to any queue manager that hosts the subscriber cluster queue, and only one clustered subscriber receives the publication.

  For example, if the clustered subscriber queue was SUBS_QUEUE and the "imaginary" subscriber queue manager was CLUSTER_QM, the broker definition is:

  ```
  DEFINE QREMOTE(CLUSTER_QM) RQMNAME(' ') RNAME(' ')
  ```

  This configuration sends broker publications for SUBS_QUEUE on CLUSTER_QM to one instance of the cluster queue named SUBS_QUEUE anywhere in the cluster.

To understand more about clusters, and the implications of using cluster queues, see the *Queue Manager Clusters* section of the WebSphere MQ Version 7 Information Center online.

Using WebSphere MQ shared queues for input and output (z/OS)

On z/OS systems, you can define WebSphere MQ shared queues as input and output queues for message flows. You might need to serialize access to those messages.

About this task

Shared queues are available only on z/OS. Use the WebSphere MQ for z/OS product facilities to define these queues and specify that they are shared.

You cannot use shared queues for broker component queues such as the SYSTEM.BROKER.CONTROL.QUEUE.

If you use shared queues, you can provide failover support between different images that are running WebSphere Message Broker on a sysplex.

Some messaging transactions depend on the exact sequence of messages from a queue, and for that sequence to be maintained in the event of a failure of the queue manager. In these instances, you must serialize the access to those messages.

Serialization of messages is achieved by using specialized connection options, and a unique connection token. This connection token is used when the application that empties the messages from a queue issues a connect call to the WebSphere MQ queue manager that owns that queue.

For example, WebSphere Message Broker can use this feature when multiple brokers, with multiple execution groups, are each running message flows that empty from a shared input queue. If one broker queue manager fails, the message flow can be started automatically on another broker. The transactional integrity and original sequencing of the messages on the shared queue are maintained.

The following examples demonstrate how these features can be applied:

• "Serialization of input between separate brokers on z/OS" on page 1547

- "Serialization of input between separate execution groups running on the same broker on z/OS" on page 1549
- "Serialization of input in an execution group on z/OS" on page 1551

To configure shared input queues and define serialization tokens for message flows, follow the instructions in "Serialization token - user tasks on z/OS" on page 1552.

For more information, see the *z/OS Concepts and Planning* section of the WebSphere MQ Version 7 Information Center online.

Related tasks:

"Customizing the z/OS environment" on page 591
If you are planning to use a z/OS environment, consider whether to create your brokers on z/OS. You must also complete a number of tasks to configure your environment.

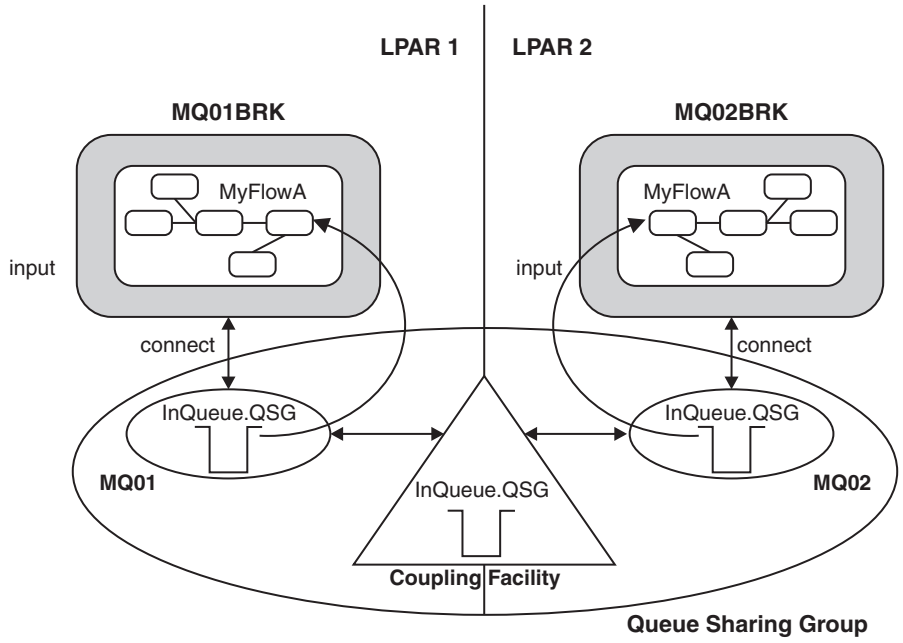
Serialization of input between separate brokers on z/OS: This example demonstrates that only one input node at a time takes messages from a shared queue when the same serialization token is used by message flows running on separate brokers.

Two brokers (`MQ01BRK` and `MQ02BRK`) are configured in this example. The respective queue managers are called `MQ01` and `MQ02`. The queue managers participate in the same queue sharing group. Each queue manager has a shared queue `INQueue.QSG` that has been defined with a disposition of `QSG`, and a local queue called `INQueue`. The queue managers can be running in the same Logical Partition (LPAR) or separate LPARs. The Coupling Facility shown in the following diagrams is a zSeries component that allows z/OS WebSphere MQ queue managers in the same system image, or different system images, to share queues.

An identical message flow `MyFlowA` is deployed to an execution group called `MYGroupA` on each broker. Note that the message flows do not have to be identical; the significant point is that an identical serialization token is used in both flows.

The simple message flow in this example consists of an `MQInput` node connected to an `MQOutput` node. The `MQInput` node in both message flows gets messages from the shared queue `INQueue.QSG`; the node attribute `Serialization Token` is configured as `MyToken123ABC` in both `MQInput` nodes.

The message flow property `additional Instances` takes the default value of zero in both message flows, which ensures that input is serialized within the flow.



A typical sequence of events for this example follows:

1. The first broker MQ01BRK starts and runs message flow MyFlowA in execution group MyGroupA. The input node MyInputNode connects to queue manager MQ01 using a serialization token MyToken123ABC. The input node successfully opens shared queue INQUeue.QSG and gets input messages.
2. The second broker MQ02BRK starts and begins to run its copy of message flow MyFlowA in execution group MyGroupA. The Input node MyInputNode attempts to connect to queue manager MQ02 , also using a serialization token MyToken123ABC.

   The following SDSF console message is logged:

   ```
   BIP2656I MQ02BRK MyGroupA 17 UNABLE TO OPEN QUEUE
   'INQueue.QSG' ON WEBSPHERE BUSINESS INTEGRATION QUEUE
   MANAGER 'MQ02': COMPLETION CODE 2; REASON CODE 2271.
   :ImbCommonInputNode(759) BECAUSE SERIALIZATION TOKEN
   MyToken123ABC is already in use. NO USER ACTION REQUIRED.
   ```

   Note that this message is output every 30 minutes.

   Message flow MyFlowA in execution group MyGroupA running on broker MQ02BRK is unable to process input because the serialization token it has passed is already in use within the queue sharing group. This is indicated by the reason code 2271 (MQRC_CONN_TAG_IN_USE) in message bip2623.
3. Broker MQ01BRK stops. Message flow MyFlowA in execution group MyGroupA in broker MQ02BRK2 is now able to get messages from the shared queue INQueue.QSG.

   A sequence of SDSF console messages is logged, of which the following two are relevant:

   ```
    BIP2091I MQ02BRK MyGroupA 17 THE BROKER HAS
   RECONNECTED TO WEBSPHERE BUSINESS INTEGRATION
   SUCCESSFULLY : ImbCommonInputNode(785)

    BIP9142I MQ01BRK 0 THE COMPONENT HAS STOPPED. :
   ImbControlService(594)
   ```

The preceding sequence of events also occurs should broker MQ01BRK fail, rather than stop through a request from the operator, or if a new broker configuration is deployed to MQ01BRK that deletes or modifies message flow MyFlowA.

This arrangement can also be used where the requirement is to migrate message processing between brokers running in different z/OS system images that are attached to the same Coupling Facility.

Overview of message serialization on z/OS
Some messaging transactions depend on the exact sequence of messages from a queue, and for that sequence to be maintained in the event of a failure of the queue manager. In these instances you must serialize the access to those messages.

"Serialization of input between separate execution groups running on the same broker on z/OS"
This example demonstrates that only one MQInput node at a time is allowed to take messages from a shared queue when the same serialization token is used by message flows running in separate execution groups on the same broker.

"Serialization of input in an execution group on z/OS" on page 1551
To allow concurrent processing within a message flow, while still serializing messages between message flows in separate execution groups, the scope of the serialization token is restricted within a single execution group.

Serialization of input between separate execution groups running on the same broker on z/OS:

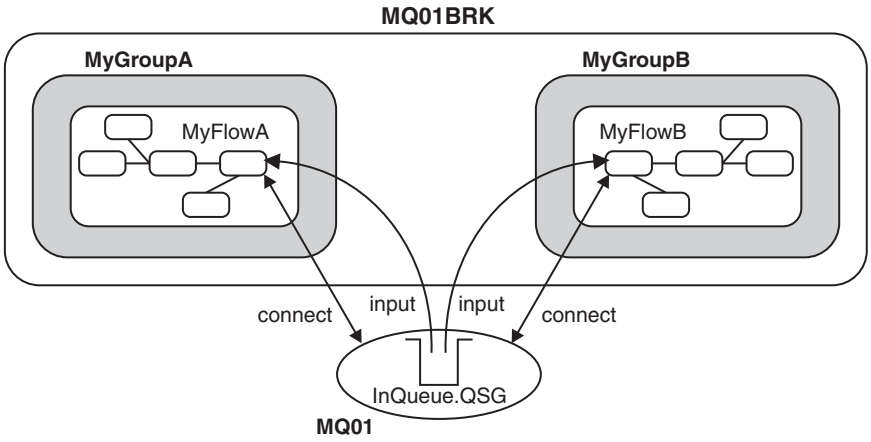
This example demonstrates that only one MQInput node at a time is allowed to take messages from a shared queue when the same serialization token is used by message flows running in separate execution groups on the same broker.

An identical message flow MyFlowA is deployed to two execution groups called MYGroupA and MYGroupB on broker MQ01BRK.

In this case it is not a requirement that the queue manager participates in a queue sharing group. The input queue INQueue is defined as local with disposition QMGR.

As in "Serialization of input between separate brokers on z/OS" on page 1547:

- Note that the message flows do not have to be identical; the significant point is that an identical serialization token is used in both flows.
- The simple message flow in this example consists of an MQInput node connected to an MQOutput node. The MQInput node in both message flows gets messages from the shared queue INQueue.QSG; the node attribute Serialization Token is configured as MyToken123ABC in both MQInput nodes.
- The message flow property additional Instances takes the default value of zero in both message flows, which ensures that input is serialized within the flow.



A typical sequence of events for this example follows:

1. Broker MQ01BRK starts and the first message flow to begin is MyFlowA in execution group MyGroupA. The MQInput node MyInputNode connects to queue manager MQ01 using the serialization token MyToken123ABC. The MQInput node successfully opens shared queue INQUeue and gets input messages.
2. The second execution group MyGroupB starts and message flow MyFlowA in execution group MyGroupB begins. The MQInput node MyInputNode now attempts to connect to queue manager MQ01 using serialization token MyToken123ABC. The following SDSF console message is logged:

   ```
   BIP2656I MQ01BRK MyGroupB 11 UNABLE TO OPEN QUEUE
   'INQueue' ON WEBSPHERE BUSINESS INTEGRATION QUEUE
   MANAGER 'MQ01':  BECAUSE SERIALIZATION TOKEN
   MyToken123ABC is already in use. NO USER ACTION REQUIRED
   ```

   Message flow MyFlowA in execution group MyGroupB is unable to process input because the serialization token it has passed is already in use within the queue manager (by the MQInput node in message flow MyFlowA in execution group MyGroupA). This is indicated by the reason code 2271 (MQRC_CONN_TAG_IN_USE) in message bip2623.
3. The first execution group is deleted or canceled.

   If the first execution group is canceled by the operator, ends with an abend, or is deleted during a redeployment of the broker configuration, the input node in the second execution group is now able to get input messages from queue INQueue.

   A sequence of SDSF console messages is logged, of which the following one is relevant:

   ```
    BIP2091I MQ01BRK MyGroupB 11 THE BROKER HAS
   RECONNECTED TO WEBSPHERE BUSINESS INTEGRATION
   SUCCESSFULLY : ImbCommonInputNode(785)
   ```

Message flow MyFlowA in execution group MyGroupB is now able to recover processing of messages from the shared queue INQueue.QSG.

Note that, although serialization of input can be achieved in a similar manner by configuring the input queue for exclusive input, this does not ensure message integrity during a recovery situation. This can be achieved only through the use of the serialization token as described in this example.

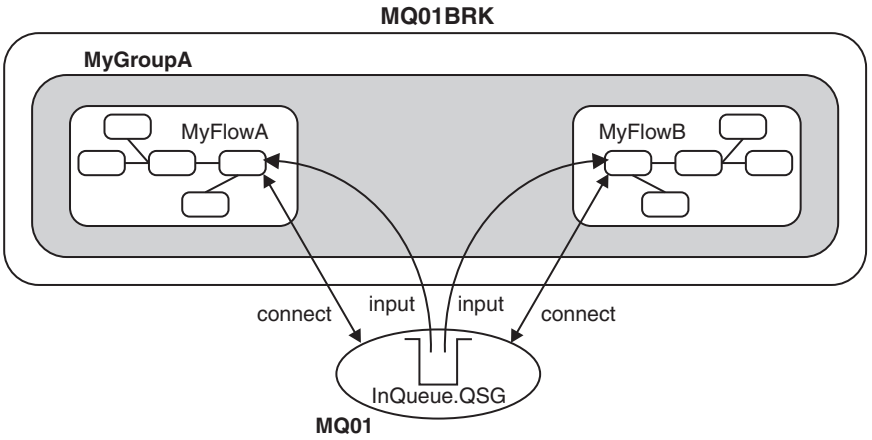
"Serialization of input in an execution group on z/OS"
To allow concurrent processing within a message flow, while still serializing messages between message flows in separate execution groups, the scope of the serialization token is restricted within a single execution group.

Serialization of input in an execution group on z/OS:

To allow concurrent processing within a message flow, while still serializing messages between message flows in separate execution groups, the scope of the serialization token is restricted within a single execution group.



This example demonstrates that the serialization token is restricted within a single execution group running on a broker::

- Two `MQInput` nodes in separate message flows (in this case `MyFlowA` and `MyFlowB`) are running within the same execution group `MyGroupA`. Both `MQInput` nodes concurrently get messages from the shared input queue even though they are using the same serialization token.
- If serialization is required within a single message flow, the message flow attribute `additional instances` must be set to zero which is the default setting. However, if greater throughput is required and serialization of input within the flow is not important, you can set `additional instances` to a value greater than zero.
- The use of the `serialization token` attribute on the `MQInput` node does not serialize input between message flows operating within the same execution group. However, setting the attribute has no adverse affect on the processing within that execution group

- In this way it is possible to maximize throughput in a message flow on one broker while still serializing input between brokers. This is useful where the requirement is to have one or more brokers acting as an immediate standby, should the currently active broker need to be stopped for servicing, or fail unexpectedly.

Serialization token - user tasks on z/OS:

Configure shared input queues and define serialization tokens for message flows.

About this task

Configure a shared input queue for message flows

The broker makes use of WebSphere MQ queue-sharing groups on z/OS.

Queue managers that can access the same set of shared queues form a group called a queue-sharing group (QSG) and they communicate with each other by means of a coupling facility (CF) that stores the shared queues. A shared queue is a type of local queue whose messages can be accessed by one or more queue managers that are in a QSG.

To further enhance the availability of messages in a QSG, WebSphere MQ detects if another queue manager in the group disconnects from the CF in an unusual way, and completes pending units of work for that queue manager where possible; this is known as peer recovery.

To understand more fully the concepts of shared-queues and queue-sharing groups, see the *Concepts and Planning Guide* section of the WebSphere MQ Version 7 Information Center online, and perform the following steps:

- Add a QSG to the DB2 tables
- Add a queue manager to a QSG
- Create the shared queue as a member of the QSG

Define a serialization token

Define the same value for the serialization token attribute for each MQInput node that is required to access the shared queue.

For the situations described in the preceding text to work you must:

- Ensure that the Coupling Facility Structure is at `CFLEVEL(3)` or above, and that you set `RECOVER=YES`.

  If you do not do this, when an MQInput node attempts to get a message from the shared queue, the action fails with the WebSphere MQ return code BIP2048 (`MQRC_PERSISTENT_NOT_ALLOWED`)
- Set the Backout Threshold for the shared queue to at least `2`.

  This value prevents input messages that are in progress being sent to the Dead Letter Queue because, during recovery, a message is restored to the input queue before another broker is able to get it and resume processing.

Configuring flows to handle WebSphere MQ message groups

WebSphere MQ allows multiple messages to be treated as a group, or as segments of one larger message. WebSphere Message Broker provides support for WebSphere MQ message grouping and partial support for message segmenting.

You can use the MQInput and MQOutput nodes to receive and send messages that are part of a WebSphere MQ message group. You can use the MQOutput node to send messages that are segments of a larger message.

For guidance about configuring the MQInput and MQOutput nodes to receive and send messages that are part of a WebSphere MQ message group, see:

- "Receiving messages in a WebSphere MQ message group" on page 1554
- "Sending messages in a WebSphere MQ message group" on page 1555
- "Sending message segments in a WebSphere MQ message" on page 1557

For more information about WebSphere MQ message groups, see the *Application Programming Guide* section of the WebSphere MQ Version 7 Information Center online.

WebSphere MQ Version 7 Information Center online

Receiving messages in a WebSphere MQ message group:

You can configure the MQInput node to receive messages that are in a WebSphere MQ message group.

About this task

The following properties on the MQInput node control the processing of messages in a WebSphere MQ message group:

- `Logical order`
- `Order mode`
- `All messages available`
- `Commit by message group`

To ensure that your message flow receives group messages in the order that has been assigned by the sending application, select `Logical order`. If you do not select this option, messages that are sent as part of a group are not received in a predetermined order. This property maps to the MQGMO_LOGICAL_ORDER option of the MQGMO of the MQI. More information about the options to which this property maps is available in the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.

If you specify a value of `By Queue Order` on the `Order mode` property, the message flow processes the messages in the group in the order that is defined by the queue attributes; this order is guaranteed to be preserved when the messages are processed. This behavior is identical to the behavior that is exhibited if the `Additional instances` property is set to zero. The message flow processes the messages on a single thread of execution, and a message is processed to completion before the next message is retrieved from the queue. If you do not specify this value, it is possible that multiple threads within a single message flow are processing multiple messages, and the final message in a group, which prompts the commit or roll back action, is not guaranteed to be processed to completion after all other messages in the group.

To ensure that only a single instance of the message flow processes the group messages in the order that has been assigned by the sending application, select `Logical order` **and** specify a value of `By Queue Order` on the `Order mode` property.

If you select `All messages available`, message retrieval and processing is performed only when all messages in a single group are available. This means that messages in a group are not received until all the messages in the group are present on the input queue. It is good practice to select this check box when your message flow needs to process group messages. If you do not select this check box, the message flow receives the messages as they arrive on the input queue; if a message in the group fails to arrive on the input queue, the message flow waits for it and cannot process any further messages until this message arrives. This property maps to the MQGMO_ALL_MESSAGES_AVAILABLE option of the

MQGMO of the MQI. More information about the options to which this property maps is available in the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.

If you select `Commit by message group`, message processing is committed only after the final message of a group has been received and processed. If you leave this check box cleared, a commit is performed after each message has been propagated completely through the message flow. This property is relevant only if you have selected `Logical order`. It is good practice to select this check box together with the `All messages available` check box because this ensures that the complete message group is retrieved and processed in the same unit of work without risk of the message flow waiting indefinitely for messages in the group to arrive on the input queue.

To ensure that the message flow that processes group messages does not wait for unavailable messages:

- Avoid having multiple message flows reading from the same input queue when group messages are being retrieved.
- Avoid deploying additional instances of a flow that retrieves group messages.
- Avoid using expired messages in message groups.
- When expired messages are to be used, ensure either that all messages have the same expiry time or that the first message in the group is set to expire before the rest of the group. If the first message in a group cannot be retrieved, the group can never be started in logical order.

If a message flow waits for a group message that does not arrive within the wait interval, a BIP2675 warning message is issued. From that point on, the message flow always attempts to retrieve the next group message and does not process any other input messages until the next group message is received.

Therefore, if the expected group message does not arrive, or has expired, the message flow must be stopped manually, and any incomplete message group cleared from the input queue.

A message flow cannot receive all the messages in a group in one operation.

If you specify a value of `Yes` or `No` on the `Transaction mode` property, all the segments in a message are received in the message flow as a single message. As a result, the message flow might receive very large messages which might lead to storage problems in the broker. If you specify a value of `Automatic` on the `Transaction mode` property, message segments are received as individual messages.

WebSphere MQ Version 7 Information Center online

Sending messages in a WebSphere MQ message group:

The MQOutput node can send multiple messages that form a WebSphere MQ message group. Configure a Compute or JavaCompute node to set the MQMD fields to specify message group options.

About this task

The message flow must set the following MQMD fields:

- **GroupId**
- **MsgSeqNumber**
- **MsgFlags**

You can use the following example of ESQL code in a Compute node, which shows how to set these fields:

```
DECLARE MSGNUM INT 0;
  DECLARE MSGTOTAL INT 5;
  WHILE MSGNUM < MSGTOTAL DO
    SET MSGNUM = MSGNUM + 1;
    CALL CopyMessageHeaders();
    -- Manually set the groupId since we cant ask the queue manager to generate one.
    -- the UUIDASBLOB function could be used here to generate one, but this must be done
    -- outside the loop to keep the same groupId throughout!
    SET OutputRoot.MQMD.GroupId = X'000000000000000000000000000000000000000000000001';
    SET OutputRoot.MQMD.MsgSeqNumber = MSGNUM;
    SET OutputRoot.MQMD.MsgFlags = MQMF_MSG_IN_GROUP;
    IF (MSGNUM = MSGTOTAL) THEN
      SET OutputRoot.MQMD.MsgFlags = MQMF_LAST_MSG_IN_GROUP;
    END IF;
    SET OutputRoot.XML.TestCase = MSGNUM;
    PROPAGATE;
  END WHILE;
  RETURN FALSE;
```

You can use the following example of Java code in a JavaCompute node, which shows how to set these fields:

```
public class mq_group_java_JavaCompute extends MbJavaComputeNode {
      public void evaluate(MbMessageAssembly assembly) throws MbException {
        MbOutputTerminal out = getOutputTerminal("out");
        int MSGTOTAL = 5;
        for(int MSGNUM = 1 ; MSGNUM <= MSGTOTAL;MSGNUM++){
           MbMessage newMessage = new MbMessage();
           MbElement root = newMessage.getRootElement();
           MbElement mqmd = root.createElementAsFirstChild("MQMD");
           mqmd.createElementAsLastChild(MbElement.TYPE_NAME_VALUE,
           "GroupId", new byte[]{0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,1});
           mqmd.createElementAsLastChild(MbElement.TYPE_NAME_VALUE, "MsgSeqNumber", MSGNUM);
           if (MSGNUM == MSGTOTAL){
               mqmd.createElementAsLastChild(MbElement.TYPE_NAME_VALUE,
               "MsgFlags", 16); // MQMF_LAST_MSG_IN_GROUP 0x00000010
           }
           else{
               mqmd.createElementAsLastChild(MbElement.TYPE_NAME_VALUE,
               "MsgFlags", 8);  // MQMF_MSG_IN_GROUP      0x00000008
           }
           MbElement xmlnsc = root.createElementAsLastChild("XMLNSC");
           MbElement body = xmlnsc.createElementAsLastChild(MbElement.TYPE_NAME,"TestCase",null);
           body.setValue(MSGNUM);
           MbMessageAssembly newAssembly = new MbMessageAssembly(assembly,newMessage);
           out.propagate(newAssembly);
        }
    }
}
```

If the message flow is sending multiple messages from one input message, it can create a **GroupId** value, increment the **MsgSeqNumber** value, and set the **MsgFlags** field. The examples of ESQL and Java code show how you can set these values. However, if the message flow is sending multiple messages from more than

one input message, it must store the **GroupId** and **MsgSeqNumber** values between flow instances, which is achieved by using shared variables.

For more information about message grouping, see the *Application Programming Guide* section of the WebSphere MQ Version 7 Information Center online. For more information about the WebSphere MQ fields that are significant in message grouping, see the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.

Enabling WebSphere MQ applications

If you want to connect WebSphere MQ applications to the broker, you must define and secure the required resources.

About this task

- "Defining WebSphere MQ resources" on page 1558
- "Securing WebSphere MQ resources" on page 1559

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

Chapter 9, "Developing message flow applications," on page 1019
Develop message flows to process your business messages and data.

Chapter 11, "Packaging and deploying," on page 3209
Package resources that you create in the WebSphere Message Broker Toolkit, such as message flows, and deploy them to execution groups on brokers.

Defining WebSphere MQ resources:

An application client can run on a computer anywhere in the WebSphere MQ network. If your applications use WebSphere MQ facilities to connect to the broker, and to interact with it (by using the MQI and AMI), you must set up the WebSphere MQ resources that they require.

About this task

The way that you set up applications is identical to the setup for clients for an WebSphere MQ server. To support client connections to a broker:

Procedure

1. If the application runs on the same computer as the broker, it can establish a local connection with the broker queue manager by using MQCONN, and you do not have to define any WebSphere MQ resources to support it.
2. If the application runs on the same computer as another queue manager in the WebSphere MQ network, it can establish a local connection to that queue manager. In this scenario, you must define the appropriate resource to support communications between the queue manager to which the client has connected and the queue manager that hosts the broker that provides the required service.
3. If the application runs on a computer that does not support a queue manager, it must make a client connection to a queue manager on another computer:
   - The broker queue manager

     You must set up the appropriate client connection and server connection definitions to support this option.
   - Another queue manager in the network

     You must set up the appropriate client connection and server connection definitions to support this option, and ensure that definitions are in place to support communications between the queue manager to which the client has connected, and the queue manager that hosts the broker that provides the required service.

Results

An application can get messages only from queues that are owned by the queue manager to which it is connected (this restriction is true for all WebSphere MQ applications). Therefore, if an application expects to receive messages from a queue populated by a service within a particular broker and owned by that broker queue manager, it must connect to that broker queue manager (by using a local or WebSphere MQ client connection).

An application that puts messages, however, can be connected to any queue manager in the WebSphere MQ network, if the queue manager can resolve the target destination in some way. In all cases, the queue manager to which the client application is connected must know the location of the queue or queues to which the application puts messages (for example, by using remote queue definitions).

When you define a WebSphere MQ queue for a node in a message flow, you must not give it a name that starts with SYSTEM_BROKER. Names that include these characters are reserved for queues that are defined for internal use by WebSphere Message Broker components.

If your application is a subscriber that receives messages published by other applications, it can specify a temporary dynamic queue as its subscriber queue. If it does so, the broker automatically deregisters the subscription when the queue is deleted.

For more details about applications, putting and getting messages, and the use of WebSphere MQ clients, see the *Clients* and *Application Programming Guide* sections of the WebSphere MQ Version 7 Information Center online.

Securing WebSphere MQ resources:

Secure the WebSphere MQ resources that your broker configuration requires.

About this task

This information does not apply to z/OS.

Brokers depend on a number of WebSphere MQ resources to operate successfully. You must control access to these resources to ensure that the brokers can access the resources on which they depend, and that these same resources are protected from other users.

Some authorizations are granted on your behalf when commands are issued. Others depend on the configuration of your broker network.

- When you issue the command **mqsicreatebroker**, it grants put and get authority on your behalf to the group mqbrkrs for the following queues:
  - SYSTEM.BROKER.ADAPTER.FAILED
  - SYSTEM.BROKER.ADAPTER.INPROGRESS
  - SYSTEM.BROKER.ADAPTER.NEW
  - SYSTEM.BROKER.ADAPTER.PROCESSED
  - SYSTEM.BROKER.ADAPTER.UNKNOWN
  - SYSTEM.BROKER.ADMIN.QUEUE
  - SYSTEM.BROKER.ADMIN.REPLYTODM
  - SYSTEM.BROKER.AGGR.CONTROL
  - SYSTEM.BROKER.AGGR.REPLY
  - SYSTEM.BROKER.AGGR.REQUEST
  - SYSTEM.BROKER.AGGR.TIMEOUT
  - SYSTEM.BROKER.AGGR.UNKNOWN
  - SYSTEM.BROKER.AUTH
  - SYSTEM.BROKER.CONTROL.QUEUE
  - SYSTEM.BROKER.DEPLOY.QUEUE
  - SYSTEM.BROKER.DEPLOY.REPLY
  - SYSTEM.BROKER.EDA.COLLECTIONS
  - SYSTEM.BROKER.EDA.EVENTS
  - SYSTEM.BROKER.EXECUTIONGROUP.QUEUE
  - SYSTEM.BROKER.EXECUTIONGROUP.REPLY
  - SYSTEM.BROKER.INTER.BROKER.COMMUNICATIONS
  - SYSTEM.BROKER.MODEL.QUEUE
  - SYSTEM.BROKER.TIMEOUT.QUEUE
  - SYSTEM.BROKER.WS.ACK
  - SYSTEM.BROKER.WS.INPUT
  - SYSTEM.BROKER.WS.REPLY
- When you start the WebSphere Message Broker Toolkit, it connects to a broker by using a WebSphere MQ client/server connection. Ensuring that messages are not lost

Messages that flow through your broker domain represent business data that you want to safeguard. Configure the messages, your environment, or both, to ensure that you do not lose messages.

About this task

Messages that are generated both by your applications and by runtime components for inter-component communication are important to the operation of your brokers. Messages used internally between components always use the WebSphere MQ protocol. Application messages can use all supported transport protocols.

For application and internal messages traveling across WebSphere MQ, two techniques protect against message loss:

- Message persistence

  If a message is persistent, WebSphere MQ ensures that it is not lost when a failure occurs, by copying it to disk.
- Sync point control

  An application can request that a message is processed in a synchronized unit-of-work (UOW)

For more information about how to use these options, refer to the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

Internal messages:
About this task

WebSphere Message Broker components use WebSphere MQ messages to communicate events and data between broker processes and subsystems. The components ensure that the WebSphere MQ features are used to protect against message loss. You do not need to take any additional steps to configure WebSphere MQ or WebSphere Message Broker to protect against loss of internal messages.

Application messages:
About this task

If delivery of application messages is critical, you must design application programs and the message flows that they use to ensure that messages are not lost. The techniques used depend on the protocol used by the applications.

WebSphere MQ Enterprise Transport

If you are using the built-in input nodes that accept messages across the WebSphere MQ protocol, you can use the following guidelines and recommendations:

- Using persistent messages

  WebSphere MQ messaging products provide *message persistence*, which defines the longevity of the message in the system and guarantees message integrity. Nonpersistent messages are lost in the event of system or queue manager failure. Persistent messages are always recovered if a failure occurs.

  You can control message persistence in the following ways:

  – Program your applications that put messages to a queue using the MQI or AMI to indicate that the messages are persistent.
  – Define the input queue with message persistence as the default setting.
  – Configure the output node to handle persistent messages.
  – Program your subscriber applications to request message persistence.

  When an input node reads a message from an input queue, the default action is to use the persistence defined in the WebSphere MQ message header (MQMD), that has been set either by the application creating the message, or by the default persistence of the input queue. The message retains this persistence throughout the message flow, unless it is changed in a subsequent message processing node.

  You can override the persistence value of each message when the message flow terminates at an output node. This node has a property that allows you to specify the message persistence of each message when it is put to the output queue, either as the required value, or as a default value. If you specify the default, the message takes the persistence value defined for the queues to which the messages are written.

  If a message passes through a Publication node, the persistence of messages sent to subscribers is determined by the registration options of the subscribers. If a subscriber has requested persistent message delivery, and is authorized to do so by explicit or implicit (inherited) ACL, the message is delivered persistently regardless of its existing persistence property. Also, if the user has requested nonpersistent message delivery, the message is delivered nonpersistent regardless of its existing persistence property.

  If a message flow creates a message (for example, in a Compute node), the persistence in the MQMD of the new message is copied from the persistence in the MQMD of the incoming message.

- Processing messages under sync point control

  The default action of a message flow is to process incoming messages under sync point in a broker-controlled transaction. This means that a message that fails to be processed for any reason is backed out by the broker. Because it was received under sync point, the failing message is reinstated on the input queue and can be processed again. If the processing fails, the error handling procedures that are in place for this message flow (defined either by how you have configured the message flow, or by the broker) are executed.

  For full details of input node processing, see “Managing errors in the input node” on page 2828.

WebSphere MQ Web Services Transport
If you are using the HTTPInput, HTTPRequest, SOAPInput, SOAPRequest nodes, or a SOAPAsyncRequest and SOAPAsyncResponse node pair that accept messages from Web services applications, no facilities are available to protect against message loss. You can, however, provide recovery procedures by configuring the message flow to handle its own errors.

Other transports and protocols
If you have created your own user-defined input nodes that receive messages from another transport protocol, you must rely on the support provided by that transport protocol, or provide your own recovery procedures.

Use the MQGet node to receive messages from clients that connect to the broker by using the WebSphere MQ Enterprise Transport, and the MQI and AMI application programming interfaces.

How the MQGet node processes messages:

The MQGet node processes each message that it receives.

This topic contains the following sections:

- "Propagating the message"
- "Constructing OutputLocalEnvironment" on page 1566
- "Constructing the Output message" on page 1567

Propagating the message

1. If an MQ Message Descriptor header (MQMD) is present in the input tree, the MQGet node uses it. If not, the node creates a default MQMD.
2. The node also creates a default MQ Get Message Options (MQGMO) structure based on the values that you have set for the node properties. If an MQGMO is present in the input tree, the node uses its content to modify the default one.

   When you include an MQGMO to override the default one, you must specify all the options that you are replacing. For example, if you set the option field to MQGMO_CONVERT, that value overrides all options that you set with the WebSphere Message Broker Toolkit. If you do not use an overriding MQGMO, WebSphere Message Broker uses the following values:
   - If `Wait interval` is not zero, MQGMO_WAIT is set; otherwise, MQGMO_NOWAIT is used.
   - If `Transaction mode` is set to `Yes`, MQGMO_SYNCPOINT is used.
   - If `Transaction mode` is set to `No`, MQGMO_NOSYNCPOINT is used.
   - If `Transaction mode` is set to `Automatic`, MQGMO_SYNCPOINT_IF_PERSISTENT is used.
   - The only other option that is used by default in the node properties is MQGMO_COMPLETE_MSG, which is set if `Transaction mode` is set to `Yes` or `No`. This option is not set when your broker is running on z/OS.
   - No other options are used by default.
3. The node makes the MQGet call to WebSphere MQ.
4. The node analyzes the completion code (CC), and propagates the message to the appropriate terminal:

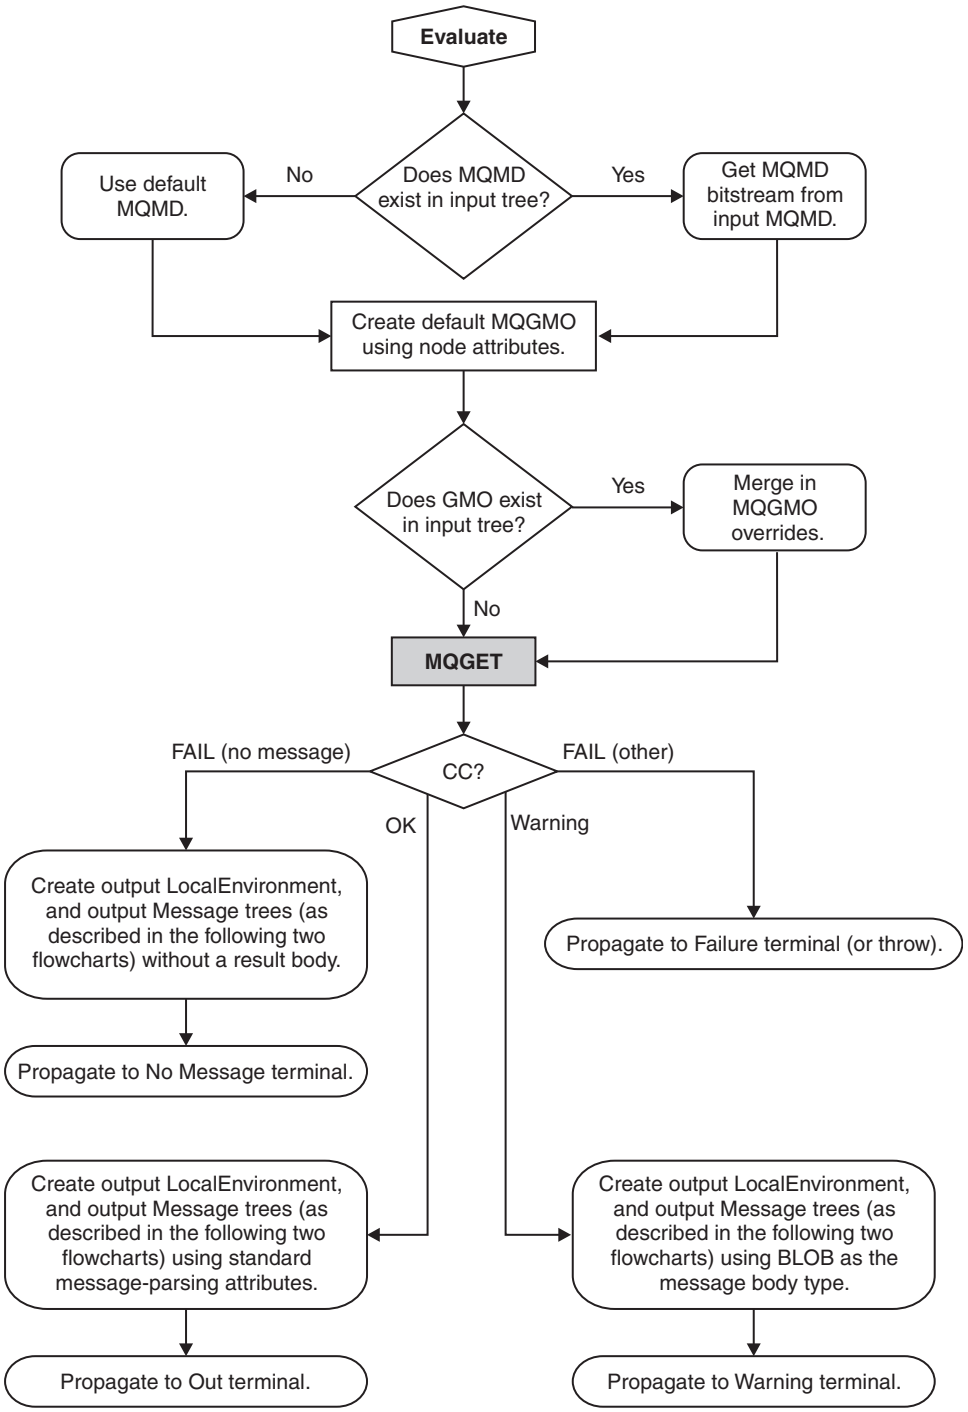
OK The node creates the output LocalEnvironment and the output message trees using standard message-parsing techniques, then propagates the message to the Out terminal.

Warning
The node creates the output LocalEnvironment and the output message trees using BLOB as the message body type, then propagates the message to the Warning terminal, if it is connected. If the Warning terminal is not connected, no propagation occurs, and the flow ends.

Fail (no message)
The node creates the output LocalEnvironment and the output message trees by copying the input trees, then propagates the message to the No Message terminal, if it is connected. If the No Message terminal is not connected, no propagation occurs. The output message that is propagated to the No Message terminal is constructed from the input message only, according to the values of the `Generate Mode` property, and the `Copy Message` or `Copy Local Environment` properties.

Fail (other)
The node propagates the message to the Failure terminal. If the Failure terminal is not connected, the broker throws an exception and returns control to the closest upstream node that can process it. For more information, see "Handling errors in message flows" on page 2823.

The following diagram shows this processing:



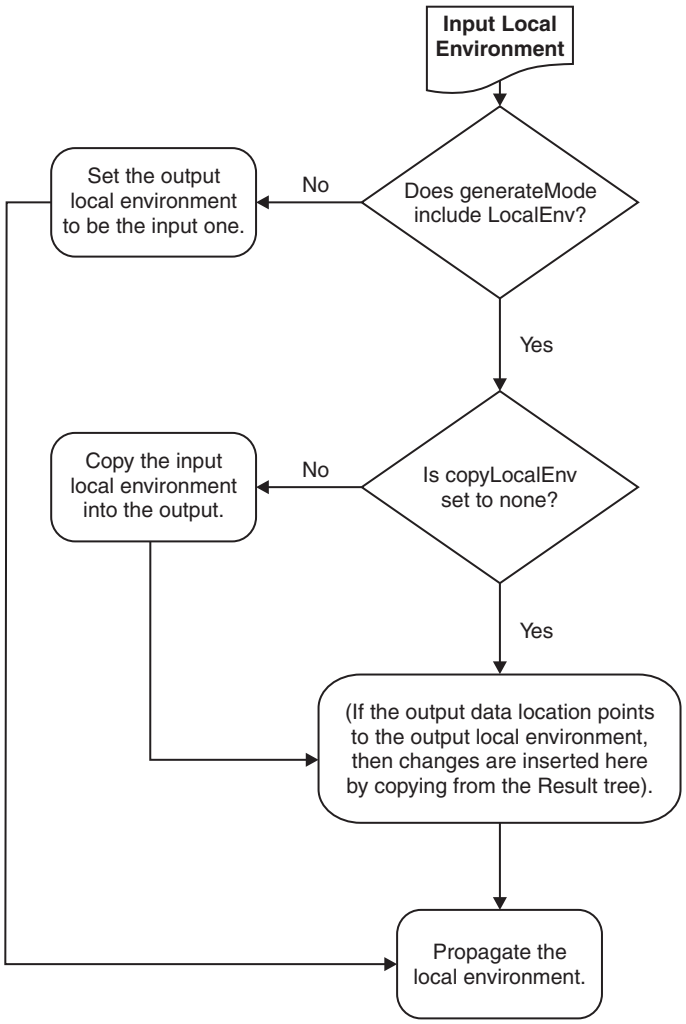
Constructing OutputLocalEnvironment

1. If the `Generate Mode` property on the MQGet node is set to an option that does not include `LocalEnvironment`, the node copies the input local environment tree to the output local environment tree.

   If this copy is made, any updates that are made in this node to the output local environment tree are not propagated downstream.
2. If the `Copy Local Environment` property is set to an option other than `None`, the node copies the input local environment tree to the output local environment tree.

3. If the output data location points to the output local environment tree, the node applies changes in that tree by copying from the result tree.
4. The local environment tree is propagated.

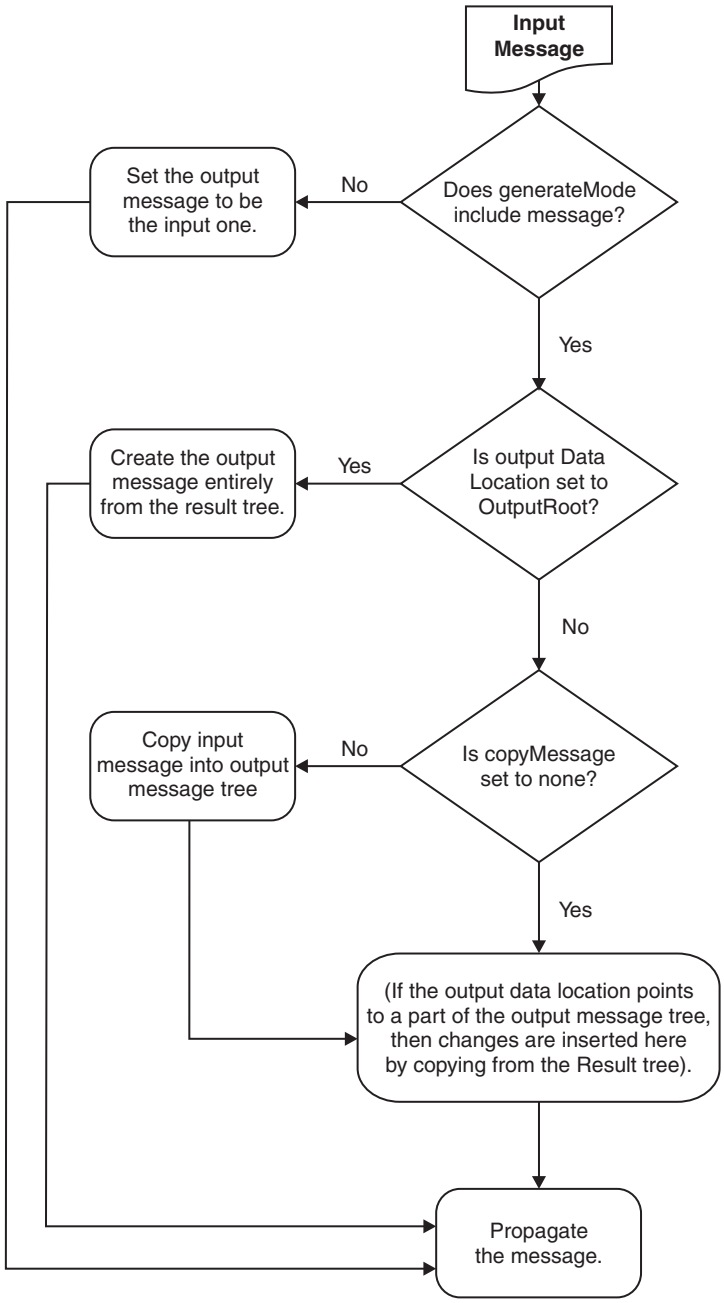
The following diagram shows this processing:



Constructing the Output message

1. If the `Generate Mode` property on the MQGet node is set to an option that does not include `Message`, the node copies the input message tree to the output message tree. Go to step 5.
2. If the `Output Data Location` property is set to `OutputRoot`, the node creates the output message tree entirely from the result tree. Go to step 5.
3. If the `Copy Message` property is set to a value other than `None`, the node copies the input message tree to the output message tree.
4. If the `Output Data Location` property points to a part of the output message tree, the node applies changes in that tree by copying from the result tree at the point that is defined by the `Result Data Location` property.
5. The message tree is propagated.

The following diagram shows this processing:



For an example of how this processing is implemented in a message flow, see "A request-response scenario that uses an MQGet node" on page 1569.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related reference:

"A request-response scenario that uses an MQGet node" on page 1569
Read about a scenario in which an MQGet node is used in a request-response flow, and how the node processes the input messages to construct the output messages, based on both the content of the local environment tree and the input parameters that you set.

"MQGet node" on page 4578
Use the MQGet node to receive messages from clients that connect to the broker by using the WebSphere MQ Enterprise Transport, and the MQI and AMI application programming interfaces.

A request-response scenario that uses an MQGet node:

Read about a scenario in which an MQGet node is used in a request-response flow, and how the node processes the input messages to construct the output messages, based on both the content of the local environment tree and the input parameters that you set.

A request-response flow is a specialized form of a point-to-point application. For a general description of these applications, see "Nodes for connectivity" on page 1028. For an example of a request-response message flow, see the following sample:

- Coordinated Request Reply

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

You can include an MQGet node anywhere in a message flow, including a flow that implements a request-response scenario. The MQGet node receives an input message on its input terminal from the preceding node in the message flow, issues an MQGET call to retrieve a message from the WebSphere MQ queue that you have configured in its properties, and builds a result message tree. Finally, it uses the input tree and the result tree to create an output tree that is then propagated to its Output, Warning, or Failure terminal, depending on the configuration of the node and the result of the MQGET operation.

How the MQGet node handles the local environment:
The MQGet node examines the local environment tree that is propagated from the preceding node, uses the content that is related to the MQGMO (MQ Get Message Options) and the MQMD (MQ Message Descriptor header), and updates the local environment:

- The node reads the MQGMO structure from `${inputMQParmsLocation}.MQGMO.*`.
- The node copies the WebSphere MQ completion and reason codes to `${outputMQParmsLocation}.CC` and `${outputMQParmsLocation}.RC`.
- The node writes the complete MQGMO that is used for the MQGET call into `${outputMQParmsLocation}.MQGMO` if `${inputMQParmsLocation}.MQGMO` exists in the input tree.
- The node writes the MQMD that is passed to the MQGET call (that contains the values that are specified in the input message or are generated by the node) into `${inputMQParmsLocation}.MQMD`, deleting any existing content.

Set the value to `${inputMQParmsLocation}` in the MQGet node property Input MQ Parameters Location on the **Request Properties** tab.

Set the value to `${outputMQParmsLocation}` in the MQGet node property Output MQ Parameters Location on the **Result Properties** tab.

For more information about these properties, see "MQGet node" on page 4578.

In summary:

${inputMQParmsLocation}

- *QueueName*: Optional override for MQGet node *Queue Name* property
- *InitialBufferSize*: Optional override for MQGet node *Initial Buffer Size* property
- *MQGMO.**: Optional MQGET message options that are used by the MQGet node

${outputMQParmsLocation}

- *CC*: MQGET call completion code
- *RC*: MQGET call result code
- *MQGMO.**: MQGET message options that are used if present in `${inputMQParmsLocation}`
- *MQMD*: unparsed MQ Message Descriptor for received messages[1]
- *Browsed*: Set to true if the message is browsed. Not present if the message is removed from the queue

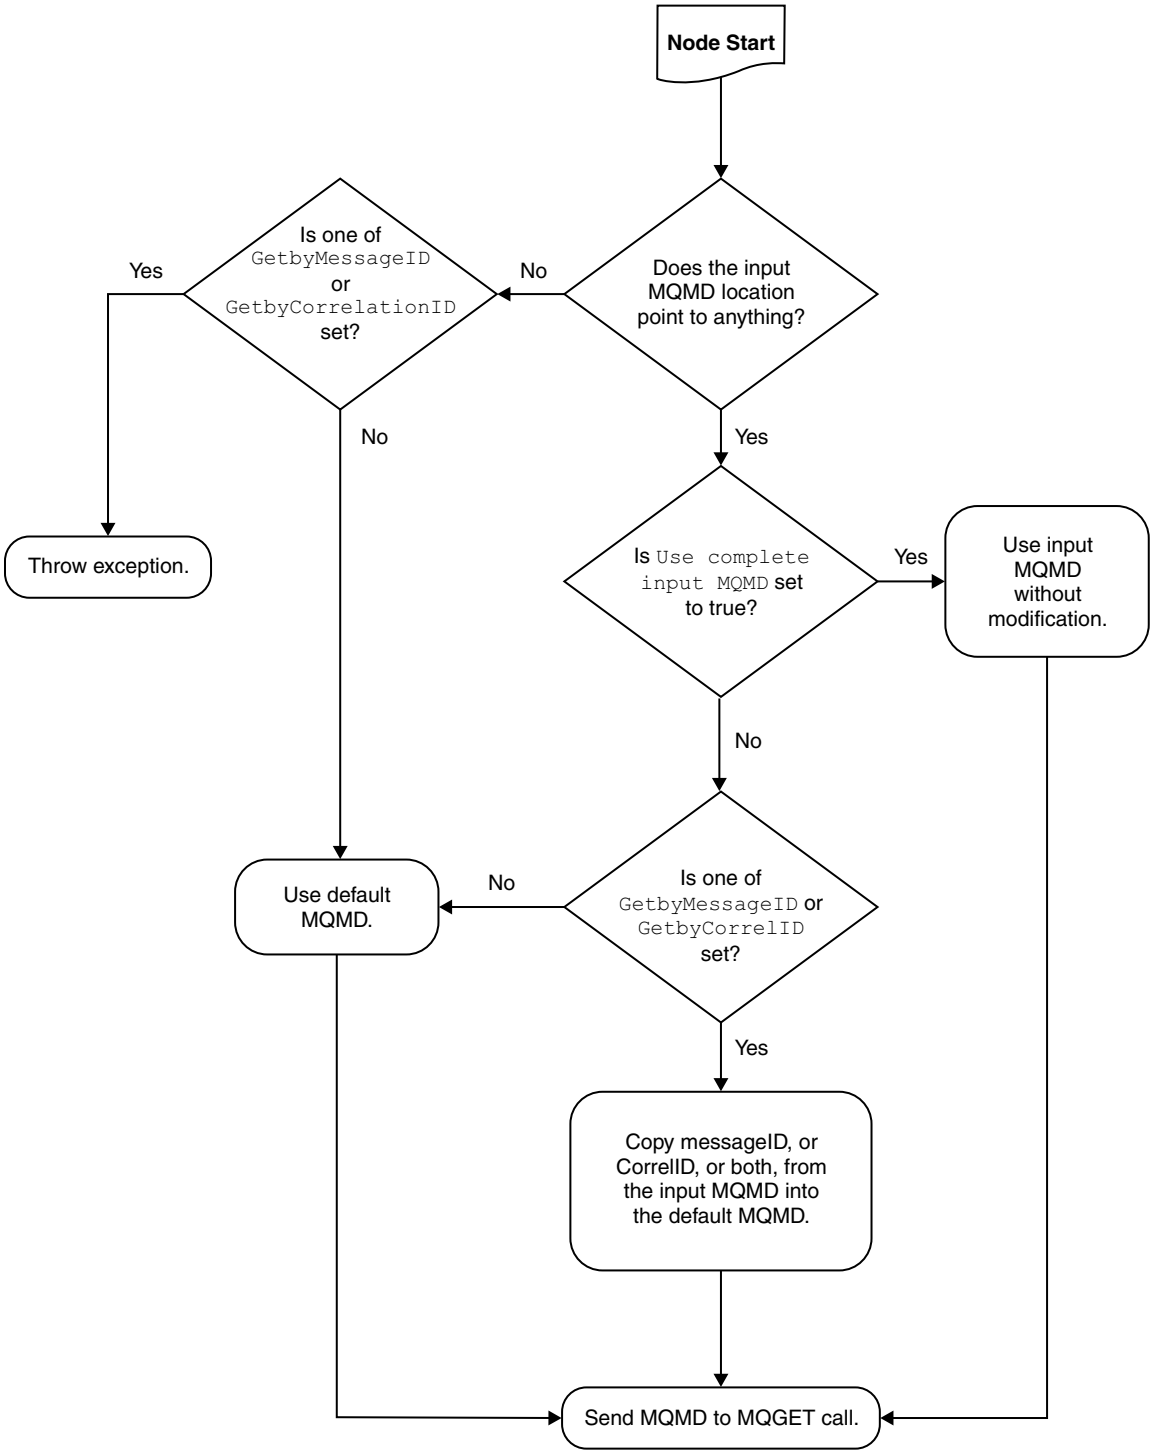
You can parse the MQMD (for example, by using ESQL), where `${outputMQParmsLocation}` is LocalEnvironment.MQ.GET:

```
DECLARE ptr REFERENCE TO OutputLocalEnvironment.MyMQParms;
CREATE FIRSTCHILD OF ptr DOMAIN('MQMD') PARSE(InputLocalEnvironment.MQ.GET.MQMD)
```

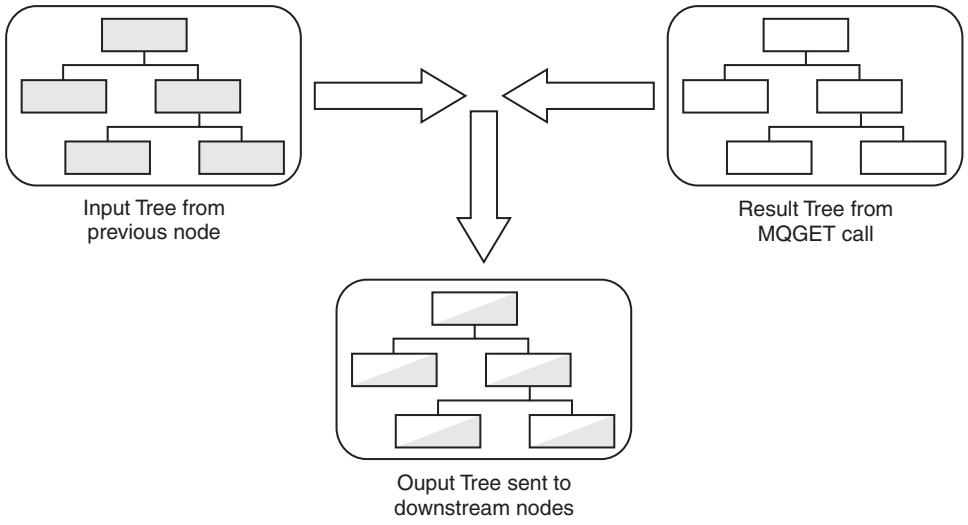
How the MQMD for the MQGET call is constructed:

- A default MQMD is prepared. For further information about the MQMD, see the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.
- If you do not supply an input MQMD, the default MQMD is used.
- If you do supply an input MQMD, the default MQMD is used after the following modifications:
  - If the property `Use all input MQMD fields` is set, all MQMD fields supplied are copied into the default MQMD from the input MQMD.
  - If the property `Use all input MQMD fields` is not set and the properties `Get by Message ID` or `Get by Correlation ID` are selected, the respective IDs are copied into the default MQMD from the input MQMD.

The following diagram shows how the MQGet node constructs the MQMD that is used on the call to WebSphere MQ:



How the output message tree is constructed:
The following diagram outlines how the MQGet node constructs the output message tree, combining the input tree from the previous node with the result tree from the MQGET call:



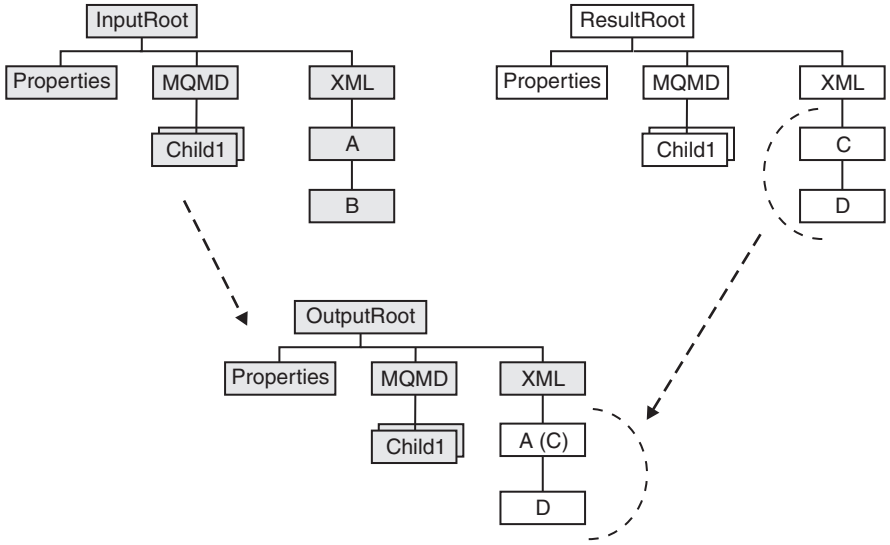
In this example, the MQGet node properties are configured as shown in the following table.

Property	**Action**
Copy Message	Copy Entire Message
Generate Mode	Message
Output Data Location	`OutputRoot.XMLNS.A`
Result Data Location	`ResultRoot.XMLNS.C`

The MQGet node constructs the output tree according to the following sequence:

1. The whole of the input tree is copied to the output tree, including the XML branch with child A, and A's child B.
2. From the result tree, the XML branch's child C, and C's child D, are put into the output tree at position `OutputRoot.XMLNS.A`. Any previous content of A (values and children) is lost, and replaced with C's content, including all values and children it has, in this case child D.
3. The position in the output tree retains the name A.

The following diagram shows this behavior:



For some examples of message trees that are constructed by the MQGet node according to the rules described above, see "MQGet node message tree examples."

MQGet node message tree examples:

The MQGet node generates message trees based on the input message assembly that it receives, and the options that you have set on the node properties.

The message trees, shown in the following table, are generated according to the rules described in “A request-response scenario that uses an MQGet node” on page 1569.

With a message assembly like this:	The message that the MQGet node returns is:
InputRoot **MQMD** {input message MQMD} **MQRFH2** {input message MQRFH2} **XMLNS** {input message body} **InputLocalEnvironment** **MQ** **GET** **MQGMO** MatchOptions = MQMO_MATCH_CORREL_ID **MQMD (with no children)** **Variables** **MQMD** {input MQMD} (with CorrelID = {correct Correlation ID as binary})	**ResultRoot** **MQMD** {result message MQMD} **MQRFH2** {result message MQRFH2} **XML** {result message body}

With the following node property settings:	The resulting output message assembly is:
Input MQMD Location InputLocalEnvironment.Variables.MQMD **Copy Message** Copy Entire Message **Copy Local Environment** Copy Entire LocalEnvironment **Generate Mode** Message and LocalEnvironment **Output Data Location** InputLocalEnvironment.Variables.ReturnedMessage	**OutputRoot** **MQMD** {input message MQMD} **MQRFH2** {input message MQRFH2} **XMLNS** {input message body} **OutputLocalEnvironment** **MQ** **GET** **MQGMO** {MQGMO used for MQGET} **MQMD** {MQMD used for MQGET} **CC = 0** **RC = 0** **Variables** **MQMD** {input MQMD} (with CorrelID = {correct Correlation ID as binary}) **ReturnedMessage** **MQMD** {result message MQMD} **MQRFH2** {result message MQRFH2} **XML** {result message body}

With the following node property settings:	The resulting output message assembly is:
Result Data Location ResultRoot.XML	**OutputRoot** **MQMD** {input message MQMD} **MQRFH2** {input message MQRFH2} **XMLNS** {input message body} **OutputLocalEnvironment** **MQ** **GET** **MQGMO** {MQGMO used for MQGET} **MQMD** {MQMD used for MQGET} **CC = 0** **RC = 0** **Variables** **MQMD** {input MQMD} (with CorrelID = {correct Correlation ID as binary}) **ReturnedMessage (with any attributes and value from ResultRoot.XML)** {result message body} This tree is effectively the result of doing an assignment from `${resultDataLocation}` to `${outputDataLocation}`. The value of the source element is copied, as are all children including attributes.

With the following node property settings:	The resulting output message assembly is:
Copy Local Environment None	**OutputRoot** **MQMD** {input message MQMD} **MQRFH2** {input message MQRFH2} **XMLNS** {input message body} **OutputLocalEnvironment** **MQ** **GET** **MQGMO** {MQGMO used for MQGET} **MQMD** {MQMD used for MQGET} **CC = 0** **RC = 0** **Variables** **ReturnedMessage (with any attributes and value from ResultRoot.XML)** {result message body} This tree has the MQMD that is used for the MQGET call in the OutputLocalEnvironment, because the input MQ parameters location had an MQMD element under it. Even though the input tree is not copied, the presence of the MQMD element causes the MQMD that is used for the MQGET call to be placed in the output tree.

With the following node property settings:	The resulting output message assembly is:
Output Data Location <blank> **Copy Local Environment** Copy Entire Local Environment	**OutputRoot** **MQMD** {result message MQMD} **MQRFH2** {result message MQRFH2} **XMLNS** {result message body} **OutputLocalEnvironment** **MQ** **GET** **MQGMO** {MQGMO used for MQGET} **MQMD** {MQMD used for MQGET} **CC = 0** **RC = 0** **Variables** **MQMD** {input MQMD} (with CorrelID = {correct Correlation ID as binary}) The value that you set for the Copy Message property makes no difference to the eventual output tree in this case.

Processing HTTP messages

Hypertext Transfer Protocol (HTTP) is an Internet protocol that is used to transfer and display hypertext and XML documents on the Web.

You can configure message flows that include the HTTP or SOAP nodes to access the HTTP transport to work with the following resources:

- SOAP-based Web services
- Other Web services standards, such as REST or XML-RPC
- General HTTP messaging, where the payload might be XML

HTTP nodes can process non-secure (HTTP) messages and secure (HTTPS or HTTP over SSL) messages.

For SOAP-based Web services, several advantages exist if you use the SOAP nodes and the SOAP message domain instead of the HTTP transport nodes and XMLNSC message domain.

- Support for WS-Addressing, WS-Security and SOAP headers.
- A common SOAP logical tree format, independent of the bitstream format.
- Runtime checking against WSDL.
- Automatic processing of SOAP with Attachments (SwA).
- Automatic processing of Message Transmission Optimization Mechanism (MTOM).

Although the HTTP nodes can process SwA messages, you must use the MIME message domain and design your flow to handle the attachments explicitly, and use custom logic to extract and parse the SOAP.

For more information about using SOAP messages and nodes, see “What is SOAP?” on page 1604

You can choose how your HTTP nodes interact with the TCP/IP network:

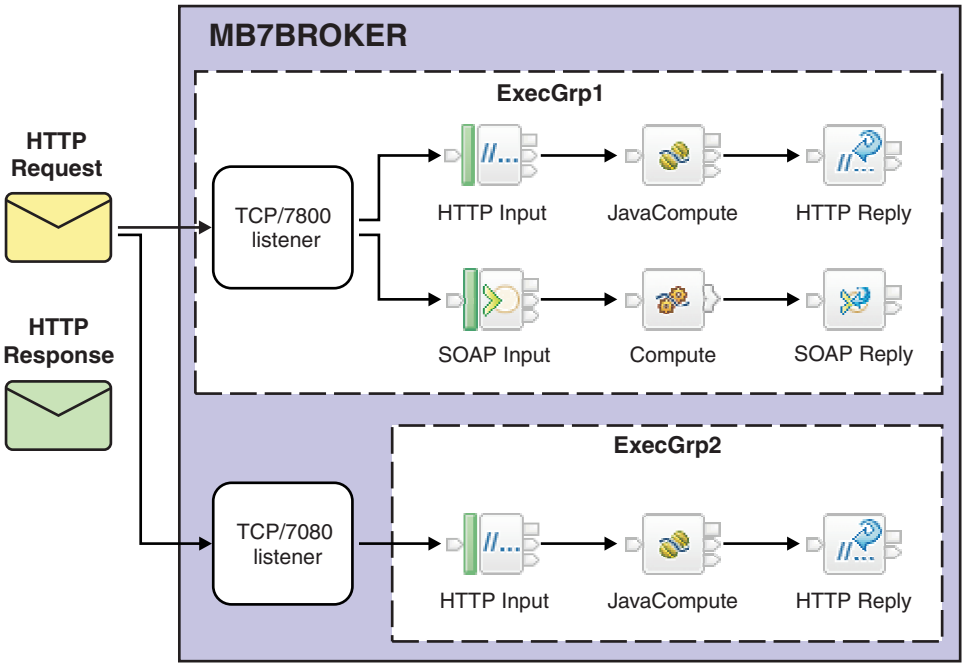
- You can use the broker-wide listener, which receives HTTP messages on one port, and HTTPS messages on a second port.

  This option is set as the default configuration for both existing and new brokers.
- You can use the listener that is embedded within each execution group, which also has two ports for HTTP and HTTPS messages.
- You can use a mixture of broker and execution group listeners by keeping the broker listener active, and configuring a subset of execution groups to use the embedded listener.

For more information about why you might choose each option, and how to configure them, see “HTTP listeners” on page 1589.

SOAP nodes always use the listener that is embedded in the execution group, and only this listener; you cannot configure them to use the broker-wide listener.

The following diagram shows the use of both types of listener, configured on default ports, for HTTP messages.



You must always use the correct reply node that matches your input node; you cannot combine an HTTPReply node with a SOAPInput, or a SOAPReply node with an HTTPInput node. The broker generates an exception when the reply is attempted.

You can include the reply node in the same message flow, or in a different message flow:

- If you have configured the HTTPInput node to use the execution group listener, you must deploy the second message flow to the same execution group.

  This restriction always applies to SOAPInput nodes, which use only the execution group listener.
- If you have configured the HTTPInput node to use the broker-wide listener, you can deploy the second message flow to any other execution group defined to the broker.
- You must pass the correct reply identifier from the input message flow to the reply node.

If you choose to handle HTTP messages by using the execution group listener, you must carefully check the URL specifications in your HTTPInput and SOAPInput nodes. If both URL specifications match an incoming message, the wrong type of node might get the message, and processing might fail or produce unexpected results. This situation occurs if you specify identical values for the Path suffix for URL properties of the HTTPInput node and the SOAPInput node. It can also occur if you use wildcards in either or both specifications, and an incoming message matches both properties.

For more information about using the WebSphere Broker HTTP Transport, see the following topics:

HTTP and SOAP nodes can both be used to interact with Web services. Typically you use SOAP nodes when working with SOAP-based Web services.

Web services: when to use SOAP or HTTP nodes

HTTP and SOAP nodes can both be used to interact with Web services. Typically you use SOAP nodes when working with SOAP-based Web services.

For SOAP-based Web services, several advantages exist if you use the SOAP nodes and the SOAP message domain instead of the HTTP transport nodes and XMLNSC message domain.

- Support for WS-Addressing, WS-Security and SOAP headers.
- A common SOAP logical tree format, independent of the bitstream format.
- Runtime checking against WSDL.
- Automatic processing of SOAP with Attachments (SwA).
- Automatic processing of Message Transmission Optimization Mechanism (MTOM).

Although the HTTP nodes can process SwA messages, you must use the MIME message domain and design your flow to handle the attachments explicitly, and use custom logic to extract and parse the SOAP.

Cases where it might be better to use HTTP nodes include:

- Message flows in which a single request node handles multiple SOAP request and responses from more than one WSDL.
- Message flows that interact with Web services that use different standards, such as REST or XML-RPC.
- Message flow that never use WS-Addressing, WS-Security, SwA, or MTOM.

HTTP message format

An HTTP message contains components that are appropriate to its type.

The bit stream containing headers and body is parsed and represented within the message tree when an input request is received by an HTTPInput node, or when a response from a Web service is received by the HTTPRequest node. A bit stream is created by parsers from the appropriate parts of the message tree when a reply is sent to the client by the HTTPReply node, or when a message is sent by the HTTPRequest node. For further details about these actions, see the individual node descriptions.

HTTP headers

When an HTTPInput or HTTPRequest node receives a message, it parses the HTTP headers to create elements in the message tree. When an HTTPReply or HTTPRequest node sends a message, it parses the HTTP headers from the message tree into a bit stream.

The HTTP headers in a message depend on the type of message that is processed. There are four message types recognized in a message flow, and a parser is associated with each of these.

1. Input. An input message is received by the HTTPInput node from a client. The HTTP headers in the input message (data up to and including the CRLFCRLF) are parsed by the HTTPInput parser and are included in the message tree under the correlation name HTTPInput. The headers shown in the following table are expected in an input message; others might also be present.

Header	Content	Example
Host	The host name to which the client issued the message.	localhost
Content-Length	The length of the body of the input message in decimal (that follows the CRLFCRLF after the last header).	520
Content-Type	The type of the body data.	text/xml; charset=utf-8
SOAPAction		"" (empty string)

The headers in the following table might also be automatically generated by the HTTPInput node depending on the request.

Header	Content	Example
X-Original-HTTP-Command	An expanded version of the original inbound request	POST http://localhost:7800/Wss001/services/Wss001 HTTP/1.1
X-Remote-Addr	The IP address of the client (or proxy if the client is connecting through a proxy)	127.0.0.1

Header	Content	Example
X-Remote-Host	The host name or address of the client (or proxy if the client is connecting through a proxy)	localhost
X-Server-Name	The broker's machine name	localhost
X-Server-Port	The broker's port	7800
X-Query-String	The query string if present in the inbound URL (optional)	a=b&x=y
X-Scheme	The scheme through which the client is connected, either http or https	http

2. Reply. A reply message is sent by the HTTPReply node to the client that sent the corresponding input message. The headers in the reply message are created in the message tree under the correlation name HTTPReply, which is also the name of the parser used to parse that part of the message tree to a bit stream. You can create your own HTTPReply header in a Compute node, or you can configure the HTTPReply node to create it by using default values, or values taken from the HTTPReply or HTTPResponse trees in the input message, or both.

   You can set the HTTPReply Status Code in the local environment; for more information, see the instructions for setting the HTTP Status Code for a reply in "Working with HTTP flows" on page 1585.

   If the HTTPReply node creates a default HTTPReply header, it contains the headers and values shown in the following table.

Header	Value
Content-Length (if present in the input message)	The calculated length of the reply message body in decimal.
Content-Type	text/xml; charset=*ccsid of the message body*

3. Request. A request message is sent by the HTTPRequest node. The HTTP headers in this message must be created in the message tree under the correlation name HTTPRequest, and are parsed by the HTTPRequest parser when the message tree is parsed to a bit stream. You can create your own HTTPRequest header in a Compute node, or you can configure the HTTPRequest node to create it using default values, or values taken from the HTTPInput or HTTPRequest trees in the input message, or both. If the HTTPRequest node creates a default HTTPRequest header, it contains the headers and values shown in the following table.

Header	Value
Host	Value set in the *Default Web Service URL* property.
Content-Length	The calculated length of the request message body in decimal.
Content-Type	text/xml; charset=*ccsid of the message body*
SOAPAction	"" (empty string)
Content-Encoding	"gzip" or "deflate" if the `Use compression` property is set to `gzip`, `zlib (deflate)`, or `deflate`.
Accept-Encoding	"gzip, deflate" if the `Accept compressed responses by default` property is selected.

4. Response. A response message is received by the HTTPRequest node from the application to which the corresponding request message was sent. The HTTP headers in the response message (data up to and including the CRLFCRLF) are parsed by the HTTPResponse parser and are included in the message tree under the correlation name HTTPResponse. The header shown in the following table is expected in a response message (though not required); others might also be present.

Header	Content	Example
Content-Length	The length of the response message body in decimal.	1585

"Web services example messages" on page 1599 provides example messages that include these headers.

Working with HTTP flows

Read this information if you are using HTTP message flows to interact with HTTP applications, including web services and RESTful services.

About this task

You might find it useful to read this information with the "Web services scenarios" on page 1620 section.

- Using secure connections with HTTPS

- Setting the HTTP Status Code for a reply
- Using LocalEnvironment.Destination.HTTP.RequestIdentifier
- Setting the HTTPRequest node URL dynamically
- Setting `Generate default HTTP headers from reply or response` for the HTTPReply node
- Setting `Generate default HTTP headers from input` for the HTTPRequest node

You must decide which listener you want the HTTP nodes to use:

- The broker listener (the httplistener component) has an HTTPConnector for handling HTTP messages, and an HTTPSConnector for handling HTTPS (HTTP over SSL) messages. Each connector has its own assigned port.

  By default, all HTTPInput and HTTPReply nodes use the broker-wide listener, which interfaces with the HTTP nodes by using a WebSphere MQ queue.
- An embedded listener is part of each execution group. The embedded listener has an HTTPConnector and an HTTPSConnector, and each connector has its own assigned port.

  You can configure one or more execution groups so that all HTTPInput and HTTPReply that you deploy to that execution group use the embedded listener.

For a discussion of the advantages of each listener, see "HTTP listeners" on page 1589.

You can use `ProxyConnectHeaders` only with HTTPS (SSL) connections; these headers do not work with HTTP connections.

Using secure connections with HTTPS

For information about setting up HTTPS connections, see "Implementing SSL authentication" on page 504.

Setting the HTTP Status Code for a reply

The default HTTP Status Code is 200, which indicates success. If you want a different status code to be returned, take one of the following actions:

- Set your status code in the field Destination.HTTP.ReplyStatusCode in the local environment tree (correlation name OutputLocalEnvironment). This field overrides any status code that is set in an HTTPResponseHeader header. This action is the preferred option, because it provides the greatest flexibility.
- Set your status code in the field X-Original-HTTP-Status-Code in the HTTPReplyHeader header.
- Set your status code in the field X-Original-HTTP-Status-Code in the HTTPResponseHeader header. This option is useful if you include an HTTPRequest node before the HTTPReply node in your flow, because the HTTPResponseHeader header is created for you. In this scenario, an HTTPResponseHeader header has been created in the logical tree, representing the HTTP headers in the response from another Web service. If you have selected the `Generate default HTTP headers from reply or response` property on the HTTPReply node, values for the response header are set as default values when the reply message is created.

Using LocalEnvironment.Destination.HTTP.RequestIdentifier

When the HTTPInput node receives an input request message, it sets the local environment field Destination.HTTP.RequestIdentifier to a unique value that identifies the Web service client that sent the request. You can refer to this value, and you can save it to another location if appropriate.

For example, if you design a pair of message flows that interact with an existing WebSphere MQ application (as described in "Broker calls existing Web service" on page 1621), you can save the identifier value in the request flow, and restore it in the reply flow, to ensure that the correct client receives the reply. If you use this technique, you must not change the data, and you must retain the data as a BLOB.

The HTTPReply node extracts the identifier value from the local environment tree and sets up the reply so that it is sent to the specific client. However, if you are using an HTTPReply node in a flow that does not have an HTTPInput node, and this field has been deleted or set incorrectly, message BIP3143S is issued.

If you design a message flow that includes both an HTTPInput and an HTTPReply node, the identifier value is set into the local environment by the HTTPInput node, but the HTTPReply node does not use it. Therefore, if your message flow includes both HTTP nodes and a Compute node in the same flow, you do not have to include the local environment tree when you specify which components of the message tree are copied from input message to output message by the Compute node (the `Compute mode` property).

Setting the HTTP request URL dynamically

You can set the property `Default Web service URL` on the HTTPRequest node to determine the destination URL for a Web service request. You can configure a Compute node before the HTTPRequest node within the message flow to override the value set in the property. Code ESQL that stores a URL string in LocalEnvironment.Destination.HTTP.RequestURL; the node retrieves and uses the URL string in place of the node property value.

Although you can also set the request URL in the special header X-Original-HTTP-URL in the HTTPRequestHeader header section of the request message (which overrides all other settings) in a Compute node, use the local environment tree content for this purpose for greater flexibility.

Setting `Generate default HTTP headers from reply or response` for the HTTPReply node

If you select `Generate default HTTP headers from reply or response` in the HTTPReply node properties, the node includes a minimum set of headers in the response that is sent to the Web service client.

To set headers explicitly, create them in an HTTPReplyHeader header. For example, a Compute node propagates a message in the XMLNSC domain and modifies the Content-Type as follows:

```
CALL CopyMessageHeaders();
SET OutputRoot.HTTPReplyHeader."Content-Type" = 'text/xml';
SET OutputRoot.XMLNSC = InputRoot.XMLNSC;
```

Do not use the ContentType property to set the Content-Type unless you are working in the MIME domain. The ContentType property is intended to set the value of Content-Type used in MIME.

The full set of HTTP headers used in the reply is built by selecting the headers using the algorithm defined in the following steps:

1. Select one or more headers in an HTTPReplyHeader header.
2. If no Content-Type header is yet defined, create one by using a non-empty value in the ContentType property.

3. Select one or more headers in an HTTPResponseHeader header (an HTTPResponseHeader header is propagated on return from an HTTPRequest node).
4. If no Content-Type header is yet defined, create one with the default value `text/xml; charset=`*`ccsid of the message body`*.
5. Create or overwrite the Content-Length header.

Attention: The HTTPReply node always rewrites the Content-Length header, even if you have cleared `Generate default HTTP headers from reply or response`. This action ensures that the content is correct.

If an HTTPReplyHeader header section existed in the message received by the HTTPReply node, and the Output terminal of the HTTPReply node is connected, the HTTPReplyHeader header section is updated with all changed or added values.

Setting `Generate default HTTP headers from input` for the HTTPRequest node

If you select `Generate default HTTP headers from input` in the HTTPRequest node properties, the node includes a minimum set of headers in the request that is sent to the server.

To explicitly set headers, create them in an HTTPRequestHeader header. For example, a Compute node propagating a message in the XMLNSC domain can modify the Content-Type as follows:

```
CALL CopyMessageHeaders();
SET OutputRoot.HTTPRequestHeader."Content-Type" = 'text/xml';
SET OutputRoot.XMLNSC = InputRoot.XMLNSC;
```

Do not use the ContentType property to set the Content-Type unless you are working in the MIME domain. The ContentType property is intended to set the value of Content-Type used in MIME.

The full set of HTTP headers used in the request is built by selecting the headers using the algorithm defined in the following steps:

1. Set the Host header, based on either the request URL or the incoming HTTPRequestHeader header section of the message.
2. Select one or more headers in an HTTPRequestHeader header.
3. If no Content-Type header is yet defined, create one by using a non-empty value in the ContentType property.
4. Select one or more headers in an HTTPInputHeader header (an HTTPInputHeader header is created automatically by an HTTPInput node).
5. If no Content-Type header is yet defined, create one with the default value `text/xml; charset=`*`ccsid of the message body`*
6. If no SOAPAction header is yet defined, create one with the default value `''`.
7. Create or overwrite the Content-Length header.

Attention: The HTTPRequest node always rewrites the Content-Length header, even if you have cleared `Generate default HTTP headers from input or request`. This action ensures that the content is correct.

If an HTTPRequestHeader header exists in the received message, the HTTPRequestHeader header is updated with all changed or added values.

HTTP listeners:

You can choose between broker-wide listeners and execution group (embedded) listeners to manage HTTP messages in your HTTP flows. Learn about the two types of listener, how ports are assigned to them, and how you can switch from one to the other for individual execution groups.

Your choice of listener affects message flows that handle inbound Web service requests by using HTTPInput or HTTPReply nodes. Message flows that do not handle inbound requests but that instigate outbound requests by using HTTPRequest nodes are not affected.

- "Execution group (embedded) listeners"
- "Broker-wide listeners"
- "Using both broker-wide and embedded listeners" on page 1591
- "Configuring listeners" on page 1591

Execution group (embedded) listeners

Each execution group has an embedded listener. The listener is associated with an HTTPConnector object and an HTTPSConnector object. The HTTPConnector object controls the runtime properties that affect the handling of HTTP messages. For example, run the following command to change the port on which the embedded listener for execution group *default* on broker *myBroker* listens for HTTP messages:

```
mqsichangeproperties myBroker -e default -o HTTPConnector
  -n explicitlySetPortNumber -v 8085
```

The HTTPSConnector object controls the runtime properties that affect the handling of HTTPS (HTTP Secure) messages. Run the following command to display these properties for execution group *default* on broker *myBroker*:

```
mqsireportproperties myBroker -e default -o HTTPSConnector -r
```

For further details, including more examples, see "Execution group HTTP listener parameters (SOAP and HTTP nodes)" on page 3805.

Each connector has its own assigned port, which is allocated from a range of numbers, as required. The default range for the HTTPConnector is `7800 - 7842`; the default range for the HTTPSConnector is `7843 - 7884`. The first execution group to start an embedded listener is allocated port `7800`, the second is allocated `7801`, and so on.

If you deploy a message flow to multiple execution groups, the port number is incremented by one for each successive deployment. Assume that no embedded listeners have as yet been started for these execution groups. In this case, the message flow that is deployed to the first execution group receives requests on port 7800. The next message flow uses port 7801, and so on, up to the specified limit of 7842. In this scenario, you typically use an intermediary router that listens on one port, then distributes the requests across the range of ports that you are using.

You can change these port number ranges, and you can allocate a specific port to an execution group, by using the **mqsichangeproperties** command.

If you restart an execution group, the embedded listeners continue to use the same ports as before the restart.

Broker-wide listeners

The broker-wide listener is associated with an HTTPConnector object for properties related to handling HTTP messages, and an HTTPSConnector object for properties related to handling HTTPS messages. For example, run the following command to change the port on which the broker-wide listener for *myBroker* listens for HTTP messages:

```
mqsichangeproperties myBroker -b httplistener -o HTTPConnector
  -n port -v 8085
```

Broker-wide listener properties that apply to HTTP and HTTPS messages are controlled by the HTTPListener object. For example, to disable the broker-wide listener for *myBroker*, run the following command:

```
mqsichangeproperties myBroker -b httplistener -o HTTPListener
  -n startListener -v false
```

Each connector has its own assigned port; default values are `7080` for HTTP and `7083` for HTTPS. You can change these port numbers by using the **mqsichangeproperties** command.

You can configure one or more execution groups so that HTTP nodes that you deploy to those execution groups use the embedded listener.

Using both broker-wide and embedded listeners

Because the option to use the embedded listener is at the execution group level, you can change your configuration such that some execution groups continue to use the broker-wide listener, while specific execution groups use the embedded listener.

However, if you disable the broker-wide listener, the execution group listeners are used for all HTTP nodes, even if you have not explicitly enabled support for them. Therefore, if you set all relevant broker and execution group properties to `false`, the execution group listeners handle all HTTP messages.

The HTTPRequest node communicates directly with the HTTP transport, and is therefore unaffected by your choice.

If you change the listener and port that are processing your HTTP or HTTPS messages, you must ensure that you also update your applications to use the updated configuration.

Configuring listeners

When you have decided on the configuration that you want:

- If you want to use the broker-wide listener for HTTP nodes in all execution groups, you do not have to change your configuration.
- If you are currently using the broker listener for one or more execution groups, and want to switch to using embedded listeners, follow the instructions in "Switching from a broker-wide listener to embedded listeners" on page 1593.
- If you are currently using the execution group listener for one or more execution groups, and want to switch to using the broker-wise listener, follow the instructions in "Switching from embedded listeners to a broker-wide listener" on page 1592.

Switching from embedded listeners to a broker-wide listener:

Configure your broker and execution groups to use the broker-wide listener for HTTP nodes in one or more execution groups.

About this task

You can change the configuration for execution groups so that HTTP nodes use the broker-wide listener. HTTP nodes use the broker-wide listener by default, but you might have configured some execution groups to use the embedded listener, and now want to switch back to using the broker-wide listener.

The commands shown in the examples here are split across multiple lines for ease of reading; when you enter the command, you must use a single line.

Procedure

1. Check that the broker is running.
2. If you disabled the broker-wide listener, run the **mqsichangeproperties** command to restart it. For example:

```
mqsichangeproperties MB7BROKER -b httplistener -o HTTPListener
 -n startListener -v true
```

3. To switch to using the broker-wide listener for a specific execution group, use the **mqsichangeproperties** command to change the execution group configuration.
   - For example:

     ```
     mqsichangeproperties MB7BROKER -e exgroup1 -o ExecutionGroup
      -n httpNodesUseEmbeddedListener -v false
     ```

     MB7BROKER is the name of your broker; *exgroup1* is the name of your execution group.

     If you want to change the status for all execution groups, you can omit the specific execution group name:

     ```
     mqsichangeproperties MB7BROKER -o ExecutionGroup
      -n httpNodesUseEmbeddedListener -v false
     ```

     This command does not change the status of the listener for SOAP messages processed by SOAP nodes; only messages to and from HTTP nodes are affected.
4. Stop and restart the broker to ensure that your changes take effect.

Example

For more information about this command, and examples of changing other properties associated with a broker or execution group, see the description of the **mqsichangeproperties** command.

Select the resources and properties associated with the broker-wide HTTP listener that you want to change.

Switching from a broker-wide listener to embedded listeners:

Configure your broker and execution groups so that some or all of the HTTP nodes use an execution group (embedded) listener.

About this task

You can change the configuration for one or more execution groups so that HTTP nodes deployed in these execution groups use the embedded listener.

Procedure

1. Check that the broker is running.
2. If you want all HTTP nodes in all execution groups to use the embedded listener, you can change the broker configuration to disable the broker-wide listener. Run the **mqsichangeproperties** command to change the broker configuration. Do not run this command if you want to keep the broker-wide listener active for at least one of your execution groups.

   ```
   mqsichangeproperties MB7BROKER -b httplistener -o HTTPListener
    -n startListener -v false
   ```

   All execution groups detect this change of status, and use the embedded listener when they are restarted, regardless of their own specific configuration. Therefore, you can switch to using embedded listeners for all execution groups by running this single command.

   If you disable the broker-wide listener in this way, you can configure an execution group to use the same port or ports that the broker-wide listener was using for HTTP, HTTPS, or both. Reusing the port numbers means that you do not have to change your client applications to send messages to a different port number.
3. To switch to using the embedded listener for a specific execution group, use the **mqsichangeproperties** command to change the execution group configuration.
   - For example:

     ```
     mqsichangeproperties MB7BROKER -e exgroup1 -o ExecutionGroup
      -n httpNodesUseEmbeddedListener -v true
     ```

     MB7BROKER is the name of your broker; *exgroup1* is the name of your execution group.
4. Stop and restart the broker to implement your changes.

Example

For more information about this command, and examples of changing other properties associated with brokers or execution groups, see the description of the **mqsichangeproperties** command.

Using timeouts with HTTP and SOAP nodes:

Connect the HTTP Timeout terminal of the HTTPInput or SOAPInput nodes to further nodes to process timeouts.

Before you begin

Before you start:

- Read the message flows overview.
- Read about the options that you have for processing Web service messages, and learn more about SOAP and HTTP.

About this task

You can configure message flows that start with an HTTPInput or SOAPInput node by connecting the HTTP Timeout terminal to further nodes for processing timeouts:

- On SOAPInput nodes, messages are propagated through this terminal only when you are using an HTTP binding.
- On HTTPInput nodes, messages are propagated through this terminal only when you have configured your execution groups such that the HTTP nodes are using the embedded execution group listener.

If these conditions are not met when you deploy the BAR file for the message flow that includes one of these nodes, a warning is generated, and the path of the message flow that you have connected to the HTTP Timeout terminal is ignored. No further warnings are generated until the next restart.

To set a static timeout value in an input node:

1. Create a message flow, or open an existing flow.
2. In the Message Flow editor, select the input node for this message flow. The node properties are displayed in the Properties view (below the editor pane).
3. Set an appropriate time for the timeout interval in the property `Maximum client wait time`. The default interval is 180 seconds.

   If this time expires, and you have not connected one or more nodes to the HTTP Timeout terminal, the listener that received the client request message responds with a SOAP Fault message indicating that a timeout has occurred.
4. If you want to provide customized timeout processing, connect one or more nodes to the HTTP Timeout terminal. You must include in this sequence the reply node that matches the input node. Therefore, if your message flow starts with an HTTPInput node, you must include an HTTPReply; if your message flow starts with a SOAPInput node, you must include a SOAPReply node.

To set a dynamic timeout value in an input node:

- Override the timeout value set on the input node by using the Java plug-in API to update it in a JavaCompute node using the `MbUtilities.changeIdentifierTimeout()` method. The following code shows an example of the `changeIdentifierTimeout` method:

```
MbMessage localEnv = assembly.getLocalEnvironment();
MbElement rootElem = localEnv.getRootElement();
MbElement repIdElement = rootElem.getFirstElementByPath(
```

```
   "/Destination/SOAP/Reply/ReplyIdentifier");
Object repId = repIdElement.getValue();
boolean success = changeIdentifierTimeout((byte[])repId, timeout);
```

- Override the timeout value set on the input node by using the "CHANGEIDENTIFIERTIMEOUT function" on page 5292.

You can derive the value that you use to replace the existing value by several means; for example:

- Create a configurable service of type UserDefined to define a timeout value, and retrieve the appropriate property.
- Read a record from a database.
- Use a value from a field within the message body.

By propagating from the HTTP Timeout terminal you can then change the contents of the responses that your message flow sends to the client. The processing on the sequence of nodes that you connect to the HTTP Timeout terminal is also subject to a further timeout, so that the client always gets a response within a known timeout interval.

When a message is propagated from the HTTP Timeout terminal the message tree contains the input headers of the original input message and a message body that is the fault timeout message. The original message body along with other information relating to the timeout can be accessed in the LocalEnvironment message tree. For example, the following record can be found in the LocalEnvironment:

```
(0x01000000:Name):HTTP = (
  (0x01000000:Name):Input = (
    (0x01000000:Name):Timeout = (
      (0x03000000:NameValue):OriginalClientLastWaitTime = 10 (INTEGER)
      (0x03000000:NameValue):OriginalClientWaitTime     = 15 (INTEGER)
      (0x03000000:NameValue):OriginalMessageMadeTheFlow = TRUE (BOOLEAN)
      (0x03000000:NameValue):OriginalRequestIdentifier  =
         X'485454500000000000000000000000c00c000000000000' (BLOB)
      (0x03000000:NameValue):OriginalInboundMessage     = X'3c3e' (BLOB)
    )
  )
)
```
