Usage	You can enable and disable this property only if the ALE update status property is set to `True`. When you set this property to `true`, the adapter sends one ALEAUD per IDoc packet which contains confirmations for all IDocs in the packet. When you set this property to `false`, the adapter sends one ALEAUD for each IDoc received at the adapter.
Globalized	No
Bidi supported	No

ALE update status (aleUpdateStatus)

This property specifies whether an audit trail is required for all message types.

Table 88. ALE update status details

Required	Yes
Possible values	`True` `False`

Table 88. ALE update status details (continued)

Default	`False`
Property type	Boolean
Usage	Set this property to `True` if you want the adapter to update a standard SAP status code after the ALE module has retrieved an IDoc object for event processing. If you set this value to `True`, you must also set following properties: • ALE failure code • ALE Success code • ALE failure text • ALE success text.
Globalized	No
Bidi supported	No

Assured once-only delivery (AssuredOnceDelivery)

This property specifies whether to provide assured once-only delivery for inbound events.

Table 89. Assured once-only delivery details

Required	Yes
Default	`True`
Property type	Boolean
Usage	When this property is set to `True`, the adapter provides assured once-only event delivery, so that each event is delivered only once. A value of `False` does not provide assured once-only event delivery, but provides better performance. When this property is set to `True`, the adapter attempts to store transaction (XID) information in the event store. If it is set to `False`, the adapter does not attempt to store the information. This property is used only if the export component is transactional. If the export component is not transactional, no transaction can be used, regardless of the value of this property.
Globalized	No
Bidi supported	No

Note: The **Assured once-only delivery** property applies only to asynchronous transactional RFC processing.

Auto create event table (EP_CreateTable)

This property determines if the event table is created automatically.

Table 90. Auto create event table details

Required	Yes if **Assured once-only event delivery** is set to `True`; otherwise, no.
Possible values	`True` `False`
Default	`True`
Property type	Boolean

Table 90. Auto create event table details (continued)

Usage	This property indicates whether the adapter should create the event recovery table automatically if it does not already exist. If you specify a value of `True` to automatically create the table, you must specify information about the event table (such as the event recovery table name). The value that is provided in **Event recovery table name** property is used to create the table.
Globalized	No
Bidi supported	No

Client

This property is the client number of the SAP system to which the adapter connects.

Table 91. Client details

Required	Yes
Possible values	You can enter a range of values from `000` to `999`.
Default	`100`
Property type	Integer
Usage	When an application attempts to log on to the SAP server, the application must have a Client number associated with it. The Client property value identifies the client (the adapter) that is attempting to log onto the SAP server.
Globalized	No
Bidi supported	No

Codepage number (Codepage)

The numeric identifier of the code page.

Table 92. Codepage number details

Required	No
Possible values	You can enter a range of values from `0000` to `9999`. For a full listing of languages and associated code page numbers that are supported by SAP, see SAP Note 7360.
Default	The default value for this property is conditionally determined by the value set for the **Language code** property.
Property type	Integer
Usage	The value that is assigned to the **Codepage number** defines the code page to be used and has a one-to-one relationship with the value set for the **Language code** property. The **Codepage number** establishes a connection to the appropriate language. Each language code value has a code page number value associated with it. For example, the language code for English is EN. If you select EN (English) as your language code, the code page number is automatically set to the numeric value that is associated with EN (English). The SAP code page number for EN (English) is `1100`.
Example	If **Language code** is set to `JA` (Japanese), **Codepage number** is set to `8000`.
Globalized	No
Bidi supported	No

Database schema name (EP_SchemaName)

This property is the schema that is used to create the event recovery table automatically.

Table 93. Database schema name details

Required	No
Default	No default value.
Property type	String
Usage	Specifies the schema name for the database used by the adapter's event persistence feature.
Example	`ALE_SCHEMA`
Globalized	Yes
Bidi supported	No

Delivery type (DeliveryType)

This property specifies the order in which events are delivered by the adapter to the export component.

Table 94. Delivery type details

Required	No
Possible values	`ORDERED` `UNORDERED`
Default	`ORDERED`
Property type	String
Usage	The following values are supported: • `ORDERED`: The adapter delivers events to the export component one at a time. • `UNORDERED`: The adapter delivers all events to the export component at once.
Globalized	No
Bidi supported	No

Enable Secure Network Connection

This property indicates whether secure network connection mode is enabled.

Table 95. Enable Secure Network Connection details

Required	No
Possible values	`0` (off) `1` (on)
Default	`0`
Property type	String

Table 95. Enable Secure Network Connection details (continued)

Usage	Set the value to 1 (on) if you want to use secure network connection. If you set this value to 1, you must also set following properties: • Secure Network Connection library path • Secure Network Connection name • Secure Network Connection partner • Secure Network Connection security level
Globalized	No
Bidi supported	No

Event recovery data source (JNDI) name (EP_DataSource_JNDIName)

This property is the JNDI name of the data source that is configured for event recovery.

Table 96. Event recovery data source (JNDI) name details

Required	Yes
Default	No default value.
Property type	String
Usage	Used in event recovery processing. The data source must be created in WebSphere Message Broker. The adapter uses the data source for persisting the event state.
Example	`jdbc/DB2`
Globalized	No
Bidi supported	No

Event recovery table name (EP_TableName)

This property is the name of the event recovery table.

Table 97. Event recovery table name details

Required	Yes
Default	No default value.
Property type	String
Usage	Used in event recovery processing. Consult database documentation for information on naming conventions. Configure a separate event recovery table for each endpoint. The same data source can be used to hold all of the event recovery tables.
Example	`EVENT_TABLE`
Globalized	No
Bidi supported	No

Event type filter

This property provides a delimited list of business object types for which the adapter should deliver events.

Table 98. Event type filter details

Required	No
Possible values	A comma-delimited (,) list of business object types.
Default	`null`
Property type	String
Usage	If this property is set, the adapter uses the delimited list as a filter, delivering events for only those business object types that are contained in the list. If the list is empty (null), the adapter does not apply filtering, and delivers events for all business object types.
Globalized	No
Bidi supported	No

Failure code (aleFailureCode)

This property determines how the adapter updates the SAP failure status code after the ALE module has retrieved an IDoc object for event processing.

Table 99. ALE failure code details

Required	Yes if AleUpdateStatus is set to `True`; otherwise, no.

Possible values	`68`
	`58`
	`51`

Default	51
Property type	Integer
Usage	Set a value for this property only if you set the value for the ALE update status property to `True`. Specify a value of `68` for this property to cause the adapter to update the SAP failure status code after the ALE module has retrieved an IDoc object for event processing. SAP converts this value to 40 (Application Document not created in receiving system). When you set the AleUpdateStatus property to `True`, the adapter updates a standard SAP status code after the adapter retrieves an IDoc object for event processing. An IDoc that is not sent successfully to the endpoint is considered to be a failure. Use the ALE failure code property to specify the code that is used to signify this failure.
Globalized	No
Bidi supported	No

Failure text (aleFailureText)

The property specifies the text that appears when an IDoc is not sent successfully to the endpoint.

Table 100. ALE failure text details

Required	Yes if AleUpdateStatus is set to `True`; otherwise, no.
Default	No default value.
Property type	String

Table 100. ALE failure text details (continued)

Usage	Use this property only if you set the ALE update status property to `True`. The length of the text string cannot exceed 70 characters. When you set the AleUpdateStatus property to `True`, the adapter updates a standard SAP status code after the adapter retrieves an IDoc object for event processing. An IDoc that is not sent successfully to the endpoint is considered to be a failure. Use the ALE failure text property to specify the descriptive text that is used to signify this failure.
Example	`ALE Dispatch Failed`
Globalized	Yes
Bidi supported	No

Folder for RFC trace files (RfcTracePath)

This property sets the fully qualified local path to the folder in which to write RFC trace files.

Table 101. Folder for RFC trace files details

Required	No
Default	No default value
Property type	String
Usage	Identifies the fully qualified local path into which RFC trace files are written. If **RFC trace on** is set to False (not selected), you are not permitted to set a value in the **Folder for RFC trace files** property.
Example	`c:\temp\rfcTraceDir`
Globalized	Yes
Bidi supported	No

Gateway host (GatewayHost)

This property is the Gateway host name. Enter either the IP address or the name of the Gateway host. Consult your SAP administrator for information on the Gateway host name.

Table 102. Gateway host details

Required	Yes
Default	No default value
Property type	String
Usage	This property is the host name of the SAP gateway. The gateway enables communication between work processes on the SAP system and external programs. The host identified is used as the gateway for the resource adapter. Maximum length of 20 characters. If the computer name is longer than 20 characters, define a symbolic name in the THOSTS table.
Globalized	No
Bidi supported	No

Gateway service (GatewayService)

This property is the identifier of the gateway on the gateway host that carries out the RFC services.

Table 103. Gateway service details

Required	Yes
Default	`sapgw00`
Property type	String
Usage	These services enable communication between work processes on the SAP server and external programs. The service typically has the format of `sapgw00`, where 00 is the SAP system number. Maximum of 20 characters.
Globalized	No
Bidi supported	No

Host name (ApplicationServerHost)

Specifies the IP address or the name of the application server host that the adapter logs on to.

Table 104. Host name details

Required	Yes (when load balancing is not used).
Default	No default value
Property type	String
Usage	When the adapter is configured to run without load balancing, this property specifies the IP address or the name of the application server that the adapter logs on to.
Example	`sapServer`
Globalized	No
Bidi supported	No

Ignore IDoc packet errors (IgnoreIDocPacketErrors)

This property determines whether IDoc packet errors are to be ignored.

Table 105. Ignore IDOC packet errors details

Required	No
Possible values	`True` `False`
Default	`False`
Property type	Boolean

Table 105. Ignore IDOC packet errors details (continued)

Usage	If the adapter encounters an error while processing the IDoc packet, it can behave in two different ways. • When this property is set to `False`, the adapter stops processing further IDocs in that packet and reports an error to the SAP system. • When this property is set to `True`, the adapter logs an error and continues to process the rest of the IDocs in that packet. The status of the transaction is marked as `INPROGRESS`. The adapter log displays the IDoc numbers that failed and you need to resubmit those individual IDocs separately. You need to manually maintain these records in the event recovery table. This property is not used for single IDocs and for non-split IDoc packets.
Globalized	No
Bidi supported	No

Language code

This property specifies the Language code in which the adapter logs on.

Table 106. Language code details

Required	Yes
Possible values	For a full listing of languages and associated code page numbers that are supported by SAP, see SAP Note 7360.
Default	The default value for the **Language code** property is based on the system locale.
Property type	String
Usage	Each of the supported languages is preceded by a two-character language code. The language itself is displayed in parentheses. If you enter a language code manually, you do not need to enter the language in parentheses. The language codes that are listed represent the SAP default set of 41 languages for non-Unicode systems plus Arabic. The value that you select determines the value of the **Codepage number** property.
Example	If the system locale is English, the value for this property is `EN (English)`.
Globalized	No
Bidi supported	No

Logon group name

This property is an identifier for the name of the group of application server instances that have been defined in transaction SMLG and linked together for logon load balancing.

Table 107. Logon group details

Required	Yes (if load balancing is used)
Possible values	Consult SAP documentation for information on creating Logon groups and on calling transaction SMLG.
Default	No default value
Property type	String

Table 107. Logon group details (continued)

Usage	When the adapter is configured for load balancing, this property represents the name of the group of application server instances that have been defined in transaction SMLG and linked together for logon load balancing. Logon load balancing allows for the dynamic distribution of logon connections to application server instances. Maximum of 20 characters. On most SAP systems, the SPACE logon group is reserved by SAP.
Globalized	No
Bidi supported	No

Maximum number of events collected during each poll

This property specifies the number of events that the adapter delivers to the export component during each poll period.

Table 108. Maximum number of events collected during each poll details

Required	Yes
Default	`10`
Property type	Integer
Usage	This value must be greater than 0
Globalized	No
Bidi supported	No

Maximum number of retries in case of system connection failure

This property specifies the number of times the adapter tries to restart the event listeners.

Table 109. Maximum number of retries in case of system failure details

Required	Yes
Default	`0`
Property type	Integer
Usage	When the adapter encounters an error related to the inbound connection (if the SAP application is down for example), this property specifies the number of times the adapter tries to restart the event listeners. A value of 0 indicates an infinite number of retries. **Note:** Configure the **Time between retries in case of system connection failure (milliseconds)** appropriately when retrying infinitely. For each retry attempt, the adapter waits based on the time interval specified in the **Time between retries in case of system connection failure (milliseconds)**. **Note:** If all the retry attempts fail, the adapter logs relevant messages and CEI events and stops attempting to recover the event listener. If you reach this point, you might have to restart the application manually.
Globalized	No
Bidi supported	No

Message server host (MessageServerHost)

This property specifies the name of the host on which the message server is running.

Table 110. Message server host details

Required	Yes (if load balancing is used)
Default	No default value
Property type	String
Usage	This property specifies the name of the host that will inform all the servers (instances) belonging to this SAP system of the existence of the other servers to be used for load balancing. The message server host contains the information about load balancing for RFC clients so that an RFC client can be directed to an appropriate application server.
Example	`SAPERP05`
Globalized	No
Bidi supported	No

Number of listeners

This property specifies the number of listeners that are started by an event.

Table 111. Number of listeners details

Required	No
Default	1
Property type	Integer
Usage	For event sequencing, this property should be set to 1. To improve adapter performance, you can increase the number of listeners. The adapter will not start if the number of listeners is zero (0).
Globalized	No
Bidi supported	No

Partner character set (PartnerCharset)

This property specifies the partner character set encoding.

Table 112. Partner character set details

Required	No
Default	UTF-8
Property type	String
Usage	When an encoding is specified, it is used; otherwise, the default encoding is used.
Globalized	No
Bidi supported	No

Password

This property is the password of the user account of the adapter on the SAP application server.

Table 113. Password details

Required	Yes
Default	No default value
Property type	String
Usage	The restrictions on the password depend on the version of SAP Web Application Server. • For SAP Web Application Server version 6.40 or earlier, the password: – Must be uppercase – Must be 8 characters in length • For versions of SAP Web Application Server later than 6.40, the password: – Is not case-sensitive – Can be up to 40 characters in length
Globalized	No
Bidi supported	Yes

Password used to connect to event data source (EP_Password)

This property is the user password for connecting to the database.

Table 114. Password to connect to event data source details

Required	Yes
Default	No default value.
Property type	String
Usage	This property specifies the password used by event-persistence processing to obtain the database connection from the data source.
Globalized	Yes
Bidi supported	No

RFC program ID

This property is the program identifier under which the adapter registers in the SAP gateway.

Table 115. RFC program ID details

Required	Yes
Possible values	Use the SAP transaction SM59 (Display and Maintain RFC Destinations) to see a list of available RFC program IDs.
Default	No default value.
Property type	String
Usage	The adapter registers with the gateway so that listener threads can process events from RFC-enabled functions. This value must match the program ID registered in the SAP application. The maximum length is 64 characters.
Globalized	No

Table 115. RFC program ID details (continued)

Bidi supported	No

RFC trace level (RcfTraceLevel)

This property specifies the global trace level.

Table 116. RFC trace level details

Required	No
Possible values	`1` - This is the default RFC trace level. When specified, SAP JCo Java API logging occurs. `3` - When specified, SAP JCo JNI API logging occurs. `5` - When specified, error diagnostic logging occurs.
Default	`1`
Property type	Integer
Usage	If **RFC trace on** is set to `False` (not selected), you cannot set a value in the **RFC trace level** property.
Globalized	No
Bidi supported	No

RFC trace on (RcfTraceOn)

This property specifies whether to generate a text file detailing the RFC activity for each event listener.

Table 117. RFC trace on details

Required	No
Possible values	`True` `False`
Default	`False`
Property type	Boolean
Usage	A value of `True` activates tracing, which generates a text file. This file is created in the directory in which the adapter process was started. The file has a prefix of `rfx` and a file type of trc (for example, rfc03912_02220.trc). Use these text files in a development environment only, because the files can grow rapidly. If **RFC trace on** is set to `False` (not selected), you cannot set values in the **Folder for RFC trace files** or **RFC trace level** properties.
Example	Examples of the information in the file are RfcCall FUNCTION BAPI_CUSTOMER_GETLIST, followed by the information for the parameters in the interface, or RFC Info rfctable, followed by the data from one of the interface tables. The trace file is created in the directory where the adapter process has been started. The trace file has a .trc file extension and the file name will start with the letters `rfc` followed by a unique identifier. For example, `rfc03912_02220.trc`.
Globalized	No
Bidi supported	No

SAP system ID (SAPSystemID)

This property specifies the system ID of the SAP system for which logon load balancing is allowed.

Table 118. SAP system ID details

Required	Yes (when load balancing is used)
Default	No default value
Property type	String
Usage	Value must be three characters
Example	`DYL`
Globalized	No
Bidi supported	No

Secure Network Connection library path (SncLib)

This property specifies the path to the library that provides the secure network connection service.

Table 119. Secure Network Connection library path details

Required	Yes, if SncMode is set to 1; no otherwise.
Default	No default value
Property type	String
Usage	If the SncMode property is set to 1 (indicating that you are using a secure network connection), specify the path to the library that provides the service.
Example	`/WINDOWS/system32/gssapi32.dll`
Globalized	No
Bidi supported	No

Secure Network Connection name (SncMyname)

This property specifies the name of the secure network connection.

Table 120. Secure Network Connection name details

Required	Yes, if SncMode is set to 1; no otherwise.
Default	No default value
Property type	String
Usage	If the SncMode property is set to 1 (indicating that you are using a secure network connection), specify a name for the connection.
Example	`DOMAINNAME/USERNAME`
Globalized	No
Bidi supported	No

Secure Network Connection partner (SncPartnername)

This property specifies the name of the secure network connection partner.

Table 121. Secure Network Connection partner details

Required	Yes, if SncMode is set to 1; no otherwise.
Default	No default value
Property type	String
Usage	If the SncMode property is set to 1 (indicating that you are using a secure network connection), specify a name for the connection partner.
Example	`CN=sap00.saperpdev, OU=Adapter, O=IBM, C=US`
Globalized	No
Bidi supported	No

Secure Network Connection security level (SncQop)

This property specifies the level of security for the secure network connection.

Table 122. Secure Network Connection security level details

Required	Yes, if SncMode is set to 1; no otherwise.
Possible values	`1` (Authentication only) `2` (Integrity protection) `3` (Privacy protection) `8` (Use the value from `snc/data_protection/use` on the application server) `9` (Use the value from `snc/data_protection/max` on the application server)
Default	`3` (Privacy protection)
Property type	String
Usage	If the SncMode property is set to 1 (indicating that you are using a secure network connection), specify a value to indicate the level of security for the connection.
Globalized	No
Bidi supported	No

Selective update (aleSelectiveUpdate)

This property specifies which IDoc Type and MessageType combinations are to be updated.

Table 123. ALE selective update details

Required	No
Default	No default value
Property type	String

Table 123. ALE selective update details (continued)

Usage	You can set values for this property only if the ALE update status property is set to `True`. When you set the AleUpdateStatus property to `True`, the adapter updates a standard SAP status code after the adapter retrieves an IDoc object for event processing. Use the ALE selective update property to specify which IDoc Type and MessageType combinations are to be updated. The syntax for this property is: `IDocType: MessageType [;IDocType: MessageType [;...]]` where a slash (/) delimiter separates each IDoc Type and MessageType, and a semicolon (;) delimiter separates entries in a set.
Example	The following example illustrates two sets. In the example, MATMAS03 and DEBMAS03 are the IDocs, and MATMAS and DEBMAS are the message types: `MATMAS03/MATMAS;DEBMAS03/DEBMAS`
Globalized	No
Bidi supported	No

Status message code (aleStatusMsgCode)

This property specifies the message code to use when the adapter posts the ALEAUD01 IDoc with message type ALEAUD.

Table 124. ALE status message code details

Required	No
Possible values	For a list of available codes, refer to the SAP table TEDS1.
Default	No default value.
Property type	String
Usage	You can set a value for this property only if the ALE update status property has been set to `True`. You must configure this message code in the receiving partner profile on SAP.
Globalized	No
Bidi supported	No

Stop the adapter when an error is encountered while polling (StopPollingOnError)

This property specifies whether the adapter stops polling for events when it encounters an error during polling.

Table 125. Stop the adapter when an error is encountered while polling details

Required	No
Possible values	`True` `False`
Default	`False`
Property type	Boolean
Usage	If this property is set to `True`, the adapter stops polling when it encounters an error. If this property is set to `False`, the adapter logs an exception when it encounters an error during polling and continues polling.
Globalized	No

Table 125. Stop the adapter when an error is encountered while polling details (continued)

Bidi supported	No

Success code (aleSuccessCode)

This property specifies the ALE success code for the successful posting of an IDoc.

Table 126. ALE success code details

Required	Yes if AleUpdateStatus is set to `True`; otherwise, no.
Possible values	`52` `53`
Default	No default value
Property type	Integer
Usage	Use this property only if you set the ALE update status property to `True`. When you set the AleUpdateStatus property to `True`, the adapter updates a standard SAP status code after the adapter retrieves an IDoc object for event processing. Use the ALE success code property to specify the code for IDoc posted as 53. After the IDoc is sent to the endpoint, the IDoc status remains as 03 (IDoc posted to port) in SAP. After posting the IDoc, the adapter posts the audit IDoc with the current IDoc number and status as 53. SAP converts the current IDoc status to 41 (Application Document Created in Receiving System).
Globalized	No
Bidi supported	No

Success text (aleSuccessText)

This property specifies the text that appears when an application document is posted successfully.

Table 127. ALE success text details

Required	Yes if AleUpdateStatus is set to `True`; otherwise, no.
Default	No default value.
Property type	String
Usage	Use this property only if you set the ALE status update property to `True`. When you set the AleUpdateStatus property to `True`, the adapter updates a standard SAP status code after the adapter retrieves an IDoc object for event processing. Use the ALE success text property to specify the descriptive text that is used to signify Application Document Posted.
Example	`ALE Dispatch OK`
Globalized	Yes
Bidi supported	No

System number (SystemNumber)

This property is the system number of the SAP application server.

Table 128. System number details

Required	Yes

Table 128. System number details (continued)

Possible values	You can enter a range of values from `00` to `99`.
Default	`00`
Property type	Integer
Usage	The system number further identifies the Gateway service.
Globalized	No
Bidi supported	No

Time between polling for events (milliseconds)

This property specifies the length of time that the adapter waits between polling periods.

Table 129. Time between polling for events (milliseconds)

Required	Yes
Possible values	Integers greater than or equal to `0`.
Default	`2000`
Unit of measure	Milliseconds
Property type	Integer
Usage	The time interval between polling events is established at a fixed rate, which means that if running the poll cycle is delayed for any reason (for example, if a prior poll cycle takes longer than expected to complete), the next poll cycle occurs immediately to make up for the time that is lost because of the delay.
Globalized	No
Bidi supported	No

Time between retries in case of system connection failure (milliseconds) (ConnectionRetryInterval)

This property specifies the time interval between attempts to restart the event listeners.

Table 130. Time between retries in case of system connection failure details

Required	No
Possible values	Positive integers
Default	`60000`
Unit of measure	Milliseconds
Property type	Integer
Usage	When the adapter encounters an error related to the inbound connection, this property specifies the time interval the adapter waits in between attempts to restart the event listeners.
Globalized	No
Bidi supported	No

User name (userName)

This property is the user account for the adapter on the SAP server.

Table 131. User name details

Required	Yes
Default	No default value
Property type	String
Usage	Maximum length of 12 characters. The user name is not case sensitive. It is recommended that you set up a CPIC user account in the SAP application and that you give this account the necessary privileges to manipulate the data required by the business objects supported by the adapter. For example, if the adapter must perform certain SAP business transactions, the adapter's account in the SAP application must have the permissions set to allow it to perform these transactions.
Example	`SapUser`
Globalized	Yes
Bidi supported	Yes

User name used to connect to event data source (EP_UserName)

This property is the user name for connecting to the database.

Table 132. User name to connect to event data source details

Required	Yes
Default	No default value.
Property type	String
Usage	User name used by event persistence for getting the database connection from the data source. Consult database documentation for information on naming conventions.
Globalized	Yes
Bidi supported	No

X509 certificate (X509cert)

This property specifies the X509 certificate to be used as the logon ticket.

Table 133. X509 certificate details

Required	No
Default	No default value
Property type	String
Usage	If the SncMode property is set to 1 (indicating that you are using a secure network connection), you can provide a value for the X509 certificate.
Globalized	No
Bidi supported	No

Related concepts:

"WebSphere Adapters nodes" on page 1914
A WebSphere Adapters node is a message flow node that is used to communicate with Enterprise Information Systems (EIS), such as SAP, Siebel, JD Edwards, and PeopleSoft.

With WebSphere Adapter for SAP Software you can create integrated processes that include the exchange of information with an SAP server, without special coding.

Related tasks:

"Preparing the environment for WebSphere Adapters nodes" on page 717
Before you can use the WebSphere Adapters nodes, you must set up the broker runtime environment so that you can access the Enterprise Information System (EIS).

"Developing message flows that use WebSphere Adapters" on page 2033
For information about how to develop message flows that use WebSphere Adapters, see the following topics.

"Adding external software dependencies for SAP" on page 2048
Before you can develop message flows that use WebSphere Adapters nodes, you must add prerequisite files to the runtime environment.

"Configuring the SAP server to work with the adapter" on page 2050
Before you configure the WebSphere Adapter for SAP Software for Application Link Enabling (ALE) processing, you must register a Remote Function Call (RFC) destination on the SAP server, and configure a receiver port, logical system, distribution model, and partner profile on the SAP server. Ask your system administrator if these items have been configured.

"Connecting to an EIS by using the Adapter Connection wizard" on page 2037
Use the Adapter Connection wizard to create the resources that enable the WebSphere Adapters to connect to an Enterprise Information System (EIS).

"Debugging message flows that contain WebSphere Adapters nodes" on page 3192
You can use various methods to monitor message flows that include WebSphere Adapters nodes.

"Deploying a message flow that uses WebSphere Adapters" on page 3240
Deploy the resources that are generated when you run the Adapter Connection wizard by adding them to a broker archive (BAR) file.

Use the SAPRequest node to send requests to an SAP application.

Outbound adapter properties for SAP:

Outbound adapter properties define how the adapter creates an outbound connection instance with the SAP server, and how operations are run on the server. Use the Adapter Connection wizard to set these properties.

The following table describes the outbound adapter properties. A more detailed description of each property is provided in the sections that follow the table.

Table 134. Interaction specification properties for Adapter for SAP Software

Property name	Description
ABAP debug (ABAPDebug)	The ABAP debugger property
Client (Client)	The client number of the SAP system to which the adapter connects
Codepage number (Codepage)	Indicates the numeric identifier of the code page
Custom retrieve function name (customFunctionName)	The name of a custom function to be used by the Query interface to SAP Software to retrieve data from an SAP table.
Enable secure network connection (SncMode)	Indicates whether secure network connection mode is used
Folder for RFC trace files (RfcTracePath)	Sets the fully qualified local path to the folder into which the RFC trace files are written
Function name (functionName)	The function name for a specific SAP interface.
Gateway host (GatewayHost)	The host name of the SAP gateway
Gateway service (GatewayService)	The identifier of the gateway on the gateway host that carries out the RFC services
Host name (ApplicationServerHost)	Specifies the IP address or the name of the application server host that the adapter logs on to
Ignore errors in BAPI return (IgnoreBAPIReturn)	Specifies if errors in BAPI return are ignored.
Language code (Language code)	Specifies the Language code in which the adapter logs on to SAP
Maximum number of hits for the discovery (ResultSetLimit)	The maximum number of result sets to return during a `RetrieveAll` operation.
Message server host (MessageServerHost)	Specifies the name of the host on which the message server is running
Partner character set (PartnerCharset)	Specifies PartnerCharset encoding
Password (Password)	The password of the user account of the adapter on the SAP application server
RFC trace level (RcfTraceLevel)	Specifies the global trace level
RFC trace on (RcfTraceOn)	Specifies whether to generate a text file detailing the RFC activity for each event listener
SAP system ID (SAPSystemID)	Specifies the system ID of the SAP system for which logon load balancing is allowed
Secure network connection library path (SncLib)	Specifies the path to the library that provides the secure network connection service
Secure network connection name (SncMyname)	Specifies the name of the secure network connection
Secure network connection partner (SncPartnername)	Specifies the name of the secure network connection partner
Secure network connection security level (SncQop)	Specifies the level of security for the secure network connection
Select the queue name (QRFCQueueName)	The name of a customer-defined queue on the SAP server.
System number (SystemNumber)	The system number of the SAP application server
Use wait parameter before calling BAPI commit	Specifies whether the WAIT parameter is set on a BAPI_TRANSACTION_COMMIT.
User name (userName)	The user account for the adapter on the SAP server

Table 134. Interaction specification properties for Adapter for SAP Software (continued)

Property name	Description
X509 certificate (X509cert)	Specifies the X509 certificate to be used as the logon ticket

ABAP debug

This property specifies whether the adapter invokes the ABAP Debugger for the appropriate function module when the adapter starts to process a business object.

Table 135. ABAP debug details

Required	No
Possible values	`True` `False`
Default	`False`
Property type	Boolean
Usage	When the property is set to `True`, the adapter opens the SAP GUI in debug mode. You must have appropriate authorization to use the debugger. Create a dialog user ID because a CPI-C user ID cannot open an SAP GUI session. You must have authorization to run in debug mode as well as any authorizations that are required by the ABAP code that is being debugged. For example, if a BAPI_CUSTOMER_CREATEFROMDATA1 is being debugged, you must have authorization to create customers. You can add breakpoints only after the debugger opens. Always set this property to `False` in a production environment. This property is supported on Windows systems only.
Globalized	No
Bidi supported	No

Client

This property is the client number of the SAP system to which the adapter connects.

Table 136. Client details

Required	Yes
Possible values	You can enter a range of values from `000` to `999`.
Default	`100`
Property type	Integer
Usage	When an application attempts to log on to the SAP server, the application must have a Client number associated with it. The Client property value identifies the client (the adapter) that is attempting to log onto the SAP server.
Globalized	No
Bidi supported	No

Codepage number (Codepage)

The numeric identifier of the code page.

Table 137. Codepage number details

Required	No
Possible values	You can enter a range of values from `0000` to `9999`. For a full listing of languages and associated code page numbers that are supported by SAP, see SAP Note 7360.
Default	The default value for this property is conditionally determined by the value set for the **Language code** property.
Property type	Integer
Usage	The value that is assigned to the **Codepage number** defines the code page to be used and has a one-to-one relationship with the value set for the **Language code** property. The **Codepage number** establishes a connection to the appropriate language. Each language code value has a code page number value associated with it. For example, the language code for English is EN. If you select EN (English) as your language code, the code page number is automatically set to the numeric value that is associated with EN (English). The SAP code page number for EN (English) is `1100`.
Example	If **Language code** is set to `JA` (Japanese), **Codepage number** is set to `8000`.
Globalized	No
Bidi supported	No

Custom retrieve function name (customFunctionName)

For the Query interface for SAP Software, this property specifies the name of a custom function that must be used to retrieve data from an SAP table.

Table 138. Custom retrieve function name details

Required	No
Default	No default value
Property type	String
Usage	This property applies to Query interface for SAP Software only. On non-Unicode systems, the default function used to retrieve data from SAP tables (RFC_READ_TABLE) might produce an exception. To avoid the problem, you can create another function on the SAP server and indicate, during configuration, that the adapter must use this custom function to retrieve data. This property specifies the name of the custom function. You must create the function on the SAP server before you specify this property on the Adapter Connection wizard. Follow the steps listed in SAP note 758278 to make a copy of RFC_READ_TABLE and modify the copy in line with the note.
Globalized	No
Bidi supported	No

Enable Secure Network Connection (SncMode)

This property indicates whether secure network connection mode is enabled.

Table 139. Enable Secure Network Connection details

Required	No
Possible values	`0` (off) `1` (on)
Default	`0`
Property type	String
Usage	Set the value to 1 (on) if you want to use secure network connection. If you set this value to 1, you must also set following properties: • Secure Network Connection library path (SncLib) • Secure Network Connection name (SncMyname) • Secure Network Connection partner (SncPartnername) • Secure Network Connection security level (SncQop)
Globalized	No
Bidi supported	No

Folder for RFC trace files (RfcTracePath)

This property sets the fully qualified local path to the folder in which to write RFC trace files.

Table 140. Folder for RFC trace files details

Required	No
Default	No default value
Property type	String
Usage	Identifies the fully qualified local path into which RFC trace files are written. If **RFC trace on** is set to False (not selected), you are not permitted to set a value in the **Folder for RFC trace files** property.
Example	`c:\temp\rfcTraceDir`
Globalized	Yes
Bidi supported	No

Function name (functionName)

The `functionName` interaction specification property controls the interaction by associating operations with the correct interface.

Table 141. Function name details

Required	Yes
Possible values	`True` `False`
Default	Null
Property type	String

Table 141. Function name details (continued)

Usage	The BAPI/RFC supports the following values for the functionName interaction specification property:
	`WBIInteractionSpec.CREATE`
	`WBIInteractionSpec.UPDATE`
	`WBIInteractionSpec.RETRIEVE`
	`WBIInteractionSpec.DELETE`
	
	The BAPI result set supports the following value for the functionName interaction specification property:
	
	`WBIInteractionSpec.RETRIEVEALL`
	
	The ALE outbound interface supports the following value:
	
	`WBIInteractionSpec.EXECUTE`
	
	The ALE inbound interface supports the following values for the functionName interaction specification property:
	
	`WBIInteractionSpec.CREATE`
	`WBIInteractionSpec.UPDATE`
	`WBIInteractionSpec.RETRIEVE`
	`WBIInteractionSpec.DELETE`
	
	The Query interface for SAP software (QISS) interface supports the following values for the functionName interaction specification property:
	• `WBIInteractionSpec.EXISTS`
	Throws the exceptions `NotExistsException` and `QISSQueryFailedException`
	• `WBIInteractionSpec.RETRIEVEALL`
	Throws the exceptions `QISSQueryFailedException`
	
	The Advanced event processing interface for inbound processing supports the following values for the functionName interaction specification property:
	
	`WBIInteractionSpec.CREATE`
	`WBIInteractionSpec.UPDATE`
	`WBIInteractionSpec.DELETE`
	
	The Advanced event processing interface for outbound processing supports the following values for the functionName interaction specification property:
	
	`WBIInteractionSpec.CREATE`
	`WBIInteractionSpec.UPDATE`
	`WBIInteractionSpec.RETRIEVE`
	`WBIInteractionSpec.DELETE`

Globalized	No
Bidi supported	No

Gateway host (GatewayHost)

This property is the Gateway host name. Enter either the IP address or the name of the Gateway host. Consult your SAP administrator for information on the Gateway host name.

Table 142. Gateway host details

Required	Yes

Table 142. Gateway host details (continued)

Default	No default value
Property type	String
Usage	This property is the host name of the SAP gateway. The gateway enables communication between work processes on the SAP system and external programs. The host identified is used as the gateway for the resource adapter. Maximum length of 20 characters. If the computer name is longer than 20 characters, define a symbolic name in the THOSTS table.
Globalized	No
Bidi supported	No

Gateway service (GatewayService)

This property is the identifier of the gateway on the gateway host that carries out the RFC services.

Table 143. Gateway service details

Required	Yes
Default	`sapgw00`
Property type	String
Usage	These services enable communication between work processes on the SAP server and external programs. The service typically has the format of `sapgw00`, where 00 is the SAP system number. Maximum of 20 characters.
Globalized	No
Bidi supported	No

Host name (ApplicationServerHost)

Specifies the IP address or the name of the application server host that the adapter logs on to.

Table 144. Host name details

Required	Yes (when load balancing is not used).
Default	No default value
Property type	String
Usage	When the adapter is configured to run without load balancing, this property specifies the IP address or the name of the application server that the adapter logs on to.
Example	`sapServer`
Globalized	No
Bidi supported	No

Ignore errors in BAPI return (IgnoreBAPIReturn)

This property indicates whether to ignore errors that are specified in a BAPI return operation. The return structure can be data or a table.

Table 145. Ignore errors in BAPI return details

Required	No
Possible values	`True` `False`
Default	`False`
Property type	Boolean
Usage	This property applies to BAPI outbound synchronous RFC processing only. When you set this property to `True`, the Adapter for SAP Software ignores the checking of error codes in the BAPI RETURN structure after BAPI has run, and returns this structure to the user as it is. The RETURN structure is part of every BAPI and contains the status of the BAPI execution. If you accept the default value of `False`, the Adapter for SAP Software processes the RETURN structure and throws an exception if an error code is found.
Globalized	No
Bidi supported	No

Language code

This property specifies the Language code in which the adapter logs on.

Table 146. Language code details

Required	Yes
Possible values	For a full listing of languages and associated code page numbers that are supported by SAP, see SAP Note 7360.
Default	The default value for the **Language code** property is based on the system locale.
Property type	String
Usage	Each of the supported languages is preceded by a two-character language code. The language itself is displayed in parentheses. If you enter a language code manually, you do not need to enter the language in parentheses. The language codes that are listed represent the SAP default set of 41 languages for non-Unicode systems plus Arabic. The value that you select determines the value of the **Codepage number** property.
Example	If the system locale is English, the value for this property is `EN (English)`.
Globalized	No
Bidi supported	No

Maximum number of hits for the discovery (ResultSetLimit)

For the Query interface for SAP Software, this property specifies the maximum number of result sets, which represents data for each row that is retrieved from a table through a RetrieveAll operation.

Table 147. Result set limit details

Required	Yes
Default	`100`
Property type	Integer

Table 147. Result set limit details (continued)

Usage	This property applies to Query interface for SAP Software only. If the number of hits in the table on the SAP server exceeds the value of the ResultSetLimit property, the adapter returns the error: `MatchesExceededLimitException`. The adapter uses this property to help avoid out-of-memory issues.
Globalized	No
Bidi supported	No

Message server host (MessageServerHost)

This property specifies the name of the host on which the message server is running.

Table 148. Message server host details

Required	Yes (if load balancing is used)
Default	No default value
Property type	String
Usage	This property specifies the name of the host that will inform all the servers (instances) belonging to this SAP system of the existence of the other servers to be used for load balancing. The message server host contains the information about load balancing for RFC clients so that an RFC client can be directed to an appropriate application server.
Example	`SAPERP05`
Globalized	No
Bidi supported	No

Partner character set (PartnerCharset)

This property specifies the partner character set encoding.

Table 149. Partner character set details

Required	No
Default	UTF-8
Property type	String
Usage	When an encoding is specified, it is used; otherwise, the default encoding is used.
Globalized	No
Bidi supported	No

Password

This property is the password of the user account of the adapter on the SAP application server.

Table 150. Password details

Required	Yes
Default	No default value
Property type	String

Table 150. Password details (continued)

Usage	The restrictions on the password depend on the version of SAP Web Application Server. • For SAP Web Application Server version 6.40 or earlier, the password: – Must be uppercase – Must be 8 characters in length • For versions of SAP Web Application Server later than 6.40, the password: – Is not case-sensitive – Can be up to 40 characters in length
Globalized	No
Bidi supported	Yes

RFC trace level (RcfTraceLevel)

This property specifies the global trace level.

Table 151. RFC trace level details

Required	No
Possible values	`1` - This is the default RFC trace level. When specified, SAP JCo Java API logging occurs. `3` - When specified, SAP JCo JNI API logging occurs. `5` - When specified, error diagnostic logging occurs.
Default	`1`
Property type	Integer
Usage	If **RFC trace on** is set to `False` (not selected), you cannot set a value in the **RFC trace level** property.
Globalized	No
Bidi supported	No

RFC trace on (RcfTraceOn)

This property specifies whether to generate a text file detailing the RFC activity for each event listener.

Table 152. RFC trace on details

Required	No
Possible values	`True` `False`
Default	`False`
Property type	Boolean
Usage	A value of `True` activates tracing, which generates a text file. This file is created in the directory in which the adapter process was started. The file has a prefix of `rfx` and a file type of trc (for example, rfc03912_02220.trc). Use these text files in a development environment only, because the files can grow rapidly. If **RFC trace on** is set to `False` (not selected), you cannot set values in the **Folder for RFC trace files** or **RFC trace level** properties.

Table 152. RFC trace on details (continued)

Example	Examples of the information in the file are RfcCall FUNCTION BAPI_CUSTOMER_GETLIST, followed by the information for the parameters in the interface, or RFC Info rfctable, followed by the data from one of the interface tables. The trace file is created in the directory where the adapter process has been started. The trace file has a .trc file extension and the file name will start with the letters `rfc` followed by a unique identifier. For example, `rfc03912_02220.trc`.
Globalized	No
Bidi supported	No

SAP system ID (SAPSystemID)

This property specifies the system ID of the SAP system for which logon load balancing is allowed.

Table 153. SAP system ID details

Required	Yes (when load balancing is used)
Default	No default value
Property type	String
Usage	Value must be three characters
Example	`DYL`
Globalized	No
Bidi supported	No

Secure Network Connection library path (SncLib)

This property specifies the path to the library that provides the secure network connection service.

Table 154. Secure Network Connection library path details

Required	Yes, if SncMode is set to 1; no otherwise.
Default	No default value
Property type	String
Usage	If the SncMode property is set to 1 (indicating that you are using a secure network connection), specify the path to the library that provides the service.
Example	`/WINDOWS/system32/gssapi32.dll`
Globalized	No
Bidi supported	No

Secure Network Connection name (SncMyname)

This property specifies the name of the secure network connection.

Table 155. Secure Network Connection name details

Required	Yes, if SncMode is set to 1; no otherwise.
Default	No default value
Property type	String

Table 155. Secure Network Connection name details (continued)

Usage	If the SncMode property is set to 1 (indicating that you are using a secure network connection), specify a name for the connection.
Example	`DOMAINNAME/USERNAME`
Globalized	No
Bidi supported	No

Secure Network Connection partner (SncPartnername)

This property specifies the name of the secure network connection partner.

Table 156. Secure Network Connection partner details

Required	Yes, if SncMode is set to 1; no otherwise.
Default	No default value
Property type	String
Usage	If the SncMode property is set to 1 (indicating that you are using a secure network connection), specify a name for the connection partner.
Example	`CN=sap00.saperpdev, OU=Adapter, O=IBM, C=US`
Globalized	No
Bidi supported	No

Secure Network Connection security level (SncQop)

This property specifies the level of security for the secure network connection.

Table 157. Secure Network Connection security level details

Required	Yes, if SncMode is set to 1; no otherwise.
Possible values	`1` (Authentication only) `2` (Integrity protection) `3` (Privacy protection) `8` (Use the value from `snc/data_protection/use` on the application server) `9` (Use the value from `snc/data_protection/max` on the application server)
Default	`3` (Privacy protection)
Property type	String
Usage	If the SncMode property is set to 1 (indicating that you are using a secure network connection), specify a value to indicate the level of security for the connection.
Globalized	No
Bidi supported	No

Select the queue name (QRFCQueueName)

For BAPI outbound processing, when Asynchronous queued RFC is selected, this property specifies the name of a queue on the SAP server to which BAPIs will be delivered.

Table 158. Select the queue name details

Required	No

Table 158. Select the queue name details (continued)

Default	The first queue defined on the SAP server. If no queue is defined on the SAP server, no default value exists.
Property type	String
Usage	This property applies to BAPI outbound asynchronous queued RFC processing only. When you want to deliver BAPI calls to a queue on the SAP server, you must specify the name of the queue. During configuration, you select an existing queue from a drop-down list. If no queues exist on the SAP server, you can type the name of a queue.
Globalized	No
Bidi supported	No

System number (SystemNumber)

This property is the system number of the SAP application server.

Table 159. System number details

Required	Yes
Possible values	You can enter a range of values from `00` to `99`.
Default	`00`
Property type	Integer
Usage	The system number further identifies the Gateway service.
Globalized	No
Bidi supported	No

Use wait parameter before calling BAPI commit

This property indicates whether the adapter calls a BAPI_TRANSACTION_COMMIT with the WAIT parameter set.

Table 160. Use wait parameter before calling BAPI commit

Required	No
Possible values	`True` `False`
Default	`False`
Property type	Boolean
Usage	This property applies to BAPI outbound synchronous RFC processing only. When you set this property to `True`, the Adapter for SAP Software calls a BAPI_TRANSACTION_COMMIT with the WAIT parameter set, so that other resource managers are committed only when the update has been completed in SAP. If you accept the default value of `False`, message flow processing might continue before the update has been completed in SAP. Therefore, after calling a BAPI, the updated data might not be available when you next access the system.
Globalized	No
Bidi supported	No

User name (userName)

This property is the user account for the adapter on the SAP server.

Table 161. User name details

Required	Yes
Default	No default value
Property type	String
Usage	Maximum length of 12 characters. The user name is not case sensitive. It is recommended that you set up a CPIC user account in the SAP application and that you give this account the necessary privileges to manipulate the data required by the business objects supported by the adapter. For example, if the adapter must perform certain SAP business transactions, the adapter's account in the SAP application must have the permissions set to allow it to perform these transactions.
Example	`SapUser`
Globalized	Yes
Bidi supported	Yes

X509 certificate (X509cert)

This property specifies the X509 certificate to be used as the logon ticket.

Table 162. X509 certificate details

Required	No
Default	No default value
Property type	String
Usage	If the SncMode property is set to 1 (indicating that you are using a secure network connection), you can provide a value for the X509 certificate.
Globalized	No
Bidi supported	No

Use the SAPInput node to accept input from an SAP application.

"SAPRequest node" on page 4685
Use the SAPRequest node to send requests to an SAP application.

SAP options for rediscovery:

In WebSphere Message Broker Version 7.0, you can add newly discovered objects into an existing adapter component without modifying any existing objects. This facility is known as *iterative discovery*. You can rediscover certain objects for an inbound or outbound adapter.

SAP outbound

The following table identifies the options that you can use to rediscover objects for an outbound adapter.

Discovery option	Existing XSD files affected	Description
BAPI	None	Rediscovery is possible. The addition of another BAPI does not require any existing XSD file to be replaced.
BAPI (Wrapper)	SAP*BusinessObjectName*Wrapper.xsd	By default, this option is cleared. Rediscovery is possible provided that you do not change the name of the business object.
BAPI (Work Unit)	SAP*BusinessObjectName*Txn.xsd	Rediscovery is possible provided that you do not change the name of the business object.

Discovery option	Existing XSD files affected	Description
BAPI (Result Set)	All XSD files need to be replaced	Incremental rediscovery is not possible because you can specify only two objects (Query and Response).
ALE passthrough IDoc	None	Rediscovery is possible provided that you do not change configuration parameters such as qRFC, which changes ASI annotations on top-level objects.
ALE	None	Rediscovery is possible provided that you do not change configuration parameters such as qRFC, which changes ASI annotations on top-level objects.
Advanced event processing (AEP)	None	Rediscovery is possible provided that you do not change configuration parameters such as the function module name, which changes ASI annotations on top-level objects.
Query interface for SAP Software (QISS)	None	Rediscovery is possible provided that you do not change configuration parameters such as custom function name, which changes ASI annotations on top-level objects.

SAP inbound

The following table identifies the options that you can use to rediscover objects for an inbound adapter.

Discovery option	Existing XSD files affected	Description
ALE events: create, update, or delete	None	Rediscovery is possible if you add a new IDoc but do not change Create, Read, Update, or Delete operations on previously discovered IDocs.
ALE passthrough	All XSD files need to be replaced	Rediscovery is possible, but you can specify only one IDoc. The IDoc is treated as opaque binary. Ensure that you select the option to replace all files.
AEP	None	Rediscovery is possible because the addition of another IDoc does not change existing XSD files.
BAPI	None	Rediscovery is possible if you add a new BAPI and do not change Create, Read, Update, or Delete operations on previously discovered BAPIs.

Business object information (Siebel):

A business object is a structure that contains application-specific information (metadata) about how the adapter should process the business object as well as the operation to be performed on the business object.

The name of the business object is generated by the Adapter Connection wizard in accordance with the naming convention for the adapter.

The Siebel business objects are created with long names by default. To generate business objects with shorter names, select **Generate business objects with shorter names** on the Configure Objects screen of the Adapter Connection wizard.

For more information about business objects, see the following topics.

- "Naming conventions for business objects representing Siebel business services" on page 4095
- "Supported data operations (Siebel)" on page 4094

"SiebelRequest node" on page 4745
Use the SiebelRequest node to interact with a Siebel application.

Supported data operations (Siebel):

An operation is the action that an adapter can perform on the Siebel server during outbound processing. The name of the operation typically indicates the type of action that the adapter takes, such as create or update.

Table 163. Supported operations of business objects

Operation	Definition
Create	Creates the business component
Delete	Deletes the business component and its children
Exists	Checks for the existence of incoming business objects
Retrieve	Retrieves the values of the business component
Retrieve all	Retrieves multiple instances of the same business component
Update	Updates the Siebel application with the incoming object

Naming conventions for business objects representing Siebel business services:

When the Adapter Connection wizard generates a business object, it provides a name for the business object based on the name of the object in the Siebel application that it uses to build the business object.

Naming conventions for business objects that represent Siebel business services and integration components

The naming conventions for business objects that represent Siebel business services are the same for both inbound and outbound processing. The names comprise the concatenation of several words, including prefix, business service name, integration object, and method name.

The following table describes the naming conventions that the Adapter Connection wizard uses to name business objects that represent Siebel business services and integration components.

Table 164. Business object naming conventions for Siebel business services and integration components

Element	Naming convention
Name of the top-level business object	*<Prefix><Business Service Name><Method Name><Names of all the integration objects selected for the Input and InputOutput complex type arguments>* • If no Input or InputOutput arguments exist, the names of all the output arguments are: *<Prefix><Business Service Name><Method Name><Names of all the integration objects selected for the output complex type arguments>* • If the method contains no complex arguments in the method, the naming convention is: *<Prefix><Business Service Name><Method Name>*
Name of the inbound object that is generated against integration components	'IO' + *<Name of Integration Object>* + 'IC' + *<Name of integration component>* For example: `IOAccountInterfaceICAccount`
Name of the outbound object that is generated against integration components	'IO' + *<Name of Integration Object>* + 'IC' + *<Name of integration component>* The name of an account interface integration object with the integration component account, as shown in the following example: `IOAccountInterfaceICAccount`

Optional: Shorter naming conventions for business objects that are generated against Siebel business services and integration components

The naming conventions for business objects that are generated against Siebel business services and integration components are valid if the optional 'Generate business objects with shorter names' property is specified on the configuration objects pane in the Adapter Connection wizard.

If this optional property is used, you should set the 'Folder' property with a unique value to avoid overwriting existing xsds that were previously generated. For example, if you select 'EAI Siebel Adapter', and click **Query** in two different Adapter Connection wizard runs for the integration objects, 'Account (PRM ANI)' and 'ATP Check Interface', the top-level object is named `EAISiebelAdapter.xsd`.

The name comprises the concatenation of several words, including prefix, business service name, and integration component name.

The following table describes the naming conventions that the Adapter Connection wizard uses to name business objects that are generated against Siebel business services and integration components.

Table 165. Shorter business object naming conventions for business objects that are generated against Siebel business services and integration components

Element	Naming convention
Name of the inbound and outbound child business objects that are generated against integration components	*<Prefix>+<Name of the Siebel Integration Component>* The Siebel business object and integration component names are stripped of all non-alphanumeric characters before being added to the business object name. If the resulting names are not unique, a counter is added to the end of the names.
Name of the inbound top-level business object that is generated against business services and integration components	*<Prefix>+<Name of the Siebel Integration Component>* The Siebel business object and integration component names are stripped of all non-alphanumeric characters before being added to the business object name. If the resulting names are not unique, a counter is added to the end of the names.
Name of the outbound top-level business object that is generated against business services and integration components	*<Prefix>+<Name of the Siebel Business Service>* The Siebel business object and integration component names are stripped of all non-alphanumeric characters before being added to the business object name. If the resulting names are not unique, a counter is added to the end of the names.

Naming conventions for business objects that represent Siebel business objects

The naming conventions for business objects that represent Siebel business objects are the same for both inbound and outbound processing. The name comprises the concatenation of several words, including prefix, business object name, and business component name.

The following table describes the naming conventions that are used by the Adapter Connection wizard to name business objects that represent Siebel business objects.

Table 166. Business object naming conventions for Siebel business objects

Element	Naming convention
Name of the business object	<*Prefix*>+<BO>+<*Business Object Name*>+<BC>+<*Business Component Name*>. The Siebel business object and component names are stripped of all non-alphanumeric characters before being added to the business object name. If the resulting names are not unique, a counter is added to the end of the names. For example, if two business objects have the name, `SiebelBOAccountBCBusinessAddress`, a counter is added as a suffix to make them unique, as shown in this example: `SiebelBOAccountBCAddress1 and SiebelBOAccountBCAddress2`
Name of the container business object that is generated for the Exists operation	<SiebelExistsResult>
Name of the container business object that is generated for the Retrieve All operation	<*Prefix*>+BO+<*Business Object Name*>+<BC>+<*Business Component Name*>+Container
Name of the top-level business object	<*Prefix*>+<BO>+<*Business Object Name*>+<BC>+<*Business Component Name*>

Optional: Shorter naming conventions for business objects that are generated against Siebel business components

The naming conventions for business objects that are generated against Siebel business components are valid if the optional 'Generate business objects with shorter names' property is specified on the configuration objects pane of the Adapter Connection wizard.

If this optional property is used, set the 'Folder' property with a unique value to avoid overwriting existing xsds that were previously generated. For example, **Siebel business object** > **Siebel business component** combination of **Account-ESP** > **Account** and Account (as the top-level object) is named `Account.xsd`.

The name comprises the concatenation of several words, including prefix and business component name.

The following table describes the naming conventions that the Adapter Connection wizard uses to name business objects that are generated against Siebel business components.

Table 167. Shorter business object naming conventions for business objects that are generated against Siebel business components

Element	Naming convention
Name of the top-level business object that is generated against business components	<*Prefix*>+<*Name of the Siebel Business Component*> The Siebel business object and integration component names are stripped of all non-alphanumeric characters before being added to the business object name. If the resulting names are not unique, a counter is added to the end of the names.

Siebel connection properties for the Adapter Connection wizard:

Set Adapter Connection wizard properties to establish a connection between the wizard, a tool that is used to create business objects, and the Siebel server. The properties that you configure in the Adapter Connection wizard specify such things as connection configuration, and logging and tracing options.

After you have established a connection between the Adapter Connection wizard and the Siebel server, the Adapter Connection wizard is able to access the metadata that it needs from the Siebel server to create business objects.

Some of the properties that you set in the Adapter Connection wizard are used as the initial value for resource adapter, managed connection factory, and activation specification properties that you can specify at a later time in the wizard.

The following table describes the Adapter Connection wizard properties and their purpose. A complete description of each property is provided in the sections that follow the table.

If you set any of these connection properties using bidirectional script, you must set values that identify the format of the bidirectional script that is entered for that property.

Table 168. Adapter Connection wizard properties

Property name in the wizard	Description
Adapter style	The service type that is associated with the adapter module
Business object namespace	The namespace value has been added as a prefix to the business object name to keep the business object schemas separated
Code page	The code page that the adapter uses to connect to the Siebel application
Connection URL	The connection URL that you need to connect to the Siebel application
Delimiter for keys in the event store	Specifies that the delimiter that is used between two name value pairs contains the object key name and value
Folder	The location of the generated business object
Generate business objects with shorter names	Ensures that the adapter generates shorter business object names, which are based on the Siebel integration components, business services, and business components rather than the concatenation of several words (which is the default)
Language code	The language code that is used to log on to the Siebel server
Method name	The name of the business service method to be implemented
Password	The password for the corresponding user name
Prefix for business object names	The prefix for the business object name
Siebel business object name for event store	The name of the business object in the event store where events are stored for inbound processing.
Siebel repository name	The name of the Siebel repository from which the objects are to be discovered
Siebel server view mode	Specifies the Siebel server mode and controls the kind of data to be retrieved and what actions can be performed
Type of Siebel objects to discover	The type of Siebel objects (business objects or business services) that need to be discovered and listed
Use resonate support for load balancing on Siebel server	Specifies that if resonate support is installed on the Siebel server, and the value is set to `True`, the adapter takes advantage of the load balancing feature to connect to the Siebel server more efficiently
User name	The user name that is used to log into the Siebel application

Adapter style (AdapterStyle)

This property specifies the service type that is associated with the adapter module.

Table 169. Service type details

Required	Yes
Default	Outbound

Table 169. Service type details (continued)

Property type	List of values
Possible values	`Outbound` `Inbound`
Usage	Specifies the service type associated with the adapter module
Globalized	No
Bidi supported	No

Business object namespace (BusinessObjectNameSpace)

This property specifies that the namespace value has been added as a prefix to the business object name to keep the business object schemas separated.

Table 170. Business object namespace details

Required	Yes
Default	`http://www.ibm.com/xmlns/prod/wbi/j2ca/siebel`
Property type	String
Usage	The namespace value is added as a prefix to the business object name to keep the business object schemas separated.
Example	`http://www.ibm.com/xmlns/prod/wbi/j2ca/siebel/IBMSiebelAccountInsertAccount`
Globalized	No
Bidi supported	No

Code page (CodePage)

Specifies the code page that the adapter uses to connect to the Siebel application.

Table 171. Code page details

Required	No
Default	No default value
Property type	String
Usage	Use this property to specify the code page details that the adapter uses to connect to the Siebel server for metadata discovery. The Siebel Java Data Bean supports a limited list of code page settings. If the current code page setting of your tooling is not supported, the adapter might not be able to connect to the Siebel server.
Globalized	No
Bidi supported	No

Connection URL (ConnectionURL)

This property specifies the connection URL that is needed to connect to the Siebel application.

Table 172. Connection URL details

Required	Yes
Default	No default value

Table 172. Connection URL details (continued)

Property type	String
Usage	The connection URLs for all versions of Siebel follow this format: `Protocol:// machinename:port/enterprisename/object manager/server name` The default port number is 2320. For Siebel version 7.5x and earlier versions, the port number (2320) and server name are specified. For Siebel version 7.8, the port and server name are not specified. If you do not select the default port, you can specify another port number (for example, 2321).
Examples	The following sample connection URLs are for different versions of Siebel: • For Siebel 7.5: `siebel://<IP_address>:2320/siebel/SSEObjMgr_ENU/sebldevl`. • For Siebel 7.8: `siebel://<IP_address>/Sieb78/SSEObjMgr_enu`. • For Siebel 8: `siebel://<IP_address>:2321/SBA_80/SSEObjMgr_enu`.
Globalized	Yes
Bidi supported	Yes

Delimiter for keys in the event store (DelimiterForKeysInTheEventStore)

Table 173. Delimiter for keys in the event store details

Required	Yes
Default	;
Property type	String
Usage	This is the delimiter that is used between two name value pairs that contain the object key name and value.
Examples	You can change the default value for this property. However, if you remove the default value and do not set it again, the default value (;) is used. If the event table key field has values, such as `AccountId=1-314:Id=1-325`, the event delimiter is the colon (:) . The object key names are `AccountId` and `Id`. The values are `1-314` and `1-325`.
Globalized	Yes
Bidi supported	Yes

Folder (Folder)

This property specifies the location of the generated business objects.

Table 174. Folder details

Required	No
Default	No default value
Property type	String
Usage	The generated business objects are copied into this folder.
Example	`inboundartifacts` and `outboundartifacts`
Globalized	No
Bidi supported	No

Generate business objects with shorter names (GenerateBusinessObjectsWithShorterNames)

This property ensures that the adapter generates shorter business object names, which are based on the Siebel integration components, business services, and business components rather than the concatenation of several words (which is the default).

Table 175. Generate business objects with shorter names details

Required	No
Default	No default value
Property type	Boolean
Usage	This property ensures that the adapter generates shorter business object names. The shorter business object names are based on the Siebel integration components, business services, and business components. The prefix is also attached to the shorter names. The adapter removes special characters from the shorter business object names. Alphanumeric characters (a-z, A-Z, and 1-9) are supported, and a counter (1-9) is added to the end of business object names to avoid duplication of names.
Example	If 'Account' is the name of the Siebel business component, and 'Siebel' is the prefix, the shorter name is 'Siebel_Account'.
Globalized	No
Bidi supported	No

Language code (LanguageCode)

This property specifies the language code that is used to log on to the Siebel server.

Table 176. Language code details

Required	Yes
Default	`ENU`
Property type	String
Usage	If the system locale is English, the value for this property is `ENU` (English). This is used to log on to the Siebel server.
Globalized	No
Bidi supported	No

Method name (MethodName)

This property specifies the name of the business service method to be implemented.

Table 177. Method name details

Required	Yes
Default	`Query`
Property type	String
Usage	The default is `Query`.
Example	`Query`, `QueryByExample`, `QueryById`, and so on.
Globalized	Yes

Table 177. Method name details (continued)

Bidi supported	Yes

Password (Password)

This property specifies the password for the corresponding user name.

Table 178. Password details

Required	Yes
Default	No default value
Property type	String
Usage	If a J2C Authentication Alias is used, a password is not required.
Example	`1-XYZ`
Globalized	Yes
Bidi supported	Yes

Prefix for business object names (PrefixForBusinessObjectNames)

This property specifies the prefix for the business object name.

Table 179. Prefix details

Required	No
Default	No default value
Property type	String
Usage	The prefix string is attached to the front of the business object name that was generated.
Example	For example, you use the prefix, `IBM`, and generate a business object for the EAI Siebel Adapter and the Insert method. Then you choose the Account Interface and Business Address Interface integration object against an Input and InputOutput method argument. The corresponding business object that is generated is: `IBMEAISiebelAdapterInsertAccountInterfacBusinessAddressInterface`
Globalized	Yes
Bidi supported	Yes

Siebel business object name for event store (SiebelBusinessObjectNameForEventStore)

This property specifies the name of the business object in the event store where events are stored for inbound processing.

Table 180. Siebel business object name for event store details

Required	Yes
Default	`IBM_EVENT`
Property type	String
Usage	To set this property, click **Advanced** on the connection properties pane on the Adapter Connection wizard, then go to the **Event configuration** tab. The two values listed are `IBM_EVENT` and `IBM2`. If you create a custom event component name, you can specify the value for it in the list box.
Globalized	Yes

Table 180. Siebel business object name for event store details (continued)

Bidi supported	No

Siebel repository name (SiebelRepositoryName)

This property specifies the name of the Siebel repository from which the objects are discovered.

Table 181. Siebel repository name details

Required	Yes
Default	`Siebel repository`
Property type	String
Usage	This default value is `Siebel Repository`. Although this is a required field, it is optional on the Adapter Connection wizard. You can edit this value to point to other repositories if needed.
Globalized	No
Bidi supported	No

Siebel server view mode (SiebelServerViewMode)

This property specifies the Siebel server view mode and controls the data that can be retrieved and what actions can be performed on it.

Table 182. Siebel server view mode details

Required	Yes
Default	`3`
Property type	Integer
Usage	This property displays when you click **Advanced** on the connection properties pane of the Adapter Connection wizard. This mode, when set to "Type of Siebel objects to discover" applies only to `Siebel business objects`, not to `Siebel business services`. The values that are supported by Siebel are `1` to `9`.
Globalized	No

Type of Siebel objects to discover (TypeOfSiebelObjectsToDiscover)

This property specifies the type of Siebel object that needs to be discovered and listed.

Table 183. Type of Siebel objects to discover details

Required	Yes
Possible values	`Siebel business objects` and `Siebel business services`
Default	`Siebel business objects`
Property type	String
Usage	Although the default is `Siebel business objects`, you can select `Siebel business services`. Based on your selection, the Adapter Connection wizard retrieves either the business objects or the business services.
Globalized	No
Bidi supported	No

Use resonate support for load balancing on Siebel server (UseResonateSupportForLoadBalancingOnSiebelServer)

This property indicates whether the Siebel server uses resonate support.

Table 184. Use resonate support for load balancing on Siebel server details

Required	No
Possible values	`True` `False`
Default	`True`
Property type	Boolean
Usage	This property displays after you click **Advanced** on the connection properties pane of the Adapter Connection wizard. If you select the check box, the property is set to `True` and the adapter takes advantage of the load balancing feature to connect to the Siebel server more efficiently. If you clear the check box, the property is set to `False`.
Globalized	No

User name (UserName)

This property specifies the user name that is used to log into the Siebel application.

Table 185. User name details

Required	Yes
Default	No default value
Property type	String
Usage	If a J2C Authentication Alias is used, a user name is not required.
Globalized	Yes
Bidi supported	Yes

Inbound adapter properties for Siebel:

Inbound adapter properties hold the configuration information for inbound event processing of a message endpoint. These properties also control the general operation of the adapter. Use the Adapter Connection wizard to set these properties.

These properties are used during endpoint activation to notify the adapter of eligible event listeners. During inbound processing, the adapter uses these event listeners to receive events before it forwards them to the endpoint.

The following table lists the properties for inbound processing that you set by using the Adapter Connection wizard. A more detailed description of each property is provided in the sections that follow the table.

Table 186. Inbound adapter properties

Property name	Description
Adapter ID property	The name of the adapter instance in the log and trace files
Connection URL	The connection URL that is needed to connect to the Siebel application
Delivery type	Determines the order in which events are delivered by the adapter to the export component.
Do not process events that have a timestamp in the future	Specifies whether the adapter filters out future events by comparing the timestamp on each event with the system time
Ensure once-only event delivery	Specifies whether the adapter provides assured once-only delivery of events.
Event component name	The name of the Siebel component for the event table
Event delimiter	Specifies whether the delimiter that is used between two name value pairs contains the object key name and value
Event types to process	A delimited list of event types that indicates to the adapter which events it should deliver
Interval between polling periods	The length of time that the adapter waits between polling periods.

Table 186. Inbound adapter properties (continued)

Property name	Description
Language code	The language code that is used to log on to the Siebel server
Maximum connections	The maximum number of connections that the adapter can use for inbound event delivery.
Maximum events in polling period	The number of events that the adapter delivers to the export component during each poll period.
Minimum connections	The minimum number of connections that the adapter can use for inbound event delivery.
Password	The password for the corresponding user name
Resonate support	Specifies that if resonate support is installed on the Siebel server, and the value is set to `True`, the adapter takes advantage of the load balancing feature to connect to the Siebel server more efficiently
Siebel server view mode	Specifies the Siebel view mode and controls the kind of data to be retrieved and what actions can be performed
Stop the adapter when an error is encountered while polling	Specifies whether the adapter stops polling for events when it encounters an error during polling.
"Retry interval if connection fails (RetryInterval)" on page 4115	The length of time that the adapter waits between attempts to establish a new connection after an error occurs during inbound operations.
User name	The user name that is used to log on to the Siebel application

Adapter ID to use for logging and tracing (AdapterID)

This property identifies a specific deployment, or instance, of the adapter.

Table 187. Adapter ID to use for logging and tracing details

Required	Yes
Default	`001`
Property type	String

Table 187. Adapter ID to use for logging and tracing details (continued)

Usage	This property identifies the adapter instance in the log and trace files, and also helps identify the adapter instance while monitoring adapters. The adapter ID is used with an adapter-specific identifier, SEBLRA, to form the component name used by the Log and Trace Analyzer tool. For example, if the adapter ID property is set to 001, the component ID is SEBLRA001. If you run multiple instances of the same adapter, ensure that the first eight characters of the adapter ID property are unique for each instance so that you can correlate the log and trace information to a particular adapter instance. By making the first seven characters of an adapter ID property unique, the component ID for multiple instances of that adapter is also unique, allowing you to correlate the log and trace information to a particular instance of an adapter. For example, when you set the adapter ID property of two instances of WebSphere Adapter for JD Edwards EnterpriseOne to 001 and 002. The component IDs for those instances, SEBLRA001 and SEBLRA002, are short enough to remain unique, enabling you to distinguish them as separate adapter instances. However, instances with longer adapter ID properties cannot be distinguished from each other. If you set the adapter ID properties of two instances to Instance01 and Instance02, you will not be able to examine the log and trace information for each adapter instance because the component ID for both instances is truncated to SEBLRAInstance. For inbound processing, this property is retrieved from the resource adapter properties. For outbound processing, it is retrieved from the managed connection factory properties.
Globalized	Yes
Bidi supported	No

Connection URL (ConnectionURL)

This property specifies the connection URL that is needed to connect to the Siebel application.

Table 188. Connection URL details

Required	Yes
Default	No default value
Property type	String
Usage	`Protocol://machinename:port/enterprisename/object manager/server name` For Siebel 7.0.5 to 7.5x : `siebel://<IP ADDRESS>/siebel/SSEObjMgr_ENU/sebldev1` For Siebel 7.8 : `siebel://<IP ADDRESS>:2321/Sieb78/SSEObjMgr_enu` For Siebel 8 : `siebel://<IP ADDRESS>:2321/SBA_80/SSEObjMgr_enu` The default port number is 2320. In the examples above (for Siebel versions 7.8 and 8), another port (2321) has been specified.
Globalized	Yes
Bidi supported	Yes

Delivery type (DeliveryType)

This property specifies the order in which events are delivered by the adapter to the export component.

Table 189. Delivery type details

Required	No

Table 189. Delivery type details (continued)

Possible values	`ORDERED` `UNORDERED`
Default	`ORDERED`
Property type	String
Usage	The following values are supported: • `ORDERED`: The adapter delivers events to the export component one at a time. • `UNORDERED`: The adapter delivers all events to the export component at once.
Globalized	No
Bidi supported	No

Do not process events that have a timestamp in the future (FilterFutureEvents)

This property specifies whether the adapter filters out future events by comparing the timestamp on each event with the system time.

Table 190. Do not process events that have a timestamp in the future details

Required	Yes
Possible values	`True` `False`
Default	`False`
Property type	Boolean
Usage	If set to `True`, the adapter compares the time of each event to the system time. If the event time is later than the system time, the event is not delivered. If set to `False`, the adapter delivers all events.
Globalized	No
Bidi supported	No

Ensure once-only event delivery (AssuredOnceDelivery)

This property specifies whether to provide ensured once-only event delivery for inbound events.

Table 191. Ensure once-only event delivery details

Required	Yes
Possible values	`True` `False`
Default	`True`
Property type	Boolean
Usage	When this property is set to `True`, the adapter provides assured once-only event delivery so that each event is delivered only once. A value of `False` does not provide assured once event delivery, but provides better performance. When this property is set to `True`, the adapter attempts to store transaction (XID) information in the event store. If it is set to `False`, the adapter does not attempt to store the information. This property is used only if the export component is transactional. If it is not, no transaction can be used, regardless of the value of this property.
Globalized	No

Table 191. Ensure once-only event delivery details (continued)

Bidi supported	No

Event component name (EventComponentName)

This property specifies the name of the event store where events are stored for inbound processing.

Table 192. Event component name details

Required	Yes
Default	`IBM2` (for Siebel version 7.x) and `IBM Event` (for Siebel version 8)
Property type	String
Usage	The default value is `IBM2` for Siebel version 7.x, and `IBM Event` for Siebel version 8. If you select one of these default values to configure the event business component on the Siebel server, it is the name of the Siebel event business component that was created. You can also select a value from the list of values provided by the adapter. You can edit the list of values. If you create your own Siebel event business component, you can edit the list to include the name of that event business component.
Globalized	Yes
Bidi supported	Yes

Event delimiter (EventDelimiter)

This property indicates that the delimiter that is used between two name value pairs contains the object key name and value.

Table 193. Event delimiter details

Required	Yes
Default	;
Property type	String
Usage	If multiple value pairs are set against the object key in the event component, they are used for the delimiter.
Globalized	No

Event types to process (EventTypeFilter)

This property contains a delimited list of event types that indicates to the adapter which events it should deliver.

Table 194. Event types to process details

Required	No
Possible values	A comma-delimited (,) list of business object types
Default	`null`
Property type	String
Usage	Events are filtered by business object type. If the property is set, the adapter delivers only those events that are in the list. A value of `null` indicates that no filter will be applied and that all events will be delivered to the export component.

Table 194. Event types to process details (continued)

Example	To receive only events that relate to the Customer and Order business objects, specify this value: `Customer,Order`
Globalized	No
Bidi supported	No

Interval between polling periods (PollPeriod)

This property specifies the length of time that the adapter waits between polling periods.

Table 195. Interval between polling periods details

Required	Yes
Possible values	Integers greater than or equal to `0`.
Default	`2000`
Unit of measure	Milliseconds
Property type	Integer
Usage	The poll period is established at a fixed rate, which means that if running the poll cycle is delayed for any reason (for example, if a prior poll cycle takes longer than expected to complete) the next poll cycle occurs immediately to make up for the lost time that was caused by the delay.
Globalized	No
Bidi supported	No

Language code (LanguageCode)

This property specifies the language code that is used to log on to the Siebel server.

Table 196. Language code details

Required	Yes
Default	`ENU`
Property type	String
Usage	If the system locale is English, the value for this property is `ENU` (English), which is used to log on to the Siebel server.
Globalized	No
Bidi supported	No

Maximum connections (MaximumConnections)

This property specifies the maximum number of connections that the adapter can use for inbound event delivery.

Table 197. Maximum connections details

Required	No
Default	1
Property type	Integer

Table 197. Maximum connections details (continued)

Usage	Only positive values are valid. The adapter considers any positive entry less than 1 to be equal to 1. Typing a negative value or 0 for this property might result in runtime errors.
Globalized	No
Bidi supported	No

Maximum events in polling period (PollQuantity)

This property specifies the number of events that the adapter delivers to the export component during each poll period.

Table 198. Maximum events in polling period details

Required	Yes
Default	`10`
Property type	Integer
Usage	The value must be greater than 0. If this value is increased, more events are processed per polling period, and the adapter might perform less efficiently. If this value is decreased, fewer events are processed per polling period, and the adapter's performance might improve slightly.
Globalized	No
Bidi supported	No

Minimum connections (MinimumConnections)

This property specifies the minimum number of connections that the adapter can use for inbound event delivery.

Table 199. Minimum connections details

Required	No
Default	`1`
Property type	Integer
Usage	Only positive values are valid. Any value less than 1 is treated as 1 by the adapter. Typing a negative value or 0 for this property might result in runtime errors.
Globalized	No
Bidi supported	No

Password (Password)

This property specifies the password for the corresponding user name.

Table 200. Password details

Required	Yes
Default	No default value
Property type	String
Usage	This property displays after you click **Advanced** on the connection properties pane of the Adapter Connection wizard. The password is saved in `.import` and `.export` files so that the adapter can connect to the Siebel application after it has been deployed. If a J2C Authentication Alias is used, a password is not required.
Example	`sadmin`

Table 200. Password details (continued)

Globalized	Yes
Bidi supported	Yes

Resonate support (ResonateSupport)

This property indicates whether the Siebel server uses resonate support.

Table 201. Resonate support details

Required	No
Possible values	`True` `False`
Default	`True`
Property type	Boolean
Usage	If you set this property to `True`, the adapter takes advantage of the load balancing feature to connect to the Siebel server more efficiently.
Globalized	No

Siebel server view mode (SiebelServerViewMode)

This property specifies the Siebel view mode and controls the data that can be retrieved and what actions can be performed on it.

Table 202. View mode details

Required	Yes
Default	`3`
Property type	Integer
Usage	The View mode property applies only to Siebel business objects and not to Siebel business services.
Globalized	No

Stop the adapter when an error is encountered while polling (StopPollingOnError)

This property specifies whether the adapter stops polling for events when it encounters an error during polling.

Table 203. Stop the adapter when an error is encountered while polling details

Required	No
Possible values	`True` `False`
Default	`False`
Property type	Boolean
Usage	If this property is set to `True`, the adapter stops polling when it encounters an error. If this property is set to `False`, the adapter logs an exception when it encounters an error during polling and continues polling.
Globalized	No

Table 203. Stop the adapter when an error is encountered while polling details (continued)

Bidi supported	No

Retry interval if connection fails (RetryInterval)

When the adapter encounters an error that is related to the inbound connection, this property specifies the length of time that the adapter waits before trying to establish a new connection.

Table 204. Retry interval details

Required	Yes
Default	`2000`
Unit of measure	Milliseconds
Property type	Integer
Usage	Only positive values are valid. When the adapter encounters an error that is related to the inbound connection, this property specifies the length of time that the adapter waits before trying to establish a new connection.
Globalized	No
Bidi supported	No

User name (UserName)

This property specifies the user name that is used to log into the Siebel application.

Table 205. User name details

Required	Yes
Default	No default value
Property type	String
Usage	This property displays after you click **Advanced** on the connection properties pane of the Adapter Connection wizard. The user name is saved in `.import` and `.export` files so that the adapter can connect to the Siebel application after it has been deployed. If a J2C Authentication Alias is used, a password is not required.
Globalized	Yes
Bidi supported	Yes

Outbound adapter properties for Siebel:

Outbound adapter properties define how the adapter creates an outbound connection instance with the Siebel application, and how operations are run on the server. Use the Adapter Connection wizard to set these properties.

The following table describes the outbound adapter properties. A more detailed description of each property is provided in the sections that follow the table.

Table 206. Managed connection factory properties

Property name	Description
Adapter ID	The name of the adapter instance in the log and trace files
Code page	Specifies the code page that the adapter uses to connect to Siebel server
Connection URL	The connection URL that is needed to connect to the Siebel application
Language code	The language code that is used to log on to the Siebel server
"Maximum records (maxRecords)" on page 4119	Maximum number of records to return during a RetrieveAll operation
Password	The password for the corresponding user name
Prefix	The prefix for the business object name
Resonate support	Specifies that if resonate support is installed on the Siebel server, and the value is set to `True`, the adapter takes advantage of the load balancing feature to connect to the Siebel server more efficiently

Table 206. Managed connection factory properties (continued)

Property name	Description
Show error on empty result set (errorOnEmptyResultSet)	For a business object, this property specifies if the adapter returns an empty business object or RecordNotFoundException when the result of RetreiveAll operation does not return any records. For a business service, the property specifies whether the adapter generates an exception when a returned Siebel message is null.
User name	The user name that is used to log into the Siebel application
View mode	Specifies the Siebel view mode and controls the data that can be retrieved and what actions can be performed on it

Adapter ID (AdapterID)

This property identifies a specific deployment or instance of the adapter.

Table 207. Connection URL details

Required	Yes
Default	`001`
Property type	String
Usage	This property identifies the adapter instance in the log and trace files, and also helps identify the adapter instance while monitoring adapters. The adapter ID is used with an adapter-specific identifier, SEBLRA, to form the component name used by the Log and Trace Analyzer tool. For example, if the adapter ID property is set to 001, the component ID is SEBLRA001. If you run multiple instances of the same adapter, ensure that the first seven characters of the adapter ID property are unique for each instance so that you can correlate the log and trace information to a particular adapter instance. By making the first seven characters of an adapter ID property unique, the component ID for multiple instances of that adapter is also unique, allowing you to correlate the log and trace information to a particular instance of an adapter. For example, when you set the adapter ID property of two instances of WebSphere Adapter for Siebel Business Applications to 001 and 002. The component IDs for those instances, SEBLRA001 and SEBLRA002, are short enough to remain unique, enabling you to distinguish them as separate adapter instances. However, instances with longer adapter ID properties cannot be distinguished from each other. If you set the adapter ID properties of two instances to Instance01 and Instance02, you will not be able to examine the log and trace information for each adapter instance because the component ID for both instances is truncated to SEBLRAInstanc.
Globalized	Yes
Bidi supported	No

Code page (codePage)

Specifies the code page that the adapter uses to connect to Siebel server.

Table 208. Code page details

Required	No
Default	No default value
Property type	String

Table 208. Code page details (continued)

Usage	Use this property to specify the code page details that the adapter uses to connect to the Siebel server. The Siebel Java Data Bean supports a limited list of code page settings. If the current code page setting of your run time is not supported, the adapter might not be able to connect to the Siebel server. The adapter uses the code page property to change the `file.encoding` property of the current Java Virtual Machine (JVM), when it establishes its first connection to the Siebel server. This change might affect other applications that run on the same JVM. Ensure that the code page has a valid value for all applications.
Globalized	No
Bidi supported	No

Connection URL (ConnectionURL)

This property specifies the connection URL that is needed to connect to the Siebel application.

Table 209. Connection URL details

Required	Yes
Default	No default value
Property type	String
Usage	`Protocol://machinename:port/enterprisename/object manager/server name` For Siebel 7.0.5 to 7.5x : `siebel://<IP ADDRESS>/siebel/SSEObjMgr_ENU/sebldev1` For Siebel 7.8 : `siebel://<IP ADDRESS>:2321/Sieb78/SSEObjMgr_enu` For Siebel 8 : `siebel://<IP ADDRESS>:2321/SBA_80/SSEObjMgr_enu` The default port number is 2320. In the examples above (for Siebel versions 7.8 and 8) another port (2321) has been specified.
Globalized	Yes
Bidi supported	Yes

Language code (LanguageCode)

This property specifies the language code that is used to log on to the Siebel server.

Table 210. Language code details

Required	Yes
Possible values	None
Default	`ENU`
Property type	String
Usage	If the system locale is English, the value for this property is `ENU` (English). This value is used to log on to the Siebel server.
Globalized	No
Bidi supported	No

Maximum records (maxRecords)

This property specifies the maximum number of records to return during a RetrieveAll operation.

Table 211. Maximum records details

Required	Yes
Default	100
Usage	If the number of hits in the database exceeds the value of the MaximumRecords property, the adapter returns the MatchesExceededLimitException error. The adapter uses this property to help avoid out-of-memory issues.
Property type	Integer
Globalized	No
Bidi supported	No

Password (Password)

This property specifies the password for the corresponding user name.

Table 212. Password details

Required	Yes
Default	No default value
Property type	String
Example	`sadmin`
Usage	This property displays after you click **Advanced** on the connection properties pane of the Adapter Connection wizard. The password is saved in `.import` and `.export` files so that the adapter can connect to the Siebel application after it has been deployed. If a J2C Authentication Alias is used, a password is not required.
Globalized	Yes
Bidi supported	Yes

Prefix (Prefix)

This property specifies the prefix for the business object name.

Table 213. Prefix details

Required	No
Default	No default value
Property type	String
Usage	The prefix string is attached to the front of the business object name.
Example	If you use the prefix `IBM`, generate a business object for the EAI Siebel Adapter and the Insert method, and choose the integration object, Account (PRM ANI), the corresponding business object generated is: `IBMEAISiebelAdapterInsertAccountU40PRMANIU41` where U40 and U41 are the unicode value replacements of `(and)`.
Globalized	Yes
Bidi supported	Yes

Resonate support (ResonateSupport)

This property indicates whether the Siebel server uses resonate support.

Table 214. Resonate support details

Required	No
Possible values	`True` `False`
Default	`True`
Property type	Boolean
Usage	If you select the check box, the property is set to `True`, and the adapter takes advantage of the load balancing feature to connect to the Siebel server more efficiently. If you clear the check box, the property is set to `False`.
Globalized	No

Show error on empty result set (errorOnEmptyResultSet)

For a business object, this property specifies if the adapter returns an empty business object or RecordNotFoundException when the result of `RetreiveAll` operation does not return any records. For a business service, this property specifies whether the adapter generates an exception when a returned Siebel message is null.

Table 215. Show error on empty result set details

Required	No
Default	For a business object: `True` For a business service: `False`
Property type	Boolean
Usage	For a business object: • When this property is set to `True`, a "record not found" exception is issued if no records are found in RetreiveAll operation. • When this property is set to `False`, an empty business object is returned if no records are found in RetreieveAll operation. For a business service: • When this property is set to `True`, a "record not found" exception is issued if no records are returned. • When this property is set to `False`, a null Siebel message is returned if no records are returned.
Globalized	No
Bidi supported	No

User name (UserName)

This property specifies the user name that is used to log into the Siebel application.

Table 216. User name details

Required	Yes
Possible values	None
Default	No default value

Table 216. User name details (continued)

Property type	String
Usage	This property displays after you click **Advanced** on the connection properties pane of the Adapter Connection wizard. The user name is saved in `.import` and `.export` files so that the adapter can connect to the Siebel application after it has been deployed. If a J2C Authentication Alias is used, a password is not required.
Globalized	Yes
Bidi supported	Yes

View mode (ViewMode)

This property specifies the Siebel view mode and controls the data that can be retrieved and what actions can be performed on it.

Table 217. View mode details

Required	Yes
Possible values	`1 - 9`
Default	`3`.
Property type	Integer
Usage	The View mode property applies only to Siebel business objects and not to Siebel business services. When this property is used for Siebel business objects, the default value is `3`.
Example	The adapter supports values `1` to `9`. For example, `1` is Manager View, `2` is Personal View, and `3` is All View.
Globalized	No

Business-object information (PeopleSoft):

Information about the content of a business object is located primarily inside the business-object definition file, a file that is generated by the Adapter Connection wizard when it creates business objects.

The business-object definition file contains application-specific information (ASI), which the adapter uses to perform operations, such as creating or updating. You can also find information about the content of a business object in the name of the business object. Although business-object names have no semantic value, they often contain clues about what the business object contains and what operation the adapter can perform on the PeopleSoft Enterprise server. For example, a business object named UpdateAddress suggests that the adapter can update an address in the PeopleSoft Enterprise server.

For more information, see "Supported operations (PeopleSoft)" on page 4124.

Supported operations (PeopleSoft):

An operation is the action that an adapter can perform on the PeopleSoft Enterprise server during outbound processing. The name of the operation typically indicates the type of action that the adapter takes, such as create or update.

The following table defines the operations that the adapter supports.

Table 218. Supported operations of business objects

Operation	Definition
Create	The adapter accesses the PeopleSoft component and retrieves values from the attributes that have the primary key application-specific information set. The adapter then opens the corresponding component interface by using the value that is provided for the ObjectName application-specific information. It sets the attribute values on the corresponding Create Keys in the component interface. An empty Component Interface is created, and the adapter maps all the business-object data to the created component interface. When mapping the data, the adapter sends all data for simple attributes in the hierarchy, and it creates items that match each of the child objects in the hierarchy, including effective-dated and effective-sequenced child records.
Retrieve	The adapter accesses the PeopleSoft component and retrieves values from the attributes that have the primary key application-specific information set. The adapter then instantiates the corresponding component interface by using the value that is provided for the ObjectName application-specific information. It sets the attribute values on the corresponding Get Keys in the component interface. The adapter then maps the component data onto the business-object hierarchy. Child objects are included in the data mapping.
RetrieveAll	This operation performs in the same way as the Retrieve operation, except that it allows retrieval of multiple instances of the same PeopleSoft component.
Update	The adapter retrieves an object from PeopleSoft and compares it to the target business object. When the comparison reveals extra child objects in PeopleSoft, the adapter deletes children. When the comparison reveals missing children in PeopleSoft, the adapter creates children. When the comparison reveals child objects that have been updated in PeopleSoft, the adapter updates them.
Exists	The adapter processes an exist operation in the same way that it processes a retrieve operation, except that it does not populate the business object with retrieved data; it checks for the existence of an object in PeopleSoft.
Delete	Based on the values that are set for the application-specific metadata elements StatusColumnName and StatusValue, the adapter updates a business object to inactive. A delete operation can be performed only on a top level object. PeopleSoft does not allow an object to be physically deleted, so the inactive object remains in the PeopleSoft database.
Apply Changes	This operation updates the PeopleSoft component based on the operation that was performed on it. The supported operations are create, update, and delete.

PeopleCode for a custom event project:

Two PeopleCode functions are required to support inbound processing. If you create a custom event project in PeopleTools for inbound support, add the PeopleCode functions to the project.

The following PeopleCode contains the IBMPublishEvent and IBMPublishFutureDatedEvent functions that are used to publish events to the event table. Calls to these functions are made from the SavePostChange PeopleCode function in the PeopleSoft component of interest.

```
/* IBM event notification */
Component string &KEYSTRING;
Component string &KEYNAME;
```

```
Component array of string &KEYARRAY;
Component string &KEYDELIM;
Component string &IBMVERB;
Local Record &IBMREC;

Function IBMPublishFutureDatedEvent(&BO, &KEYS, &EFFDATE)
; /* == create a new record object for cw_event_tbl == */
   &IBMREC = CreateRecord(Record.IBM_EVENT_TBL);

PeopleSoft connection properties for the Adapter Connection wizard:

Connection properties for the Adapter Connection wizard are used to establish a connection between the Adapter Connection wizard and the application from which the wizard obtains metadata. These properties specify such things as connection configuration, and logging options.

If you set any of these connection properties using bidirectional script, you must set values that identify the format of the bidirectional script entered for that property.

The connection properties and their purpose are described in the following table. A complete description of each property is provided in the sections that follow the table.

Table 219. Connection properties

Property name	Description
"Component interface jar file"	The PeopleSoft Enterprise component interface that the adapter uses to establish a connection to the PeopleSoft components that are targets of integration transactions
"Host name " on page 4133	The name or address of the server that hosts PeopleSoft Enterprise
"Password " on page 4133	The password of the user account of the adapter on the PeopleSoft Enterprise server
"Port number" on page 4133	The port number at which PeopleSoft Enterprise is configured to listen for client requests.
"Prefix for business object names" on page 4133	A prefix to be added to generated business objects
"User name" on page 4134	The name of the user account that the adapter uses on the PeopleSoft Enterprise server

Component interface jar file

This property specifies the PeopleSoft Enterprise component interface that the adapter uses to establish a connection to the PeopleSoft components that are targets of integration transactions.

Table 220. Component interface jar file details

Required	Yes
Default	No default
Property type	String
Usage	The name of the JAR file that the adapter uses to connect to the PeopleSoft Enterprise components of interest
Example	`CWYES_PeopleSoft\connectorModule\WbiEvent.jar`
Globalized	No
Bidi supported	No

Host name

This property specifies the name or address of the server that hosts PeopleSoft Enterprise.

Table 221. Host name details

Required	Yes
Default	No default value
Property type	String
Usage	Identifies the server, either by name or IP address, that hosts PeopleSoft Enterprise
Example	`9.26.248.202`
Globalized	No
Bidi supported	No

Password

This property specifies the password of the user account of the adapter on the PeopleSoft Enterprise server.

Table 222. Password details

Required	Yes
Default	No default value
Property type	String
Usage	The restrictions (case, length, and character) are determined by the PeopleSoft Enterprise version.
Globalized	Yes
Bidi supported	Yes

Port number

This property specifies the port number at which PeopleSoft Enterprise is configured to listen for client requests.

Table 223. Port number details

Required	Yes
Default	The port number that is entered when you run the Adapter Connection wizard
Property type	Integer
Example	9000
Globalized	No
Bidi supported	No

Prefix for business object names

This property specifies a prefix to be added to generated business objects.

Table 224. Prefix details

Required	No
Default	No default

Table 224. Prefix details (continued)

Property type	String
Usage	Use this property to distinguish between different business objects that are generated against the same PeopleSoft component interface.
Example	If you use `IB` as a prefix, all business objects that are generated by this service are named using this prefix.
Globalized	Yes
Bidi supported	No

User name

This property specifies the name of the user account that the adapter uses on the PeopleSoft Enterprise server.

Table 225. User name details

Required	Yes
Default	No default value
Property type	String
Usage	The restrictions (case, length, and character) are determined by the PeopleSoft Enterprise version.
Example	`DV1`
Globalized	Yes
Bidi supported	Yes

Related concepts:

"WebSphere Adapters nodes" on page 1914
A WebSphere Adapters node is a message flow node that is used to communicate with Enterprise Information Systems (EIS), such as SAP, Siebel, JD Edwards, and PeopleSoft.

"Overview of WebSphere Adapter for PeopleSoft Enterprise" on page 2013
With the adapter for PeopleSoft Enterprise you can create integrated processes that exchange information with PeopleSoft Enterprise through a standard interface. This interface shields the message flow developer from having to understand the lower level details about implementation of the application or data structures used on the PeopleSoft Enterprise server.

Related tasks:

"PeopleSoftRequest node" on page 4635
Use the PeopleSoftRequest node to interact with a PeopleSoft application.

Inbound adapter properties for PeopleSoft:

Inbound adapter properties hold the configuration information for inbound event processing of an export component. These properties also control the general operation of the adapter, such as specifying the namespace for business objects. Use the Adapter Connection wizard to set these properties.

The following table lists the properties for inbound processing that you set by using the Adapter Connection wizard. A more detailed description of each property is provided in the sections that follow the table.

Table 226. Inbound adapter properties

Property name	Purpose
Adapter ID to use for logging and tracing (AdapterID)	The name of the adapter instance in the log and trace files.
Ensure once-only event delivery (AssuredOnceDelivery)	Specifies whether the adapter provides assured once-only delivery of events.
Component interface for testing failed connections (PingCompIntfc)	The component interface that the adapter uses to validate a connection to the PeopleSoft Enterprise server
Component interface name for event notification (EventCIName)	The component interface that the adapter uses for event notification
Delivery type (DeliveryType)	Determines the order in which events are delivered by the adapter to the export component.
Delimiter for keys in the event store (EventKeyDelimiter)	The name and value for an object key in the event table
Event types to process (EventTypeFilter)	A delimited list of event types that indicates to the adapter which events it should deliver
Java date format for event timestamp (DateFormat)	The format that is used to create the event timestamp
Maximum connections (MaximumConnections)	The maximum number of connections that the adapter can use for inbound event delivery.
Minimum connections (MinimumConnections)	The minimum number of connections that the adapter can use for inbound event delivery.

Table 226. Inbound adapter properties (continued)

Property name	Purpose
Interval between polling periods (PollPeriod)	The length of time that the adapter waits between polling periods.
Maximum number of events collected during each poll (PollQuantity)	The number of events that the adapter delivers to the export component during each poll period.
Stop polling on error (StopPollingOnError)	Specifies whether the adapter stops polling for events when it encounters an error during polling.
Retry interval if connection fails (RetryInterval)	The length of time that the adapter waits between attempts to establish a new connection after an error occurs during inbound operations.

Adapter ID to use for logging and tracing (AdapterID)

Required	Yes
Default	`001`
Property type	String
Usage	This property identifies the adapter instance in the log and trace files, and also helps identify the adapter instance while monitoring adapters. The adapter ID is used with an adapter-specific identifier, PSOFTRA, to form the component name used by the Log and Trace Analyzer tool. For example, if the adapter ID property is set to 001, the component ID is PSOFTRA001. If you run multiple instances of the same adapter, ensure that the first eight characters of the adapter ID property are unique for each instance so that you can correlate the log and trace information to a particular adapter instance. By making the first seven characters of an adapter ID property unique, the component ID for multiple instances of that adapter is also unique, allowing you to correlate the log and trace information to a particular instance of an adapter. For example, when you set the adapter ID property of two instances of WebSphere Adapter for PeopleSoft Enterprise to 001 and 002. The component IDs for those instances, PSOFTRA001 and PSOFTRA002, are short enough to remain unique, enabling you to distinguish them as separate adapter instances. However, instances with longer adapter ID properties cannot be distinguished from each other. If you set the adapter ID properties of two instances to Instance01 and Instance02, you will not be able to examine the log and trace information for each adapter instance because the component ID for both instances is truncated to PSOFTRAInstance. For inbound processing, this property is retrieved from the resource adapter properties. For outbound processing, it is retrieved from the managed connection factory properties.
Globalized	Yes
Bidi supported	No

Ensure once-only event delivery (AssuredOnceDelivery)

This property specifies whether to provide ensured once-only event delivery for inbound events.

Table 227. Ensure once-only event delivery details

Required	Yes
Possible values	`True` `False`
Default	`True`
Property type	Boolean
Usage	When this property is set to `True`, the adapter provides assured once-only event delivery so that each event is delivered only once. A value of `False` does not provide assured once event delivery, but provides better performance. When this property is set to `True`, the adapter attempts to store transaction (XID) information in the event store. If it is set to `False`, the adapter does not attempt to store the information. This property is used only if the export component is transactional. If it is not, no transaction can be used, regardless of the value of this property.
Globalized	No
Bidi supported	No

Component interface for testing failed connection (PingCompInterface)

This property specifies the name of the PeopleSoft Enterprise component interface that the adapter uses to validate a connection to the PeopleSoft Enterprise server.

Table 228. Component interface for testing failed connection details

Row	**Explanation**
Required	Yes
Default	The name of the first component interface in the list
Property type	String
Usage	The name of the component interface that the adapter uses to test connectivity to the PeopleSoft Enterprise server. Specify a component interface name that already exists in your PeopleSoft Enterprise applications.
Globalized	No
Bidi supported	No

Component interface name for event notification (EventCIName)

This property specifies the name of the PeopleSoft Enterprise component interface that the adapter uses to for inbound processing.

Table 229. Component interface name for event notification details

Row	**Explanation**
Required	Yes
Default	`IBM_EVENT_CI`
Property type	String
Usage	The name of the component interface that the adapter uses for inbound processing. To use inbound processing, create a component interface specifically for event notification in PeopleSoft Enterprise.
Globalized	No
Bidi supported	No

Delivery type (DeliveryType)

This property specifies the order in which events are delivered by the adapter to the export component.

Table 230. Delivery type details

Required	No
Possible values	`ORDERED` `UNORDERED`
Default	`ORDERED`
Property type	String
Usage	The following values are supported: • `ORDERED`: The adapter delivers events to the export component one at a time. • `UNORDERED`: The adapter delivers all events to the export component at once.
Globalized	No
Bidi supported	No

Delimiter for keys in the event store (EventKeyDelimiter)

This property specifies the delimiter for the object key name-value pair in the event table.

Table 231. Delimiter for keys in the event store details

Row	**Explanation**
Required	No
Default	`=:`
Property type	String
Usage	Use this property to specify an object name and value to be used as an object key in the event store.
Example	`CustomerID=2001`
Globalized	No
Bidi supported	No

Do not process events that have a timestamp in the future (FilterFutureEvents)

This property specifies whether the adapter filters out future events by comparing the timestamp on each event with the system time.

Table 232. Do not process events that have a timestamp in the future details

Required	Yes
Possible values	`True` `False`
Default	`False`
Property type	Boolean

Table 232. Do not process events that have a timestamp in the future details (continued)

Usage	If set to `True`, the adapter compares the time of each event to the system time. If the event time is later than the system time, the event is not delivered. If set to `False`, the adapter delivers all events.
Globalized	No
Bidi supported	No

Event types to process (EventTypeFilter)

This property contains a delimited list of event types that indicates to the adapter which events it should deliver.

Table 233. Event types to process details

Required	No
Possible values	A comma-delimited (,) list of business object types
Default	`null`
Property type	String
Usage	Events are filtered by business object type. If the property is set, the adapter delivers only those events that are in the list. A value of `null` or `*` indicates that no filter will be applied and that all events will be delivered to the export component.
Example	To receive only events that relate to the Customer and Order business objects, specify this value: `Customer,Order`
Globalized	No
Bidi supported	No

Java date format for event timestamp (DateFormat)

This property specifies the format that is used for the event timestamp.

Table 234. Java date format for event timestamp details

Row	**Explanation**
Required	Yes
Default	`MM/dd/yy`
Property type	String
Usage	This property is used to format the date values from the PeopleSoft Enterprise server.
Globalized	No
Bidi supported	No

Maximum connections (MaximumConnections)

This property specifies the maximum number of connections that the adapter can use for inbound event delivery.

Table 235. Maximum connections details

Required	No
Default	1

Table 235. Maximum connections details (continued)

Property type	Integer
Usage	Only positive values are valid. The adapter considers any positive entry less than 1 to be equal to 1. Typing a negative value or 0 for this property might result in runtime errors.
Globalized	No
Bidi supported	No

Minimum connections (MinimumConnections)

This property specifies the minimum number of connections that the adapter can use for inbound event delivery.

Table 236. Minimum connections details

Required	No
Default	1
Property type	Integer
Usage	Only positive values are valid. Any value less than 1 is treated as 1 by the adapter. Typing a negative value or 0 for this property might result in runtime errors.
Globalized	No
Bidi supported	No

Interval between polling periods (PollPeriod)

This property specifies the length of time that the adapter waits between polling periods.

Table 237. Interval between polling periods details

Required	Yes
Possible values	Integers greater than or equal to `0`.
Default	`2000`
Unit of measure	Milliseconds
Property type	Integer
Usage	The poll period is established at a fixed rate, which means that if running the poll cycle is delayed for any reason (for example, if a prior poll cycle takes longer than expected to complete) the next poll cycle occurs immediately to make up for the lost time that was caused by the delay.
Globalized	No
Bidi supported	No

Maximum events in polling period (PollQuantity)

This property specifies the number of events that the adapter delivers to the export component during each poll period.

Table 238. Maximum events in polling period details

Required	Yes
Default	`10`
Property type	Integer

Table 238. Maximum events in polling period details (continued)

Usage	The value must be greater than 0. If this value is increased, more events are processed per polling period, and the adapter might perform less efficiently. If this value is decreased, fewer events are processed per polling period, and the adapter's performance might improve slightly.
Globalized	No
Bidi supported	No

Number of times to retry the system connection (RetryLimit)

This property specifies the number of times that the adapter tries to reestablish an inbound connection.

Table 239. Number of times to retry the system connection details

Required	No
Possible values	Positive integers
Default	`0`
Property type	Integer
Usage	Only positive values are valid. When the adapter encounters an error that is related to the inbound connection, this property specifies the number of times that the adapter tries to restart the connection. A value of `0` indicates an infinite number of retries.
Globalized	Yes
Bidi supported	No

Stop the adapter when an error is encountered while polling (StopPollingOnError)

This property specifies whether the adapter stops polling for events when it encounters an error during polling.

Table 240. Stop the adapter when an error is encountered while polling details

Required	No
Possible values	`True` `False`
Default	`False`
Property type	Boolean
Usage	If this property is set to `True`, the adapter stops polling when it encounters an error. If this property is set to `False`, the adapter logs an exception when it encounters an error during polling and continues polling.
Globalized	No
Bidi supported	No

Retry interval if connection fails (RetryInterval)

When the adapter encounters an error that is related to the inbound connection, this property specifies the length of time that the adapter waits before trying to establish a new connection.

Table 241. Retry interval details

Required	Yes
Default	2000
Unit of measure	Milliseconds
Property type	Integer
Usage	Only positive values are valid. When the adapter encounters an error that is related to the inbound connection, this property specifies the length of time that the adapter waits before trying to establish a new connection.
Globalized	No
Bidi supported	No

Outbound adapter properties for PeopleSoft:

Outbound adapter properties define how the adapter creates an outbound connection instance with the PeopleSoft Enterprise server, and how operations are run on the server. Use the Adapter Connection wizard to set these properties.

The following table describes the outbound adapter properties. A more detailed description of each property is provided in the sections that follow the table.

Table 242. Managed connection factory properties

Property	Description
Component interface for testing failed connection	The component interface that the adapter uses to validate a connection to the PeopleSoft Enterprise server
Host name	The name or address of the server that hosts PeopleSoft Enterprise
"Language (Language)" on page 4144	The language code that the adapter uses to log on to the PeopleSoft Enterprise server
Maximum number of records for RetrieveAll operation	The maximum number of records to return during a RetrieveAll operation
"Password (Password)" on page 4144	The password of the user account of the adapter on the PeopleSoft Enterprise server
"Port number (Port)" on page 4145	The port number that the adapter uses to access the PeopleSoft Enterprise server
"User name (UserName)" on page 4145	The name of the user account that the adapter uses on the PeopleSoft Enterprise server

Component interface for testing failed connection (PingCompInterface)

This property specifies the name of the PeopleSoft Enterprise component interface that the adapter uses to validate a connection to the PeopleSoft Enterprise server.

Table 243. Component interface for testing failed connection details

Required	Yes
Default	The name of the first component interface in the list
Property type	String
Usage	Specify a component interface name that already exists within your PeopleSoft Enterprise applications.
Example	`WBI_CUSTOMER_CI`
Globalized	No
Bidi supported	No

Host name (HostName)

This property specifies the name or address of the server that hosts PeopleSoft Enterprise.

Table 244. Host name details

Required	Yes
Default	No default value
Property type	String
Usage	Identifies, either by name or IP address, the server that hosts PeopleSoft Enterprise
Example	`9.26.248.202`
Globalized	No
Bidi supported	No

Language (Language)

This property specifies the language code that the adapter uses to log on to the PeopleSoft Enterprise server.

Table 245. Language details

Required	Yes
Default	The default value for the Language property is based on the system locale.
Property type	String
Usage	Each of the supported languages is preceded by a three-character language code. The language itself is presented in parentheses.
Example	If the system locale is English, the value for this property is `ENG (English)`.
Globalized	No
Bidi supported	No

Maximum number of records for RetrieveAll operation (MaxRecords)

This property specifies the maximum number of records to return during a RetrieveAll operation.

Table 246. Maximum number of records for RetrieveAll operation details

Required	Yes
Default	100
Usage	If the number of hits in PeopleSoft Enterprise exceeds the value of the Maximum number of records for the RetrieveAll operation property, the adapter returns an error. The adapter uses this property to help avoid out-of-memory issues.
Property type	Integer
Globalized	No
Bidi supported	No

Password (Password)

This property specifies the password of the user account of the adapter on the PeopleSoft Enterprise server.

Table 247. Password details

Required	Yes
Default	No default value

Table 247. Password details (continued)

Property type	String
Usage	The restrictions (case, length, and character) are determined by the PeopleSoft Enterprise version.
Globalized	No
Bidi supported	No

Port number (Port)

This property specifies the port number that the adapter uses to access the PeopleSoft Enterprise server.

Table 248. Port number details

Required	Yes
Default	The port number that is entered when you use the Adapter Connection wizard to discover objects and services
Property type	Integer
Example	`9000`
Globalized	No
Bidi supported	No

User name (UserName)

This property specifies the name of the user account that the adapter uses on the PeopleSoft Enterprise server.

Table 249. User name details

Required	Yes
Default	No default value
Property type	String
Usage	The restrictions (case, length, and character) are determined by the PeopleSoft Enterprise version.
Example	`DV1`
Globalized	No
Bidi supported	No

Business object information (JD Edwards):

You can determine the purpose of a business object by examining both the application-specific information in the business object definition file and the name of the business object.

The application-specific information dictates what operations can be performed on the JD Edwards EnterpriseOne server. The name typically reflects the operation to be performed and the structure of the business object.

For more information about business objects, see the following topics:

- "Application-specific information (JD Edwards)" on page 4148

Application-specific information (JD Edwards):

Application-specific information (ASI) is metadata that specifies adapter-dependent information about how to process business objects for the WebSphere Adapter for JD Edwards EnterpriseOne.

When the Adapter Connection wizard generates a business object, it automatically generates a business object definition, which is saved as an XSD (XML Schema Definition) file. The business object definition contains the ASI for that business object.

The WebSphere Adapter for JD Edwards EnterpriseOne uses ASI to create queries for Create, Retrieve, Update, and Delete operations. ASI is generated by the Adapter Connection wizard at three levels: the business-object level, the property level, and the operation level.

Application-specific information at the business-object-level

ASI at the business-object level is typically used to specify the name of the corresponding database table and to provide information necessary to perform a physical or logical delete operation. The following table describes the ASI at the business-object level.

Application-specific information	Description
Name	The name of the operation.
BSFN	The list of business functions associated with the operation.
AlwaysReturnResponse	Used to designate if the adapter returns a response business object for every request. If the value is set to true, the adapter always returns a response business object. If the value is set to false, an exception is generated after a JD Edwards EnterpriseOne business function is completed. This exception is generated against the user's component. The default value is false. For runtime exceptions, for example, if the adapter cannot establish a connection with the JD Edwards EnterpriseOne server, the exception is still generated against the user's component.

Application-specific information at the property level

ASI at the property level is typically used to specify the metadata for a property, and represents either child objects or an array of child objects. The following table describes the ASI of a complex property (a child) or a structure or table property (an array of child objects).

Application-specific information	Description	Possible values
Name	The business function parameter name as represented in JD Edwards EnterpriseOne.	BSFNName
Type	The type of the business function parameter as it exists in JD Edwards EnterpriseOne.	BSFN
IOType	The type of the business function parameter as it exists in JD Edwards EnterpriseOne.	• `IN`: the parameter is mapped from the business object to the business function. • `OUT`: the parameter is mapped from the business function to the business object. • `INOUT`: the parameter is mapped both ways. • `DEFAULT`: the parameter is mapped by using the default JD Edwards EnterpriseOne value. For adapter purposes, it is processed as INOUT.
RequiredType	Identifies if the parameter is required.	• `YES`: the parameter is required. • `NO`: the parameter is not required. • `DEFAULT`: the parameter is using the JD Edwards EnterpriseOne value. For adapter purposes, it is processed as `NO`.
Length	The maximum length for the parameter value.	None

Reference	The XPath of the business object property that is used to obtain the value of this attribute. The XPath expression starts at the business function level	`BusinessFunctionContainer`
		` BusinessFunction1`
		`  Prop1`
		` BusinessFunction2`
		`  Prop2`
		
		If the `BusinessFunction2/Prop2` property must be set with the value of `BusinessFunction1/Prop1`, the value of **Reference** for `BusinessFunction2/Prop2` must be set to `BusinessFunction1/Prop1`.

Application-specific information at the operation level

ASI at the operation level is used by the adapter to complete operations, such as to retrieve or update information in the JD Edwards EnterpriseOne server. The following table describes the ASI at the operation level.

Application-specific information	Description	Value
Name	The name of the business object operation.	• Create • Retrieve • Update • Delete • RetrieveAll
BSFN.Name	The name of the business functions to process.	• Name • RollbackOnWarnings
BSFN.RollbackOnWarnings	Indicates if the adapter must roll back the current transaction when the business function returns with warnings.	False (default setting)
RunOnError	Used to designate if the adapter should continue to process the sequential JD Edwards EnterpriseOne server business functions when a business function encounters an error while completing the business function. If the value is set to Yes, the adapter continues to process the subsequent business functions, even if the business function fails. The error message is stored to the attribute, BSFNExecutionErrors. If the value is set to false, the adapter stops the execution process and a rollback operation is performed. If the ASI `RunOnError` property is set to true for all business functions, the rollback operation is not performed. An error message for each business function that has failed is stored in the attribute BSFNExecutionErrors, against each business function in the response business object.	False (default setting)

Supported operations (JD Edwards):

An operation is the action that an adapter can perform on the JD Edwards EnterpriseOne server during outbound processing. The name of the operation typically indicates the type of action that the adapter takes, such as create or update.

The following tables define the operations that the WebSphere Adapter for JD Edwards EnterpriseOne supports during outbound processing for business functions and XML Lists.

Table 250. Supported operations of business functions

Operation	Definition
Create	The top-level business object and all contained children are created.
Update	The top-level business object is modified. This operation can include adding and deleting child objects.
Delete	The top-level business object and any contained children are deleted.
Retrieve	The top-level business object and any contained children are retrieved.

Table 251. Supported operations of XML Lists

Operation	Definition
RetrieveAll	Retrieves all records from the JD Edwards EnterpriseOne server that correspond to the query values specified in the XML List. Returns a result set in the form of a container of JD Edwards EnterpriseOne query business objects, which represent the data for each row retrieved from the table.

Naming conventions for JD Edwards EnterpriseOne:

When the Adapter Connection wizard generates a business object, it provides a name for the business object based on the name of the object in the JD Edwards EnterpriseOne server that it uses to build the business object.

When the Adapter Connection wizard provides a name for the business object, it converts the name of the object to mixed case, removing separators, such as spaces or underscores, then capitalizes the first letter of each word. For example, if the Adapter Connection wizard uses a JD Edwards EnterpriseOne server object called CUSTOMER_ADDRESS to generate a business object, it generates a business object called CustomerAddress.

The generated business object name can indicate the structure of the business object. However, business objects names have no semantic value to the adapter. Therefore, if you change the business object name, the behavior of the business object remains the same.

Element	Naming convention	Example
Name of the business object container	<*name_of_business_object*>Container	GetEffectiveAddressContainer
Name of the business function	Name of the business function discovered by the Adapter Connection wizard	GetEffectiveAddress

Element	Naming convention	Example
Name of the XML List	Name of the XML List table discovered by the Adapter Connection wizard	F0116

Adapter configuration properties for JD Edwards:

The WebSphere Adapter for JD Edwards EnterpriseOne has several categories of connection configuration properties, which you set with the Adapter Connection wizard while generating or creating objects and services.

You can change the connection properties for the Adapter Connection wizard, and the inbound and outbound adapter properties. For more information, see the following topics:

- "Connection properties for the Adapter Connection wizard (JD Edwards)" on page 4154
- "Inbound adapter properties for JD Edwards" on page 4158

Connection properties for the Adapter Connection wizard (JD Edwards):

Adapter configuration properties establish a connection between the Adapter Connection wizard and the JD Edwards EnterpriseOne server. The properties that you configure in the Adapter Connection wizard specify such things as connection configuration, bidirectional properties, and logging and tracing options.

After a connection between the Adapter Connection wizard and the JD Edwards EnterpriseOne server is established, the Adapter Connection wizard is able to access the metadata it needs from the JD Edwards EnterpriseOne server to create business objects.

The adapter connection properties and their purposes are described in the following table. A complete description of each property is provided in the sections that follow the table.

Important: If you set any of these connection properties using bidirectional script, you must set values that identify the format of the bidirectional script entered for that property.

Property	Description
“Environment”	Specifies the JD Edwards EnterpriseOne environment name.
“Log file output location”	Specifies the location of the log file for the discovery process.
“Logging level”	Specifies the type error for which logging occurs during the discovery process.
“Password” on page 4156	Password of the adapter user account on the JD Edwards EnterpriseOne environment.
“Role” on page 4156	Name of the role that is associated with the user name used to access the JD Edwards EnterpriseOne environment.
“User name” on page 4157	Name of the adapter user account on the JD Edwards EnterpriseOne environment.

Environment

This property specifies the JD Edwards EnterpriseOne environment name.

Required	Yes
Default	No default value
Property type	String
Usage	A JD Edwards EnterpriseOne environment is a user-defined pointer that indicates the location of data and objects on a JD Edwards EnterpriseOne server. Users can be authorized to use multiple JD Edwards EnterpriseOne environments on a single JD Edwards EnterpriseOne server.
Globalized	Yes
Bidi supported	Yes

Log file output location

This property specifies the location of the log file for the discovery process.

Required	Yes
Default	The `.metadata` directory of the workspace
Property type	String
Usage	Use this directory to hold the log file that lists the errors that occur during the discovery process. The type of discovery errors for which logging occurs is controlled by the `Logging level` property.
Example	`C:\IBM\wmbt70\workspace\.metadata\JDEMetadataDiscovery.log`
Globalized	Yes
Bidi supported	No

Logging level

This property specifies the type of error for which logging occurs during the discovery process.

Required	No

Possible values	ALL OFF FINE FINER FINEST CONFIG INFO SEVERE WARNING
Default	SEVERE
Property type	String
Usage	Use this property to tailor tracing capabilities. By specifying an error type, you are indicating that trace operations occur only for errors of the type specified.
Example	Accepting the default value of SEVERE provides trace information about errors that fall into the SEVERE category. Severe errors indicate that an operation cannot continue, although the adapter can still function. Severe errors also include error conditions that indicate an impending unrecoverable error, that is, reporting on situations that strongly suggest that resources are on the verge of being depleted. Other error descriptions are described in the following list: • Fatal – The adapter cannot continue. The adapter cannot function. • Warning – A potential error or impending error, which includes conditions that indicate a progressive failure; for example, the potential leaking of resources. • Audit – A significant event affecting adapter state or resources. • Info – General information outlining overall operation progress. • Config – Configuration change or status. • Detail – General information detailing operation progress.
Globalized	Yes
Bidi supported	No

Password

This property specifies the password of the adapter user account on the JD Edwards EnterpriseOne environment.

Required	No
Default	No default value
Property type	String
Usage	Passwords are created and named by the JD Edwards EnterpriseOne administrator. No restrictions exist on the type of characters used, the number of characters used, or the case of the characters used in passwords.
Globalized	No
Bidi supported	Yes

Role

This property specifies the name of the role that is associated with the user name used to access the JD Edwards EnterpriseOne environment.

Required	Yes
Default	No default value

Property type	String
Usage	Roles define what authority users have. Users can have multiple roles. A user's access to applications, forms, table columns, data sources, and so on, is based on one or more roles to which the user is assigned. Roles are created and named by the JD Edwards EnterpriseOne administrator.
Examples	• System administrator • Human resources • Accounting
Globalized	No
Bidi supported	Yes

User name

This property specifies the name of the adapter user account on the JD Edwards EnterpriseOne environment.

Required	No
Default	No default value
Property type	String
Usage	User names are created by the JD Edwards EnterpriseOne administrator. No restrictions exist on the type of characters used, the number of characters used, or the case of the characters used in user names.
Globalized	Yes
Bidi supported	Yes

Inbound adapter properties for JD Edwards:

Inbound adapter properties hold the inbound event processing configuration information for a message endpoint. These properties also control the general operation of the adapter. Use the Adapter Connection wizard to set these properties.

The following table lists the properties for inbound processing that you set by using the Adapter Connection wizard. A more detailed description of each property is provided in the sections that follow the table.

Property	Description
"Adapter ID to use for logging and tracing (AdapterID)" on page 4159	The name of the adapter instance in the log and trace files.
"Auto acknowledge (AutoAcknowledge)" on page 4159	Specifies the event acknowledge mode that is used.
"Delivery type (DeliveryType)" on page 4160	Determines the order in which events are delivered by the adapter to the export component.
"Ensure once-only event delivery (AssuredOnceDelivery)" on page 4160	Specifies whether the adapter provides assured once-only delivery of events.
"Failed events folder" on page 4160	The absolute path to the file folder on the local system where unsuccessfully processed events are archived in file format.
Retry limit for failed events	The number of times the adapter attempts to deliver an event before marking the event as failed.
"Interval between polling periods (PollPeriod)" on page 4161	The length of time that the adapter waits between polling periods.
"Maximum connections (MaximumConnections)" on page 4162	The maximum number of connections that the adapter can use for inbound event delivery.
"Maximum events in polling period (PollQuantity)" on page 4162	The number of events that the adapter delivers to the export component during each poll period.
"Minimum connections (MinimumConnections)" on page 4162	The minimum number of connections that the adapter can use for inbound event delivery.
"No wait (NoWait)" on page 4162	Specifies whether the adapter waits for a time interval to get an event from the JD Edwards EnterpriseOne transaction server by calling the Dynamic Java Connector API.
Retry EIS connection on startup	Controls whether the adapter retries the connection to the JD Edwards EnterpriseOne transaction server if it cannot connect at startup.
"Retry interval if connection fails (RetryInterval)" on page 4164	The length of time that the adapter waits between attempts to establish a new connection after an error occurs during inbound operations.
"Stop the adapter when an error is encountered while polling (StopPollingOnError)" on page 4164	Specifies whether the adapter stops polling for events when it encounters an error during polling.

Property	Description
"Wait time (WaitTime)" on page 4164	Specifies the waiting time if the No Wait property is set to false.

Adapter ID to use for logging and tracing (AdapterID)

This property identifies a specific deployment, or instance, of the adapter.

Required	Yes
Default	001
Property type	String
Usage	This property identifies the adapter instance in the log and trace files, and also helps identify the adapter instance while monitoring adapters. The adapter ID is used with an adapter-specific identifier, JDERA, to form the component name used by the Log and Trace Analyzer tool. For example, if the adapter ID property is set to 001, the component ID is JDERA001. If you run multiple instances of the same adapter, ensure that the first eight characters of the adapter ID property are unique for each instance so that you can correlate the log and trace information to a particular adapter instance. By making the first seven characters of an adapter ID property unique, the component ID for multiple instances of that adapter is also unique, allowing you to correlate the log and trace information to a particular instance of an adapter. For example, when you set the adapter ID property of two instances of WebSphere Adapter for JD Edwards EnterpriseOne to 001 and 002. The component IDs for those instances, JDERA001 and JDERA002, are short enough to remain unique, enabling you to distinguish them as separate adapter instances. However, instances with longer adapter ID properties cannot be distinguished from each other. If you set the adapter ID properties of two instances to Instance01 and Instance02, you will not be able to examine the log and trace information for each adapter instance because the component ID for both instances is truncated to JDERAInstance. For inbound processing, this property is retrieved from the resource adapter properties. For outbound processing, it is retrieved from the managed connection factory properties.
Globalized	Yes
bidi supported	No

Auto acknowledge (AutoAcknowledge)

This property specifies the event acknowledge mode that is used. You can specify either the auto acknowledge mode or the client acknowledge mode.

Required	No
Possible values	`True` `False`
Default	`False`
Property type	Boolean
Usage	Specifies the event acknowledge mode, which is either the auto acknowledge mode or the client acknowledge mode.
Example	False
Globalized	No
bidi supported	Yes

Delivery type (DeliveryType)

This property specifies the order in which events are delivered by the adapter to the export component.

Required	No
Possible values	`ORDERED` `UNORDERED`
Default	`ORDERED`
Property type	String
Usage	The following values are supported: • `ORDERED`: The adapter delivers events to the export component one at a time. • `UNORDERED`: The adapter delivers all events to the export component at once.
Globalized	No
bidi supported	No

Ensure once-only event delivery (AssuredOnceDelivery)

This property specifies whether to provide ensured once-only event delivery for inbound events.

Required	Yes
Possible values	`True` `False`
Default	`True`
Property type	Boolean
Usage	When this property is set to `True`, the adapter provides assured once-only event delivery so that each event is delivered only once. A value of `False` does not provide assured once event delivery, but provides better performance. When this property is set to `True`, the adapter attempts to store transaction (XID) information in the event store. If it is set to `False`, the adapter does not attempt to store the information. This property is used only if the export component is transactional. If it is not, no transaction can be used, regardless of the value of this property.
Globalized	No
bidi supported	No

Failed events folder

This property specifies the file folder on the local system where unsuccessfully processed events are archived in file format.

Required	No
Possible values	No default value
Default	Null
Property type	String

Usage	Create this folder manually on the same system before the adapter is run. If no failed events folder is specified, the adapter does not archive unsuccessfully processed events.
Globalized	Yes
bidi supported	No

Retry limit for failed events (FailedEventRetryLimit)

This property specifies the number of times that the adapter attempts to deliver an event before marking the event as failed.

Required	No
Possible values	Integers
Default	5
Property type	Integer
Usage	Use this property to control how many times the adapter tries to send an event before marking it as failed. It accepts the following values: **Default** If this property is not set, the adapter tries five additional times before marking the event as failed. **0** The adapter tries to deliver the event an infinite number of times. When the property is set to 0, the event remains in the event store and the event is never marked as failed. **> 0** For integers greater than zero, the adapter retries the specified number of times before marking the event as failed. **< 0** For negative integers, the adapter does not retry failed events.
Globalized	No
bidi supported	No

Interval between polling periods (PollPeriod)

This property specifies the length of time for which the adapter waits between polling periods.

Required	Yes
Possible values	Integers greater than or equal to 0.
Default	2000
Unit of measure	Milliseconds
Property type	Integer
Usage	The poll period is established at a fixed rate, so that if running the poll cycle is delayed for any reason (for example, if a prior poll cycle takes longer than expected to complete), the next poll cycle occurs immediately to make up for the lost time that was caused by the delay.
Globalized	No
bidi supported	No

Maximum connections (MaximumConnections)

This property specifies the maximum number of connections that the adapter can use for inbound event delivery.

Required	No
Default	1
Property type	Integer
Usage	Only positive values are valid. The adapter considers any positive entry less than 1 to be equal to 1. Typing a negative value or 0 for this property might result in runtime errors.
Globalized	No
bidi supported	No

Maximum events in polling period (PollQuantity)

This property specifies the number of events that the adapter delivers to the export component during each poll period.

Required	Yes
Default	10
Property type	Integer
Usage	The value must be greater than 0. If this value is increased, more events are processed per polling period, and the adapter might perform less efficiently. If this value is decreased, fewer events are processed per polling period, and the performance of the adapter might improve slightly.
Globalized	No
bidi supported	No

Minimum connections (MinimumConnections)

This property specifies the minimum number of connections that the adapter can use for inbound event delivery.

Required	No
Default	1
Property type	Integer
Usage	Only positive values are valid. Any value less than 1 is treated as 1 by the adapter. Typing a negative value or 0 for this property might result in runtime errors.
Globalized	No
bidi supported	No

No wait (NoWait)

This property specifies whether the adapter waits for a time interval to get an event from the JD Edwards EnterpriseOne transaction server by calling the Dynamic Java Connector API.

Required	No

Possible values	`True` `False`
Default	`True`
Property type	Boolean
Usage	Specifies whether the adapter waits for a time interval to get an event from the JD Edwards EnterpriseOne transaction server by calling the Dynamic Java Connector API.
Example	True
Globalized	No
bidi supported	Yes

Number of times to retry the system connection (RetryLimit)

This property specifies the number of times that the adapter tries to reestablish an inbound connection.

Required	No
Possible values	Positive integers
Default	`0`
Property type	Integer
Usage	Only positive values are valid. When the adapter encounters an error that is related to the inbound connection, this property specifies the number of times that the adapter tries to restart the connection. A value of `0` indicates an infinite number of retries.
Globalized	Yes
bidi supported	No

Retry EIS connection on startup (RetryConnectionOnStartup)

This property controls whether the adapter attempts to connect again to the JD Edwards EnterpriseOne server if it cannot connect at startup.

Required	No
Possible values	`True` `False`
Default	`False`
Property type	Boolean
Usage	This property indicates whether the adapter retries the connection to the JD Edwards EnterpriseOne server if the connection cannot be made when the adapter is started. • Set the property to `False` when you want immediate feedback about whether the adapter can establish a connection to the JD Edwards EnterpriseOne server; for example, when you are building and testing the application that receives events from the adapter. If the adapter cannot connect, the adapter writes log and trace information, and stops. The application status is shown as `Stopped`. After you resolve the connection problem, start the adapter manually. • Set the property to `True` if you do not need immediate feedback about the connection. If the adapter cannot connect during startup, it writes log and trace information, and then attempts to reconnect, by using the `RetryInterval` property to determine how frequently to retry and the value of the `RetryLimit` property to retry multiple times until that value is reached. The application status is shown as `Started`.

Globalized	No
bidi supported	No

Retry interval if connection fails (RetryInterval)

When the adapter encounters an error that is related to the inbound connection, this property specifies the length of time that the adapter waits before trying to establish a new connection.

Required	Yes
Default	`2000`
Unit of measure	Milliseconds
Property type	Integer
Usage	Only positive values are valid. When the adapter encounters an error that is related to the inbound connection, this property specifies the length of time that the adapter waits before trying to establish a new connection.
Globalized	Yes
bidi supported	No

Stop the adapter when an error is encountered while polling (StopPollingOnError)

This property specifies whether the adapter stops polling for events when it encounters an error during polling.

Required	No
Possible values	`True` `False`
Default	`False`
Property type	Boolean
Usage	If this property is set to `True`, the adapter stops polling when it encounters an error. If this property is set to `False`, the adapter logs an exception when it encounters an error during polling, and continues polling.
Globalized	No
bidi supported	No

Wait time (WaitTime)

This property specifies the waiting time if the No Wait property is set to false.

Required	No
Possible values	Any positive integer. Any negative integer is treated as the default value (`3000 milliseconds`)
Default	`3000`
Unit of measure	Milliseconds
Property type	Integer
Usage	This property specifies the waiting time if the No Wait property is set to false.
Example	5000

Globalized	No
bidi supported	Yes

Outbound adapter properties for JD Edwards:

Outbound adapter properties define how the adapter creates an outbound connection instance with the JD Edwards EnterpriseOne server, and how operations are run on the server. Use the Adapter Connection wizard to set these properties.

The following table describes the outbound adapter properties. A more detailed description of each property is provided in the sections that follow the table.

Property	Description
Adapter ID	The name of the adapter instance in the log and trace files.
"Environment" on page 4166	The JD Edwards EnterpriseOne environment name.

Property	Description
Maximum records for RetrieveAll operation	The maximum number of records to return during a RetrieveAll operation
"Password" on page 4167	The password of the adapter user account on the JD Edwards EnterpriseOne environment.
"Role" on page 4167	The name of the role that is associated with the user name used to access the JD Edwards EnterpriseOne environment.
"User name" on page 4168	The name of the adapter user account on the JD Edwards EnterpriseOne environment.

Adapter ID to use for logging and tracing (AdapterID)

This property identifies a specific deployment, or instance, of the adapter.

Required	Yes
Default	CWYMY_Adapter
Property type	String
Usage	This property identifies the adapter instance in the log and trace files, and also helps identify the adapter instance while monitoring adapters. The adapter ID is used with an adapter-specific identifier, JDERA, to form the component name used by the Log and Trace Analyzer tool. For example, if the adapter ID property is set to 001, the component ID is JDERA001. If you run multiple instances of the same adapter, ensure that the first eight characters of the adapter ID property are unique for each instance so that you can correlate the log and trace information to a particular adapter instance. By making the first seven characters of an adapter ID property unique, the component ID for multiple instances of that adapter is also unique, allowing you to correlate the log and trace information to a particular instance of an adapter. For example, when you set the adapter ID property of two instances of WebSphere Adapter for JD Edwards EnterpriseOne to 001 and 002. The component IDs for those instances, JDERA001 and JDERA002, are short enough to remain unique, enabling you to distinguish them as separate adapter instances. However, instances with longer adapter ID properties cannot be distinguished from each other. If you set the adapter ID properties of two instances to Instance01 and Instance02, you will not be able to examine the log and trace information for each adapter instance because the component ID for both instances is truncated to JDERAInstance. For inbound processing, this property is retrieved from the resource adapter properties. For outbound processing, it is retrieved from the managed connection factory properties.
Globalized	Yes
bidi supported	No

Environment

This property specifies the JD Edwards EnterpriseOne environment name.

Required	Yes
Default	No default value
Property type	String

Usage	A JD Edwards EnterpriseOne environment is a user-defined pointer that indicates the location of data and objects on a JD Edwards EnterpriseOne server. Users can be authorized to use multiple JD Edwards EnterpriseOne environments on a single JD Edwards EnterpriseOne server.
Example	
Globalized	Yes
bidi supported	Yes

Maximum number of records for RetrieveAll operation

This property specifies the maximum number of records to return for a RetrieveAll operation.

Required	Yes
Default	100
Usage	If the number of hits in the database exceeds the value of the `Maximum number of records` property, the adapter returns the errors MatchesExceededLimitException and MatchesExceededLimitFault. Use this property to avoid out-of-memory issues.
Property type	Integer
Globalized	No
bidi supported	No

Password

This property specifies the password of the adapter user account on the JD Edwards EnterpriseOne environment.

Required	Yes
Default	No default value
Property type	String
Usage	Passwords are created and named by the JD Edwards EnterpriseOne administrator. No restrictions exist for the type of characters used, the number of characters used, or the case of the characters used in passwords.
Example	
Globalized	No
bidi supported	Yes

Role

This property specifies the name of the role that is associated with the user name used to access the JD Edwards EnterpriseOne environment.

Required	Yes
Default	No default value
Property type	String

Usage	Roles define what authority users have. Users can have multiple roles. A user's access to applications, forms, table columns, data sources, and so on, is based on one or more roles to which the user is assigned. Roles are created and named by the JD Edwards EnterpriseOne administrator.
Examples	• System administrator • Human resources • Accounting
Globalized	No
bidi supported	Yes

User name

This property specifies the name of the adapter user account on the JD Edwards EnterpriseOne environment.

Required	Yes
Default	No default value
Property type	String
Usage	User names are created by the JD Edwards EnterpriseOne administrator. No restrictions exist for the type of characters used, the number of characters used, or the case of the characters used in user names.
Example	
Globalized	Yes
bidi supported	Yes

Validation properties

You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

Validation options are available on the following nodes:

Node type	Nodes with validation options
Input node	FileInput, FTEInput, HTTPInput, JMSInput, MQInput, SCAInput, , SOAPInput,TimeoutNotification,
Output node	FileOutput, FTEOutput, HTTPReply, JMSOutput, JMSReply, MQOutput, MQReply, SCAReply, SOAPReply
Other nodes	Compute, CICSRequest, DatabaseRetrieve, HTTPRequest, JavaCompute, Mapping, MQGet, ResetContentDescriptor, SCAAsyncResponse, SCARequest, SOAPRequest, SOAPAsyncResponse, Validate, XSLTransform

For an overview of message validation in the broker, refer to "Validating messages" on page 1478.

You can set the properties that are shown in the following table.

Tab	Properties that affect validation
Validation	Validate, Failure Action
Parser Options	Parse Timing

Validation tab properties:

Validate

Sets whether validation is required. All nodes provide the following options:

None The default value. No validation is performed.

Content
Indicates that you want to perform content checks, such as Content validation and Composition.

Content and Value
Indicates that you want to perform content checks, such as Content validation and Composition, and value checks, such as whether the value conforms to data type, length, range, and enumeration.

Note: Even if **`Content`** is selected, the SOAP and XMLNSC domains always perform **`Content and Value`** validation.

Some nodes also provide the following option:

Inherit

Instructs the node to use all the validation options that are provided with the input message tree in preference to any supplied on the node. Inherit therefore resolves to `None`, `Content`, or `Content And Value`. If Inherit is selected, the other validation properties on the tab are not available.

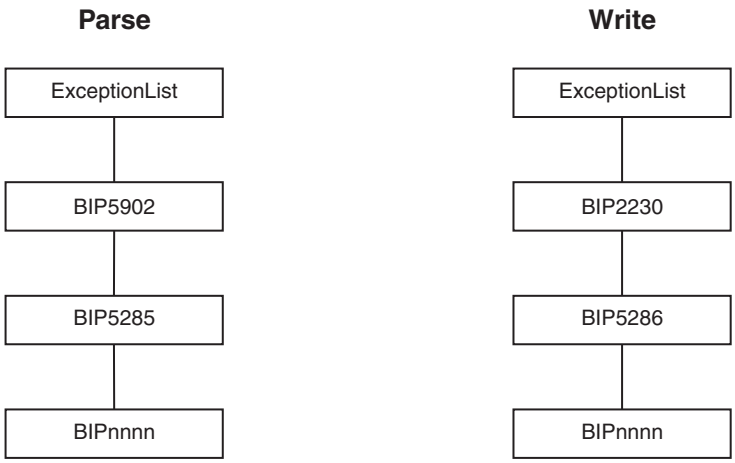
Failure Action

The action that you want to be taken when a validation failure occurs. You can set it to the following values:

Exception

The default value. An exception is thrown on the first validation failure encountered. The resulting exception list is shown below. The failure is also logged in the user trace if you have asked for user tracing of the message flow, and validation stops. Use this setting if you want processing of the message to halt as soon as a failure is encountered.

MRM and IDOC



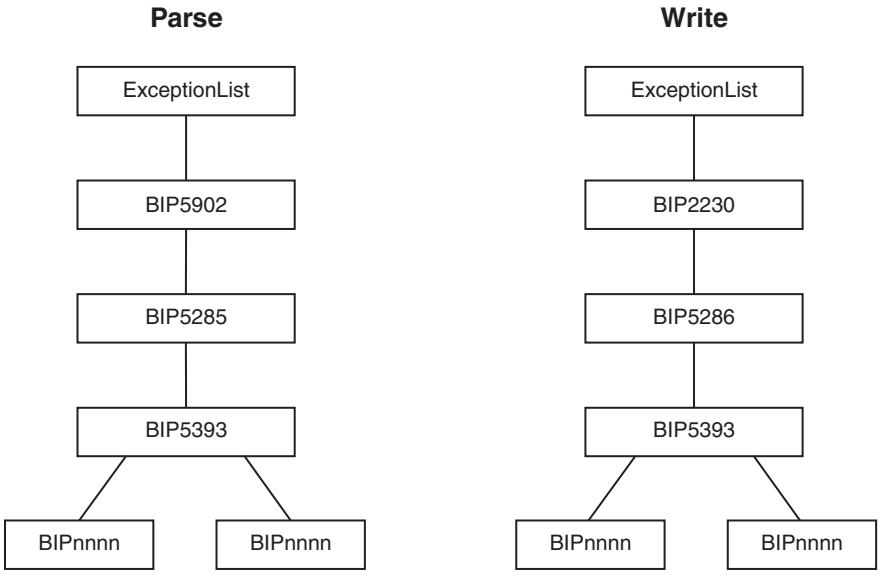
XMLNSC and SOAP

Exception List

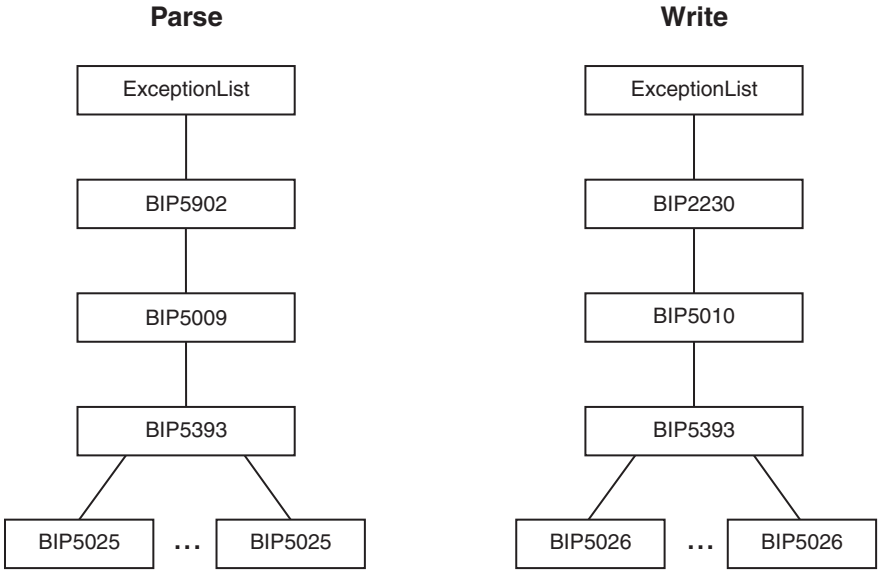
Throws an exception if validation failures are encountered, but only when the current parsing or writing operation has completed.

The resulting exception list is shown below. Each failure is also logged in the user trace if you have asked for user tracing of the message flow, and validation stops. Use this setting if you want processing of the message to halt if a validation failure occurs, but you want to see the full list of failures encountered. This property is affected by the Parse Timing property; when partial parsing is selected the current parsing operation parses only a portion of an input message, so only the validation failures in that portion of the message are reported.

MRM and IDOC



XMLNSC and SOAP



User Trace

Logs all validation failures to the user trace, even if you have not

asked for user tracing of the message flow. Use this setting if you want processing of the message to continue regardless of validation failures.

Local Error Log
Logs all validation failures to the error log (for example, the Event Log on Windows). Use this setting if you want processing of the message to continue regardless of validation failures.

Parser Options tab properties:

Parse Timing

The `Parse Timing` property determines whether on-demand parsing is to be used when parsing a message. It also gives you control over the timing of input message validation:

- If you select a Parse Timing value of `On Demand`, validation of a field in the message is delayed until it is parsed by on-demand parsing.
- If you select a Parse Timing value of `Immediate`, on-demand parsing is overridden, and everything in the message is parsed and validated except, if the message domain is MRM, those complex types with a Composition of Choice or Message that cannot be resolved at the time
- If you select a Parse Timing value of `Complete`, on-demand parsing is overridden, and everything is parsed and validated. If the message domain is MRM, complex types with a Composition of Choice or Message that cannot be resolved at the time cause a validation failure.

If you enable message validation, and you select `On Demand` or `Immediate` for Parse Timing, validation errors might not be detected until later in the processing of a message by a message flow, or might never be detected if a portion of the message is never parsed. To make sure that all fields in a message are validated, either select `Complete` or, if the message domain is MRM, select `Immediate` and make sure that you resolve all unresolved types with a Composition of Choice or Message at the start of your message flow.

The `Parse Timing` property does not affect the validation of output messages.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Parsers" on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

"MRM parser and domain" on page 1111
You can use the MRM domain to parse and write a wide range of message formats.

"SOAP parser and domain" on page 1082
You can use the SOAP parser to create a common WSDL-based logical tree format for working with Web services, independent of the physical bitstream format.

"XML parsers and domains" on page 1084
You can use XML domains to parse and write messages that conform to the W3C XML standard.

"XMLNSC parser" on page 1090
The XMLNSC parser is a flexible, general-purpose XML parser that offers high performance XML parsing and optional XML Schema validation.

Related tasks:

The broker provides validation based on the message model for predefined messages.

"Designing a message flow" on page 1455
A message flow can perform a wide range of operations, depending on your business and operational requirements. For best performance and capability, you must design it to include the most appropriate nodes.

"Creating a message flow" on page 1431
Create a message flow to specify how to process messages in the broker. You can create one or more message flows and deploy them to one or more brokers.

"Defining message flow content" on page 1488
You can define message flow content by adding and configuring message flow nodes and connecting them to form flows.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Parsing on demand

On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

An input message can be of any length. To improve performance of message flows, a message is parsed only when necessary to resolve the reference to a particular part of its content. If none of the message content is referenced within the message flow (for example, the entire message is stored in a database by the DataUpdate node, but no manipulation of the message content takes place), the message body is not parsed.

If a parser can parse an input bit stream on demand, instead of immediately parsing the entire bit stream, the Parse Timing property of a message flow node controls the on-demand behavior of the parser.

You can set the Parse Timing property to On Demand (the default), Immediate, or Complete.

On Demand causes partial parsing to occur. When fields in the message are referenced, as much of the message is parsed as is necessary to completely resolve the reference. Therefore, fields might not be parsed until late in the message flow, or never. This restriction applies to both the message body and the message headers.

Immediate and Complete both override partial parsing and parse the entire message, including any message headers, except when the MRM parser encounters an element with a complex type with Composition set to Choice or Message that cannot be resolved at the time; for example, the content must be resolved by the user in ESQL. If Composition is set to Choice, the data is added to the message tree as an unresolved item, and parsing continues with the next element. If

Composition is set to Message, parsing terminates at that point. The only difference in behavior between Immediate and Complete occurs when MRM validation is enabled.

The Parse Timing property also gives you control over how MRM message validation interacts with partial parsing. Refer to “Validation properties” on page 4169 for a full description.

The Parse Timing property has no effect on the serialization of output messages.

Related concepts:

“Parsers” on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

Impact analysis: reference

Some artifacts are excluded from secondary analysis.

Artifacts that are excluded from secondary analysis

The following artifacts are excluded from secondary analysis:

- Message set projects
- Message set folders
- Namespaces
- Message set file files
- Message set physical formats
- Message category files
- Adapter files (`.inadapter` and `.outadapter`)
- WebSphere Message Broker SCA definitions files (`.insca` and `.outsca`)
- Message flow projects
- WebSphere Message Broker schemas
- Message flow test files
- Data Design Projects
- DBM files
- Java projects
- Java artifacts
- BAR files

If you analyze the effect of renaming a local element or attribute, and that local element or attribute is used in an ESQL or mapping path, the path is not reported as a secondary impact.

ESQL paths

Only ESQL paths that start with one of the following identifiers are found as secondary impacts:

InputRoot

OutputRoot

Root

InputBody

Body

In other paths, such as paths that start with locally defined reference paths, the root element might not be identifiable (the reference is loosely typed). For example, you might have a complex type `PurchaseOrder` with attribute `address`. The reference path might be `ref.address`. If this path occurs in a routine, it cannot be identified that the attribute `address` is from `PurchaseOrder`, and the path cannot be indexed correctly.

One important result of this restriction is if there are any ESQL references to a message set artifact, and those references are within an ESQL routine that is not an ESQL Module, these references are not shown as secondary impacts. This is because message set artifact references satisfying this criteria cannot begin with one of the previously mentioned identifiers. Schema-scope routines have the advantage of being reusable, but there is a loss of impact analysis awareness associated with using message set artifact references within them.

For performance reasons, ESQL paths are indexed only as far as the first wildcard. For example, consider the following paths:

```
InputRoot.XMLNSC.a.b.*.d
InputRoot.XMLNSC.a.b.*
InputRoot.XMLNSC.a.b.*.e.*.f
```

If impact analysis is performed on artifacts `d`, `e`, or `f`, none of the preceding paths are reported as an impact. If artifacts `a` or `b` are analyzed, all three paths are reported as an impact.

Related concepts:

"Impact analysis: analyzing the effects of planned changes to your applications" on page 1150

The Impact Analysis view shows information about selected resources, which changes have been marked as complete, and previous results. You can also use this view to copy results to the clipboard.

Supported code pages

Application messages must conform to supported code pages.

The message flows that you create, configure, and deploy to a broker can process and construct application messages in any code page that is listed in the following tables. You can also generate a new code page converter.

This behavior might be affected by the use of other products with WebSphere Message Broker. Check the documentation for other products, including any databases that you use, for further code page support information.

If you experience code page translation problems on HP-UX, check the WebSphere MQ queue manager attribute *CodedCharSetID* (CCSID). The default value for this attribute is 1051. Change this attribute value to 819 for queue managers that host WebSphere Message Broker components.

When you handle UTF-16 data, CCSIDs 1200, 13488 and 17584 are treated differently to others. Traditionally, in ICU usage, the endian encoding of these CSSIDs was platform-specific, and WebSphere Message Broker uses an encoding parameter with these CSSIDs. You can specify the encoding parameter as MQENC_INTEGER_REVERSED to use these CCSIDs to explicitly produce little endian data.

For detailed information about Chinese code page GB18030 support, see "Chinese code page GB18030" on page 4221.

By default, WebSphere Message Broker supports the code pages that are given in the following tables. To find a code page for a specific CCSID, search for an internal converter name in the form `ibm-ccsid`, where *ccsid* is the CCSID for which you are looking.

WebSphere MQ Version 7 Information Center online

Chinese code page GB18030:

If you are working with messages in Chinese code page GB18030, your messages might be subject to some restrictions.

The broker can input, manipulate, and output application messages that are encoded in code page IBM-5488 (GB18030 support) with the following restrictions:

- If you configure a message flow to store GB18030 data in character form in a user database, ensure that the database manager that you are using supports GB18030.
- To enable support for GB18030 in the WebSphere Message Broker Toolkit:
  - If you run a WebSphere Message Broker Toolkit that requires GB18030 support on a computer that is running Windows 2003, apply the GB18030 patch supplied by Microsoft. This support is included in Windows XP.
  - Change the text font preference in the WebSphere Message Broker Toolkit to use GB18030:
    - Select **Window** > **Preferences**.
    - Expand the **Workbench** item in the left pane of the Preferences dialog (click the plus sign), and select **Fonts**.
    - In the Fonts window, select **Text Font**. Click **Change**, and select the correct values in the Fonts selection dialog box.
    - Click **OK** to confirm the selection and close the dialog box.
    - Click **Apply** to apply the change, then click **OK** to close the Preferences dialog box.

WebSphere MQ connections

The number of WebSphere MQ connections a broker requires to its queue manager depends on the actions of the message flows that access the WebSphere MQ resource.

For each broker flow that accesses a queue, one connection is required for every message flow thread. If a different node on the same thread uses the same queue manager, the same connection is used.

The number of queue handles required also depends on the behavior of the flow. For each flow that accesses queues, one queue handle is required for each unique queue name for every message flow thread. Nodes that access the same queue name in the same flow use the same queue handle.

When you start a broker, and while it is running, it opens WebSphere MQ queue handles. The broker caches these queue handles. For example, when a message flow node initiates access to the first WebSphere MQ resource it uses, it opens a connection for the queue manager and opens the queue. This connection is opened

the first time that a message is processed by that message flow node. For MQInput nodes, the connection is opened when the flow is started. This queue handle remains open until:

The message flow becomes idle, and has not been used for 1 minute

The execution group is stopped

The broker is stopped

The queue handle for the input node is not released when the flow is idle. The queue handle is released only when you stop the message flow.

A thread performing WebSphere MQ work becomes idle when it has not received any messages on its input queue for 1 minute. The allowed idle time starts from when the input queue being read becomes empty. If a message flow gets a message from the input queue, the timer is reset.

When a message flow is idle, the execution group periodically releases WebSphere MQ queue handles. Therefore, connections held by the broker reflect its current use of these resources.

Related concepts:

"User database connections" on page 2110
User databases contain business data that is written and accessed by deployed message flows. You must create connections from the broker to the user database by using ODBC or JDBC.

Data integrity in message flows

Code pages in which data is manipulated must be compatible between brokers and databases that are accessed by those brokers.

Subscription data that is retrieved from client applications (for example, topics from publishers and subscribers, and content filters from subscribers), and the character data entered through the WebSphere Message Broker Toolkit (for example, message flow names), are stored by the broker. This data is translated from its originating code page to the code page of the process in which the broker is running, then by the database manager to the code page in which the database or databases were created.

To preserve data consistency and integrity, ensure that all this subscription data and WebSphere Message Broker Toolkit character data is originated in a compatible code page to the two code pages to which it is translated. If you do not do so, you might get unpredictable results and lose data.

The restrictions described do not apply to user data in messages. Ensure that any data in messages generated by your applications is compatible with the code page of all databases that you access from your message flows.

SQL statements that are generated as a result of explicit reference to databases in message processing nodes can contain character data that has a variety of sources. For example, the data might have been entered through the WebSphere Message

Broker Toolkit, derived from message content, or read from another database. All this data is translated from its originating code page to the code page in which the broker was created, then by the database manager to the code page in which the database was created. Ensure that these three code pages are compatible to avoid data conversion problems.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Message flow transactions" on page 1281
A transaction describes a set of updates that are made by an application program, which must be managed together. The updates might be made to one or more systems. The updates made by the program are controlled by the environment in which the program executes, and either all are completed, or none. This property of a transaction is known as *consistency*: transactions might have other properties of *atomicity*, *isolation*, and *durability*.

Related tasks:

"Creating a message flow" on page 1431
Create a message flow to specify how to process messages in the broker. You can create one or more message flows and deploy them to one or more brokers.

"Defining message flow content" on page 1488
You can define message flow content by adding and configuring message flow nodes and connecting them to form flows.

"Configuring transactionality for message flows" on page 1290
A message flow runs in a single transaction, which is started when data is received by an input node, and can be committed or rolled back when all processing has completed.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

"Database connections for coordinated message flows" on page 4235
When you configure a message flow to access a database, the broker establishes a connection to that database based on the ODBC DSN.

"Database support for coordinated message flows" on page 4236
If the message flow processing includes interaction with an external database, you can coordinate the transaction by using XA technology.

Exception list structure

An exception list contains information about exceptions, such as error numbers, the name of the node that generated the exception, and the reason for the exception.

The following figure shows one way in which to construct an exception list.

```
ExceptionList {
    RecoverableException = {                 1
        File     = 'f:/build/argo/src/DataFlowEngine/ImbDataFlowNode.cpp'
        Line     = 538
        Function = 'ImbDataFlowNode::createExceptionList'
        Type     = 'ComIbmComputeNode'
        Name     = '0e416632-de00-0000-0080-bdb4d59524d5'
        Label    = 'mf1.Compute1'
        Text     = 'Node throwing exception'
        Catalog  = 'WebSphere Message
Broker2'
        Severity = 3
```

```
        Number   = 2230
        RecoverableException = {               2
            File     = 'f:/build/argo/src/DataFlowEngine/ImbRdlBinaryExpression.cpp'
            Line     = 231
            Function = 'ImbRdlBinaryExpression::scalarEvaluate'
            Type     = 'ComIbmComputeNode'
            Name     = '0e416632-de00-0000-0080-bdb4d59524d5'
            Label    = 'mf1.Compute1'
            Text     = 'error evaluating expression'
            Catalog  = 'WebSphere Message
Broker2'
            Severity = 2
            Number   = 2439
            Insert   = {
               Type = 2
               Text = '2'
            }
            Insert   = {
               Type = 2
               Text = '30'
            }
            RecoverableException = {             3
                File     = 'f:/build/argo/src/DataFlowEngine/ImbRdlValueOperations.cpp'
                Line     = 257
                Function = 'intDivideInt'
                Type     = 'ComIbmComputeNode'
                Name     = '0e416632-de00-0000-0080-bdb4d59524d5'
                Label    = 'mf1.Compute1'
                Text     = 'Divide by zero calculating '%1 / %2''
                Catalog  = 'WebSphere Message
Broker2'
                Severity = 2
                Number   = 2450
                Insert   = }
                   Type = 5
                   Text = '100 / 0'
                }
            }
        }
    }
}
```

Notes:

1. The first exception description 1 is a child of the root. This identifies error number 2230, indicating that an exception has been thrown. The node that has thrown the exception is also identified (*mf1.Compute1*).
2. Exception description 2 is a child of the first exception description 1. This identifies error number 2439.
3. Exception description 3 is a child of the second exception description 2. This identifies error number 2450, which indicates that the node has attempted to divide by zero.

The following topics provide examples of exception lists that have been written to the trace output destination (by the Trace node):

- "Database exception trace output" on page 4226
- "Conversion exception trace output" on page 4228
- "Parser exception trace output" on page 4230

Message flow porting

If you have configured a message flow that runs on a broker on a distributed system, and you now want to deploy it to a broker that runs on z/OS, you might have to take additional actions to port the flow successfully.

Consider the following resources and attributes:

WebSphere MQ queue manager and queue names

WebSphere MQ imposes some restrictions for resource names on z/OS:

- The queue manager name cannot be greater than four characters.
- All queue names must be in uppercase. Although using quotation marks preserves the case, certain WebSphere MQ activities on z/OS cannot find the queue names being referenced.

For more information about configuring on z/OS, refer to the *Concepts and Planning Guide* section of the WebSphere MQ Version 7 Information Center online

File system references

File system references must reflect a UNIX file path. If you deploy a

message flow to z/OS that you have previously run on Windows, you might have to make changes. If you have previously deployed the message flow to a UNIX system (AIX, Linux, Solaris, or HP-UX), you do not have to make any changes.

Databases
If the message flow accesses one or more databases, it might be subject to some restrictions based on the system on which the database is defined. These restrictions are described in "Database locations" on page 3595.

Related concepts:

"Message flows overview" on page 1022

Coordinated message flows

A coordinated message flow runs in a single transaction, which is started when a message is received by an input node, and can be committed or rolled back when all processing has completed.

The following topics provide reference information for database use in coordinated message flows:

- "Database connections for coordinated message flows" on page 4235
- "Database support for coordinated message flows" on page 4236

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an

input message is received.

"Message flow transactions" on page 1281
A transaction describes a set of updates that are made by an application program, which must be managed together. The updates might be made to one or more systems. The updates made by the program are controlled by the environment in which the program executes, and either all are completed, or none. This property of a transaction is known as *consistency*: transactions might have other properties of *atomicity*, *isolation*, and *durability*.

Related tasks:

"Creating a message flow" on page 1431

"Defining message flow content" on page 1488
You can define message flow content by adding and configuring message flow nodes and connecting them to form flows.

"Configuring transactionality for message flows" on page 1290
A message flow runs in a single transaction, which is started when data is received by an input node, and can be committed or rolled back when all processing has completed.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Database connections for coordinated message flows:

When you configure a message flow to access a database, the broker establishes a connection to that database based on the ODBC DSN.

When you configure a message flow to access a database, the broker establishes a connection to that database based on the ODBC or JDBC DSN. To coordinate the database updates with other updates (determined by the configuration you have set for each node that accesses a database), the broker makes a connection for each transaction mode for each DSN accessed on each message flow thread.

Therefore, if you set the `Transaction Mode` property for one node in the message flow to Automatic, and for another node to Commit, the broker establishes two separate connections to this DSN from the same thread. Take this action into account when you calculate the number of connections required between a broker and a specific DSN.

For further information about connections made by the broker to user databases, see "User database connections" on page 2110.

For details of these connections, refer to "Enabling ODBC connections to the databases" on page 668 and "Enabling JDBC connections to the databases" on page 683.

Related concepts:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Database support for coordinated message flows:

If the message flow processing includes interaction with an external database, you can coordinate the transaction by using XA technology.

XA coordination ensures that all participants update or return to a consistent state. This external coordination support is provided by the underlying WebSphere MQ facilities on distributed systems, and by Resource Recovery Services (RRS) on z/OS.

The following databases provide the correct level of XA support for coordinating message flows on distributed systems:

- DB2
- Oracle
- Sybase

On z/OS, database support for coordinated message flows is provided by DB2 only.

Element definitions for message parsers

The topics in this section discuss data types for the WebSphere MQ headers, and define the element names, types, and attributes for each of the supported headers:

For each parser, the following terms are defined:

- Root element name: the name of the syntax element created by the parser at the root of its own part of the tree.
- Class name: the name by which the parser defines itself to WebSphere Message Broker.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Data types for elements in the MQ DestinationData subtree"
The DestinationData subtree is part of the Destination subtree in the local environment. Local environment trees are created by input nodes when they receive a message and, optionally, by Compute nodes. When created, the trees are empty but you can create data in them by using ESQL statements coded in any of the SQL nodes.

"Data types for elements in an MRM message" on page 6254
A parser is supplied for the body of a message in the MRM domain; it associates each field with a specific data type.

"Data types for an unstructured (BLOB) message" on page 4244
A parser is supplied for the body of a message in the BLOB domain; it associates each field with a specific data type.

Data types for elements in the MQ DestinationData subtree:

The DestinationData subtree is part of the Destination subtree in the local environment. Local environment trees are created by input nodes when they receive a message and, optionally, by Compute nodes. When created, the trees are empty but you can create data in them by using ESQL statements coded in any of the SQL nodes.

The Destination subtree consists of subtrees for zero or more protocols; for example, WebSphere MQ and WebSphere MQ Everyplace, or a subtree for routing destinations (RouterList), or both.

The protocol tree has two children:

- Defaults is the first element; there can be only one.

- DestinationData is the following element, and can be repeated any number of times, to represent each destination to which a message is sent.

"Local environment tree structure" on page 1056 includes a picture of a typical tree, showing a Destination tree that has both protocol and RouterList subtrees.

The structure of data within the DestinationData folder is the same as that in Defaults for the same protocol, and can be used to override the default values in Defaults. You can therefore set up Defaults to contain values that are common to all destinations, and set only the unique values in each DestinationData subtree. If a value is set neither in DestinationData, nor in Defaults, the value that you have set for the corresponding node property is used.

The fields, data type, and valid values for each element of Defaults and DestinationData subtrees for WebSphere MQ are shown in the following table. "MQOutput node" on page 4612 describes the corresponding node properties.

Refer to "Accessing the local environment tree" on page 2463 for information about using DestinationData.

Data type of the element	Represented as	Corresponding node property	Valid values
queueManagerName	CHARACTER	Queue Manager Name	
queueName	CHARACTER	Queue Name	
transactionMode	CHARACTER	Transaction Mode	no, yes, automatic
persistenceMode	CHARACTER	Persistence Mode	no, yes, automatic, asQdef
newMsgId	CHARACTER	New Message ID	no, yes
newCorrelId	CHARACTER	New Correlation ID	no, yes
segmentationAllowed	CHARACTER	Segmentation Allowed	no, yes
alternateUserAuthority	CHARACTER	Alternate User Authority	no, yes
replyToQMgr	CHARACTER	Reply-to queue manager	
replyToQ	CHARACTER	Reply-to queue	

Case-sensitivity for data types and values

When you create these fields in the DestinationData folder, enter the data type and value exactly as shown in the table. If any variations in spelling or case are used, these fields or values are ignored in the DestinationData records and the next available value is used.

For example, the following ESQL samples could result in unexpected output:

```
SET OutputLocalEnvironment.Destination.MQ.DestinationData[1].persistenceMode = 'YES';
SET OutputLocalEnvironment.Destination.MQ.DestinationData[2].PersistenceMode = 'yes';
```

In each case, the DestinationData folder might not write a persistent message for these destinations. In the first example, the persistenceMode field has been given a value of 'YES', which is not one of the valid values listed in the table, and this value is ignored. In the second example, the field named 'PersistenceMode' is specified incorrectly and is ignored. Either the persistenceMode value of the Defaults folder, or the value of the associated attribute on the MQOutput node are used. If this behavior causes a value of 'no' or 'automatic' to be used, a persistent message is not written.

If a DestinationData folder is producing unexpected output, check that you have used the correct case and spelling in the fields and values.

A parser is supplied for the body of a message in the BLOB domain; it associates each field with a specific data type.

Using LocalEnvironment variables with JMSOutput and JMSReply nodes:

The LocalEnvironment data elements related to the processing of JMS Messages in the JMSOutput and JMSReply nodes.

LocalEnvironment.WrittenDestination.JMS.DestinationData fields

The DestinationData element is a data structure created by the JMSOutput and JMSReply nodes for each message that is sent to a JMS Queue or published to a JMS Topic when:

- The Out terminal of the node is connected to another node in the message flow
- An output message callback routine has been enabled for the message flow. See "cciOutputMessageCallback" on page 6626.

The fields in the DestinationData structure are described in the following table, and can be used by a receiving application, or an output message callback routine, to link request messages with reply messages:

Element name	Element Data Type	Description
destinationName	CHARACTER	The name of the JMS Queue to which the node sends an outgoing message or the JMS Topic to which the node publishes. This value can specified in these formats: • a JNDI administered object (predefined in the JNDI bindings specified in the `Location JNDI bindings` node property). In which case the format of the value is `jndi://<JNDI Object name>` • a character string that represents the JMS Destination name in an internal format that recognized by that particular JMS provider. For example, when using WebSphere MQ as the JMS provider a JMS Queue Destination would be represented by the character string `queue://<queue manager>/<queue name>`
initialContext	CHARACTER	The Java Class name of the Initial Context Factory for the JMS provider that the JMSOutput or JMSReply node connects to.
JMSMessageID	CHARACTER	A JMS message ID is the value assigned by a JMS Provider when a message is sent to a JMS Queue or published to a JMS Topic. This value is retrieved from the JMS Message object after the message is sent or published.
JMSCorrelationID	CHARACTER	The JMS Message header property called JMSCorrelationID can be used to hold a value referencing some external information to be used for linking request with reply messages. When creating the DestinationData element in the LocalEnvironment this correlation ID value is obtained from the JMSCorrelationID message tree field in the folder OutputRoot.JMSTransport.Transport_Folders. Header_Values.

LocalEnvironment.Destination.JMSDestinationList fields

Transformation nodes can write data elements called DestinationData[n] in the LocalEnvironment folder called Destination.JMSDestinationList. The DestinationData elements are written with an array subscript format where the subscript is an integer that identifies an individual element in the destination list.

A JMSOutput node searches for DestinationData[n] entries in the LocalEnvironment if it has been configured to send to a destination list. The node sends an output message to each entry found in the destination list. The following table describes the format of a DestinationData element.

Element name	Element Data Type	Description
DestinationData	CHARACTER	The name of the JMS Queue to which the node sends an outgoing message or the JMS Topic to which the node publishes. This value can specified in the following formats: • A JNDI administered object (predefined in the JNDI bindings specified in the `Location JNDI bindings` node property). In this case, the format of the value is `jndi://<JNDI Object name>` • A character string that represents the JMS Destination name in an internal format that is recognized by that particular JMS provider. For example, when using WebSphere MQ as the JMS provider, a JMS Queue Destination is represented by the character string `queue://<queue manager>/<queue name>` • A complex element with DestinationName and DestinationType child elements that specify the name and type of the JMS Destination.
DestinationData.DestinationName	CHARACTER	A character string that represents the name of the JMS destination in an external format that is recognized by the JMS provider. If this field is specified, you must set the DestinationType field.
DestinationData.DestinationType	CHARACTER	The type of the JMS destination referred to in the DestinationName element. If the DestinationType field is set, you must set the DestinationName field. Set the DestinationType field to `Queue` or `Topic`.

Data types for an unstructured (BLOB) message:

A parser is supplied for the body of a message in the BLOB domain; it associates each field with a specific data type.

An unstructured (BLOB) message has the data types shown in the following table.

Data type of the element	Represented as
BLOB	BLOB
UnknownParserName	CHARACTER

If the broker cannot find a parser that corresponds to the domain that is requested by the user, the message is assigned to the BLOB parser, and the requested domain is preserved in the *UnknownParserName* field. If a BLOB parser is explicitly created, the UnknownParserName field is still present. It can contain the values of "BLOB" or "none" or can be the zero length string ("").

This information is used by the header integrity routine (described in “Parsers” on page 1072) to ensure that the semantic meaning of the message is preserved.

Related concepts:

“Parsers” on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

The MQMD parser:

The elements of the MQMD parser are listed in this topic.

The root name for this parser is MQMD. The class name is MQHMD.

The following table lists the orphan elements adopted by the MQMD header.

Element Name	Element Data Type	Element Attributes
SourceQueue	CHARACTER	Name Value
Transactional	BOOLEAN	Name Value

The following table lists the elements native to the MQMD header.

Element Name	Element Data Type	Element Attributes
Format	CHARACTER	Name Value
Version	INTEGER	Name Value
Report	INTEGER	Name Value
MsgType	INTEGER	Name Value
Expiry[1]	INTEGER/GMTTIMESTAMP	Name Value
Feedback	INTEGER	Name Value
Encoding	INTEGER	Name Value
CodedCharSetId	INTEGER	Name Value
Priority	INTEGER	Name Value
Persistence	INTEGER	Name Value
MsgId	BLOB	Name Value
CorrelId	BLOB	Name Value
BackoutCount	INTEGER	Name Value
ReplyToQ	CHARACTER	Name Value
ReplyToQMgr	CHARACTER	Name Value
UserIdentifier	CHARACTER	Name Value
AccountingToken	BLOB	Name Value
ApplIdentityData	CHARACTER	Name Value
PutApplType	INTEGER	Name Value
PutApplName	CHARACTER	Name Value
PutDate	TIMESTAMP/CHARACTER	Name Value
PutTime	TIMESTAMP/CHARACTER	Name Value
ApplOriginData	CHARACTER	Name Value
GroupId	BLOB	Name Value
MsgSeqNumber	INTEGER	Name Value
Offset	INTEGER	Name Value
MsgFlags	INTEGER	Name Value
OriginalLength	INTEGER	Name Value

Note:

1. The Expiry field in the MQMD is a special case:
   - An INTEGER value represents an expiry interval in tenths of a second. If the Expiry field is set to -1, it represents an unlimited expiry interval (that is, the message never expires) If the Expiry field is a positive INTEGER, it represents an expiry interval of that number of tenths of a second (for example, if it is set to 4, it represents 4 tenths of a second, if it is set to 15, it represents one and a half seconds).
   - A GMTTIMESTAMP value represents a specific expiration time.

   If Expiry contains a GMTTIMESTAMP in the past, or an INTEGER of less than 1 (excluding -1), it is set to the value 1 (one tenth of a second, the minimum value).

XML constructs

A self-defining XML message carries the information about its content and structure within the message in the form of a document that adheres to the XML specification. Its definition is not held anywhere else.

When the broker receives an XML message, it interprets the message using the generic XML parser, and created an internal message tree structure according to the XML definitions contained within that message.

A self-defining message is also known as a generic XML message. It does not have a recorded format.

The information provided with WebSphere Message Broker does not provide a full definition or description of XML terminology, concepts, and message constructs: it is a summary that highlights aspects that are important when you use XML messages with brokers and message flows.

For further information about XML, see the developerWorks Web site.

Example XML message:
The name elements used in this description (for example, XmlDecl) are provided by WebSphere Message Broker, and are referred to as field type constants. They are available for symbolic use within the ESQL that defines the processing of message content performed by the nodes, such as a Filter node, within a message flow. They are not part of the XML specification.

A simple XML message might take the form:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE s1 PUBLIC "http://www.ibm.com/example.dtd" "example.dtd">
<s1>.........</s1>
```

The corresponding syntax element tree (top level elements only) is shown in the following diagram:

The WhiteSpace elements within the tree are there because of the line breaks in the original XML document, and have no business meaning. White space is used in XML for readability; if you process XML messages that contain line breaks (as shown above), blanks lines, or spaces between tags, these all appear as elements in the message tree.

WhiteSpace within an XML element (between start and end tags) has business meaning and is represented using the Content syntax element. See "XML WhiteSpace and DocTypeWhiteSpace" on page 4287 for more information.

The field type constants for XML name elements (for example, Element and XmlDecl) equate to a constant value of the form `0x01000000`. You can see these constants in the output created by the Trace node when a message, or a portion of the message, is traced.

Related concepts:

"Correlation names" on page 1069
A correlation name is a field reference that identifies a well-defined starting point in the logical message tree and is used in field references to describe a standard part of the tree format.

Every XML message must have a body. The body comprises a top-level XML element that contains all the message data.

"XML document type declaration" on page 4271
The document type declaration (DTD) of an XML message is represented by a syntax element of type DocTypeDecl and its children and descendants. These comprise the DOCTYPE construct.

"XML DocTypeDecl" on page 4272
The DocTypeDecl represents the DOCTYPE declaration.

The XML declaration:

The beginning of an XML message can contain an XML declaration.

The following is an example of a declaration:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE s1 PUBLIC "http://www.ibm.com/example.dtd" "example.dtd">
<s1>.........</s1>
```

The XML declaration includes the following field type constants:

- "XML encoding" on page 4259
- "XML standalone" on page 4259
- "XML version" on page 4260
- "XMLDecl" on page 4261

"XML declaration example" on page 4261 includes another example of an XML declaration and the tree structure it forms.

Related concepts:

The MRM XML physical format describes the physical representation of an XML message for use by the MRM parser.

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

"Manipulating messages in the XML domains" on page 2535
You can manipulate messages in the XML, XMLNS, and XMLNSC domains.

"Adding an XML wire format" on page 2853
You can add an XML wire format physical format layer to a message set by using the Message Set editor.

Related reference:

"XML declaration example" on page 4261
The following example shows an XML declaration in an XML document.

"XML document type declaration" on page 4271
The document type declaration (DTD) of an XML message is represented by a syntax element of type DocTypeDecl and its children and descendants. These comprise the DOCTYPE construct.

XML encoding:

The encoding element is a value element and is always a child of the XmlDecl element.

The value of the encoding element is a string that corresponds to the value of the encoding string in the declaration. In the following example, the encoding element has a value of `UTF-8`.

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE s1 PUBLIC "http://www.ibm.com/example.dtd" "example.dtd">
<s1>.........</s1>
```

You cannot specify WebSphere MQ encodings in this element.

Related concepts:

"MRM XML physical format" on page 1247
The MRM XML physical format describes the physical representation of an XML message for use by the MRM parser.

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

"Manipulating messages in the XML domains" on page 2535
You can manipulate messages in the XML, XMLNS, and XMLNSC domains.

"Adding an XML wire format" on page 2853
You can add an XML wire format physical format layer to a message set by using the Message Set editor.

XML standalone:

The XML standalone element defines the existence of an externally-defined DTD.

It is a value element and stores the data corresponding to the value of the standalone string in the declaration. It is always a child of the XmlDecl element. Valid values for the standalone element are `yes` and `no`. The following is an example of this:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE s1 PUBLIC "http://www.ibm.com/example.dtd" "example.dtd">
<s1>.........</s1>
```

A value of `no` indicates that this XML document is not standalone and depends on an externally-defined DTD. A value of `yes` indicates that the XML document is self-contained. However, the current release of WebSphere Message Broker does not resolve externally-defined DTDs, so the setting of standalone is irrelevant and is ignored.

Related concepts:

"MRM XML physical format" on page 1247
The MRM XML physical format describes the physical representation of an XML message for use by the MRM parser.

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

You can add an XML wire format physical format layer to a message set by using the Message Set editor.

"Manipulating messages in the XML domains" on page 2535
You can manipulate messages in the XML, XMLNS, and XMLNSC domains.

XML version:

The XML version element is a value element and stores the data corresponding to the version string in the declaration.

It is always a child of the XmlDecl element. In the following example, the version element contains the string value `1.0`:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE s1 PUBLIC "http://www.ibm.com/example.dtd" "example.dtd">
<s1>.........</s1>
```

Related concepts:

"Adding an XML wire format" on page 2853
You can add an XML wire format physical format layer to a message set by using the Message Set editor.

XMLDecl:

XMLDecl is a name element that corresponds to the XML declaration itself.

The XmlDecl element is a child of the XML parser and is written first to a bit stream. Although the XMLDecl element is a named element, its name has no relevance. The following shows an example:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE s1 PUBLIC "http://www.ibm.com/example.dtd" "example.dtd">
<s1>.........</s1>
```

Related reference:

"The XML declaration" on page 4258
The beginning of an XML message can contain an XML declaration.

The XML message body:

Every XML message must have a body. The body comprises a top-level XML element that contains all the message data.

The body contains complex XML markup, which translates to many syntax element types in the parsed tree. Each syntax element type is introduced here, with a series of example XML fragments.

The following common element types are discussed:
- "XML element" on page 4267
- "XML attribute" on page 4264
- "XML content" on page 4267

"XML message body example: elements, attributes, and content" on page 4269 provides an example of an XML message body and the tree structure that is created from it using the syntax elements types listed above.

More complex XML messages might use some of the following syntax element types:
- "XML CDataSection" on page 4265
- "XML EntityReferenceStart and EntityReferenceEnd" on page 4268
- "XML comment" on page 4266
- "XML ProcessingInstruction" on page 4270
- "XML AsisElementContent" on page 4263
- "XML BitStream" on page 4264

Related concepts:

Related reference:

"XML declaration example" on page 4261
The following example shows an XML declaration in an XML document.

"XML document type declaration" on page 4271
The document type declaration (DTD) of an XML message is represented by a syntax element of type DocTypeDecl and its children and descendants. These comprise the DOCTYPE construct.

XML AsisElementContent:

AsisElementContent is a special value syntax element that is used to precisely control generated XML.

The AsisElementContent syntax element is a special value element. The element is used to precisely control the XML generated in an output message without the safeguards of the Element, Attribute, and Content syntax elements. If you use AsisElementContent, you must ensure that the output message is well-formed XML.

You might choose to use this syntax element if, for example, you want to suppress the usual behavior in which occurrences of ampersand (&), less than (<), greater than (>), quotation mark ("), and apostrophe (') are replaced by the predefined XML entities `&`, `<`, `>`, `&quot;`, and `&apos;`.

The following example illustrates the use of AsisElementContent. The statement:

```
Set OutputRoot.XMLNS.(XML.Element)Message.(XML.Content) = '<rawMarkup>';
```

generates the following XML in an output message:

```
<Message>&lt;rawMarkup&gt;</Message>
```

However, the following statement:

```
Set OutputRoot.XMLNS.(XML.Element)Message.(XML.AsisElementContent) = '<rawMarkup>';
```

generates the following output message:

```
<Message><rawMarkup></Message>
```

These examples show that the value of an AsisElementContent syntax element is not modified before it is written to the output message.

"XML comment" on page 4266
An XML comment encountered outside the document type declaration is represented by the Comment value syntax element. It contains the comment text from the XML message.

"XML ProcessingInstruction" on page 4270
ProcessingInstruction is a syntax element used with XML processing instructions.

"XML BitStream"
BitStream is a specialized name-value element designed to aid the processing of very large messages.

XML attribute:
This syntax element is the default name-value element supported by the XML parser. Use it to represent the attributes that are associated with its parent element. The name and value of the syntax element correspond to the name and value of the attribute that is being represented. Attribute elements have no children, and must always be children of an element.

When attributes are written to a message, occurrences of ampersand (&), less than (<), greater than (>), double quotation mark ("), and apostrophe (') within the attribute value are replaced by the predefined XML entities `&`, `<`, `>`, `&quot;`, and `&apos;`.

The `attr` element is also supported for compatibility with earlier versions of the product.

The XML document contains elements, attributes, and content.

XML BitStream:

BitStream is a specialized name-value element designed to aid the processing of very large messages.

The XML BitStream syntax element is a name-value element. When writing an XML message, the value of the BitStream element is written directly into the message, and the name is not important. The BitStream element might be the only element in the message tree.

The value of the element must be of type BLOB; any other data type generates an error while writing the element. Ensure that the content of the element is appropriate for use in the output message.

Use of the BitStream element is similar to the AsisElementContent element, except that the AsisElementContent type converts its value into a string, whereas the BitStream element uses its BLOB value directly. This is a specialized element designed to aid processing of very large messages.

The following ESQL excerpts demonstrate a typical use for this element. First, declare the element:

```
DECLARE StatementBitStream BLOB
```

Initialize the contents of StatementBitStream from an appropriate source, such as an input message. If the source field is not of type BLOB, use the CAST statement to convert the contents to BLOB. Then create the new field in the output message, for example:

```
CREATE LASTCHILD OF resultCursor
 Type XML.BitStream
 NAME 'StatementBitStream'
 VALUE StatementBitstream;
```

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

AsisElementContent is a special value syntax element that is used to precisely control generated XML.

"XML element" on page 4267

"XML attribute" on page 4264

"XML content" on page 4267
The content element represents character data that occurs in the XML message.

"XML comment" on page 4266
An XML comment encountered outside the document type declaration is represented by the Comment value syntax element. It contains the comment text from the XML message.

"CAST function" on page 5245

"XML message body example: elements, attributes, and content" on page 4269
The XML document contains elements, attributes, and content.

XML CDataSection:

The CDataSection value element represents CData sections in the XML message.

The content of the CDataSection element is the value of the CDataSection element without the `<![CDATA[` that marks its beginning and the]]> that marks its end.

For example, the following Cdata section:

```
<![CDATA[<greeting>Hello, world!</greeting>]]>
```

is represented by a CDataSection element with a string value of:

```
"<greeting>Hello, world!</greeting>"
```

Unlike Content, occurrences of <,>, &, ", and ' are not translated to their escape sequences when the CDataSection is written out to a serialized message (bit stream).

Related concepts:

Every XML message must have a body. The body comprises a top-level XML element that contains all the message data.

"XML message body example: elements, attributes, and content" on page 4269
The XML document contains elements, attributes, and content.

"XML document type declaration" on page 4271
The document type declaration (DTD) of an XML message is represented by a syntax element of type DocTypeDecl and its children and descendants. These comprise the DOCTYPE construct.

XML content:

The content element represents character data that occurs in the XML message.

This syntax element is the default value element supported by the XML parser. Use content to represent character data (including white space characters) that is part of the element content. There might be many content elements as children of a single element, in which case they are separated by other syntax element types such as nested elements or attributes.

When content is written to a message, occurrences of ampersand (&), less than (<), greater than (>), double quotation mark ("), and apostrophe (') are replaced by the predefined XML entities `&`, `<`, `>`, `&quot;`, and `&apos;`.

The pcdata element is also supported for compatibility with earlier versions of the product.

Related concepts:

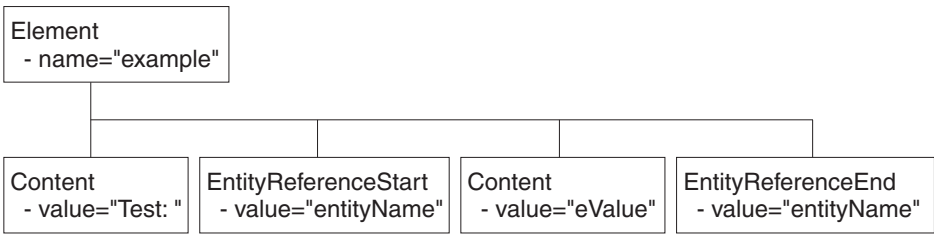
XML EntityReferenceStart and EntityReferenceEnd:

The EntityReferenceStart and EntityReferenceEnd elements are used to store entity references that occur in the XML message.

When an entity reference is encountered in the XML message, both the expanded form and the original entity name are stored in the syntax element tree. The name of the entity is stored as the value of the EntityReferenceStart and EntityReferenceEnd syntax elements, and any syntax elements between contain the entity expansion.

The following examples show the XML entity references in an XML document and in tree structure form:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<!DOCTYPE example [ <!ENTITY entityName "eValue"> ]>
<example>Test: &entityName;</example>
```



The XML declaration and the document type declaration are not shown here. Refer to “The XML declaration” on page 4258 and “XML document type declaration” on page 4271 for details of those sections of the syntax element tree.

"XML content" on page 4267
The content element represents character data that occurs in the XML message.

XML ProcessingInstruction:

ProcessingInstruction is a syntax element used with XML processing instructions.

An XML processing instruction, encountered outside the document type declaration, is represented by the ProcessingInstruction syntax element. This is a name-value element; the name of the syntax element is the processing instruction target name, and the value of the syntax element is the character data of the processing instruction. The value of the syntax element must not be empty. The name cannot be XML in either uppercase or lowercase.

If the value of the element contains the character sequence ?>, the sequence is replaced with the text ?>. This ensures that the content of the processing instruction cannot prematurely end the processing instruction. Occurrences of <,>, &, ", and ' are not translated to their escape sequences.

Examples of the XML ProcessingInstruction in an XML document and in tree structure form are shown in the following:

```
<example><?target This is a PI.?></example>
```

AsisElementContent is a special value syntax element that is used to precisely control generated XML.

"XML BitStream" on page 4264
BitStream is a specialized name-value element designed to aid the processing of very large messages.

XML document type declaration:

The document type declaration (DTD) of an XML message is represented by a syntax element of type DocTypeDecl and its children and descendants. These comprise the DOCTYPE construct.

Only internal (inline) DTD subsets are represented in the syntax element tree. An inline DTD is a DTD that is declared within the XML document itself. It can be a complete DTD definition, or can extend the definition in an external DTD.

External DTD subsets (identified by the SystemID or PublicId elements described later in this section) can be referenced in the message, but those referenced are not resolved by the broker.

Field type constants are defined by WebSphere Message Broker:
- DocTypeDecl
- NotationDecl
- Entities
- ElementDef
- AttributeList
- AttributeDef
- DocTypePI
- WhiteSpace and DocTypeWhiteSpace
- DocTypeComment

DTD example is an example of an XML DTD.

The ElementDef element represents the <!ELEMENT construct in a DTD.

"XML AttributeList" on page 4281
The AttributeList name element represents the <!ATTLIST construct in a DTD.

"XML AttributeDef" on page 4282
The AttributeDef name element describes the definition of an attribute within an <!ATTLIST construct.

"XML DocTypePI" on page 4286
The DocTypePI element represents a processing instruction found within the DTD.

"XML WhiteSpace and DocTypeWhiteSpace" on page 4287
The WhiteSpace and DocTypeWhiteSpace XML elements represent white space characters in the message.

"XML DocTypeComment" on page 4286
Comments in the XML DTD are represented by the DocTypeComment element.

"XML DTD example" on page 4288

XML DocTypeDecl:

The DocTypeDecl represents the DOCTYPE declaration.

DocTypeDecl is a named element and is a child of the XML parser. DocTypeDecl is written to the bit stream before the element that represents the body of the document during serialization. The following attributes can be specified within this element:

- IntSubset
- PublicId
- SystemId

The following example is included in DTD example:

```
<!DOCTYPE test PUBLIC "//this/is/a/URI/test" "test.dtd" [
...
...
]>
```

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

The document type declaration (DTD) of an XML message is represented by a syntax element of type DocTypeDecl and its children and descendants. These comprise the DOCTYPE construct.
"XML DocTypeDecl" on page 4272
The DocTypeDecl represents the DOCTYPE declaration.
"XML PublicId"
PublicId is an element that represents a public identifier in an XML message.
"XML SystemId" on page 4274
SystemId is a value element that represents a system identifier in an XML message.

"XML DTD example" on page 4288

XML PublicId:

PublicId is an element that represents a public identifier in an XML message.

The PublicId element can be part of a DocTypeDecl, NotationDecl, or UnparsedEntityDecl element. The value of the PublicId element is typically a URL. A public identifier of the form `PUBLIC "//this/is/a/URI/test"` has a string value of `//this/is/a/URI/test`.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

The DocTypeDecl represents the DOCTYPE declaration.

"XML IntSubset" on page 4273
The IntSubset element groups all elements that represent the DTD constructs contained in the internal subset of the message.

"XML SystemId"
SystemId is a value element that represents a system identifier in an XML message.

"XML NotationDecl" on page 4275
The NotationDecl element represents a notation declaration in an XML message.

"XML UnparsedEntityDecl" on page 4280
An UnparsedEntityDecl is used to include data in an XML document that is not well-formed XML, and is not parsed by an XML processor.

"XML DTD example" on page 4288

XML SystemId:

SystemId is a value element that represents a system identifier in an XML message.

SystemId can be part of a DocTypeDecl, NotationDecl, or UnparsedEntityDecl element. The value of the SystemId is a URI, and is typically a URL or the name of a file on the current system. A system identifier of the form `SYSTEM "Note.dtd"` has a string value of `Note.dtd`.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"XML PublicId" on page 4273
PublicId is an element that represents a public identifier in an XML message.

"XML NotationDecl" on page 4275
The NotationDecl element represents a notation declaration in an XML message.

"XML UnparsedEntityDecl" on page 4280
An UnparsedEntityDecl is used to include data in an XML document that is not well-formed XML, and is not parsed by an XML processor.

"XML DTD example" on page 4288

XML NotationDecl:

The NotationDecl element represents a notation declaration in an XML message.

NotationDecl is a name element whose name corresponds to the name given with the notation declaration. It must have a SystemId as a child and it can optionally have a child element of type PublicId. For example:

```
<!NOTATION gif SYSTEM "image.gif">
```

The name of the NotationDecl is `gif`.

Related concepts:

PublicId is an element that represents a public identifier in an XML message.

"XML SystemId" on page 4274
SystemId is a value element that represents a system identifier in an XML message.

"XML DTD example" on page 4288

XML entities:

Entities in the DTD are represented by one of six named element types described in the following topics:

- EntityDecl
- EntityDeclValue
- ExternalParameterEntityDecl
- ExternalEntityDecl
- ParameterEntityDecl
- UnparsedEntityDecl

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

Chapter 9, "Developing message flow applications," on page 1019

The document type declaration (DTD) of an XML message is represented by a syntax element of type DocTypeDecl and its children and descendants. These comprise the DOCTYPE construct.

"XML DocTypeDecl" on page 4272
The DocTypeDecl represents the DOCTYPE declaration.

"XML EntityDecl"
The EntityDecl element represents a general entity and is declared in the internal subset of the DTD.

"XML ParameterEntityDecl" on page 4279
The ParameterEntityDecl represents a parameter entity definition in the internal subset of the DTD.

"XML ExternalParameterEntityDecl" on page 4278
The ExternalParameterEntityDecl element represents a parameter entity definition where the entity definition is contained externally to the current message.

"XML ExternalEntityDecl" on page 4279
The ExternalEntityDecl element represents a general entity where the entity definition is contained externally to the current message.

"XML UnparsedEntityDecl" on page 4280
An UnparsedEntityDecl is used to include data in an XML document that is not well-formed XML, and is not parsed by an XML processor.

"XML EntityDeclValue" on page 4277
The EntityDeclValue element represents the value of an EntityDecl or ParameterEntityDecl defined internally in the DOCTYPE construct.

"XML DTD example" on page 4288

XML EntityDecl:

The EntityDecl element represents a general entity and is declared in the internal subset of the DTD.

The EntityDecl is a named element and has a single child element, which is of type EntityDeclValue.

An entity declaration of the form:

```
<!ENTITY bookTitle "User Guide">
```

has an EntityDecl element of name bookTitle and a child element of type EntityDeclValue with a string value of `User Guide`.

Related concepts:

"XML ExternalParameterEntityDecl" on page 4278
The ExternalParameterEntityDecl element represents a parameter entity definition where the entity definition is contained externally to the current message.
"XML ExternalEntityDecl" on page 4279
The ExternalEntityDecl element represents a general entity where the entity definition is contained externally to the current message.
"XML UnparsedEntityDecl" on page 4280
An UnparsedEntityDecl is used to include data in an XML document that is not well-formed XML, and is not parsed by an XML processor.
"XML EntityDeclValue"
The EntityDeclValue element represents the value of an EntityDecl or ParameterEntityDecl defined internally in the DOCTYPE construct.
"XML ElementDef" on page 4281
The ElementDef element represents the `<!ELEMENT` construct in a DTD.
"XML AttributeList" on page 4281
The AttributeList name element represents the `<!ATTLIST` construct in a DTD.
"XML AttributeDef" on page 4282
The AttributeDef name element describes the definition of an attribute within an `<!ATTLIST` construct.
"XML DocTypePI" on page 4286
The DocTypePI element represents a processing instruction found within the DTD.

"XML WhiteSpace and DocTypeWhiteSpace" on page 4287
The WhiteSpace and DocTypeWhiteSpace XML elements represent white space characters in the message.
"XML DocTypeComment" on page 4286
Comments in the XML DTD are represented by the DocTypeComment element.
"XML DTD example" on page 4288

XML EntityDeclValue:

The EntityDeclValue element represents the value of an EntityDecl or ParameterEntityDecl defined internally in the DOCTYPE construct.

The EntityDeclValue is always a child of either an EntityDecl element or a ParameterEntityDecl element, and is a value element. For the following entity:

```
<!ENTITY  bookTitle "User Guide">
```

the EntityDeclValue element has the string value `User Guide`.

“XML EntityDecl” on page 4276
The EntityDecl element represents a general entity and is declared in the internal subset of the DTD.

“XML ParameterEntityDecl” on page 4279
The ParameterEntityDecl represents a parameter entity definition in the internal subset of the DTD.

“XML DTD example” on page 4288

XML ExternalParameterEntityDecl:

The ExternalParameterEntityDecl element represents a parameter entity definition where the entity definition is contained externally to the current message.

The ExternalParameterEntityDecl is a named element and has a child of type SystemId. It can also have a child of type PublicId. The name of the entity does not include the percent sign %. In XML an external parameter entity declaration takes the form:

```
<!ENTITY % bookDef SYSTEM "BOOKDEF.DTD">
```

This represents an ExternalParameterEntityDecl element of name bookDef with a single child of type SystemId with a string value of `BOOKDEF.DTD`.

Related concepts:

“Message flows overview” on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

“XML DocTypeDecl” on page 4272
The DocTypeDecl represents the DOCTYPE declaration.

“XML PublicId” on page 4273
PublicId is an element that represents a public identifier in an XML message.

“XML SystemId” on page 4274
SystemId is a value element that represents a system identifier in an XML message.

"XML NotationDecl" on page 4275
The NotationDecl element represents a notation declaration in an XML message.
"XML entities" on page 4275

"XML DTD example" on page 4288

XML ExternalEntityDecl:

The ExternalEntityDecl element represents a general entity where the entity definition is contained externally to the current message.

The ExternalEntityDecl is a named element and has a child of type SystemId. It can also have a child of type PublicId.

An external entity declaration of the form:

```
<!ENTITY  bookAppendix SYSTEM "appendix.txt">
```

has an EntityDecl element of name bookAppendix and a child element of type SystemId with a string value of `appendix.txt`.

Related concepts:

"XML DocTypeDecl" on page 4272
The DocTypeDecl represents the DOCTYPE declaration.

"XML PublicId" on page 4273
PublicId is an element that represents a public identifier in an XML message.

"XML SystemId" on page 4274
SystemId is a value element that represents a system identifier in an XML message.

"XML entities" on page 4275

"XML DTD example" on page 4288

XML ParameterEntityDecl:

The ParameterEntityDecl represents a parameter entity definition in the internal subset of the DTD.

The ParameterEntityDecl is a named element and has a single child element that is of type EntityDeclValue. For parameter entities, the name of the entity does not include the percent sign %. In XML a parameter entity declaration takes the form:

```
<!ENTITY % inline "#PCDATA | emphasis | link">
```

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

Chapter 9, "Developing message flow applications," on page 1019
Develop message flows to process your business messages and data.

Related reference:

"XML document type declaration" on page 4271
The document type declaration (DTD) of an XML message is represented by a syntax element of type DocTypeDecl and its children and descendants. These comprise the DOCTYPE construct.

"XML DocTypeDecl" on page 4272
The DocTypeDecl represents the DOCTYPE declaration.

"XML EntityDeclValue" on page 4277
The EntityDeclValue element represents the value of an EntityDecl or ParameterEntityDecl defined internally in the DOCTYPE construct.

"XML DTD example" on page 4288

XML UnparsedEntityDecl:

An UnparsedEntityDecl is used to include data in an XML document that is not well-formed XML, and is not parsed by an XML processor.

An unparsed entity is an external entity whose external reference is not parsed by an XML processor. This means that you can include data in an XML document that is not well-formed XML, such as a graphic file. The UnparsedEntityDecl is named element and a child of type SystemId that identifies the URI for the entity (a URL or a local file location). UnparsedEntityDecl can optionally have a child of type PublicId.

UnparsedEntityDecl can also have a child of type NotationReference, a value element that represents a reference to a notation declaration elsewhere in the XML document. It defines the type of data of the unparsed entity.

An unparsed entity declaration takes the form:

```
<!ENTITY pic SYSTEM "scheme.gif" NDATA gif>
```

In this example, the SystemId has a string value of `scheme.gif`. The value of NotationReference is `gif`. It refers to a NOTATION defined within the XML document:

```
<!NOTATION gif SYSTEM "image/gif">
```

The next entity is included in the DTD example:

```
<!ENTITY unpsd PUBLIC "//this/is/a/URI/me.gif" "me.gif" NDATA TeX>
```

This shows the optional PublicId element, which has the string value of `//this/is/a/URI/me.gif`.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

The document type declaration (DTD) of an XML message is represented by a syntax element of type DocTypeDecl and its children and descendants. These comprise the DOCTYPE construct.

“XML DocTypeDecl” on page 4272
The DocTypeDecl represents the DOCTYPE declaration.

“XML PublicId” on page 4273
PublicId is an element that represents a public identifier in an XML message.

“XML SystemId” on page 4274
SystemId is a value element that represents a system identifier in an XML message.

“XML NotationDecl” on page 4275
The NotationDecl element represents a notation declaration in an XML message.

“XML DTD example” on page 4288

XML ElementDef:

The ElementDef element represents the `<!ELEMENT` construct in a DTD.

The ElementDef element is a child of the DOCTYPE element. The name of the element that is defined corresponds to the name of the syntax element. The value corresponds to the element definition.

This example is included in the DTD example:

```
<!ELEMENT subel2 (#PCDATA)>
```

The name of the element is `subel2` and the value is `(#PCDATA)`.

Related concepts:

“Message flows overview” on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

Chapter 9, “Developing message flow applications,” on page 1019
Develop message flows to process your business messages and data.

Related reference:

The document type declaration (DTD) of an XML message is represented by a syntax element of type DocTypeDecl and its children and descendants. These comprise the DOCTYPE construct.

“XML DocTypeDecl” on page 4272
The DocTypeDecl represents the DOCTYPE declaration.

“XML DTD example” on page 4288

XML AttributeList:

The AttributeList name element represents the `<!ATTLIST` construct in a DTD.

The name of the AttributeList element corresponds to the name of the element for which the list of attributes is being defined. Its content represents one or more AttributeDef elements.

This example is included in the DTD example:

```
<!ATTLIST el5  el5satt CDATA #IMPLIED>
```

This example shows an AttributeList that defines one AttributeDef, and its content is explained in AttributeDef.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

The document type declaration (DTD) of an XML message is represented by a syntax element of type DocTypeDecl and its children and descendants. These comprise the DOCTYPE construct.

"XML DocTypeDecl" on page 4272
The DocTypeDecl represents the DOCTYPE declaration.

"XML AttributeDef"
The AttributeDef name element describes the definition of an attribute within an `<!ATTLIST` construct.

"XML DTD example" on page 4288

XML AttributeDef:

The AttributeDef name element describes the definition of an attribute within an `<!ATTLIST` construct.

The AttributeDef element is always a child of the AttributeList element. The name of the syntax element is the name of the attribute being defined. It can have three children:

- AttributeDefValue
- AttributeDefType
- AttributeDefDefaultType

This example is included in the DTD example:

```
<!ATTLIST el5  el5satt CDATA #IMPLIED>
```

The name of the AttributeDef is `el5satt` and it is a child of AttributeList `el5`. The name of the AttributeDefType is `CDATA`, and the value of the AttributeDefDefaultType is `IMPLIED`.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

The document type declaration (DTD) of an XML message is represented by a syntax element of type DocTypeDecl and its children and descendants. These comprise the DOCTYPE construct.

“XML DocTypeDecl” on page 4272
The DocTypeDecl represents the DOCTYPE declaration.

“XML NotationDecl” on page 4275
The NotationDecl element represents a notation declaration in an XML message.

“XML entities” on page 4275

“XML ElementDef” on page 4281
The ElementDef element represents the `<!ELEMENT` construct in a DTD.

“XML AttributeList” on page 4281
The AttributeList name element represents the `<!ATTLIST` construct in a DTD.

“XML AttributeDefValue”
the AttributeDefValue gives the default value of attributes of type CDATA or attributes defined by an enumerated list.

“XML AttributeDefDefaultType” on page 4285
The AttributeDefDefaultType syntax element is a value element that represents the attribute default as defined under the attribute definition.

“XML AttributeDefType” on page 4284
The AttributeDefType syntax element is a name-value element whose name corresponds to the attribute type found in the attribute definition.

“XML DocTypePI” on page 4286
The DocTypePI element represents a processing instruction found within the DTD.

“XML WhiteSpace and DocTypeWhiteSpace” on page 4287
The WhiteSpace and DocTypeWhiteSpace XML elements represent white space characters in the message.

“XML DocTypeComment” on page 4286
Comments in the XML DTD are represented by the DocTypeComment element.

“XML DTD example” on page 4288

XML AttributeDefValue:

the AttributeDefValue gives the default value of attributes of type CDATA or attributes defined by an enumerated list.

For attributes of type CDATA, see “XML AttributeDefType” on page 4284.

For an example of AtrtibuteDefValue, see DTD example.

Related concepts:

“Message flows overview” on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

Chapter 9, “Developing message flow applications,” on page 1019
Develop message flows to process your business messages and data.

Related reference:

The document type declaration (DTD) of an XML message is represented by a syntax element of type DocTypeDecl and its children and descendants. These comprise the DOCTYPE construct.

"XML DocTypeDecl" on page 4272
The DocTypeDecl represents the DOCTYPE declaration.

"XML AttributeList" on page 4281
The AttributeList name element represents the `<!ATTLIST` construct in a DTD.

"XML AttributeDef" on page 4282
The AttributeDef name element describes the definition of an attribute within an `<!ATTLIST` construct.

"XML AttributeDefDefaultType" on page 4285
The AttributeDefDefaultType syntax element is a value element that represents the attribute default as defined under the attribute definition.

"XML AttributeDefType"
The AttributeDefType syntax element is a name-value element whose name corresponds to the attribute type found in the attribute definition.

"XML DTD example" on page 4288

XML AttributeDefType:

The AttributeDefType syntax element is a name-value element whose name corresponds to the attribute type found in the attribute definition.

Possible values for the name are:
- CDATA
- ID
- IDREF
- IDREFS
- ENTITY
- ENTITIES
- NMTOKEN
- NMTOKENS
- NOTATION

If there is an enumeration present for the attribute definition, the entire enumeration string is held as a string in the value member of the name-value syntax element. In this case, the name member of the name-value syntax element is empty. The value string starts with an open parenthesis (and ends with a close parenthesis). Each entry in the enumeration string is separated by a vertical bar | character. If the Attribute value is not defined by an enumerated list, the value member of the syntax element is empty.

An example is included in AttributeDef.

Related concepts:

Develop message flows to process your business messages and data.

Related reference:

"XML document type declaration" on page 4271
The document type declaration (DTD) of an XML message is represented by a syntax element of type DocTypeDecl and its children and descendants. These comprise the DOCTYPE construct.

"XML DocTypeDecl" on page 4272
The DocTypeDecl represents the DOCTYPE declaration.

"XML NotationDecl" on page 4275
The NotationDecl element represents a notation declaration in an XML message.

"XML entities" on page 4275

"XML ElementDef" on page 4281
The ElementDef element represents the `<!ELEMENT` construct in a DTD.

"XML AttributeList" on page 4281
The AttributeList name element represents the `<!ATTLIST` construct in a DTD.

"XML AttributeDef" on page 4282
The AttributeDef name element describes the definition of an attribute within an `<!ATTLIST` construct.

"XML WhiteSpace and DocTypeWhiteSpace"
The WhiteSpace and DocTypeWhiteSpace XML elements represent white space characters in the message.

"XML DocTypeComment" on page 4286
Comments in the XML DTD are represented by the DocTypeComment element.

"XML DTD example" on page 4288

XML WhiteSpace and DocTypeWhiteSpace:

The WhiteSpace and DocTypeWhiteSpace XML elements represent white space characters in the message.

The WhiteSpace element represents any white space characters outside the message body and DTD that are not represented by any other element. For example, white space within the body of the message (within elements) is reported as element content using the Content element type, but white space characters between the XML declaration and the beginning of the message body are represented by the WhiteSpace element.

```
<?xml version="1.0"?>       <BODY>....</BODY>
```

The characters between "1.0"?> and <BODY> are represented by the WhiteSpace element.

White space is used in XML for readability and has no business meaning. Input XML messages can include line breaks, blanks lines, and spaces between tags (all shown in the following example). If you process XML messages that contain any of these spaces, they are represented as elements in the message tree. Therefore they appear when you view the message in the debugger, and in any trace output.

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE s1 PUBLIC "http://www.ibm.com/example.dtd" "example.dtd">
<s1>.........
<s2>abc</s2>   <s2>def</s2>

<s3>123</s3>
</s1>
```

If you do not want white space elements in your message trees, you must present the input message as a single line, or use the XMLNSC compact parser in its default mode

The DocTypeWhiteSpace element represents white space that is found inside the DTD that is not represented by any other element. White space characters found within a DocType between two definitions are represented by the DocTypeWhiteSpace element.

```
    <!ENTITY % bookDef SYSTEM "BOOKDEF.DTD">  <!ENTITY bookTitle "User Guide">
```

The characters between DTD"> and <!ENTITY are represented by the DocTypeWhiteSpace element.

Comments in the XML DTD are represented by the DocTypeComment element.

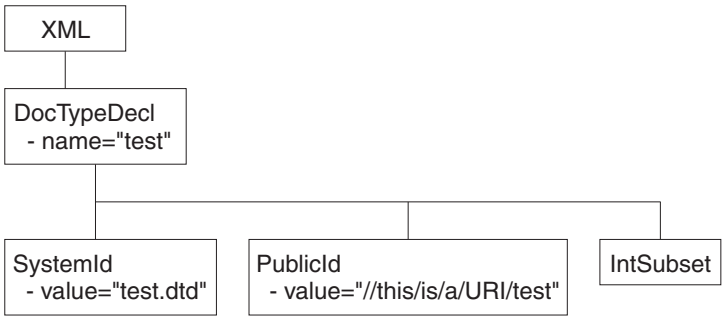
"XML DTD example"

XML DTD example:

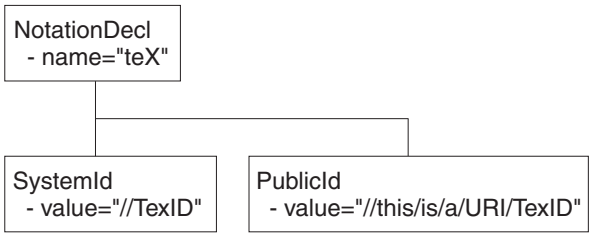
This example shows an XML DTD in an XML document and the tree structure form of that document:

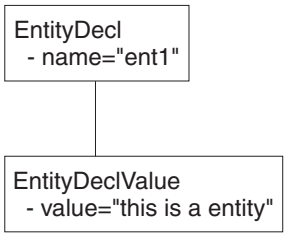
```
<!DOCTYPE test PUBLIC "//this/is/a/URI/test" "test.dtd" [
<!NOTATION TeX  PUBLIC "//this/is/a/URI/TexID" "//TexID">
<!ENTITY ent1 "this is an entity">
<!ENTITY % ent2 "#PCDATA | subel2">
<!ENTITY % extent1 PUBLIC "//this/is/a/URI/extent1" "more.txt">
<!ENTITY extent2 PUBLIC "//this/is/a/URI/extent2" "more.txt">
<!ENTITY unpsd PUBLIC "//this/is/a/URI/me.gif" "me.gif" NDATA TeX>
<?test Do this?>
<!--this is a comment-->
<!ELEMENT subel2 (#PCDATA)>
<!ELEMENT subel1 (subel2 | el4)+>
<!ELEMENT el1 (#PCDATA)>
<!ELEMENT el2 (#PCDATA | subel2)*>
<!ELEMENT el3 (#PCDATA | subel2)*>
<!ELEMENT el4 (#PCDATA)>
<!ELEMENT el5 (#PCDATA | subel1)*>
<!ELEMENT el6 (#PCDATA)>
<!ATTLIST subel1
 size (big | small) "big"
 shape (round | square) #REQUIRED>
<!ATTLIST el5
 el5satt CDATA #IMPLIED>
]>
```

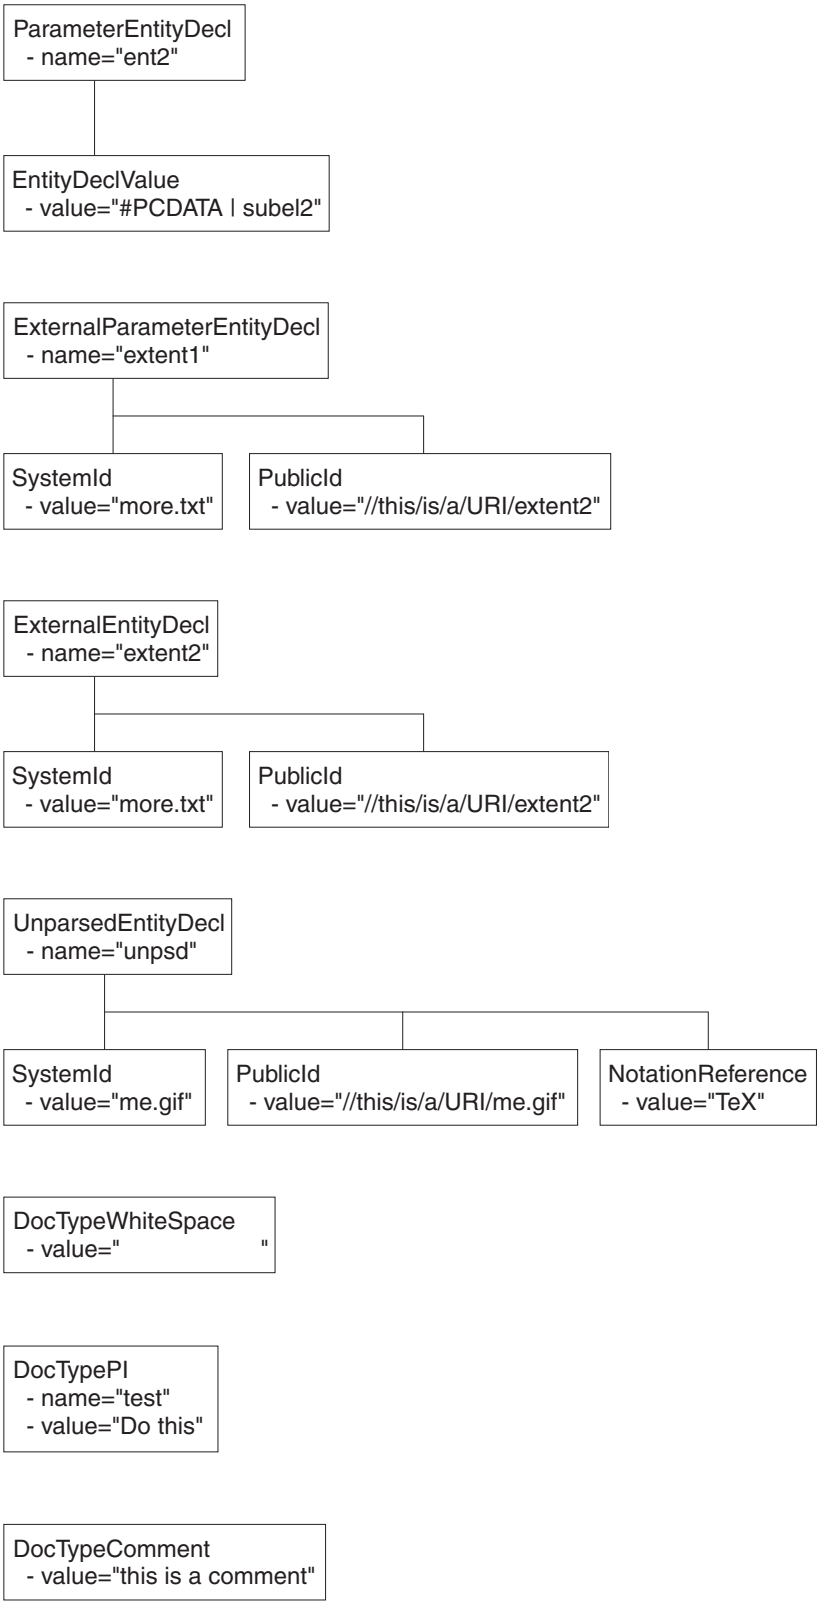
When a message is parsed by the generic XML parser, the relevant part of the message tree looks like this (assuming that there are no carriage returns or white space between tags):



The IntSubset structure contains the following structures at the next level of nesting: the tree structure for each of these is shown in the following tree structures.







ParameterEntityDecl
- name="ent2"
EntityDeclValue
- value="#PCDATA | subel2"
ExternalParameterEntityDecl
- name="extent1"
SystemId

Built-in nodes

WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

The mode that your broker is working in can affect the types of node that you can use; see "Restrictions that apply in each operation mode" on page 3657.

For information about each of these built-in nodes, use the following links. The nodes are listed in the categories under which they are grouped in the node palette, see "Message flow node palette" on page 1027.

A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

“Designing a message flow” on page 1455
A message flow can perform a wide range of operations, depending on your business and operational requirements. For best performance and capability, you must design it to include the most appropriate nodes.

“Creating a message flow” on page 1431
Create a message flow to specify how to process messages in the broker. You can create one or more message flows and deploy them to one or more brokers.

“Defining message flow content” on page 1488
You can define message flow content by adding and configuring message flow nodes and connecting them to form flows.

AggregateControl node

Use the AggregateControl node to mark the beginning of a fan-out of requests that are part of an aggregation.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow"
- "Terminals and properties"

Purpose:
Aggregation is an extension of the request/reply application model. It combines the generation and fan-out of a number of related requests with the fan-in of the corresponding replies, and compiles those replies into a single aggregated reply message.

The aggregation function is provided by the following three nodes:

- The AggregateControl node marks the beginning of a fan-out of requests that are part of an aggregation. It sends a control message that is used by the AggregateReply node to match the different requests that have been made. The information that is propagated from the Control terminal includes the broker identifier, the aggregate name property, and the timeout property. You must not change the aggregation information that is added to the message Environment by the AggregateControl node.
- The AggregateRequest node records the fact that the request messages have been sent. It also collects information that helps the AggregateReply node to construct the aggregated reply message. You must preserve the information that is added to the message Environment by the AggregateControl node, otherwise the aggregation fails.
- The AggregateReply node marks the end of an aggregation fan-in. It collects replies and combines them into a single aggregated reply message.

This node creates the `LocalEnvironment.ComIbmAggregateControlNode` folder. This folder and the fields in it are for internal use by WebSphere Message Broker and you should not rely on their existence or values when developing your message flows.

The AggregateControl node is contained in the **Routing** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following samples to see how to use this node:

- Aggregation
- Airline Reservations

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:

When you have put an instance of the AggregateControl node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The AggregateControl node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Out	The output terminal to which the original message is routed when processing completes successfully.
Control	The output terminal to which a control message is routed. The control message is sent to a corresponding AggregateReply node. The Control terminal is deprecated in Version 6.0; to use connections from the Control terminal, see "Using control messages in aggregation flows" on page 2745.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The AggregateControl node Description properties are described in the following table:

Property	M	C	Default	Description
Node name	No	No	The node type (AggregateControl)	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The AggregateControl node Basic properties are described in the following table:

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
Aggregate Name	Yes	Yes		A name that is used to associate the fan-out message flow with the fan-in message flow. This value must be contextually unique in a broker. This name is also used to identify an Aggregation configurable service (if one exists) to be used by the node.	aggregateName

Property	M	C	Default	Description	mqsiapplybaroverride command property
Timeout (sec)	Yes	No	0	The amount of time, in seconds, that it waits for replies to arrive at the fan-in. The default value is zero; if you accept this default value, the timeout is disabled for fan-outs from this node (that is, it waits for replies indefinitely). If not all responses are received, the message flow continues to wait, and does not complete. Set a value greater than zero to ensure that the message flow can complete, even if not all responses are received. For further information about timeouts, see "AggregateReply node" on page 4299. z/OS On z/OS, if the Timeout property is not set to zero, set the queue manager parameter **EXPRYINT** to 5. The value specified by the `Timeout (sec)` property is overridden by the value set in the **timeoutSeconds** property of the Aggregation configurable service, if it is set. Timeout values specified by the node and the configurable service are overridden by a timeout value defined in the message, at the location specified by the `Timeout location` property of the AggregateControl node.	

The AggregateControl node Advanced properties are described in the following table:

Property	M	C	Default	Description
Timeout location	No	No	`'$LocalEnvironment/Aggregation/Timeout'`	The location in the message tree where the aggregation timeout value is defined. The value specified in the message tree overrides the `Timeout (sec)` property of the AggregateControl node and the **timeoutSeconds** property of the Aggregation configurable service.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

AggregateReply node

Use the AggregateReply node to mark the end of an aggregation fan-in. This node collects replies and combines them into a single compound message.

This topic contains the following sections:

Purpose:

Aggregation is an extension of the request/reply application model. It combines the generation and fan-out of a number of related requests with the fan-in of the corresponding replies, and compiles those replies into a single aggregated reply message.

The aggregation function is provided by the following three nodes:

- The AggregateControl node marks the beginning of a fan-out of requests that are part of an aggregation. It sends a control message that is used by the AggregateReply node to match the different requests that have been made. The information that is propagated from the Control terminal includes the broker identifier, the aggregate name property, and the timeout property. The aggregation information that is added to the message Environment by the AggregateControl node must not be changed.
- The AggregateRequest node records the fact that the request messages have been sent. It also collects information that helps the AggregateReply node to construct

the aggregated reply message. The information that is added to the message Environment by the AggregateRequest must be preserved, otherwise the aggregation fails.

- The AggregateReply node marks the end of an aggregation fan-in. It collects replies and combines them into a single aggregated reply message.

The AggregateReply node is contained in the **Routing** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

When incoming messages are stored by the AggregateReply node before all responses for the aggregation are received, the persistence of the message determines whether the message is retained across a restart.

If, during an aggregation, one or more of the response messages are not received by the AggregateReply node, the normal timeout or unknown message processing deals with the responses that have been received already.

The MQMD.Expiry value of each AggregateReply message is set to -1 in the compound output message. This value is set because the MQMD.Expiry value has no meaning once the reply message is no longer on the WebSphere MQ Transport and has been stored by the broker during the aggregation process.

Using this node in a message flow:
Look at the following samples to see how to use this node:

- Aggregation
- Airline Reservations

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
When you have put an instance of the AggregateReply node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The AggregateReply node terminals are described in the following table.

Terminal	Description
Control	The input terminal that accepts control messages that are sent by a corresponding AggregateControl node. The Control terminal is deprecated in Version 6.0; to use connections to the Control terminal, see “Using control messages in aggregation flows” on page 2745.
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the message is routed if a failure is detected during processing.
Unknown	The output terminal to which messages are routed when they cannot be identified as valid reply messages.

Terminal	Description
Out	The output terminal to which the compound message is routed when processing completes successfully.
Timeout	The output terminal to which the incomplete compound message is routed when the timeout interval that is specified in the corresponding AggregateControl node has expired.
Catch	The output terminal to which the message is routed if an exception is thrown downstream and then caught by this node.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the AggregateReply node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type (AggregateReply)	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The AggregateReply node Basic properties are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Aggregate Name	Yes	Yes		A name that is used to associate the fan-in message flow with the fan-out message flow. This value must be contextually unique within a broker. This name is also used to identify an Aggregation configurable service (if one exists) to be used by the node.	aggregateName
Unknown Message Timeout	No	No	`0`	The amount of time, in seconds, for which messages that cannot be identified as replies are held before they are propagated to the Unknown terminal. The default value is zero; if you accept this default value, the timeout is disabled, and unknown messages are propagated to the Unknown terminal upon receipt. z/OS On z/OS, if the Unknown Message Timeout property is not set to zero, set the queue manager parameter **EXPRYINT** to 5.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Transaction Mode	Yes	No	Selected	This property defines the transactional characteristics of this message: • If you select the check box (the default), the subsequent message flow is under transaction control. This setting remains true for messages that derive from the output message and are produced by an MQOutput node, unless the MQOutput node explicitly overrides the transaction status. No other node can change the transactional characteristics of the output message. • If you clear the check box, the subsequent message flow is not under transaction control. This setting remains true for messages that derive from the output message and are produced by an MQOutput node, unless the MQOutput node has specified that the message must be put under sync point.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

- "Terminals and properties" on page 4304

Purpose:
Aggregation is an extension of the request/reply application model. It combines the generation and fan-out of a number of related requests with the fan-in of the corresponding replies, and compiles those replies into a single aggregated reply message.

The aggregation function is provided by the following three nodes:

- The AggregateControl node marks the beginning of a fan-out of requests that are part of an aggregation. It sends a control message that is used by the AggregateReply node to match the different requests that have been made. The information that is propagated from the Control terminal includes the broker identifier, the aggregate name property, and the timeout property. The aggregation information that is added to the message Environment by the AggregateControl node must not be changed.
- The AggregateRequest node records the fact that the request messages have been sent. It also collects information that helps the AggregateReply node to construct the aggregated reply message. The information that is added to the message Environment by the AggregateRequest node must be preserved, otherwise the aggregation fails.
- The AggregateReply node marks the end of an aggregation fan-in. It collects replies and combines them into a single aggregated reply message.

The AggregateRequest node is contained in the **Routing** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following samples to see how to use this node:

- Aggregation
- Airline Reservations

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
When you have put an instance of the AggregateRequest node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The AggregateRequest node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts messages sent as part of an aggregate request.
Out	The output terminal to which the input message is routed when processing completes successfully.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The AggregateRequest node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type (AggregateRequest)	The name of the node
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The AggregateRequest node Basic property is described in the following table.

Property	M	C	Default	Description
Folder Name	Yes	No		The name that is used as a folder in the AggregateReply node's compound message to store the reply to this request. You must enter a value for this property, but the value does not need to be unique.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Message flow aggregation" on page 2718
Aggregation is the generation and fan-out of related requests that are derived from a single input message, and the fan-in of the corresponding replies to produce a single aggregated reply message.

Related tasks:

"Deciding which nodes to use" on page 1457
WebSphere Message Broker includes many message processing nodes that you can use in your message flows.

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

"Configuring aggregation flows" on page 2721
Use aggregation message flows to generate and fan-out a number of related requests, fan-in the corresponding replies, and compile those replies into a single aggregated reply message, by using the AggregateControl, AggregateRequest, and AggregateReply nodes.

Related reference:

"AggregateControl node" on page 4296
Use the AggregateControl node to mark the beginning of a fan-out of requests that are part of an aggregation.

"AggregateReply node" on page 4299
Use the AggregateReply node to mark the end of an aggregation fan-in. This node collects replies and combines them into a single compound message.

CDInput node

Use the CDInput node to preview files when using IBM Sterling Connect:Direct in conjunction with WebSphere Message Broker.

This topic contains the following sections:

Purpose:

You can use the CDInput node to extend WebSphere Message Broker support for file processing through its integration with IBM Sterling Connect:Direct.

On z/OS, when the CDInput node receives notification of the arrival of a dataset that it needs to process, the node copies that dataset into Unix System Services temporarily, before processing.

The CDInput node is contained in the **File** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
You can use the CDInput node in any flow that is designed to accept files from an IBM Sterling Connect:Direct network.

Terminals and properties:
The CDInput node terminals are described in the following table.

Terminal	Description
Failure	The output terminal to which a message is routed if an error occurs before a message is propagated to the Out terminal. Messages propagated to this terminal are not validated, even if you have specified, using the `Validate` property, that validation is to take place.
Out	The output terminal to which a message is routed if it has been successfully extracted from the input file. If no errors occur within the input node, a message received from an external resource is always sent to the Out terminal first.
End of Data	The output terminal to which the End of Data message is routed after all the messages in a file have been processed. The End of Data message flow transaction is initiated only if this terminal is attached. The end of data structure consists of an empty message body, and the Local Environment information propagated from the out terminal.
Catch	The output terminal to which the message is routed if an exception is thrown downstream and caught by this node. Exceptions are caught only if this terminal is attached.

The following tables describe the node properties that you can set on a specified tab. The column headed M indicates whether the property is *mandatory* (marked in the toolkit with an asterisk if you must enter a value when no default is defined). The column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

When the CDInput node propagates a message, it stores information about it in the LocalEnvironment.CD and LocalEnvironment.CD.Transfer message trees. If the input file is empty, an empty message is propagated (assuming that it is valid). If you specify a file name pattern that contains wildcard characters in the `File name filter` property, the CDInput node copies the characters in the file name matched by wildcard characters, together with any intermediate characters, to the LocalEnvironment.Wildcard.WildcardMatch message tree. See “Using local environment variables with file nodes” on page 1820 for more information.

Description properties

Property	M	C	Default	Description
Node name	No	No	`CDInput`	The name of the node.
Short Description	No	No	None	A brief description of the node.

Property	M	C	Default	Description
Long Description	No	No	None	Text that describes the purpose of the node in the message flow.

Basic properties

Property	M	C	Default	Description
Directory filter	No	Yes	None	Specify the directory from which the node can process files. If this property is left blank, the node can process files from all directories. If multiple CDInput nodes are deployed to the same execution group, files are distributed randomly between the nodes unless filtering is defined. The directory must exist. If the WebSphere Message Broker and IBM Sterling Connect:Direct server are on different machines, this is the path to the directory on the broker machine. For information on various configurations when using IBM Sterling Connect:Direct, see "Advanced configuration properties when using IBM Sterling Connect:Direct nodes" on page 727 and refer to the Input sections. If the `brokerPathToInputDir` field in the configurable service is set, the directory filter can be a path relative to that value; otherwise it must be an absolute path. On z/OS, if the file is a sequential dataset, partitioned dataset, or partitioned dataset member, leave the Directory filter field blank.
File name filter	Yes	Yes	None	Specify either a file name, or a character sequence that matches a file name. Either the file name or the character sequence can contain at least one of the following wildcard characters: • * (any sequence of zero or more characters) • ? (any single character) By default the node processes all files. If multiple CDInput nodes are deployed to the same execution group, files are distributed randomly between the nodes unless filtering is defined. The CDInput node can process z/OS sequential datasets, entire partitioned datasets or partitioned dataset members. The syntax to address a dataset is based on the full name for the dataset, for example, `MBUSER.TEST1`. Wildcard characters can be used anywhere within a dataset file name filter, this works in the same way as for normal file name filter patterns. For a member within a partitioned dataset, use brackets to specify the member name, for example, `MBUSER.TEST(MEME01)`. When receiving an entire partitioned dataset, each member in the received dataset is processed as an individual message.

Property	M	C	Default	Description
Connect:Direct server configurable service	No	Yes	Default	The name of the configurable service being used to connect to the Connect:Direct server, in order to collect transfer information. If this value is not set, the default configurable service (named "Default") is used. The default configurable service connects to a Connect:Direct server located on the same machine as the broker, and using default port configurations. The default configurable service also uses the "default" security identity, which must be created using the mqsisetdbparms command; for example: `mqsisetdbparms MB7BROKER -n cd::default -u mqbroker -p xxxxxxx` For information on various configurations when using IBM Sterling Connect:Direct, see "Advanced configuration properties when using IBM Sterling Connect:Direct nodes" on page 727 and refer to the Input sections.
Action on successful processing	Yes	No	No Action	Select the action to take once the node has successfully processed the file. You can choose to leave the file in the input directory if other processes also need access to the file. In this case the notification from IBM Sterling Connect:Direct is deleted, and the file is left in place. Deleting files prevents the build up of processed files. Use the timestamp option if an archive of the file is required to record all transfers made. Note that on z/OS the Add Time Stamp option is not supported when using datasets.

Input Message Parsing properties

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Message Domain	No	No	None	The domain that is used to parse the incoming message.	
Message Set	No	No	None	The name or identifier of the message set in which the incoming message is defined. If you set this property, and then update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message Set` property, or restore the reference to this message set project.	
Message Type	No	No	None	The name of the incoming message.	
Message Format	No	No	None	The name of the physical format of the incoming message.	
Message coded character set ID	Yes	Yes	`Broker System Default`	The ID of the coded character set used to interpret bytes of the file being read.	messageCodedCharSetIdProperty

Property	M	C	Default	Description	mqsiapplybaroverride command property
Message encoding	Yes	Yes	Broker System Determined	The encoding scheme for numbers used to interpret bytes of the file being read. Valid values are Broker System Determined or a numeric encoding value. For more information about encoding, see "Data conversion" on page 1151.	messageEncodingProperty

Parser Options properties

Property	M	C	Default	Description
Parse timing	No	No	On Demand	Specifies when an input message is parsed. Valid values are: • On Demand • Immediate • Complete For a full description of this property, see "Parsing on demand" on page 4173.
Build tree using XML schema data types	No	No	Cleared	Specifies whether the syntax elements in the message tree have data types taken from the XML schema.
Use XMLNSC compact parser for XMLNS domain	No	No	Cleared	Specifies whether the XMLNSC Compact Parser is used for messages in the XMLNS Domain. If you set this property, the message data appears under XMLNSC in nodes that are connected to the output terminal when either of the following items is XMLNS: • The input MQRFH2 header. • The Input Message Parsing property, Message Domain.
Retain mixed content	No	No	Cleared	Specifies whether the XMLNSC parser creates elements in the message tree for mixed text in an input message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	No	No	Cleared	Specifies whether the XMLNSC parser creates elements in the message tree for comments in an input message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	Specifies whether the XMLNSC parser creates elements in the message tree for processing instructions in an input message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.
Opaque elements	No	No	Blank	Specifies a list of elements in the input message that are to be opaquely parsed by the XMLNSC parser. Opaque parsing is performed only if validation is not enabled (that is, if Validate is None); entries that are specified in Opaque Elements are ignored if validation is enabled.

Retry properties

Property	M	C	Default	Description	mqsiapplybaroverride command property
Retry mechanism	Yes	No	Failure	How the node handles a flow failure. Valid options are: • Failure • Short retry • Short and long retry	
Retry threshold	Yes	Yes	0	The number of times to try the flow transaction again when the Retry mechanism property value is Short retry.	retryThreshold
Short retry interval (seconds)	No	Yes	0	The interval, in seconds, between each retry if the Retry threshold property is not zero.	shortRetryInterval
Long retry interval (seconds)	No	Yes	300	The interval between retries, if the Retry mechanism property is Short and long retry and the retry threshold has been exhausted.	longRetryInterval
Action on failing file	Yes	Yes	No Action	The action that the node takes with the input file if all attempts to process the contents of the input file fail. Valid options are: • No Action • Delete • Add Time Stamp This option is not available on z/OS	

Records and Elements properties

Property	M	C	Default	Description
Record detection	Yes	No	Whole File	The mechanism used to identify records in the input file. Valid options are: • Whole File • Fixed Length • Delimited • Parsed Record Sequence
Length	Yes	No	80	The length of each record, in bytes, when Fixed Length record detection is selected.
Delimiter	Yes	Yes	DOS or UNIX Line End	The type of delimiter bytes that separate, or end, each record when Delimited record detection is selected. Valid options are: • DOS or UNIX Line End • Custom Delimiter
Custom delimiter	No	Yes	None	The delimiter bytes, expressed in hexadecimal, when Delimited record detection and Custom Delimiter are selected. This property is mandatory only if the Delimiter property is set to Custom Delimiter.
Delimiter type	Yes	No	Postfix	The position of the delimiter when Delimited record detection is selected. Valid options are: • Postfix • Infix This property is ignored unless the Delimiter property is set to Custom Delimiter.

Validation properties

For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Validate	No	Yes	None	This property controls whether validation takes place. Valid values are: • None • Content and Value • Content	validateMaster
Failure action	No	No	Exception	This property controls what happens if validation fails. Valid values are: • User Trace • Local Error Log • Exception • Exception List	

Transactions properties

Property	M	C	Default	Description
Transaction mode	No	No	No	The transaction mode on this input node determines whether the rest of the nodes in the flow are processed under sync point. Valid options are: • Yes • No

Instances properties.

For a full description of these properties, see "Configurable message flow properties" on page 4020.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Additional instances pool	No	Yes	Use Pool Associated with Message Flow	The pool from which additional instances are obtained. • If you select Use Pool Associated with Message Flow, additional instances are obtained from the message flow pool. • If you select Use Pool Associated with Node, additional instances are allocated from the additional instances of the node based on the number specified in the Additional instances property.	componentLevel
Additional instances	No	Yes	0	The number of additional instances that the node can start if the Additional instances pool property is set to Use Pool Associated with Node.	additionalInstances

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

An overview of IBM Sterling Connect:Direct and its terminology when used with WebSphere Message Broker.

"Using local environment variables with file nodes" on page 1820
You can use fields in the local environment to dynamically alter the behavior of the FileInput, FileOutput, FTEInput, and FTEOutput nodes. You can also find what values the output nodes used to process the file.

"File name patterns" on page 1830
You can specify a file name pattern, using wildcard characters, to identify a file to be read by the FileInput and FTEInput nodes. You can also specify a file name pattern, using a single wildcard character, to name the file to be created by the FileOutput and FTEOutput nodes.

Related tasks:

"Initiating a managed file transfer using IBM Sterling Connect:Direct" on page 1873
Use a CDOutput node to send a file from a specified directory on your primary Connect:Direct server (PNODE) to a filename and directory on a secondary Connect:Direct server (SNODE).

"Advanced configuration properties when using IBM Sterling Connect:Direct nodes" on page 727
CDInput and CDOutput nodes can get connection details and staging directories in conjunction with a configurable service. To pick up new values when a configurable service is created or modified, you must reload the broker or execution group, by using the **mqsistop** and **mqsistart** commands, or the **mqsireload** command.

Related reference:

"CDOutput node"
Use the CDOutput node when using IBM Sterling Connect:Direct with WebSphere Message Broker.

CDOutput node

Use the CDOutput node when using IBM Sterling Connect:Direct with WebSphere Message Broker.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow" on page 4313
- "Terminals and properties" on page 4313

Purpose:
Use the CDOutput node to serialize the message tree to a file and then transfer it between two Connect:Direct servers. A directory under the work path within the

execution group is used as the staging area, until the file is ready to be transferred. Once the file is transferred, it is deleted from the staging area.

The CDOutput node is contained in the **File** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
You can use the CDOutput node in conjunction with another transport input node, for example, MQInput. Any data received from WebSphere MQ is sent to the CDOutput node which writes the file to an internal directory using the file name given on the node. The file is then transferred across to the destination Connect:Direct server, where it is written to the directory and file name given on the node.

Terminals and properties:
The CDOutput node terminals are described in the following table:

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Finish File	The input terminal that accepts a message that triggers the final processing of a file.
Out	The message received on the In terminal is propagated to this terminal if the record is written successfully. The message is unchanged except for status information in the Local Environment.
End of Data	The message received on the Finish File terminal is propagated to this terminal if the file is processed successfully.
Failure	The output terminal to which the message is routed if a failure is detected when a message is propagated.

The following tables describe the node properties that you can set on a specified tab. The column headed M indicates whether the property is *mandatory* (marked in the toolkit with an asterisk if you must enter a value when no default is defined). The column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

When the CDOutput node propagates a message, either to the Out terminal or to the End of Data terminal, it stores information about it in the `LocalEnvironment.WrittenDestination.CD` message tree.

You can override the:

- `Secondary Connect:Direct server (SNODE)name`
- `Process name`
- `Accounting data`
- `Destination file directory`
- `Destination file name`
- `Copy from options including SYSOPTS`
- `Copy to options including SYSOPTS`

by making changes to the `LocalEnvironment.Destination.CD` message tree; see "Using local environment variables with file nodes" on page 1820 for more information.

Description properties

Property	M	C	Default	Description
Node name	No	No	`CDOutput`	The name of the node.
Short Description	No	No	None	A brief description of the node.
Long Description	No	No	None	Text that describes the purpose of the node in the message flow.

Basic properties

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
SNODE	No	Yes	The same as the PNODE being used	The secondary Connect:Direct server (SNODE) to which the file is being transferred. If this is not set, the file is transferred back to the primary Connect:Direct server server (PNODE). You must set up a Netmap on the PNODE to ensure that the transfer reaches the SNODE. The Netmap entry for this SNODE must contain the operating system type in the appropriate field. If the PNODE is on a UNIX operating system, you must use the description field in the Netmap to store this information. The description must contain the string remoteos=xxx, where the value is Windows, UNIX or OS390. The CDOutput node cannot be used to transfer to a SNODE on operating systems other than these.	snode
Destination file directory	No	Yes	Empty string	The directory to which the file is being transferred on the secondary Connect:Direct server (SNODE). Note that the directory must exist. If this field is left blank, the default directory is used by the SNODE. On z/OS, if the File name is a sequential dataset, or partitioned dataset member, leave the directory field blank.	destinationDirectory

Property	M	C	Default	Description	mqsiapplybaroverride command property
Destination file name	Yes	Yes	None	The specific file name or a pattern containing a single wildcard that defines the name of the file to be created by the secondary Connect:Direct server (SNODE). The File name can be a pattern that contains a single wildcard. The wildcard value is taken from the element in the local environment folder called `LocalEnvironment.Wildcard.WildcardMatch` . This value is normally set by CDInput or FileInput nodes. For example, if the CDInput node sets its file pattern to `*.in`, it matches the file `test.in` as "`test`". If the CDOutput node's file pattern is set to `*.out`, the "`test`" is substituted to make a file name of `test.out`. The file name must be set, but can be overridden using the local environment field `LocalEnvironment.Destination.CD.Name` You can specify z/OS sequential datasets or partitioned data set members. For whole, sequential data sets, specify the full name for the dataset, for example, `MBUSER.TEST1` For a member within a partitioned dataset, use brackets to specify the member name, for example, `MBUSER.TEST(MEME01)`. One wildcard character can be used anywhere within a dataset name, and works in the same way as for normal file name patterns.	destinationFileName
`CDServer` configurable service	No	Yes	Default	The name of the configurable service being used to connect to the primary Connect:Direct server (PNODE), in order to initiate the transfer. If this value is not set, the default configurable service (named "Default") is used. The default configurable service connects to a PNODE located on the same machine as the broker, and using default port configurations. The default configurable service also uses the "default" security identity, which must be created using the mqsisetdbparms command; for example: `mqsisetdbparms MB7BROKER -n cd::default -u mqbroker -p xxxxxxx` For information on various configurations when using IBM Sterling Connect:Direct, see “Advanced configuration properties when using IBM Sterling Connect:Direct nodes” on page 727 and refer to the Output sections.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Process name	No	Yes	None	The name used for the process script generated to send the file from the primary Connect:Direct server (PNODE) to the secondary Connect:Direct server (SNODE). Use this option if you want to identify this transfer uniquely. If this value is not set, the process name WMBPROC is used. You can use any name you want in the process script. Note, however, that the name must be a maximum of eight characters and cannot contain any spaces.	processName
Disposition	Yes	Yes	`RPL - replace file`	How to create the file on the secondary system: RPL - Replace or create a new file MOD - Append to existing file. This option is not available on z/OS NEW - Create a new file On z/OS, for partitioned datasets, only RPL and NEW options are supported. NEW attempts to allocate a new partitioned dataset, with the following IBM Sterling Connect:Direct SPACE options: `'(23036,(2,1,1))'` You can override these values in the local environment by using: `LocalEnvironment.Destination.CD.Copy.To.Option.SPACE =`	disposition
Transfer Mode	yes	Yes	Binary transfer (no conversion)	The mode in which to transfer the file. binary - The file is transferred as binary, with no conversion text - The file is transferred with conversion between local codepages, as required. When using transfer mode "text" on z/OS, IBM Sterling Connect:Direct requires that the file contains at least one newline character. You must ensure that the file is created in the correct form for IBM Sterling Connect:Direct to successfully complete the text transfer.	transferMode

Request properties

Property	M	C	Default	Description
Data location	No	No	`$Body`	The location in the input message tree that contains the record to be written to the output file. The default value, `$Body`, means the entire message.

Records and Elements properties

Property	M	C	Default	Description
Record definition	Yes	No	`Record is Whole File`	Specifies how records are placed in the output file. Valid options are: • `Record is Whole File` • `Record is Unmodified Data` • `Record is Fixed Length Data` • `Record is Delimited Data`
Length (bytes)	Yes	No	`80`	The required length of the output record. The property is available only when `Record is Fixed Length Data` is specified in `Record definition`.
Padding byte (hexadecimal)	Yes	No	`20`	The 2-digit hexadecimal byte to be used to pad short messages. The property is available only when `Record is Fixed Length Data` is specified in `Record definition`.
Delimiter	Yes	No	`Broker System Line End`	The delimiter to be used. The property is available only when `Record is Delimited Data` is specified in `Record definition`. Valid options are: • `Broker System Line End` • `Custom Delimiter (hexadecimal)`
Custom delimiter (hexadecimal)	Yes	No	None	The delimiter byte sequence to be used. The property is available only when `Record is Delimited Data` is specified in the `Record definition` property, and `Custom Delimiter (hexadecimal)` is specified in the `Delimiter` property.
Delimiter type	Yes	No	`Postfix`	This property specifies how delimiters are to be inserted between records. The property is available only when `Record is Delimited Data` is specified in `Record definition`. Valid options are: • `Postfix` • `Infix`

Validation properties

For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Validate	Yes	Yes	`Inherit`	This property controls whether validation takes place. Valid values are: • `None` • `Content and Value` • `Content` • `Inherit`	validateMaster
Failure action	Yes	No	`Exception`	This property controls what happens if validation fails. The property is available only if you set `Validate` to `Content` or `Content and Value`. Valid values are: • `User Trace` • `Local Error Log` • `Exception` • `Exception List`	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Check node

Use the Check node to compare the template of a message that is arriving on its input terminal with a message template that you supply when you configure the Check node.

Attention: The Check node is deprecated in WebSphere Message Broker Version 6.0 and subsequent versions. Although message flows that contain a Check node remain valid, redesign your message flows where possible to replace Check nodes with Validate nodes.

This topic contains the following sections:

Purpose:
The message domain, message set, and message type of the message are collectively called the *message template*. The domain defines the parser that is used for the message. The set is the message set to which the message belongs. The type

is the structure of the message itself. You can check the incoming message against one or more of these properties. The message property is checked only if you select its corresponding `Check` property, which means that a message property that contains a null string can be compared.

If the message properties match the specification, the message is propagated to the Match terminal of the node. If the message properties do not match the specification, the message is propagated to the Failure terminal. If the Failure terminal is not connected to some failure handling processing, an exception is generated.

The Check node is contained in the **Validation** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Use the Check node to ensure that the message is routed appropriately through the message flow. For example, you can configure the node to direct a message that requests stock purchases through a different route from that required for a message that requests stock sales.

Another example of this node's use is for the receipt of electronic messages from staff at your head office. These messages are used for multiple purposes; for example, to request technical support or stationery, or to advise you about new customer leads. These messages can be processed automatically because your staff complete a standard form. If you want these messages to be processed separately from other messages received, use the Check node to ensure that only staff messages with a specific message type are processed by this message flow.

Terminals and properties:
When you have put an instance of the Check node into a message flow, node into a message flow, you can configure it. For more information, see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The Check node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the message is routed if the incoming message does not match the specified properties.
Match	The output terminal to which the message is routed if the incoming message matches the specified properties.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Check node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	Check	The name of the node
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Check node Basic properties are described in the following table.

Property	M	C	Default	Description
Domain	No	No		The name of the domain.
Check domain	Yes	No	Cleared	This property checks that a message belongs to a particular domain. To check the parser that is to be used for the incoming message, select this check box and select one of the values from the `Domain` list.
Set	No	No		The message set to which the incoming message belongs. If you are using the MRM, IDOC, or XMLNSC parser, check that the incoming message belongs to a particular message set by selecting `Check set` and entering the name of the message set in `Set`. Leave `Set` clear for other parsers. If you set this property, then subsequently update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project.
Check set	Yes	No	Cleared	If you select this check box, the incoming message is checked against the `Set` property.
Type	No	No		The message name. If you are using the MRM parser, check that the incoming message is a particular message type by selecting `Check type` and entering the name of the message in `Type`. Leave `Type` clear for other parsers.
Check type	Yes	No	Cleared	If you select this check box, the incoming message is checked against the `Type` property.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

The broker provides validation based on the message model for predefined messages.

Related reference:

"Validate node" on page 4959
Use the Validate node to check that the message that arrives on its input terminal is as expected. You can use this node to check that the message has the expected message template properties, and to check that the content of the message is correct by selecting message validation.

CICSRequest node

Use the CICSRequest node to call CICS Transaction Server for z/OS programs over TCP/IP-based IP InterCommunications (IPIC) protocol.

This topic contains the following sections:

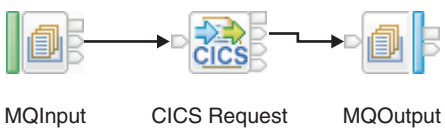
- "Purpose"
- "Using the CICSRequest node in a message flow"
- "Configuring the CICSRequest node" on page 4323
- "Local environment overrides" on page 4323
- "Terminals and properties" on page 4323

Purpose:

You can use the CICSRequest node to connect WebSphere Message Broker to CICS applications. The CICSRequest node communicates with CICS by sending Distributed Program Link (DPL) requests over TCP/IP-based IP InterCommunications protocol (IPIC). You can create a message flow that contains a CICSRequest node, which calls a CICS application on a targeted region. The CICSRequest node can be used by a message flow that is deployed to any broker platform. The CICSRequest node supports CICS Transaction Server for z/OS Version 3.2 and later.

Using the CICSRequest node in a message flow:

One possible use of a CICSRequest node is to connect to a CICS application by using a synchronous style of message flow. You can achieve this connection by creating the following message flow:



The CICSRequest node support in WebSphere Message Broker provides direct communication with CICS (two-tier connection) by sending Distributed Program Link (DPL) requests over TCP/IP-based IPIC, or communication with CICS through CICS Transaction Gateway for Multiplatforms (three-tier connection). For more information about the two-tier and three-tier connection models, see "CICS Transaction Server for z/OS overview" on page 2173 for a high-level overview, or "CICS Transaction Server for z/OS two-tier connectivity" on page 2177 and "CICS Transaction Server for z/OS three-tier connectivity" on page 2181 for detailed conceptual information.

You can specify either a COMMAREA data structure or a channel data structure on the CICSRequest node to use as input for linking to CICS programs. The data structure that is specified as input returns the same data structure as output. Channels are an alternative for COMMAREAs, providing relief from the COMMAREA maximum size of `32767` bytes, and allowing greater flexibility in input/output data structures. For more information about using a COMMAREA or channel data structure, see "COMMAREA or channel data structures" on page 2183.

CICS channels hold a number of structures called containers. In WebSphere Message Broker, a CICS channel is represented as a message collection structure. A message collection can hold child messages, each treated as a container by the CICSRequest node. For information about using ESQL to create a message collection, see "Creating a message collection by using ESQL" on page 2758.

If a single container is required for input only, a message collection does not need to be constructed. Instead a regular message can be used, provided the 16-character maximum alphanumeric channel name and the single 16-character maximum alphanumeric container name are specified in the local environment. For more information about using single message mode, see "COMMAREA or channel data structures" on page 2183.

Because it is not possible to know how many containers are in the response, a message collection is always produced as output. However, the CICSRequest node `Result data location` property can be used to reduce the result tree down to a single message folder, or down to a single field or subtree for output.

You can add name-value attributes to a message collection to create CICS containers. Name-value attributes in the message collection, apart from *`CollectionName`*, can be used in lieu of full message-folders for simple data. For example, a name-value string attribute can be set in the message collection and used directly by the CICSRequest node without needing to create a message set for the element. For information about using attributes, see "COMMAREA or channel data structures" on page 2183.

Name-value attributes can be produced from containers on output, as well as accepted for input. To create an attribute instead of a message folder from a container, select the check box that is available on the Response Message Parsing tab.

The CICSRequest node is contained in the **CICS** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

View the following sample to see how to use the CICSRequest node:

- CICS Transaction Server for z/OS Connectivity

View the following sample to see how to call a channel-based CICS program by creating and populating a message collection for the CICSRequest node, and how to process the collection after the call:

- CICS Transaction Server for z/OS Channel Connectivity

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

The CICSRequest node can use an identity that is present on an input message, and propagate it to CICS, by using the `Propagate` property on the security profile that is defined for the node. For more information, see "Propagating security credentials to CICS Transaction Server for z/OS" on page 2208 and "Identity and security token propagation" on page 426.

You can specify a mirror transaction name on the CICSRequest node for CICS tasks and programs to run under. This grouping greatly assists stat collection, accounting, and aids decision making about task priority. For more information about mirror transactions, see "CICS Transaction Server for z/OS mirror transactions" on page 2189.

Using configurable services for the CICSRequest node

You can configure the CICSRequest node to get connection details from a configurable service. For details about creating, changing, reporting, and deleting the configurable services, see "Changing connection information for the CICSRequest node" on page 738.

Configuring the CICSRequest node:
When you have put an instance of the CICSRequest node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

All mandatory properties for which you must enter a value (properties that do not have a default value defined) are marked with an asterisk.

Local environment overrides:
You can dynamically override values, on a per message basis, in the local environment. You can override the CICS program that you are calling, the COMMAREA length, mirror transactions, and the processing of the response message. For more information, see "Local environment overrides for the CICSRequest node" on page 2191.

Terminals and properties:
The CICSRequest node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node. The CICSRequest node is driven by a message arriving on the In terminal. Data is taken from the message tree and is sent to CICS.
Out	The output terminal from which the message tree is propagated, including the data returned from CICS.
Failure	The output terminal to which a message is routed if a CICSRequest node exception is detected, or a CICSRequest node to CICS connection failure occurs.
Error	The output terminal to which a message is propagated if a CICS error (abend) occurs. The input message is propagated with a CICS\AbendCode field in the LocalEnvironment. If the Error terminal is not connected and CICS abend occurs, the abend is lost.
Timeout	The output terminal to which the message is propagated if a per-request timeout occurs when an individual request is sent to CICS, but the request takes too long. The output message contains the input message body and a timeout exception in the ExceptionList. If the Timeout terminal is not connected and a timeout occurs, the request timeout exception is routed to the Failure terminal. If the Failure terminal is not connected, the broker throws an exception and returns control to the closest upstream node that can process it. The default behavior is that the message is returned to the input node.

The following tables describe the CICSRequest node properties.

The table column headed M indicates whether the property is *mandatory*. For example, the property is marked with an asterisk meaning that you must enter a value if no default is defined.

The column headed C indicates whether the property is *configurable*. For example, you can change the value when you add the message flow to the BAR file to deploy it.

The CICSRequest node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	Yes	No	CICS Request	The name of the node.
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

The CICSRequest node Basic properties are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
CICS server	Yes	Yes	None	The `CICS server` property is defined either as a configurable service name, for example: *myCICSConnection*, or as a URL. A URL allows you to specify a protocol, host name, and port number, which is the minimum information you need to connect to the CICS target region. The URL must be made up of the following structure: *protocol*`://`*hostname*`:`*port* Where: • *protocol* can be `tcp` or `ssl`. • *hostname* is the Internet Protocol version 4 (IPv4) TCP/IP address or DNS-resolvable hostname of the CICS host. • *port* is the port number of the TCPIPSERVICE listener in CICS that is listening for IPIC requests over TCP/IP or Secure Sockets Layer (SSL) protocol. You can enter an integer in the range 1 - 65535. For example: `tcp://mycicsregion.com:12345` or `ssl://mycicsregion.com:56789`. You can obtain the *hostname* and *port* values from the IPIC TCPIPSERVICE definition in the target CICS region.	cicsServer
Program name	Yes	No	None	The Program name property is the name of the application that is on the target CICS region that you are calling. Programs that use COMMAREAs or channels are supported. You can override this property in the local environment by specifying a value in the following location: `$LocalEnvironment/Destination/CICS/CICSProgramName`	
Data structure	Yes	No	Commarea	Whether to use a COMMAREA or a channel data structure. The default for this property is `Commarea`. The decision depends on the targeted CICS program, for example; whether the target program is channel-based or not.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Commarea length	Yes	No	0	The Commarea length property is the size, in bytes, of the COMMAREA that is used by the CICS program. The byte size value is sent to CICS, and before the program is started, an area of memory is created to match that number. For example, if you send a Commarea length value of 100, 100 bytes are allocated. The program accesses this area as the DFHCOMMAREA. Ensure that the Commarea length property value is large enough to contain the input request data, or the output response data, but that it does not exceed the maximum value of 32767 bytes. If the Commarea length value is not large enough to be used for the response data, or the request data, a memory leak occurs in CICS. The size of the COMMAREA cannot be changed by the CICS program. If the serialized request data is larger than the Commarea length, the data is truncated to the Commarea length. You can obtain the Commarea length value from the CICS administrator or developer. You can override this property in the local environment by specifying a value in the following location: $LocalEnvironment/Destination/CICS/CICSCommareaLen This property is not configurable if a value of Channel is selected for the Data structure property.	
Security identity	No	Yes	None	The name of the security identity object that is created and configured by the **mqsisetdbparms** command, which contains the user ID and password to be used by the broker to authenticate the connection to CICS. Use the **mqsisetdbparms** command to set the security identity user ID and password to be accessed by the broker. The default value for this property is None, which signifies that the user ID and password are not passed to CICS. For more information about CICS security identity support, see “**mqsisetdbparms** command” on page 3954.	securityIdentity

Property	M	C	Default	Description	mqsiapplybaroverride command property
Request timeout (in seconds)	Yes	Yes	120	If individual requests sent to CICS take more time than specified here, the request attempt is abandoned. Because the CICSRequest node is non-transactional, the state of the work in CICS cannot be guaranteed and might need to be manually purged. A request timeout causes an exception to be propagated from the Timeout terminal. If the Timeout terminal is not connected, the request timeout exception is routed to the Failure terminal. If the Failure terminal is not connected, the broker throws an exception and returns control to the closest upstream node that can process it. The default behavior is that the message is returned to the input node. A value of 0 indicates that no timeout occurs.	requestTimeoutSecs
Mirror transaction ID	No	Yes	None	You can specify a mirror transaction name by configuring this property, however the `Mirror transaction ID` property value that you specify must correspond to a defined TRANSACTION resource in CICS. For example, if you have a defined TRANSACTION resource of `ATRN` in CICS, and you want tasks and programs to run under that transaction, you must configure `ATRN` as the `Mirror transaction ID` property value. When the message flow containing the configured CICSRequest node is deployed, any CICS programs that are started thereafter appear in CICS as running under the specified mirror transaction. If the value of the `Mirror transaction ID` property is not set, the mirror transaction name defaults to `CPMI` if called by a distributed platform, or `CSMI` if called by a z/OS system. For more information about mirror transactions, see “CICS Transaction Server for z/OS mirror transactions” on page 2189.	mirrorTran

Property	M	C	Default	Description	mqsiapplybaroverride command property
Set EIBTRNID only	No	Yes	Cleared	You can use a weaker form of mirror transaction that does not change the TRANSACTION resource, but instead sets a variable called `EIBTRNID`, which is available to the called program. You can configure the `EIBTRNID` variable to tell the program what TRANSACTION resource it is running under, without the TRANSACTION resource being defined in CICS. For example, you can specify this weaker form of mirror transaction by configuring the `Mirror transaction ID` property with the name of the required TRANSACTION resource; for example `ATRN`, and by selecting this property. When the message flow containing the configured CICSRequest node is deployed, any CICS programs that are started thereafter appear in CICS as running under the specified mirror transaction. If the value of the `Mirror transaction ID` property is not set, the mirror transaction name defaults to `CPMI` if called by a distributed platform, or `CSMI` if called by a z/OS system. For more information about mirror transactions, see "CICS Transaction Server for z/OS mirror transactions" on page 2189.	eibtrnidOnly

The CICSRequest node Request properties are described in the following table.

Property	M	C	Default	Description
Data location	Yes	No	`$Body`	The location in the incoming message tree from which data is retrieved to form the request that is sent from the CICSRequest node to CICS. The default value, `$Body`, represents the incoming message body. You can enter any XPath or ESQL expression that defines the location of the message tree to serialize and send to CICS.
Program name override location	No	No	`$LocalEnvironment/Destination/CICS/CICSProgramName`	The element of the message assembly that contains the name of the program to run in CICS.

The CICSRequest node Result properties are described in the following table.

Property	M	C	Default	Description
Result data location	No	No	`$ResultRoot`	This property specifies which subtree of the result to place in the message. If a value is not specified for this property, `$ResultRoot` is used as the default and the whole response is placed in the output message at the location that is specified in `Output data location`.
Output data location	No	No	`$OutputRoot`	The message tree location to which the CICSRequest node sends output. The default value, `$OutputRoot`, replaces the incoming message with the response.

Property	M	C	Default	Description
Copy local environment	No	No	Selected	This property controls whether to copy the incoming local environment or propagate the incoming local environment. By default, this check box is selected, which signifies that the local environment is copied so that the incoming local environment is preserved. The additions to the local environment are visible only to nodes downstream of this node. If this check box is cleared, the incoming local environment is used for the outgoing message. Any modifications that are made to the local environment by this node are visible to both downstream and upstream nodes after this node has completed.

The CICSRequest node default Response Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	None	**If using a COMMAREA data structure:** The domain to use to parse the response COMMAREA bit stream. **If using a channel data structure:** The domain to use to parse the response container bit stream. You can override this property in the local environment by specifying a value in the following location: `$LocalEnvironment/Destination/CICS/Response/messageDomain`
Message set	No	No	None	**If using a COMMAREA or channel data structure:** The name of the message set in which the response message is defined. If you set this property, and then update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project. You can override this property in the local environment by specifying a value in the following location: `$LocalEnvironment/Destination/CICS/Response/messageSet`
Message type	No	No	None	**If using a COMMAREA or channel data structure:** The type of the response message. You can override this property in the local environment by specifying a value in the following location: `$LocalEnvironment/Destination/CICS/Response/messageType`
Message format	No	No	None	**If using a COMMAREA or channel data structure:** The name of the physical format of the response message. You can override this property in the local environment by specifying a value in the following location: `$LocalEnvironment/Destination/CICS/Response/messageFormat`

Property	M	C	Default	Description
Message coded character set ID	No	No	`EBCDIC (037)`	**If using a COMMAREA data structure:** The ID of the coded character set (CCSID) that is used to interpret bytes of the response COMMAREA. This property defines the CCSID for the message that is returned from CICS. **If using a channel data structure:** The ID of the coded character set (CCSID) that is used to interpret bytes of the response container, however this is ignored for character containers. You can override this property in the local environment by specifying a value in the following location: `$LocalEnvironment/Destination/CICS/Response/messageCCSID` For a list of valid values, see "Supported code pages" on page 4176.
Message encoding	No	No	`Big Endian, with S390 Floating Point (785)`	**If using a COMMAREA data structure:** The encoding scheme for numbers and large characters that is used to interpret bytes of the response COMMAREA. This property defines the message encoding for the message that is returned from CICS. **If using a channel data structure:** The encoding scheme for numbers and large characters that is used to interpret bytes of the response container, however this is ignored for character containers. Valid values are: • Little Endian, with IEEE Floating Point (546) • Big Endian, with IEEE Floating Point (273) • Big Endian, with S390 Floating Point (785) (the default value) • Broker System Determined For more information about encoding, see "Data conversion" on page 1151. You can override this property in the local environment by specifying a value in the following location: `$LocalEnvironment/Destination/CICS/Response/messageEncoding`

Channel Options

If a value of `Channel` is selected for the `Data structure` property on the Basic tab, an additional table is available on the Response Message Parsing tab named Channel Options. The Channel Options table allows you to override the default message template properties by specifying parsing options for individual response containers, on a per-folder basis, when output from the CICSRequest node. You can also create a name-value attribute in the message collection to hold the container by selecting the check box provided.

If the container details are specified in the Channel Options table, those container details are used in preference to the default message template properties. If the container details are not specified in the Channel Options table and the attribute check box is selected, a name-value pair is created.

If the container details are not specified in the Channel Options table and the name-value attribute check box is not selected, the default message template properties are used.

The CICSRequest node Parser Options properties are described in the following table.

Property	M	C	Default	Description
Parse timing	Yes	No	`On Demand`	This property controls when a response message is parsed. Valid values are `On Demand`, `Immediate`, and `Complete`. For a full description of this property, see "Parsing on demand" on page 4173.
Build tree using XML schema data types	Yes	No	Cleared	This property controls whether the XMLNSC parser creates syntax elements in the message tree with data types taken from the XML Schema. You can select this property only if you set the `Validate` property on the **Validation** tab to `Content` or `Content and Value`.
Use XMLNSC compact parser for XMLNS domain	Yes	No	Cleared	This property controls whether the XMLNSC Compact Parser is used for messages in the XMLNS Domain. If you set this property, the response message data appears under XMLNSC in nodes that are connected to the output terminal when the input MQRFH2 header or Response Message Parsing properties Domain is XMLNS.
Retain mixed content	Yes	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in a response message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	Yes	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in a response message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	Yes	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in a response message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the response message that are to be opaquely parsed by the XMLNSC parser. Opaque parsing is performed only if validation is not enabled (that is, if `Validate` is `None`); entries that are specified in `Opaque Elements` are ignored if validation is enabled.

The CICSRequest node Validation properties are described in the following table.

For a full description of these properties see "Validation properties" on page 4169.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Validate	Yes	Yes	`None`	This property controls whether validation takes place. Valid values are `None`, `Content and Value`, `Content`, and `Inherit`.	validateMaster

Property	M	C	Default	Description	mqsiapplybaroverride command property
Failure action	Yes	No	Exception	This property controls what happens if validation fails. You can set this property only if you set Validate to Content or Content and Value. Valid values are User Trace, Local Error Log, Exception, and Exception List.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

CICS Transaction Server for z/OS provides general-purpose transaction processing software for z/OS. CICS is a powerful application server that meets the transaction-processing needs of both large and small enterprises.

"CICS Transaction Server for z/OS connectivity" on page 2174
Use the CICSRequest node to connect WebSphere Message Broker with CICS Transaction Server for z/OS applications.

"CICS Transaction Server for z/OS mirror transactions" on page 2189
You can use a mirror transaction to group CICS Transaction Server for z/OS tasks and programs together. This grouping greatly assists stat collection, accounting, and aids decision making about task priority.

"Configurable services" on page 1296
Configurable services are typically runtime properties. You can use them to define properties that are related to external services on which the broker relies; for example, an SMTP server or a JMS provider.

"Identity and security token propagation" on page 426
Identity and security token propagation enables the identity and security tokens (associated with each message) to be propagated throughout a message flow, and on to target applications through output or request nodes.

"Resource statistics" on page 3306
Resource statistics are collected by a broker to record performance and operating details of resources that are used by execution groups.

"Samples" on page 98
The WebSphere Message Broker Toolkit provides samples that show the features that are available in WebSphere Message Broker, and how to use them. This topic provides links to the information about the individual samples.

Related tasks:

"Connecting to a CICS Transaction Server for z/OS application" on page 2192
Connecting to a CICS Transaction Server for z/OS application involves creating a message flow, building a message, and processing the response from the CICSRequest node.

"Changing connection information for the CICSRequest node" on page 738
You can create a configurable service that the CICSRequest node or message flow refers to at run time for connection information, instead of defining the connection properties on the node or the message flow. The advantage being that you can change the host name and performance values without needing to redeploy your message flow.

"Securing the connection to CICS Transaction Server for z/OS by using SSL" on page 547
Configure the CICSRequest node to communicate with CICS Transaction Server for z/OS over the Secure Sockets Layer (SSL) protocol by updating a CICSConnection configurable service or the CICSRequest node to use SSL.

"Editing configurable properties" on page 3227
You can edit configurable properties in the deployment descriptor file (`broker.xml`) of your broker archive.

"Validating messages" on page 1478
The broker provides validation based on the message model for predefined messages.

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

Collector node

Use the Collector node to create message collections based on rules that you configure in the node.

This topic contains the following sections:

Purpose:

Use the Collector node to create a message collection from one or more sources based on configurable criteria. For example, you might need to extract, combine, and transform information from three different sources. The messages from these different sources might arrive at the input terminals at different times and in an unknown order. A collection is defined by configuring an event handler for each input terminal. Each event handler controls the acceptance of a message into a collection according to the following properties:

- Number of messages
- Collect messages for a set period
- Match the contents of a correlation path
- Match the contents against a correlation pattern

The correlation properties allow collections to be made according to the content of the messages. The content is specified by using an XPath expression. The Collector node ensures that each collection contains an identical correlation string across all its inputs. For more information about XPath 1.0 query syntax, see W3C XPath 1.0 Specification.

A message collection is created when the first message arrives at any of the dynamic input terminals on the Collector node. Message collections are stored on a WebSphere MQ queue.

When the conditions set by the event handlers for a message collection have been met, the message collection is complete and ready to be propagated. For example, if you set the event handlers on the Collector node to wait for two messages from each input terminal, the message collection is complete when two messages have been received by every terminal. When the next message arrives on an input terminal, it is added to a new message collection. You can select from a number of options to determine how the propagation of the message collection is coordinated. You can specify that the message collection is propagated automatically for processing, or alternatively that the message collection is propagated when a control message is received.

You can also set an expiry timeout for message collections that fail to be completed in a satisfactory time by using a property on the Collector node. The timeout starts when the first message is added to a message collection. If the timeout expires before the message collection is complete, the incomplete message collection is propagated to the **Expire** terminal. Set a value for the collection expiry to ensure that incomplete message collections do not remain stored on a queue indefinitely. Add appropriate processing to your message flow to handle incomplete message collections.

The Collector node is contained in the **Routing** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following sample to see how to use this node:

- Collector Node

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Use the Collector node to group messages from different input sources for further processing. A message collection can be processed by the following nodes only:

- Compute
- JavaCompute
- PHPCompute

Errors might be generated if you try to process a message collection with a node that does not support message collections.

The Collector node has one static input terminal, **Control**, and four static output terminals: **Out**, **Expire**, **Failure** and **Catch**. These static terminals are always present on the node. In addition to the static input and output terminals, you can add dynamic input terminals for each input source that you want to use with the Collector node.

You can add and configure as many input terminals as required to the Collector node. You can configure the properties of each input terminal separately to control how the messages received on each input terminal are added to the appropriate message collection.

You can use the **Control** terminal to trigger the output of completed message collections from the Collector node. Configure the `Event coordination` property to set the behavior of the Collector node when messages are received on the **Control** terminal.

When a message collection is successfully completed, it is ready to be propagated to the **Out** terminal. If a value greater than zero is set on the `Collection expiry` property, any incomplete message collections are propagated to the **Expire** terminal.

A new transaction is created when a message collection is complete, and is propagated to the next node. Any exceptions that are caught from downstream nodes cause the message collection to be propagated to the **Catch** terminal on the Collector node, together with the exception list. If the **Catch** terminal is not connected to any other nodes, the transaction is caused to roll back. Messages in the message collection are backed out onto the queue of the Collector node. The exception list is written to the system log. This step is repeated until the message collection is successfully processed. To avoid an exception that causes the message collection to fail to be propagated successfully, ensure that you connect the **Catch** terminal to a flow to handle any exceptions. Also, ensure that you set an expiry timeout to propagate incomplete message collections.

Note: Any exceptions that occur downstream of the Collector node are routed to the **Catch** terminal. The exception is not processed any further upstream because the completion of the message collection in the Collector node is the start of the transaction. This behavior is like the AggregateReply node. Do not connect a Throw node to the **Catch** terminal of the Collector node, because control is returned to the same **Catch** terminal.

If you use additional instances of a message flow or multiple inputs to the Collector node, you can use the `Correlation path` and `Correlation pattern` properties to ensure that related messages are added to the same message collection. If you use additional instances, or multiple inputs to the Collector node the order of messages in the message collection can be unpredictable. The order of messages is also unpredictable if you use WebSphere MQ cluster queues as inputs to the Collector node.

Configuring the Collector node:
When you have put an instance of the Collector node into a message flow, you can configure it; see “Configuring the Collector node” on page 2767. The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those properties that do not have a default value defined) are marked with an asterisk.

Terminals and properties:
The Collector node terminals are described in the following table.

Terminal	Description
Control	The static input terminal that accepts control messages. Any message received by the Control terminal is treated as a control message.

Terminal	Description
Out	The output terminal to which the complete message collection is routed if the received messages satisfy the configured conditions for the message collection.
Expire	The output terminal to which the incomplete message collection is routed if the received messages do not satisfy the configured conditions within the time specified on the Collection expiry property. If you have not set a value for the Collection expiry property this terminal is not used.
Failure	The output terminal to which the message collection is routed if a failure is detected during processing.
Catch	The output terminal to which the message collection is routed if an exception is thrown downstream and caught by this node.

The Collector node can have further dynamic input terminals. You can create numeric terminal labels for the Collector node; however, the Compute node does not support numeric labels. Therefore, when you are defining a custom terminal for the Collector node, ensure that the name begins with an alphabetic character.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Collector node Description properties are described in the following table:

Property	M	C	Default	Description
Node name	No	No	The node type, Collector	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The Collector node has two types of Basic properties. You can set properties for each dynamic input terminal that you add to the Collector node in the Collection Definition table in the Basic properties. The properties in the Collection Definition table define the event handlers for the messages arriving on the individual input terminals. The properties that you can set for each of the dynamic input terminals are described in the following table:

Property	M	C	Default	Description
Terminal	Yes	No	The terminal name	`Terminal` is not a property of the node, but a label to show the name of the dynamic input terminal. Enter values for the event handler properties for each dynamic input terminal that you have added to the Collector node in the Collection Definition table.

Property	M	C	Default	Description
Quantity	Yes	No	1	This property specifies the number of messages that the input terminal accepts to add to a message collection. The default value is 1; if you accept this default value, only one message is added to a collection. If a second message is received on the terminal, a new collection instance is created for it. If you select `0` (zero) or do not specify a value, there is no limit to the number of messages accepted. In this case, the value that is set on the `Timeout` property must be greater than zero. If you set both the `Timeout` and `Quantity` properties to values that are greater than zero, the terminal stops accepting messages when the first of the two thresholds is reached. When this threshold is reached, and other criteria have also been satisfied, the collection is complete and it is propagated to the Out terminal.
Timeout	Yes	No	0	This property specifies the maximum time in seconds for which the input terminal accepts messages. If you select `0` (zero), the timeout is disabled and there is no limit on the time to wait for messages. In this case, the value that is set on the `Quantity` property must be greater than zero. If you set both the `Timeout` and `Quantity` properties to values that are greater than zero, the terminal stops accepting messages when the first of the two thresholds is reached. When this threshold is reached, and other criteria have also been satisfied, the collection is complete and it is propagated to the Out terminal.
Correlation path	No	No		Messages are only accepted into a message collection if they have the same correlation string. If the message has a different correlation string, it is offered to the next collection in the queue. If none of the collections accept the message, a new collection is created with correlation string set to the value of the correlation string in the message. Messages are grouped by the value from the correlation path. The correlation path is defined by using XPath. You can define your own correlation path by using XPath, or select from the following predefined paths: • `$LocalEnvironment/Wildcard/WildcardMatch` • `$Root/MQMD/CorrelId` • `$LocalEnvironment/FileInput/Name` • `$Root/JMSTransport/Transport_Folders/Header_Values/JMSCorrelationID` If you define a value for `Correlation path`, you can optionally configure a `Correlation pattern`.
Correlation pattern	No	No		This property specifies a pattern to match the contents of a correlation path value against. You must set the `Correlation path` property before you set the value for the `Correlation pattern` property. If you set the correlation pattern, you must use one `*` character, optionally surrounded by other text. For example, `*.dat`. If the correlation pattern is blank, the entire text from the correlation path must be matched by the incoming message.

The remaining Basic properties for the Collector node are shown in the following table:

Property	M	C	Default	Description	mqsiapplybaroverride command property
Collection name	No	No		This property specifies the name of the message collection. • If you set this property to contain the wildcard *, the wildcard is replaced by the correlation string from the relevant event handler. • If you leave this property blank or use * and the correlation string is empty, then the collection name is set to an empty string.	
Collection expiry	No	Yes		The amount of time, in seconds, that the Collector node waits for messages to arrive. After this time an incomplete message collection is expired and propagated to the Expire output terminal. If you set this property to zero, the collection expiry is disabled and the Collector node waits for messages indefinitely. Set a value greater than zero to ensure that the message collection is processed, even if not all messages are received. A warning is issued if this property is not set. This property overrides the `Timeout` properties that are set on the input terminals. The `Timeout` property specifies the maximum time in seconds for which the input terminal accepts messages. After this time, the collection is complete and is propagated to the Out terminal. If one input terminal does not have a timeout set, or if its timer has not started, a message collection might wait for an input message indefinitely. In this situation, the `Collection expiry` property is used to ensure that the incomplete message collection is not left in an unresolved state, but is propagated to the Expiry terminal. This property is overridden by the **`Collection expiry`** property, if set, in the Collector configurable service.	collectionExpiry

The Collector node Advanced properties are described in the following table:

Property	M	C	Default	Description
Persistence mode	No	No	The node type, Collector	This property specifies whether messages are stored on the queues of the Collector node persistently.

Property	M	C	Default	Description
Event coordination	Yes	No	`Disabled`	This property specifies how messages received on the Control terminal for event coordination processing are handled in the Collector node. • If you accept the default value (`Disabled`), messages to the Control terminal are ignored and collections are propagated when they are complete. • If you select `All complete collections`, complete message collections are held on a WebSphere MQ queue. When a message is received on the control terminal, all complete message collections on the WebSphere MQ queue are propagated to the Out terminal. • If you select `First complete collection`, complete message collections are held on a WebSphere MQ queue. When a message is received on the control terminal, the first complete message collection on the WebSphere MQ queue is propagated to the Out terminal. The collections are propagated in the same order that they become complete. If the WebSphere MQ queue is empty when the message is received on the Control terminal, the next complete message collection is immediately propagated to the Out terminal.
Configurable service	No	Yes	None set	This property specifies the name of the Collector configurable service to be used by the Collector node. The properties set by the Collector configurable service override the equivalent properties set on the Collector node. For more information about the properties than you can set with this configurable service, see "Configurable services properties" on page 3766.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

You cannot use monitoring properties to configure transaction events on the following nodes:

"Collector node" on page 4333

"Resequence node" on page 4651

Use a monitoring profile instead; see "Configuring monitoring event sources using a monitoring profile" on page 762.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Message collections" on page 2755
A message collection is a single message that contains multiple messages derived from one or more sources.

Related tasks:

"Deciding which nodes to use" on page 1457
WebSphere Message Broker includes many message processing nodes that you can use in your message flows.

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

"Editing configurable properties" on page 3227
You can edit configurable properties in the deployment descriptor file (`broker.xml`) of your broker archive.

"Creating a flow that uses message collections" on page 2764
Use a Collector node in your message flow to group messages from one or more sources into a message collection. You can add dynamic input terminals to your Collector node for each message source that you want to configure for your message flow.

"Configuring the Collector node" on page 2767
You can configure the Collector node to determine how messages are added to message collections. You can also use properties on the Collector node to control when message collections are propagated.

"Adding an input terminal to a Collector node for each input source" on page 2768
Add new dynamic input terminals to the Collector node for all of the sources of messages for your message collections.

"Using message collections" on page 2755
A message collection is a single message that contains multiple messages derived from one or more sources. You can use a Collector node to group together messages from one or more sources into a message collection, so that they can be processed together by downstream nodes.

Compute node

Use the Compute node to construct one or more new output messages.

This topic contains the following sections:

Purpose:

The output messages that you create in the Compute node might be created by modifying the information that is provided in the input message, or by using only new information which can be taken from a database or from other sources. Elements of the input message (for example, headers, header fields, and body data), its associated environment, and its exception list can be used to create the new output message.

Specify how the new messages are created by coding ESQL in the message flow ESQL resource file. For more information, see “Specifying ESQL” on page 4342.

Use the Compute node to:
- Build a new message using a set of assignment statements
- Copy messages between parsers
- Convert messages from one code set to another
- Transform messages from one format to another

The Compute node is contained in the **Transformation** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following samples to see how to use this node:
- Airline Reservations
- Aggregation
- JMS Nodes
- Large Messaging
- Message Routing
- Scribble
- Timeout Processing
- Video Rental

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Consider a message flow in which you want to give each order that you receive a unique identifier for audit purposes. The Compute node does not modify its input message; it creates a new, modified copy of the message as an output message. You can use the Compute node to insert a unique identifier for your order into the output message, which can be used by subsequent nodes in the message flow.

Configuring the Compute node:
When you have put an instance of the Compute node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

Configure the Compute node by:
1. “Defining database interaction”
2. “Specifying ESQL” on page 4342
3. “Setting the mode” on page 4344
4. “Validating messages” on page 4346

Defining database interaction:
To access a database from this node:
- On the **Basic** tab, specify in `Data Source` the name by which the appropriate database is known on the system on which this message flow is to run. The

broker connects to this database with user ID and password information that you have specified on the **mqsicreatebroker**, **mqsichangebroker**, or **mqsisetdbparms** command.

z/OS On z/OS systems, the broker uses the broker started task ID, or the user ID and password that were specified on the **mqsisetdbparms** command JCL, BIPSDBP in the customization data set <hlq>.SBIPPROC.

- Select the `Transaction` setting from the list. The values are:
  - `Automatic` (the default). The message flow, of which the Compute node is a part, is committed if it is successful. That is, the actions that you define in the ESQL module are performed on the message and it continues through the message flow. If the message flow fails, it is rolled back. If you choose `Automatic`, the ability to commit or roll back the action of the Compute node on the database depends on the success or failure of the entire message flow.
  - `Commit`. To commit the action of the Compute node on the database, irrespective of the success or failure of the message flow as a whole, select `Commit`. The database update is committed even if the message flow itself fails.

  The value that you choose is implemented for the one or more database tables that you have added; you cannot select a different value for each table.
- To treat database warning messages as errors and have the node propagate the output message to the Failure terminal, select `Treat warnings as errors`. The check box is cleared initially.

  When you select the check box, the node handles all positive return codes from the database as errors and generates exceptions in the same way as it does for the negative, or more serious, errors.

  If you do not select the check box, the node treats warnings as typical return codes, and does not raise any exceptions. The most significant warning raised is `not found`, which can be handled as a typical return code safely in most circumstances.
- To force the broker to generate an exception when a database error is detected, select `Throw exception on database error`. The check box is selected initially.

  If you clear the check box, you must include ESQL to check for any database error that might be returned after each database call that you make (you can use SQLCODE and SQLSTATE to do this). If an error occurs, you must handle the error in the message flow to ensure the integrity of the broker and the database; the error is ignored if you do not handle it through your own processing because you have chosen not to invoke the default error handling by the broker. For example, you can include the ESQL THROW statement to throw an exception in this node, or you can use the Throw node to generate your own exception at a later point in the message flow.

Specifying ESQL:
Code ESQL statements to customize the behavior of the Compute node. For example, you can customize the node to create a new output message or messages, using input message or database content (unchanged or modified), or new data. For example, you might want to modify a value in the input message by adding a value from a database, and storing the result in a field in the output message.

Code the ESQL statements that you want in an ESQL file that is associated with the message flow in which you have included this instance of the Compute node. The ESQL file, which by default has the name `<message_flow_name>.esql`, contains ESQL for every node in the message flow that requires it. Each portion of code that is related to a specific node is known as a module.

If an ESQL file does not already exist for this message flow, double-click the Compute node, or right-click the node and click **Open ESQL**. This action creates and opens a new ESQL file in the ESQL editor view. If you prefer, you can open the appropriate ESQL file in the Broker Development view and select this node in the Outline view.

If the file exists already, click **Browse** beside the `ESQL Module` property to display the Module Selection dialog box, which lists the available Compute node modules defined in the ESQL files that are accessible by this message flow (ESQL files can be defined in other, dependent, projects). Select the appropriate module and click **OK**. If no suitable modules are available, the list is empty.

If the module that you have specified does not exist, it is created for you and the editor displays it. If the file and the module exist already, the editor highlights the correct module.

If a module skeleton is created for this node in a new or existing ESQL file, it consists of the following ESQL. The default module name is shown in this example:

```
CREATE COMPUTE MODULE <flow_name>_Compute
       CREATE FUNCTION Main() RETURNS BOOLEAN
       BEGIN
              -- CALL CopyMessageHeaders();
              -- CALL CopyEntireMessage();
              RETURN TRUE;
       END;

       CREATE PROCEDURE CopyMessageHeaders() BEGIN
              DECLARE I INTEGER 1;
              DECLARE J INTEGER CARDINALITY(InputRoot.*[]);
              WHILE I < J DO
                     SET OutputRoot.*[I] = InputRoot.*[I];
                     SET I = I + 1;
              END WHILE;
       END;

       CREATE PROCEDURE CopyEntireMessage() BEGIN
              SET OutputRoot = InputRoot;
       END;
END MODULE;
```

If you create your own ESQL module, you must create this skeleton exactly as shown except for the procedure calls and definitions (described later in this section). You can change the default name, but ensure that the name you specify matches the name of the corresponding node property `ESQL Module`. If you want the module name to include one or more spaces, enclose the name in double quotation marks in the `ESQL Module` property.

Add your own ESQL to customize this node after the BEGIN statement that follows CREATE FUNCTION, and before RETURN TRUE. You can use the two calls included in the skeleton, to procedures CopyEntireMessage and CopyMessageHeaders.

These procedures, defined following function Main, provide common functions that you might want when you manipulate messages. The calls in the skeleton are commented out; remove the comment markers if you want to use the procedure. If you do not want to use a procedure, remove both the call and the procedure definition from the module.

Setting the mode:
The `Compute Mode` property controls which components are used by default in the output message. Select the property to specify whether the `Message`, `LocalEnvironment` (previously specified as DestinationList), and `Exception List` components that are either generated in the node or contained in the incoming message are used.

This default value is used when the transformed message is routed to the Out terminal when processing in the node is completed. The default value is also used whenever a PROPAGATE statement does not specify the composition of its output message.

Those components that are not included in your selection are passed on unchanged; even if you modify those components, the updates are local to this node.

Conversely, those components that are included in the selection are not passed on and the updates that are made in the node persist.

The seven possible values that the `Compute Mode` property can take are listed in the following table.

Mode	**Description**
Message (the default)	The message is generated or passed through by the Compute node as modified in the node. The message contains the modified OutputRoot tree, the original InputLocalEnvironment tree, and the original InputExceptionList tree.
LocalEnvironment	The LocalEnvironment tree structure is generated or passed through by the Compute node as modified in the node. The message contains the original InputRoot tree, the modified OutputLocalEnvironment tree, and the original InputExceptionList tree.
LocalEnvironment And Message	The LocalEnvironment tree structure and message are generated or passed through by the Compute node as modified by the node. The message contains the modified OutputRoot tree, the modified OutputLocalEnvironment tree, and the original InputExceptionList tree.
Exception	The Exception List is generated or passed through by the Compute node as modified by the node. The message contains the original InputRoot tree, the original InputLocalEnvironment tree, and the modified OutputExceptionList tree.
Exception And Message	The Exception List and message are generated or passed through by the Compute node as modified by the node. The message contains the modified OutputRoot tree, the original InputLocalEnvironment tree, and the modified OutputExceptionList tree.

Mode	Description
Exception and LocalEnvironment	The Exception List and LocalEnvironment tree structure are generated or passed through by the Compute node as modified by the node. The message contains the original InputRoot tree, the modified OutputLocalEnvironment tree, and the modified OutputExceptionList tree.
All	The message, Exception List, and LocalEnvironment are generated or passed through by the Compute node as modified by the node. The message contains the modified OutputRoot tree, the modified OutputLocalEnvironment tree, and the modified OutputExceptionList tree.

The value of the `Compute Mode` property specifies which new message trees are propagated from the Compute node. Therefore, for those message trees that are selected, the input messages are discarded unless they are explicitly copied into the new equivalent output message tree.

If `All` is selected, the Compute node is expecting to generate all three new message trees for the Root, LocalEnvironment, and ExceptionList by populating the OutputRoot, OutputLocalEnvironment, and OutputExceptionList. The input message trees are not passed to the output unless they are copied explicitly from the Input to the Output.

Therefore, if the `Compute Mode` property is set to `All`, you must code the following ESQL to allow the input trees to be propagated to the output terminal:

```
SET OutputRoot = InputRoot;
SET OutputLocalEnvironment = InputLocalEnvironment;
SET OutputExceptionList = InputExceptionList;
```

If the ESQL was `CopyEntireMessage()`, the LocalEnvironment and ExceptionList are not copied across and are not propagated to the output terminal; they are lost at that node in the message flow.

To produce a new or changed output message, and propagate the same LocalEnvironment and ExceptionList, set the `Compute Mode` property to `Message` so that the LocalEnvironment and ExceptionList that are passed to the Compute or Mapping node, are passed on from the Compute node.

The `Compute Mode` applies only to propagation from the node. You can create all three output trees in a Compute or Mapping node and these can be manipulated and exist in the node. However, the `Compute Mode` determines whether such output trees are used on propagation from the node.

On propagation from the node, the following trees are propagated from the Compute or Mapping node for the following settings.

Compute Mode	**Trees propagated**
All	OutputRoot, OutputLocalEnvironment, OutputExceptionList
Message	OutputRoot, InputLocalEnvironment, InputExceptionList
LocalEnvironment	InputRoot, OutputLocalEnvironment, InputExceptionList

Compute Mode	Trees propagated
LocalEnvironment and Message	OutputRoot, OutputLocalEnvironment, InputExceptionList
Exception	InputRoot, InputLocalEnvironment, OutputExceptionList
Exception and Message	OutputRoot, InputLocalEnvironment, OutputExceptionList
Exception and LocalEnvironment	InputRoot, OutputLocalEnvironment, OutputExceptionList

Where an output tree is named, ESQL creates this message tree before propagation. If your ESQL does not create the tree, no tree is propagated for that correlation name, and the input tree is not used in its place because the `Compute Mode` property did not indicate this option. Therefore, dependent on `Compute Mode` property settings and your ESQL, you might delete a tree that was input to the node, because you did not transfer it to the output tree, or propagate a changed tree as you intended.

The converse is also true. If your ESQL interrogates the input trees and does not need to propagate these trees, the `Compute Mode` property value might mean that the message tree propagates when you do not intend it to. For example, you might not want to propagate the LocalEnvironment and ExceptionList from a Compute node, but because you selected `Message`, the input versions of the trees are propagated. Even if the ESQL explicitly deletes the OutputLocalEnvironment and OutputExceptionList, these changes are local to that node because the `Compute Mode` property setting causes the input trees to be propagated.

The Environment component of the message tree is not affected by the `Compute Mode` property setting. Its contents, if any, are passed on from this node in the output message.

Set this property to reflect the output message format that you require. If you select an option (or accept the default value) that does not include a particular part of the message, that part of the message is not included in any output message that is constructed.

The Compute node has both an input and output message, so that you can use ESQL to refer to fields in either message. You can also work with both InputLocalEnvironment and OutputLocalEnvironment, and InputExceptionList and OutputExceptionList, as well as the input and output message bodies.

Validating messages:
Set the validation properties to define how the message that is produced by the Compute node is to be validated. These properties do not cause the input message to be validated. It is expected that, if such validation is required, the validation has already been performed by the input node or a preceding validation node.

For more details, see “Validating messages” on page 1478 and “Validation properties” on page 4169.

Terminals and properties:
The Compute node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the input message is routed if an unhandled exception occurs during the computation.
Out	The output terminal to which the transformed message is routed when processing in the node is completed. The transformed message might also be routed to this terminal by a PROPAGATE statement.
Out1	The first alternative output terminal to which the transformed message might be routed by a PROPAGATE statement.
Out2	The second alternative output terminal to which the transformed message might be routed by a PROPAGATE statement.
Out3	The third alternative output terminal to which the transformed message might be routed by a PROPAGATE statement.
Out4	The fourth alternative output terminal to which the transformed message might be routed by a PROPAGATE statement.

For the syntax of the PROPAGATE statement, see "PROPAGATE statement" on page 5150.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file for deployment).

The Compute node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The Compute node Basic properties are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Data Source	No	Yes		The ODBC data source name for the database that contains the tables to which you refer in the ESQL file that is associated with this message flow (identified in the `ESQL Module` property). You can specify only one data source for the node. If the ESQL that is associated with this node includes a PASSTHRU statement or SELECT function and a database reference, you must specify a value for the `Data Source` property.	dataSource
Transaction	Yes	No	Automatic	The transaction mode for the node. Valid options are `Automatic` and `Commit`. The property is valid only if you have selected a database table for input.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
ESQL Module	No	No	Compute	The name of the module in the ESQL file that contains the statements to run against the database and input and output messages.	
Compute Mode	Yes	No	`Message`	Choose from: • `Message` • `LocalEnvironment` • `LocalEnvironment And Message` • `Exception` • `Exception And Message` • `Exception And LocalEnvironment` • `All` For more information about setting the mode options, see "Setting the mode" on page 4344.	
Treat warnings as errors	Yes	No	Cleared	If you select the check box, database SQL warnings are treated as errors.	
Throw exception on database error	Yes	No	Selected	If you select this check box, database errors cause the broker to throw an exception.	

The Validation properties of the Compute node are described in the following table. For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	Yes	`None`	This property controls whether validation takes place. Valid values are `None`, `Content and Value`, `Content`, and `Inherit`.	validateMaster
Failure Action	No	No	`Exception`	This property controls what happens if a validation failure occurs. You can set this property only if `Validate` is set to `Content` or `Content and Value`. Valid values are `User Trace`, `Local Error Log`, `Exception`, and `Exception List`.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

CORBARequest node

Use the CORBARequest node to call an external CORBA application over Internet Inter-Orb Protocol (IIOP).

This topic contains the following sections:

- "Purpose" on page 4350

- "Using this node in a message flow"
- "Configuring the CORBARequest node"
- "Terminals and properties" on page 4351

Purpose:
You can use the CORBARequest to connect WebSphere Message Broker to CORBA applications. CORBA is a standard for distributing objects across networks so that operations on those objects can be called remotely. CORBA objects are described in Interface Definition Language (IDL) files. You can create a message flow that contains a CORBARequest node, which calls a CORBA server. The message flow uses the IDL file to configure which operation is called on which interface. By using a message flow that includes a CORBARequest node, you can give existing CORBA applications a new external interface; for example, a SOAP interface. The IDL file is stored in a message set project inside a folder called `CORBA IDLs`, and is used to configure the CORBARequest node in the message flow.

Using this node in a message flow:
One possible use of a CORBARequest node is to connect a SOAP-based Web service application to an existing CORBA IIOP application by using a synchronous style of message flow. You can achieve this connection by creating the following message flow:

In this example, the SOAPInput node receives a Web service request, the Mapping node transforms the data in the SOAP message to a CORBA request, and a request is made to the CORBA server. The second Mapping node transforms the response message back into a SOAP reply, which is propagated by the SOAPReply node.

The CORBARequest node is not transactional. After the node has made a request, it cannot roll back the request. The CORBA nodes use the DataObject domain.

The CORBARequest node is contained in the **CORBA** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Look at the following sample to see how to use this node:

- CORBA nodes

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Configuring the CORBARequest node:
When you have put an instance of the CORBARequest node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

All mandatory properties for which you must enter a value (properties that do not have a default value defined) are marked with an asterisk.

Terminals and properties:
The CORBARequest node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node. Data is taken from the message tree and sent to the CORBA server.
Out	The output terminal from which return parameters are propagated.
Failure	The output terminal to which a message is routed if a failure is detected.
Error	CORBA exception messages that are received in response to the sent request are sent to the Error terminal. If the Error terminal is not connected, and an error is received, no further processing occurs in the message flow. The error is logged as a warning in user trace.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined; the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The CORBARequest node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node name	The name of the node.
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

The CORBARequest node Basic properties are described in the following table.

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
Naming service	Yes	Yes		The location of the naming service that contains the object that you are calling. For this property, you can specify either the host name of the naming service or a CORBA configurable service. • Specify the host name of the naming service from which to get the object reference in the format *host:port*, where *port* is optional. For example, localhost:2809. If you do not specify a port number, the default value is 2809. You can obtain this value from the administrator of the CORBA application that you are calling. • Specify the name of a configurable service of type CORBA. If you specify a configurable service name, you can use the configurable service to override the `Naming service` and `Object reference name` properties. For more information about using a configurable service to specify a naming service, see "Defining where the CORBARequest node gets the object reference" on page 734.	namingService

Property	M	C	Default	Description	mqsiapplybaroverride command property
Object reference name	Yes	Yes		The name of the reference to the object in the naming service. You can obtain this value from the CORBA server that you are calling. For more information about how to specify the object reference name, see "CORBA naming service" on page 2154. You can also use a configurable service to specify an object reference name. For more information, see "Defining where the CORBARequest node gets the object reference" on page 734.	referenceName
IDL file	Yes	No		The IDL file in a message set project that is used to configure the CORBARequest node. Click **Browse** to select an IDL file in a referenced message set. If you have dragged an imported IDL file onto the canvas or onto the CORBARequest node, the `IDL file` property is set to the name of the IDL file. When you specify an IDL file, the `Interface name` property is populated with a list of available interfaces.	
Interface name	Yes	No		The interface from the IDL file that the node calls. Either type a valid interface name, or click **Select interface** and select an interface from the list. If the list contains a large number of interfaces, you can filter the results. The values that are listed for this property are the interfaces in the selected IDL file that have one or more operations. This list is populated only when an IDL file is specified. If you have dragged an imported IDL file onto the canvas or onto the CORBARequest node, the `Interface name` property is set according to the IDL file. If the interface name is contained in a module in the IDL file, the interface name is qualified with the name of the module. If the module is nested in another module, the interface name is qualified with all module names, starting from the root module; for example: *ModuleNameA.ModuleNameB.InterfaceName* When you specify an interface name, the `Operation name` property is populated with a list of available operations.	
Operation name	Yes	No		The operation to call from the interface. The values that are listed for this property are the supported operations that are available in the selected interface. This list is populated only when an interface name is specified. If you have dragged an imported IDL file onto the canvas or onto the CORBARequest node, the `Operation name` property is set according to the IDL file. You can override this property in the local environment by specifying a value in the following location: `$LocalEnvironment/Destination/CORBA/Request/OperationName`	

The CORBARequest node Response Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	`DataObject`	The domain that is used to parse the response message. By default, the message that is propagated from the CORBARequest node is in the DataObject domain. You cannot specify a different domain.
Message set	No	No	Set automatically	The name of the message set in which the incoming message is defined. The node detects the message set automatically.
Message type	No	No		The name of the response message. The node detects the message type automatically. You cannot set this property.
Message format	No	No		The name of the physical format of the response message. You cannot set this property.

The CORBARequest node Request properties specify how to make a request, and are described in the following table.

Property	M	C	Default	Description
Data location	Yes	No	$Body	The location in the incoming message tree from which data is retrieved to form the request that is sent by the CORBARequest node.

The CORBARequest node Result properties specify where to store the reply, and are described in the following table.

Property	M	C	Default	Description
Output data location	No	No	$OutputRoot	The message tree location to which the CORBARequest node sends output.
Copy local environment	No	No	Selected	This property controls how the local environment is copied to the output message. If you select this check box, a new copy of the local environment is created in the tree (at each node in the message flow), and it is populated with the contents of the local environment from the preceding node. Therefore, if a node changes the local environment, the previous nodes in the flow do not see those changes because they have their own copies. This behavior might be an issue if you are using a FlowOrder node, or if you use the propagate command on a Compute node. If you clear the check box, each node does not generate its own copy of the local environment, but it uses the local environment that is passed to it by the previous node. Therefore, if a node changes the local environment, those changes are seen by the upstream nodes.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see “Configuring monitoring event sources using monitoring properties” on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Advice for dealing with common problems that can arise when you develop message flows that contain CORBA nodes.

Database node

Use the Database node to interact with a database in the specified ODBC data source.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow" on page 4355
- "Terminals and properties" on page 4355

Purpose:
You define the nature of the interaction by coding ESQL statements that specify the data from the input message, and perhaps transform it in some way (for example, to perform a calculation), and assign the result to a database table.

You can set a property to control whether the update to the database is committed immediately, or deferred until the message flow completes, at which time the update is committed or rolled back, according to the overall completion status of the message flow.

You can use specialized forms of this node to:
- Update values within a database table (the DataUpdate node)
- Insert rows into a database table (the DataInsert node)
- Delete rows from a database table (the DataDelete node)
- Store the message, or parts of the message, in a warehouse (the Warehouse node)

The Database node is contained in the **Database** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following samples to see how to use this node:
- Airline Reservations
- Error Handler

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Consider a situation in which you receive an order for 20 monitors. If you have sufficient numbers of monitors in your warehouse, you want to reduce the stock level on your stock database. You can use the Database node to check that you have enough monitors available, and reduce the value of the quantity field in your database.

Terminals and properties:
When you have put an instance of the Database node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those properties that do not have a default value defined) are marked with an asterisk.

The terminals of the Database node are described in the following table. For more information about the PROPAGATE statement, including its syntax, see "PROPAGATE statement" on page 5150

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the input message is propagated if a failure is detected during the computation. If you have selected `Treat warnings as errors`, the node propagates the message to this terminal even if the processing completes successfully.
Out	The output terminal to which the transformed message is routed when processing in the node is completed. The transformed message might also be routed to this terminal by a PROPAGATE statement.
Out1	The first alternative output terminal to which the transformed message might be routed by a PROPAGATE statement.

Terminal	Description
Out2	The second alternative output terminal to which the transformed message might be routed by a PROPAGATE statement.
Out3	The third alternative output terminal to which the transformed message might be routed by a PROPAGATE statement.
Out4	The fourth alternative output terminal to which the transformed message might be routed by a PROPAGATE statement.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the Database node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, Database	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The Database node Basic properties are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Data Source	No	Yes		The ODBC data source name of the database that contains the tables to which you refer in the ESQL that is associated with this node (identified by the `Statement` property). This name identifies the appropriate database as it is known on the system on which this message flow is to run. The broker connects to this database with user ID and password information that you have specified on the **mqsisetdbparms** command. If the ESQL that is associated with this node includes a PASSTHRU statement or SELECT function and a database reference, you must specify a value for the `Data Source` property.	dataSource

Property	M	C	Default	Description	mqsiapplybaroverride command property

Statement	No	No	Database	The name of the module in the ESQL file that contains the statements to use against the database. If you want the module name to include one or more spaces, enclose the name in double quotation marks.
				
				The ESQL file, which by default has the name <message_flow_name>.esql, contains ESQL for every node in the message flow that requires it. Each portion of code that is related to a specific node is known as a module. When you code ESQL statements that interact with tables, those tables are assumed to exist within this database. If they do not exist, a database error is generated by the broker at run time.
				
				Code ESQL statements to customize the behavior of the Database node in an ESQL file that is associated with the message flow in which you have included this instance of the Database node. If an ESQL file does not exist for this message flow, double-click the Database node, or right-click the node and click **Open ESQL** to create and open a new ESQL file in the ESQL editor view.
				
				If an ESQL file exists, click **Browse** beside the Statement property to display the Module Selection dialog box, which lists the available Database node modules that are defined in the ESQL files that are accessible by this message flow (ESQL files can be defined in other, dependent, projects). Select the appropriate module and click **OK**. If no suitable modules are available, the list is empty.
				
				If the module that you have specified does not exist, it is created for you and the editor displays it. If the file and the module exist, the editor highlights the correct module. If a module skeleton is created for this node in a new or existing ESQL file, it consists of the following ESQL. The default module name is shown in this example:
				`CREATE DATABASE MODULE <flow_name>_Database`
				`  CREATE FUNCTION Main() RETURNS BOOLEAN`
				`  BEGIN`
				`  RETURN TRUE;`
				`  END;`
				`END MODULE;`
				
				If you create your own ESQL module, create exactly this skeleton. You can update the default name, but ensure that the name that you specify matches the name of the corresponding node property Statement.
				
				To customize this node, add your own ESQL after the BEGIN statement and before RETURN TRUE. You can use all the ESQL statements including SET, WHILE, DECLARE, and IF in this module, but (unlike the Compute node) the Database node propagates, unchanged, the message that it receives at its input terminal to its output terminal. Therefore, like the Filter node, you have only one message to refer to in a Database node.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Transaction	Yes	No	`Automatic`	The transaction mode for the node. The values are: • `Automatic` (the default). The message flow, of which the Database node is a part, is committed if it is successful; that is, the actions that you define in the ESQL module are performed and the message continues through the message flow. If the message flow fails, it is rolled back. If you select `Automatic`, the ability to commit or roll back the action of the Database node on the database depends on the success or failure of the entire message flow. • `Commit`. To commit all uncommitted actions that are performed in this message flow on the database that is connected to this node, irrespective of the success or failure of the message flow as a whole, select `Commit`. The changes to the database are committed even if the message flow itself fails.	
Treat Warnings as Errors	Yes	No	Cleared	For database warning messages to be treated as errors, and for the node to propagate the output message to the Failure terminal, select `Treat Warnings as Errors`. The check box is cleared initially. When you select the check box, the node handles all positive return codes from the database as errors, and generates exceptions in the same way that it does for the negative, or more serious, errors. If you do not select the check box, the node treats warnings as normal return codes, and does not raise an exception. The most significant warning raised is `not found`, which can be handled safely as a typical return code in most circumstances.	
Throw Exception on Database Error	Yes	No	Selected	For the broker to generate an exception when a database error is detected, select `Throw Exception on Database Error`. The check box is selected initially. If you clear the check box, include ESQL to check for database errors that might be returned after each database call that you make (you can use SQLCODE and SQLSTATE to get this information). If an error has occurred, you must handle the error in the message flow to ensure the integrity of the broker and the database; the error is ignored if you do not handle it through your own processing because you have chosen not to use the default error handling by the broker. For example, you can include the ESQL THROW statement to throw an exception in this node, or you can use the Throw node to generate your own exception at a later point.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

DatabaseInput node

Use the DatabaseInput node to detect events recorded in a database, and to retrieve the data affected by those events.

This topic contains the following sections:
- "Purpose"
- "Terminals and properties"

Purpose:
The DatabaseInput node is contained in the **Database** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon: 

Terminals and properties:
The DatabaseInput node terminals are described in the following table.

Terminal	Description
Failure	The output terminal to which a message is routed if an error occurs before a message is propagated to the Out terminal.
Out	If no errors occur within the input node, a message received from an external resource is always sent to the Out terminal first.
Catch	The output terminal to which the message is routed if an exception is thrown downstream and caught by this node. Exceptions are caught only if this terminal is attached.

The following tables describe the node properties that you can set on a specified tab. The column headed M indicates whether the property is *mandatory* (marked in the toolkit with an asterisk if you must enter a value when no default is defined). The column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

Description properties:

Property	M	C	Default Value	Description
Node Name	Yes	No	`Database Input`	The name of the node.
Short Description	No	No	None	A brief description of the node.
Long Description	No	No	None	Text that describes the purpose of the node in the message flow.

Basic properties:

Property	M	C	Default	Description	mqsiapplybaroverride command property
Data Source	Yes	Yes	None	The ODBC data source name of the database that contains the tables to which you refer in the ESQL file that is associated with this message flow (identified by the `ESQL Module` property). You can specify only one data source for the node.	dataSource
ESQL Module	Yes	No	None	The name of the DATABASEEVENT module in the ESQL file that contains the statements to run against the database and output messages.	

Polling properties:

Property	M	C	Default	Description	mqsiapplybaroverride command property
Polling interval (seconds)	Yes	Yes	`5`	The polling interval in seconds.	waitInterval

Retry properties:

Property	M	C	Default	Description	mqsiapplybaroverride command property
Retry mechanism	Yes	No	`Failure`	How the node handles a flow failure. Valid options are: • `Failure` • `Short retry` • `Short and long retry`	
Retry threshold	Yes	Yes	`0`	The number of times to try the flow transaction again when the `Retry mechanism` property value is `Short retry` or `Short and long retry`.	retryThreshold
Short retry interval	No	Yes	`0`	The interval, in seconds, between each retry if `Retry threshold` property is not zero.	shortRetryInterval
Long retry interval	No	Yes	`300`	The interval between retries, if `Retry mechanism` property is `Short and long retry` and the retry threshold has been exhausted.	longRetryInterval

Transactions properties:

Property	M	Read Only	C	Default	Description	mqsiapplybaroverride command property
Transaction mode	No	Yes	No	`Yes`	The transaction mode of `Yes` on this input node determines that the interactions between this node and the database are under transactional control. It also determines that the rest of the nodes in the flow are executed under sync point if those downstream nodes are configured with automatic transaction (that is, if `Transaction mode` property is `Automatic`). It is not possible to make the database interactions non-transactional.	

Instances properties:

Property	M	C	Default	Description	mqsiapplybaroverride command property
Additional instances pool	No	Yes	`Use Pool Associated with Message Flow`	The pool from which additional instances are obtained. • If you select `Use Pool Associated with Message Flow`, additional instances are obtained from the message flow pool. • If you select `Use Pool Associated with Node`, additional instances are allocated from the additional instances of the node based on the number specified in the `Additional instances` property.	componentLevel
Additional instances	No	Yes	`0`	The number of additional instances that the node can start if the `Additional instances pool` property is set to `Use Pool Associated with Node`.	additionalInstances

For a full description of the Instances properties, see “Configurable message flow properties” on page 4020.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

DatabaseRetrieve node

Use the DatabaseRetrieve node to ensure that information in a message is up to date.

This topic contains the following sections:

Purpose:
Use the DatabaseRetrieve node to modify a message using information from a database. For example, you can add information to a message using a key that is contained in a message; the key can be an account number.

The DatabaseRetrieve node is contained in the **Database** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following sample to see how to use this node:

- Simplified Database Routing

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Input parameter values that are acquired from message elements in the incoming message are supported for insertion into prepared statements that are used by this node. These values are acquired from name, value, and name-value elements in the incoming parsed input message. Elements are acquired initially in the form of a com.ibm.broker.plugin.MbElement object, therefore the range of supported Java object types that values can take is governed by this object's interface. When values are in the form of Java primitive types or Objects they are converted to their equivalent JDBC data type, as shown in the following table.

Java	**JDBC**
Integer	INTEGER
Long	BIGINT
Double	DOUBLE
BigDecimal	NUMERIC
Boolean	BIT
byte[]	VARBINARY or LONGVARBINARY
BitSet	VARBINARY or LONGVARBINARY
String	VARCHAR or LONGVARCHAR
MbTime	java.sql.Time
MbTimestamp	java.sql.Timestamp
MbDate	java.sql.Date

Values are used from an element only if the element is of a known type, and its

value state is valid, otherwise an exception is issued. Output column values that are acquired in the result set from SQL queries that are carried out by this node are converted first into matching Java types, then into internal message element value types, as shown in the following table.

JDBC	Java	ESQL Type
SMALLINT	Integer	INTEGER
INTEGER	Integer	INTEGER
BIGINT	Long	DECIMAL
DOUBLE	Double	FLOAT
REAL	Double	FLOAT
FLOAT	Double	FLOAT
NUMERIC	BigDecimal	DECIMAL
DECIMAL	BigDecimal	DECIMAL
BIT	Boolean	BOOLEAN
BOOLEAN	Boolean	BOOLEAN
BINARY	byte[]	BLOB
VARBINARY	byte[]	BLOB
LONGVARBINARY	byte[]	BLOB
CHAR	String	CHARACTER
VARCHAR	String	CHARACTER
LONGVARCHAR	String	CHARACTER
TINYINT	byte[1]	BLOB
TIME	java.util.Date	TIME
TIMESTAMP	java.util.Date	TIMESTAMP
DATE	java.util.Date	DATE

You can route a message to the same location, whether a query is successful against a specified database, by wiring both of the non-failure output terminals to the same output location.

If an error is found in the XPath expression of a pattern, it is reported during validation in the WebSphere Message Broker Toolkit. The reported error message might include the incorrect expression string and its associated unique dynamic or static terminal name, or the string might be marked as broker in the table.

The DatabaseRetrieve node looks up values from a database and stores them as elements in the outgoing message assembly trees. The type of information that is obtained from the database in the form of output column values, which is acquired and passed back in the result set from SQL queries, is converted first into a matching Java type, then into an internal message element value type when it is finally stored in a location in am outgoing message assembly tree. If a message element already exists in the outgoing message tree, the new value overwrites the old value. If the target element does not exist, it is created, and the value is stored.

The node needs query information that is used to form an SQL select query, which can access multiple tables in a database using multiple test conditions. Sometimes, not all the information that you want to retrieve in a result set is in a single database table. To get the column values that you want, you might need to retrieve them from two or more tables. This node supports the use of SELECT statements

that facilitate getting columns from one or more tables in a single result set. The normal join syntax that is supported is also referred to as *inner join*.

Inner join information that is collected to form a query includes a list of table qualified column values to retrieve and a list of test conditions, which form the WHERE clause of the SELECT statement. Table qualified column values can form the left hand operand in a test condition. Choose a comparison operator to apply to this operand and, optionally, specify an operand on the right to complete the test condition. The operator could be a null comparison test, in which case an operand on the right is not needed. The value of the operand on the right can be a database type (such as Integer, Boolean, or Long), another table qualified column, or a value that is acquired from an element in the incoming message, as expressed through an XPath 1.0 general expression.

The application of the expression must result in a single element, double, Boolean, or string being returned, otherwise an exception occurs. If the query returns multiple rows, the first row is chosen and the rest are ignored, unless the `Multiple rows` option is selected. In this case, all rows are processed, and values in those rows are used to update the outgoing message assembly trees.

It can be useful to combine a DatabaseRetrieve node with other message flow nodes. For example, you can use an XSLTransform node to manipulate data before or after the DatabaseRetrieve node is invoked.

The DatabaseRetrieve node has one input terminal (In) and three output terminals (Out, KeyNotFound, and Failure). If the message is modified successfully, it is routed to the Out terminal. If the message is not modified successfully or a failure is detected during processing, the message is routed to the Failure terminal. If no rows are returned in the result set following execution of a specified SQL select query, the original message is routed to the KeyNotFound terminal.

Making the JDBC provider service available to the DatabaseRetrieve node:
The DatabaseRetrieve node constructs its JDBC connections using connection details that are stored in the broker's registry as a configurable service. JDBCProvider configurable services are supplied for all supported databases.

Use the WebSphere Message Broker Explorer to modify or create the supplied service; see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644 for more information.

You can also use the **mqsichangeproperties** command to modify the settings of the supplied service for your chosen database, or create a new service using the **mqsicreateconfigurableservice** command. See "Setting up a JDBC provider for type 4 connections" on page 684 for further information and assistance on working with JDBCProvider services. You must set up a different JDBCProvider service for each database to which you want to connect.

Note: The `maxConnectionPoolSize` property does not apply to the JDBC connections used by the DatabaseRetrieve or DatabaseRoute nodes.

When you have defined the service, set the `Data source name` property of this node to the name of the JDBCProvider service; the attributes of the service are used to establish connections for the DatabaseRetrieve node.

You must stop and restart the broker for your changes to take effect, unless you intend to create a new execution group on the broker to which you will deploy the message flow that contains this node.

Using the Data Source Explorer view to query data sources:
Use the Data Source Explorer view to discover the names of tables in a target database, and the names of any columns in those tables. You must import database definitions for your databases into the WebSphere Message Broker Toolkit before you can view them in the Data Source Explorer view. See "Adding database definitions to the WebSphere Message Broker Toolkit" on page 2278 for more information.

1. Switch to the Broker Application Development perspective.
2. In the Data Source Explorer view, expand **Connections**. The database connections are listed.
3. Expand a database connection to list the databases, then expand the appropriate database.
4. Expand **Schemas** to list the schemas, then expand the appropriate schema.
5. Expand **Tables** to list all the tables.
6. Click a table to show its properties in the Properties view.
7. In the Properties view, click the **Columns** tab to view the column names.

Configuring the DatabaseRetrieve node:
When you have put an instance of the DatabaseRetrieve node into a message flow, you can configure it. For more information, see "Configuring a message flow node" on page 1503. The properties of the node are displayed in the Properties view.

All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

Example:
The following example adds new elements (family name and wage) to the incoming message structure. This example uses a database table called Employee.

EmployeeNumber	FamilyName	FirstName	Salary
00001	Smith	John	20000
00002	Jones	Harry	26000
00003	Doe	Jane	31000

To make a copy of the incoming message, select `Copy message`. When this property is selected, the node always creates an outgoing message assembly that is based on the incoming message assembly, and these trees in the new outgoing message assembly are modified and propagated to the node's Out terminal. This behavior enables modification of the outgoing message tree itself ($OutputRoot), in addition to the other logical trees in the message assembly: $OutputLocalEnvironment, $OutputDestinationList, $OutputExceptionList and $Environment. If the logical trees only in the message assembly are to be modified by this node, for performance reasons do not select `Copy message`. When this property is not selected, the node always works against the original incoming message assembly, and it expects that no updates are attempted against the message tree. If an XPath expression in the Data elements table tries to update this message tree through a reference to $OutputRoot, an MbReadOnlyMessageException occurs. The incoming message is:

```
<EmployeeRecord>
 <EmployeeNumber>00001</EmployeeNumber>
</EmployeeRecord>
```

Here is an example of the Query elements table.

Table name	Column name	Operator	Value Type	Value
Employee	FamilyName			
Employee	Salary			
Employee	EmployeeNumber	=	Element	$InputRoot/XMLNSC/ EmployeeRecord/ EmployeeNumber

Here is an example of the Data elements table.

Column name	Message element
Employee.FamilyName	$OutputRoot/XMLNSC/EmployeeRecord/FamilyName
Employee.Salary	$OutputRoot/XMLNSC/EmployeeRecord/Wage

The DatabaseRetrieve node connects to the Employee database table and extracts the value to compare from each incoming message. The XPath expression that is used to navigate to the message body is `$InputBody/EmployeeRecord/ EmployeeNumber`. The SQL query is:

```
SELECT Employee.FamilyName, Employee.Salary
FROM Employee
WHERE EmployeeNumber=?
ORDER BY Employee.FamilyName ASC, Employee.Salary ASC
```

where *?* is the value that is retrieved from the incoming message, which is located through the `Value` property in the third row of the Query elements table, which has a `Value Type` of `Element`.

- If the value at this location is *00001*, information for John Smith is retrieved. The first data element row says get the value of the FamilyName column that is returned from the query, and insert it into a new element named "FamilyName" under EmployeeRecord. The second data element row says get the value of the Salary column that is returned from the query, and insert it into a new element named "Wage" under EmployeeRecord. The resulting outgoing message is:

  ```
  <EmployeeRecord>
   <EmployeeNumber>00001</EmployeeNumber>
   <FamilyName>Smith</FamilyName>
   <Wage>20000</Wage>
  </EmployeeRecord>
  ```

- If the value at this location is *00002*, information for Harry Jones is retrieved. The resulting outgoing message is:

  ```
  <EmployeeRecord>
   <EmployeeNumber>00002</EmployeeNumber>
   <FamilyName>Jones</FamilyName>
   <Wage>26000</Wage>
  </EmployeeRecord>
  ```

If you select the `Multiple rows` property, and details of both of the employees are returned from a query in the form of two rows in the result set, the resulting outgoing message is:

```
<EmployeeRecord>
 <EmployeeNumber>00001</EmployeeNumber>
 <FamilyName>Smith</FamilyName>
 <Wage>20000</Wage>
 <EmployeeNumber>00002</EmployeeNumber>
 <FamilyName>Jones</FamilyName>
 <Wage>26000</Wage>
</EmployeeRecord>
```

Validating messages:
Set the Validation properties to define how the message that is produced by the DatabaseRetrieve node is to be validated. These properties do not cause the input message to be validated. It is expected that, if such validation is required, the validation has already been performed by the input node or a preceding validation node.

For more details, see "Validating messages" on page 1478 and "Validation properties" on page 4169.

Terminals and properties:
The DatabaseRetrieve node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Out	The output terminal to which the outgoing message is routed when it has been modified successfully.
KeyNotFound	The output terminal to which the original message is routed, unchanged, when the result set is empty.
Failure	The output terminal to which the message is routed if a failure is detected during processing.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The DatabaseRetrieve node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	DatabaseRetrieve	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The DatabaseRetrieve node Basic properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Data source name	Yes	Yes	DB2	The alias that is used to locate JDBCProvider service definition that is stored in the broker registry. The alias is used to locate and build the JDBC connection URL that is used to connect to a DBMS. The connection URL is driver specific, but it includes the database name to which to connect. If connection to the database is by a login account and password, the node also uses this property as a lookup key, through which these values can be acquired from an expected matching broker registry DSN entry. If the DBMS is password protected, define the **-n** parameter on the **mqsisetdbparms** command for the JDBC unique security key before you deploy the message flow that contains this DatabaseRetrieve node.	dataSource
Copy message	No	Yes	Cleared	This property indicates if a copy of the original incoming message is required because the message tree is to be updated, possibly in addition to logical trees in the message assembly. By default, this check box is cleared. For performance reasons, select this property only if the input message will be augmented.	
Multiple rows	No	Yes	Cleared	This property indicates if all rows are processed when a query returns multiple rows. If you select `Multiple rows`, all rows are processed, and values in those rows are used to update the outgoing message assembly trees. If you do not select this property, the first row is chosen and the rest are ignored.	
Query elements	Yes	No		A table of query elements that are used to compose a single SQL select statement. The table consists of five columns and one or more rows. The columns are `Table name`, `Column name`, `Operator`, `Value Type`, and `Value`. These five properties describe a query element, indicating a table qualified column value to be retrieved from a database. In this case, the element forms part of the SELECT and ORDER BY clauses in the generated query. Otherwise, the query element acts as a test condition that forms a predicate in the WHERE clause in the generated query.	
Table name	Yes	No		The name of a database table that forms part of the SQL select statement, including the schema name; for example, *myschema.mytable*.	
Column name	Yes	No		The name of the column in the database table to be retrieved in the results set, as qualified by the value of the `Table name` property. This SELECT clause can refer to this name as a column value to return from a query or to be referenced in a test condition in the WHERE clause.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Operator	Yes	No		A comparison operator to apply to an operand on the left (the table column that is specified in the row's first two columns) and optionally a value to apply to an operand on the right. If you specify an Ascending 'ASC' or Descending 'DESC' operator value for this property, this row signifies the declaration of a table qualified column that forms part of the SELECT and ORDER BY clauses in the generated query and optionally can be referenced in future rows as a value to an operand on the right.	
Value Type	Yes	No		A value that is either set to `None`, or that indicates the type of value that is expressed in the last column of this row. If this property is not set to `None`, it refers to a row that describes a test condition in the WHERE clause of the SQL select statement.	
Value	Yes	No		A value that is either set to `None`, or that specifies one of a specified set of property types as expressed by the `Value Type` property. For example, if the `Value Type` property is set to `Element`, the `Value` property collects an XPath 1.0 general expression. The value that is returned from the expression when it is applied to the node's incoming message is used as value of the operand on the right to be compared through this predicate. The compared value of the operand on the right must match the type that is retrieved for the table column that is compared against as the operand on the left. Complex expressions are possible, where zero or more values can be acquired from the incoming message, and manipulated to formed a single value for comparison. For example, the sum of multiple field values in the incoming message can be calculated by a general expression that is presented for a value type of `Element`.	

The DatabaseRetrieve node Data elements table properties are described in the following table.

Property	M	C	Default	Description
Data elements	Yes	No		A list of data elements. A data element is described by the `Column name` and `Message element` properties.
Column name	Yes	No		The name of the database column from which to obtain the element value. The list of names is updated dynamically based on the column entries that are entered in the Query elements table.
Message element	Yes	No		An XPath 1.0 read-write path expression that describes the path location of a message element. The message element is where the database value is stored. The XPath expression must evaluate to a single element in the message.

The DatabaseRetrieve node Validation properties are described in the following table.

For a full description of these properties, see “Validation properties” on page 4169.

Property	M	C	Default	Description
Validate	No	Yes	`None`	This property controls whether validation takes place. Valid values are `None`, `Content and Value`, `Content`, and `Inherit`.
Failure action	No	No	`Exception`	This property controls what happens if a validation failure occurs. You can set this property only if `Validate` is set to `Content` or `Content and Value`. Valid values are `User Trace`, `Local Error Log`, `Exception`, and `Exception List`.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Use the **mqsicreateconfigurableservice** command to create an object name for a broker external resource.

"**mqsideleteconfigurableservice** command" on page 3866
Use the **mqsideleteconfigurableservice** command to delete a configurable service, such as a JMS provider, JDBC provider, or FTP server, that you have created by using the **mqsicreateconfigurableservice** command.

"**mqsireportproperties** command" on page 3937
Use the **mqsireportproperties** command to display properties that relate to a broker, an execution group, or a configurable service.

"**mqsichangeproperties** command" on page 3756
Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

DatabaseRoute node

Use the DatabaseRoute node to route messages using information from a database in conjunction with XPath expressions.

This topic contains the following sections:

Purpose:
The DatabaseRoute node uses a collection of named column values from a selected database row and synchronously applies one or more XPath expressions to these acquired values to make routing decisions.

For more information about XPath 1.0 query syntax, see W3C XPath 1.0 Specification.

The DatabaseRoute node is contained in the **Database** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following sample to see how to use this node:

- Simplified Database Routing

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Input parameter values that are acquired from message elements in the incoming message are supported for insertion into prepared statements that are used by this node. These values are acquired from name, value, and name-value elements in the incoming parsed input message. Elements are acquired initially in the form of a com.ibm.broker.plugin.MbElement object, therefore the range of supported Java

object types that values can take is governed by this object's interface. When values are in the form of Java primitive types or Objects they are converted into their equivalent JDBC data type, as shown in the following table.

Java	JDBC
Integer	INTEGER
Long	BIGINT
Double	DOUBLE
BigDecimal	NUMERIC
Boolean	BIT
byte[]	VARBINARY or LONGVARBINARY
BitSet	VARBINARY or LONGVARBINARY
String	VARCHAR or LONGVARCHAR
MbTime	java.sql.Time
MbTimestamp	java.sql.Timestamp
MbDate	java.sql.Date

Values are used from an element only if the element is of a known type, and its value state is valid, otherwise an exception is issued. Output column values that are acquired in the result set from SQL queries that are carried out by this node are converted first into matching Java types, then into internal message element value types, as shown in the following table.

JDBC	Java	ESQL Type
SMALLINT	Integer	INTEGER
INTEGER	Integer	INTEGER
BIGINT	Long	DECIMAL
DOUBLE	Double	FLOAT
REAL	Double	FLOAT
FLOAT	Double	FLOAT
NUMERIC	BigDecimal	DECIMAL
DECIMAL	BigDecimal	DECIMAL
BIT	Boolean	BOOLEAN
BOOLEAN	Boolean	BOOLEAN
BINARY	byte[]	BLOB
VARBINARY	byte[]	BLOB
LONGVARBINARY	byte[]	BLOB
CHAR	String	CHARACTER
VARCHAR	String	CHARACTER
LONGVARCHAR	String	CHARACTER
TINYINT	byte[1]	BLOB
TIME	java.util.Date	TIME
TIMESTAMP	java.util.Date	TIMESTAMP
DATE	java.util.Date	DATE

You can route a message to the same location, whether a query is successful

against a specified database, by wiring both of the non-failure output terminals to the same output location.

If an error is found in the XPath expression of a pattern, it is reported during validation in the WebSphere Message Broker Toolkit. The reported error message might include the incorrect expression string and its associated unique dynamic or static terminal name, or the string might be marked as broken within the table.

The node needs query information that is used to form an SQL select query, which can access multiple tables in a database using multiple test conditions. Sometimes, not all the information that you want to retrieve in a result set is in a single database table. To get the column values that you want, you might need to retrieve them from two or more tables. This node supports the use of SELECT statements that facilitate getting columns from one or more tables in a single result set. The typical join syntax that is supported is also referred to as *inner join*.

Inner join information that is collected to form a query includes a list of table qualified column values to retrieve and a list of test conditions, which form the WHERE clause of the SELECT statement. Table qualified column values can form the left operand in a test condition. Choose a comparison operator to apply to this operand and, optionally, specify a right operand to complete the test condition. The operator can be a null comparison test, in which no right operand is needed. The value of the right operand can be a database type (such as Integer, Boolean, or Long), another table qualified column, or a value that is acquired from an element in the incoming message, as expressed through an XPath 1.0 general expression.

When you deploy a DatabaseRoute node in a message flow, you can select a value that is associated with the `Data Source Name` property. The list of values contains references to existing IBM predefined JDBC provider entries that are defined when a broker is first created. These entries are incomplete, therefore you must modify them to access the data source definition with which you want to work. If an existing default IBM predefined JDBC provider is already referenced and in use by another JDBC database node that requires different settings, use the WebSphere Message Broker Explorer; see “Using the WebSphere Message Broker Explorer to work with configurable services” on page 644 for more information, or the **mqsicreateconfigurableservice** command to specify a new JDBC provider entry.

Use the WebSphere Message Broker Explorer, or the **mqsideleteconfigurableservice** command to delete any unwanted JDBC provider entries.

You can delete only custom-named configurable services; you cannot delete IBM-defined configurable services.

The DatabaseRoute node has one input terminal and a minimum of four output terminals: Match, keyNotFound, Default, and Failure. The keyNotFound, Default, and Failure output terminals are static, therefore they are always present on the node. The dynamic Match terminal is created automatically each time a new DatabaseRoute node is selected and used in the Message Flow editor. This behavior means that you do not always need to create this node's first dynamic output terminal, which is the minimum number of terminals needed for this node to operate. You can rename this dynamic terminal if "Match" is not an appropriate name.

A message is copied to the Default terminal if none of the filter expressions are true. If an exception occurs during filtering, the message is propagated to the

Failure terminal. If the database query that is applied to the node's data source produces an empty result set (that is, no database rows are matched), a message is copied to the keyNotFound terminal. The DatabaseRoute node can define one or more dynamic output terminals. For all terminals, the associated filter expression is applied to the input message and, if the result is true, a copy of the message is routed to the specified terminal.

Each filter expression in the Filter table can be applied to:

- The input message
- The collection of named column values that are selected from a matched database row
- Both the input message and the returned column values
- Neither

because expressions can be any valid general XPath 1.0 expression.

As with the Route node, expressions are applied in the order that they are given in the filter table. If the result is true, a copy of the message is routed to its associated dynamic output terminal. If you set the `Distribution Mode` property to First, the application of all filter expressions might not occur.

The filter expression can fail if you compare a returned column value to a string literal. How a column entry is stored (for example, a fixed-length character field) determines what is returned for a specified column from the database. White space padding occurs for fixed-length character fields that are retrieved from a database, where the value that is stored is less than the specified column character storage length. In this case, padding occurs to the right of the character string that is returned, forming part of the string. You should remember this when comparing such a column value to a string literal, because an equality comparison expression might fail if the literal does not contain the exact same string, including padding characters.

For example, in a table called Employee, a database column called LastName that is defined as `char(10)` with the value 'Smith', is returned as 'Smith ', therefore the filter expression must be:

```
$Employee_LastName = 'Smith     '
```

which resolves to true. The expression:

```
$Employee_LastName = 'Smith'
```

resolves to false.

Alternatively, the XPath expression can use the following function:

```
Function: string normalize-space(string?)
```

The normalize-space function returns the argument string with white space normalized by stripping leading and trailing white space and replacing sequences of white space characters with a single space. Therefore the expression is:

```
normalize-space($Employee_LastName) = 'Smith'
```

Making the JDBC provider service available to the DatabaseRoute node:
The DatabaseRoute node constructs its JDBC connections using connection details that are stored in the broker's registry as a configurable service. JDBCProvider configurable services are supplied for all supported databases. Use the **mqsichangeproperties** command to modify the settings of the supplied service for

your chosen database, or create a new service using the **mqsicreateconfigurableservice** command. See "Setting up a JDBC provider for type 4 connections" on page 684 for further information and assistance on working with JDBCProvider services. You must set up a different JDBCProvider service for each database to which you want to connect.

Note: The `maxConnectionPoolSize` property does not apply to the JDBC connections used by the DatabaseRetrieve or DatabaseRoute nodes.

When you have defined the service, set the `Data Source Name` property of this node to the name of the JDBCProvider service; the attributes of the service are used to establish connections for the DatabaseRoute node.

You must stop and restart the broker for your changes to take effect, unless you intend to create a new execution group on the broker to which you will deploy the message flow that contains this node.

Using the Data Source Explorer view to query data sources:

Use the Data Source Explorer view to discover the names of tables within a target database, and the names of any columns in those tables. You must import database definitions for your databases into the WebSphere Message Broker Toolkit before you can view them in the Data Source Explorer view. See "Adding database definitions to the WebSphere Message Broker Toolkit" on page 2278 for more information.

1. Switch to the Broker Application Development perspective.
2. In the Data Source Explorer view, expand **Connections**. The database connections are listed.
3. Expand a database connection to list the databases, then expand the appropriate database.
4. Expand **Schemas** to list the schemas, then expand the appropriate schema.
5. Expand **Tables** to list all the tables.
6. Click a table to show its properties in the Properties view.
7. In the Properties view, click the **Columns** tab to view the column names.

Configuring the DatabaseRoute node:
When you have put an instance of the DatabaseRoute node into a message flow, you can configure it. For more information, see "Configuring a message flow node" on page 1503. The properties of the node are displayed in the Properties view.

All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

Example:
Consider the following example, which uses a database table called Employee.

EmployeeNumber	FamilyName	FirstName	Salary
00001	Smith	John	20000
00002	Jones	Harry	26000
00003	Doe	Jane	31000

The following DatabaseRoute node properties are set as specified:

Table Name	Column Name	Operator	Value Type	Value
Employee	FamilyName	ASC	None	None
Employee	Salary	ASC	None	None
Employee	EmployeeNumber	=	Element	$Body/EmployeeRecord/EmployeeNumber

The DatabaseRoute node connects to the Employee database table and extracts the value to compare from each incoming message. The XPath expression that is used to navigate to the message body is `$Body/EmployeeRecord/EmployeeNumber`. The SQL query is:

```
SELECT Employee.FamilyName, Employee.Salary
FROM Employee
WHERE EmployeeNumber=?
ORDER BY Employee.FamilyName ASC, Employee.Salary ASC
```

where *?* is the value that is retrieved from the incoming message. This value is located through the `Value` property in the third row of the query elements table, which has a value type of `Element`.

- If the value at this location is *00001*, information for John Smith is retrieved. The first XPath expression, which is associated with the out_expr1 dynamic terminal, is not met, therefore it does not meet its condition, and no message is propagated to the Out terminal. The second XPath expression is met, so that a copy of the input message is routed to the out_expr2 dynamic terminal.
- If the value at this location is *00002*, information for Harry Jones is retrieved. The first XPath expression, which is associated with the out_expr1 dynamic terminal, is met, so that a copy of the input message is routed to the out_expr1 terminal. The second XPath expression is not processed because the `Distribution Mode` property is set to `First`.

Terminals:
The DatabaseRoute node terminals are described in the following table.

Terminal	Description
In	The static input terminal that accepts a message for processing by the node.
Match	A dynamic output terminal to which the original message can be routed when processing completes successfully. You can create additional dynamic terminals; see "Dynamic terminals."
Default	The static output terminal to which the message is routed if no filter expression resolves to true.
keyNotFound	The static output terminal to which the message is copied if no database rows are matched.
Failure	The static output terminal to which the message is routed if a failure is detected during processing.

Dynamic terminals

The DatabaseRoute node can have further dynamic output terminals. Not all dynamic output terminals that are created on a DatabaseRoute node need to be mapped to an expression in the filter table. For unmapped dynamic output terminals, messages are never propagated to them. Several expressions can map to the same single dynamic output terminal. For more information about using dynamic terminals, see "Using dynamic terminals" on page 1518.

Properties:
The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The DatabaseRoute node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, DatabaseRoute	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The DatabaseRoute node Basic properties are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Data Source Name	Yes	Yes	`DB2`	The alias that is used to locate JDBCProvider service definition that is stored in the broker registry. The alias is used to locate and build the JDBC connection URL for connection to a DBMS. The connection URL is driver specific, but it includes the database name to which to connect. If connection to the database is by a login account and password, the node also uses this property as a lookup key, through which these values can be acquired from an expected matching broker registry DSN entry. If the DBMS is password protected, define the **-n** parameter on the **mqsisetdbparms** command for the JDBC unique security key before you deploy the message flow that contains this DatabaseRoute node.	dataSource
Query Elements	Yes	No		A table of query elements that are used to compose a single SQL select statement. The table consists of five columns and one or more rows. The columns are `Table Name`, `Column Name`, `Operator`, `Value Type`, and `Value`. These five properties describe a query element, indicating a table qualified column value to be retrieved from a database. In this case, the element forms part of the SELECT and ORDER BY clauses in the generated query. Otherwise, the query element acts as a test condition that forms a predicate within the WHERE clause in the generated query.	
Table Name	Yes	No		The name of a database table that forms part of the SQL select statement, including the schema name; for example, *myschema.mytable*.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Column Name	Yes	No		The name of the column in the database table to be retrieved in the results set, as qualified by the value of the `Table Name` property. This SELECT clause can refer to this name as a column value to return from a query, or to be referenced in a test condition in the WHERE clause.	
Operator	Yes	No		A comparison operator to apply to a left operand (the table column that is specified in the row's first two columns) and optionally a right operand value. If you specify an Ascending 'ASC' or Descending 'DESC' operator value for this property, this row signifies the declaration of a table qualified column that forms part of the SELECT and ORDER BY clauses in the generated query and optionally can be referenced in future rows as a right operand value.	
Value Type	Yes	No		A value that is either set to `None`, or that indicates the type of value that is expressed in the last column of this row. If this property is not set to `None`, it refers to a row that describes a test condition in the WHERE clause of the SQL select statement.	
Value	Yes	No		A value that is either set to `None`, or that specifies one of a specified set of property types as expressed by the `Value Type` property. For example, if the `Value Type` property is set to `Element`, the `Value` property collects an XPath 1.0 general expression. The value that is returned from the expression when it is applied to the node's incoming message is used as the right operand value to be compared through this predicate. The compared value of the right operand must match the type that is retrieved for the table column that is compared against as the left operand. Complex expressions are possible, where zero or more values can be acquired from the incoming message, and manipulated to form a single value for comparison. For example, the sum of multiple field values in the incoming message can be calculated by a general expression that is presented for a value type of `Element`.	
Distribution mode	No	Yes	`All`	This property specifies the routing behavior of this node when an inbound message matches multiple expressions. If the `Distribution Mode` property is set to `First`, the message is propagated to the first matching output terminal. If the `Distribution Mode` property is set to `All`, the message is propagated to all matching output terminals. If there is no matching output terminal, the message is propagated to the Default terminal.	

The DatabaseRoute node Filter Expression Table properties are described in the following table.

Property	M	C	Default	Description
Filter table	Yes	No		A table of filters (XPath 1.0 general expressions) and associated terminal names that define any extra filtering that is performed by this node. The table consists of two columns and one or more rows. You must have at least one row in this table so that the node can perform routing logic. As with the Route node, expressions are evaluated in the order in which they are displayed in the table. To improve performance, put the XPath expressions that are satisfied most frequently at the top of the filter table.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

W3C XPath 1.0 Specification

DataDelete node

Use the DataDelete node to interact with a database in the specified ODBC data source.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow"
- "Terminals and properties" on page 4383

Purpose:
The DataDelete node is a specialized form of the Database node, and the interaction is restricted to deleting one or more rows from a table within the database. You specify what is deleted by defining mapping statements that use the data from the input message to identify the action required.

You can set a property to control whether the update to the database is committed immediately, or deferred until the message flow completes, at which time the update is committed or rolled back, according to the overall completion status of the message flow.

The DataDelete node is contained in the **Database** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Consider a situation in which you are running a limited promotion. The goods are available only for the period of the promotion, and each customer can order only

one item. When stocks of the sale goods run out, you want to remove their details from the stock database. When a message containing an order for the last item comes in, the DataDelete node is triggered to remove all the details about that item from the database.

Terminals and properties:
When you have put an instance of the DataDelete node into a message flow, you can configure it. For more information, see "Configuring a message flow node" on page 1503. The properties of the node are displayed in the Properties view. (If you double-click the DataDelete node, you open the New Message Map dialog box.) All mandatory properties for which you must enter a value (those properties that do not have a default value defined) are marked with an asterisk.

The terminals of the DataDelete node are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the input message is propagated if a failure is detected during the computation. If you have selected `Treat warnings as errors`, the node propagates the message to this terminal even if the processing completes successfully.
Out	The output terminal that outputs the message following the execution of the database statement.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The DataDelete node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	DataDelete	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The DataDelete node Basic properties are described in the following table.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Data source	No	Yes		The ODBC data source name of the database that contains the tables to which you refer in the mappings that are associated with this node (identified by the `Statement` property). This name identifies the appropriate database as it is known on the system on which this message flow is to run. The broker connects to this database with user ID and password information that you have specified on the **`mqsisetdbparms`** command.	dataSource

Property	M	C	Default	Description	mqsiapplybaroverride command property
Statement	Yes	No	DataDelete	The name of the mapping routine that contains the statements that are to be executed against the database or the message tree. The routine is unique to this type of node. By default, the name that is assigned to the mapping routine is identical to the name of the mappings file in which the routine is defined. The default name for the file is the name of the message flow concatenated with the name of the node when you include it in the message flow (for example, `MFlow1_DataDelete.msgmap` for the first DataDelete node in message flow MFlow1). You cannot specify a value that includes spaces. If you click **Browse** next to this entry field, a dialog box is displayed that lists all the available mapping routines that can be accessed by this node. Select the routine that you want and click **OK**; the routine name is set in `Statement`. To work with the mapping routine that is associated with this node, double-click the node, or right-click the node and click **Open Mappings**. If the mapping routine does not exist, it is created for you with the default name in the default file. If the file exists, you can also open file *`flow_name_node_name`*`.msgmap` in the Broker Development view. A mapping routine is specific to the type of node with which it is associated; you cannot use a mapping routine that you have developed for a DataDelete node with a different node that uses mappings (for example, a DataInsert node). If you create a mapping routine, you cannot call it from another mapping routine, although you can call it from an ESQL routine. For more information about working with mapping files, and defining their content, see "Using message mappings" on page 2228.	
Transaction	Yes	No	Automatic	The transaction mode for the node. The values are: • Automatic (the default). The message flow, of which the DataDelete node is a part, is committed if it is successful; that is, the actions that you define in the mappings are performed and the message continues through the message flow. If the message flow fails, it is rolled back. Therefore, if you select Automatic, the ability to commit or roll back the action of the DataDelete node on the database depends on the success or failure of the entire message flow. • Commit. To commit any uncommitted actions performed in this message flow on the database connected to this node, irrespective of the success or failure of the message flow as a whole, select Commit. The changes to the database are committed even if the message flow itself fails.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Treat warnings as errors	Yes	No	Cleared	For database warning messages to be treated as errors, and the node to propagate the output message to the failure terminal, select `Treat warnings as errors`. The check box is cleared by default. When you select the check box, the node handles all positive return codes from the database as errors, and generates exceptions in the same way as it does for the negative, or more serious, errors. If you do not select the check box, the node treats warnings as typical return codes, and does not raise an exception. The most significant warning raised is `not found`, which can be handled as a typical return code safely in most circumstances.	
Throw exception on database error	Yes	No	Selected	For the broker to generate an exception when a database error is detected, select `Throw exception on database error`. The check box is selected by default. If you clear the check box, you must handle the error in the message flow to ensure the integrity of the broker and the database: the error is ignored if you do not handle it through your own processing because you have chosen not to run the default error handling by the broker. For example, you can connect the Failure terminal to an error processing subroutine.

"Database node" on page 4354
Use the Database node to interact with a database in the specified ODBC data source.

"DataInsert node"
Use the DataInsert node to interact with a database in the specified ODBC data source.

DataInsert node

Use the DataInsert node to interact with a database in the specified ODBC data source.

This topic contains the following sections:

Purpose:

The DataInsert node is a specialized form of the Database node, and the interaction is restricted to inserting one or more rows into a table within the database. You specify what is inserted by defining mapping statements that use the data from the input message to define the action required.

You can set a property to control whether the update to the database is committed immediately, or deferred until the message flow completes, at which time the update is committed, or rolled back according to the overall completion status of the message flow.

The DataInsert node is contained in the **Database** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:

Consider a situation in which your company has developed a new product. The details about the product have been sent from your engineering department. Your message flow must extract details from the message and add them as a new row in your stock database.

Terminals and properties:
When you have put an instance of the DataInsert node into a message flow, you can configure it. For more information, see "Configuring a message flow node" on page 1503. The properties of the node are displayed in the Properties view. (If you double-click the DataInsert node, you open the New Message Map dialog box.) All mandatory properties for which you must enter a value (those properties that do not have a default value defined) are marked with an asterisk.

The terminals of the DataInsert node are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the input message is propagated if a failure is detected during the computation. If you have selected `Treat warnings as errors`, the node propagates the message to this terminal even if the processing completes successfully.
Out	The output terminal that outputs the message following the execution of the database statement.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The DataInsert node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	DataInsert	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The DataInsert node Basic properties are described in the following table.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Data source	No	Yes		The ODBC data source name of the database that contains the tables to which you refer in the mappings that are associated with this node (identified by the `Statement` property). This name identifies the appropriate database as it is known on the system on which this message flow is to run. The broker connects to this database with user ID and password information that you have specified on the **`mqsisetdbparms`** command.	dataSource

Property	M	C	Default	Description	mqsiapplybaroverride command property
Statement	Yes	No	DataInsert	The name of the mapping routine that contains the statements that are to be executed against the database or the message tree. The routine is unique to this type of node. By default, the name that is assigned to the mapping routine is identical to the name of the mappings file in which the routine is defined. The default name for the file is the name of the message flow concatenated with the name of the node when you include it in the message flow (for example, `MFlow1_DataInsert.msgmap` for the first DataInsert node in message flow MFlow1). You cannot specify a value that includes spaces. If you click **Browse** next to this entry field, a dialog box is displayed that lists all the available mapping routines that can be accessed by this node. Select the routine that you want and click **OK**; the routine name is set in `Statement`. To work with the mapping routine that is associated with this node, double-click the node, or right-click the node and select **Open Mappings**. If the mapping routine does not exist, it is created for you with the default name in the default file. If the file exists, you can also open file *`flow_name_node_name`*`.msgmap` in the Broker Development view. A mapping routine is specific to the type of node with which it is associated; you cannot use a mapping routine that you have developed for a DataInsert node with a different node that uses mappings (for example, a DataDelete node). If you create a mapping routine, you cannot call it from another mapping routine, although you can call it from an ESQL routine. For more information about working with mapping files, and defining their content, see "Using message mappings" on page 2228.	
Transaction	Yes	No	Automatic	The transaction mode for the node. The values are: • Automatic (the default). The message flow, of which the DataInsert node is a part, is committed if it is successful. That is, the actions that you define in the mappings are taken and the message continues through the message flow. If the message flow fails, it is rolled back. Therefore if you select Automatic, the ability to commit or roll back the action of the DataInsert node on the database depends on the success or failure of the entire message flow. • Commit. To commit all uncommitted actions that are taken in this message flow on the database that is connected to this node, irrespective of the success or failure of the message flow as a whole, select Commit. The changes to the database are committed even if the message flow itself fails.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Treat warnings as errors	Yes	No	Cleared	For database warning messages to be treated as errors, and the node to propagate the output message to the failure terminal, select `Treat warnings as errors`. The check box is cleared by default. When you select the check box, the node handles all positive return codes from the database as errors and generates exceptions in the same way as it does for the negative, or more serious, errors. If you do not select the check box, the node treats warnings as typical return codes, and does not raise an exception. The most significant warning raised is `not found`, which can be handled as a typical return code safely in most circumstances.	
Throw exception on database error	Yes	No	Selected	For the broker to generate an exception when a database error is detected, select `Throw exception on database error`. The check box is selected by default. If you clear the check box, you must handle the error in the message flow to ensure the integrity of the broker and the database. The error is ignored if you do not handle it through your own processing because you have chosen not to run the default error handling by the broker. For example, you can connect the failure terminal to an error processing subroutine.

DataUpdate node

Use the DataUpdate node to interact with a database in the specified ODBC data source.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow"
- "Terminals and properties" on page 4391

Purpose:
The DataUpdate node is a specialized form of the Database node, and the interaction is restricted to updating one or more rows in a table within the database. You define what is updated by defining mapping statements that use the data from the input message to identify the action required.

You can set a property to control whether the update to the database is committed immediately, or deferred until the message flow completes, at which time the update is committed or rolled back according to the overall completion status of the message flow.

The DataUpdate node is contained in the **Database** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Consider a scenario in which you have added the details of a new product, a keyboard, to your stock database. Now you have received a message from the Goods In department that indicates that 500 keyboards have been delivered to

your premises. You can use the DataUpdate node to change the quantity of keyboards in your database from zero to 500.

Terminals and properties:
When you have put an instance of the DataUpdate node into a message flow, you can configure it. For more information, see "Configuring a message flow node" on page 1503. The properties of the node are displayed in the Properties view. (If you double-click the DataUpdate node, you open the New Message Map dialog box.) All mandatory properties for which you must enter a value (those properties that do not have a default value defined) are marked with an asterisk.

The terminals of the DataUpdate node are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the input message is propagated if a failure is detected during the computation. If you have selected `Treat warnings as errors`, the node propagates the message to this terminal even if the processing completes successfully.
Out	The output terminal that outputs the message following the execution of the database statement.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The DataUpdate node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	DataUpdate	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The DataUpdate node Basic properties are described in the following table.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Data source	No	Yes		The ODBC data source name of the database that contains the tables to which you refer in the mappings that are associated with this node (identified by the `Statement` property). This name identifies the appropriate database as it is known on the system on which this message flow is to run. The broker connects to this database with user ID and password information that you have specified on the **`mqsisetdbparms`** command.	dataSource

Property	M	C	Default	Description	mqsiapplybaroverride command property
Statement	Yes	No	DataUpdate	The name of the mapping routine that contains the statements that are to be executed against the database or the message tree. The routine is unique to this type of node. By default, the name that is assigned to the mapping routine is identical to the name of the mappings file in which the routine is defined. The default name for the file is the name of the message flow concatenated with the name of the node when you include it in the message flow (for example, MFlow1_DataUpdate.msgmap for the first DataUpdate node in message flow MFlow1). You cannot specify a value that includes spaces. If you click **Browse** next to this entry field, a dialog box is displayed that lists all available mapping routines that can be accessed by this node. Select the routine that you want and click **OK**; the routine name is set in Statement. To work with the mapping routine that is associated with this node, double-click the node, or right-click the node and click **Open Mappings**. If the mapping routine does not exist, it is created for you with the default name in the default file. If the file exists, you can also open file *flow_name_node_name*.msgmap in the Broker Development view. A mapping routine is specific to the type of node with which it is associated; you cannot use a mapping routine that you have developed for a DataUpdate node with a different node that uses mappings (for example, a DataInsert node). If you create a mapping routine, you cannot call it from another mapping routine, although you can call it from an ESQL routine. For more information about working with mapping files, and defining their content, see "Using message mappings" on page 2228.	
Transaction	Yes	No	Automatic	The transaction mode for the node. The values are: • Automatic (the default). The message flow, of which the DataUpdate node is a part, is committed if it is successful. That is, the actions that you define in the mappings are performed and the message continues through the message flow. If the message flow fails, it is rolled back. Therefore, if you choose Automatic, the ability to commit or roll back the action of the DataUpdate node on the database depends on the success or failure of the entire message flow. • Commit. To commit all uncommitted actions that are performed in this message flow on the database that is connected to this node, irrespective of the success or failure of the message flow as a whole, select Commit. The changes to the database are committed even if the message flow itself fails.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Treat warnings as errors	Yes	No	Cleared	For database warning messages to be treated as errors, and the node to propagate the output message to the Failure terminal, select `Treat warnings as errors`. The check box is cleared by default. When you select the check box, the node handles all positive return codes from the database as errors, and generates exceptions in the same way as it does for the negative, or more serious, errors. If you do not select the check box, the node treats warnings as normal return codes, and does not raise an exception. The most significant warning raised is `not found`, which can be handled safely as a normal return code in most circumstances.	
Throw exception on database error	Yes	No	Selected	For the broker to generate an exception when a database error is detected, select `Throw exception on database error`. The check box is selected by default. If you clear the check box, you must handle the error in the message flow to ensure the integrity of the broker and the database: the error is ignored if you do not handle it through your own processing, because you have chosen not to run the default error handling by the broker. For example, you can connect the Failure terminal to an error processing subroutine.

EmailInput node

Use the EmailInput node to retrieve an email, with or without attachments, from an email server that supports Post Office Protocol 3 (POP3) or Internet Message Access Protocol (IMAP).

This topic contains the following sections:
- "Purpose"
- "Using the EmailInput node in a message flow" on page 4395
- "Configuring the EmailInput node" on page 4396
- "Terminals and properties" on page 4396

Purpose:
The EmailInput node receives an email, with or without attachments, from an email server that supports Post Office Protocol 3 (POP3) or Internet Message Access Protocol (IMAP). The body of the email message, and any attachments, are propagated in the Multipurpose Internet Mail Extensions (MIME) domain. All other information relating to the email is stored in the `Root.EmailInputHeader` MIME logical tree. The fields in this structure are described in the following table:

Element Location	Element Data Type	Description
Root.EmailInputHeader.To	CHARACTER	A comma-separated list of email addresses.
Root.EmailInputHeader.Cc	CHARACTER	A comma-separated list of email addresses.
Root.EmailInputHeader.From	CHARACTER	A comma-separated list of email addresses.
Root.EmailInputHeader.ReplyTo	CHARACTER	A comma-separated list of email addresses.
Root.EmailInputHeader.Subject	CHARACTER	The summary of the email content or the subject of the email.
Root.EmailInputHeader.Size	INTEGER	The size of the email, including any attachments.
Root.EmailInputHeader.SentDate	CHARACTER	The sent delivery date of the email.

This structure is propagated with each message written to the Out terminal of the EmailInput node. For more information about the MIME logical tree, see "MIME parser and domain" on page 1117.

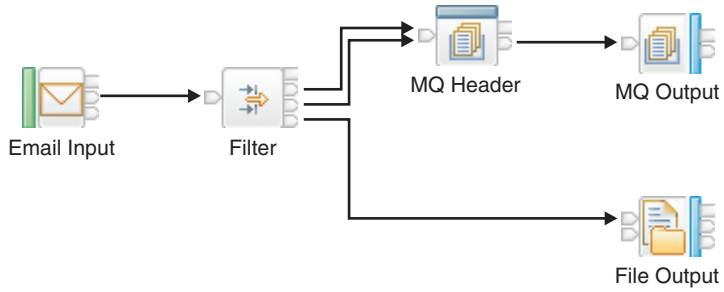
Using the EmailInput node in a message flow:
To enable function that becomes available in WebSphere Message Broker fix packs, use the **-f** parameter on the **mqsichangebroker** command. For more information, see "**mqsichangebroker** command" on page 3723.

You can configure the EmailInput node by using the node properties in the WebSphere Message Broker Toolkit. One possible use of the EmailInput node is to poll an email server for email messages at regular intervals, and to retrieve an email message when an email is available. The message flow receives the email from the email server as a MIME message.

In the following example message flow, the EmailInput node then passes the email message, which is associated with the MIME parser, onto a Filter node. The Filter node processes the email and directs it either to an MQHeader node or to a FileOutput node based on whether the email has an attachment or not.

If the email message does not contain an attachment, the Filter node sends the email to an MQHeader node for MQ Message Descriptor (MQMD) customization. The MQHeader node adds a WebSphere MQ header to the message tree and passes the message onto the MQOutput node. The MQOutput node serializes the message body, for example; the text contents of the email, and places the body of the email on a WebSphere MQ queue for further processing.

If the email message does contain an attachment, the Filter node sends the email onto a FileOutput node. The FileOutput node then saves the attachment as a file named `email_attachment.dat` to a hard disk drive that you specify and, in this example, the text content of the email is discarded. You can achieve this example by creating the following message flow:



The EmailInput node is contained in the **Email** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

View the following sample to see how to use the EmailInput node:

- Email

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Using configurable services for the EmailInput node

You can configure the EmailInput node to get the email server URL and security identity information from a configurable service. For details about creating, changing, reporting, and deleting the configurable services, see "Changing connection information for the EmailInput node" on page 1805.

Using a security identity to authenticate with an email server

You can use the **mqsisetdbparms** command to set a user ID and password security identity object for the EmailInput node or EmailServer configurable service to use for accessing the email server. For detailed information about how to configure email server security identity support, see "**mqsisetdbparms** command" on page 3954.

Configuring the EmailInput node:
When you have put an instance of the EmailInput node into a message flow, you can configure it. For more information, see "Configuring a message flow node" on page 1503. The properties of the node are displayed in the Properties view.

All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

To configure the EmailInput node by using the node properties in the WebSphere Message Broker Toolkit to retrieve an email, with or without attachments, see "Receiving an email" on page 1801.

Terminals and properties:
The EmailInput node terminals are described in the following table.

Terminal	Description
Failure	The output terminal to which the message is routed if an EmailInput node failure is detected when a message is propagated, or an EmailInput node fails to access the email server. Connect the Failure terminal of this node to another node in the message flow to process errors.
Out	The output terminal to which the message is routed if it has been propagated successfully. Connect the Out terminal of this node to another node in the message flow to process the message further, or send the message to an additional destination.
Catch	The output terminal to which the message is routed if an exception is thrown downstream and caught by this node. Exceptions are caught only if this terminal is attached.

The following tables describe the EmailInput node properties.

The table column headed M indicates whether the property is *mandatory*. For example, the property is marked with an asterisk meaning that you must enter a value if no default is defined.

The column headed C indicates whether the property is *configurable*. For example, you can change the value when you add the message flow to the BAR file to deploy it.

The EmailInput node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	Email Input	The name of the node.

Property	M	C	Default	Description
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

The EmailInput node Basic properties are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Email server	Yes	Yes	None	The Email server property is defined either as a configurable service name, for example: *myEmailConfigurableServiceName*, or as a URL. A URL allows you to specify a protocol, host name, and port number, which is the minimum information you need to access the email server. The URL must be made up of the following structure: *protocol*`://`*hostname*`:`*port* Where: • *protocol* can be `pop3` or `imap`. • *hostname* is the Internet Protocol version 4 (IPv4) TCP/IP address or DNS-resolvable host name of the email host. • *port* is the port number that the email server is listening on for connections over POP3 or IMAP. You can enter an integer in the range 1- 65535. For example: `pop3://myemailserver.com:12345` or `imap://myemailserver.com:56789`. There is no default value for this property, however this property is mandatory, and therefore must be configured with a configurable service name or a URL. You can obtain the *hostname* and *port* values from the email server or email server administrator.	emailServer

The EmailInput node Polling properties are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Polling interval (in seconds)	Yes	Yes	5	The interval at which the EmailInput node polls the email server for new emails.	waitInterval

The EmailInput node Security properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Security identity	No	Yes	None	The name of the security identity object that is created and configured by the **mqsisetdbparms** command, which contains the user ID and password to be used by the broker to authenticate with the email server. Use the **mqsisetdbparms** command to set the security identity user ID and password to be accessed by the broker. The default value for this property is None, which signifies that the user ID and password are not passed to the email server. For more information about email server security identity support, see "**mqsisetdbparms** command" on page 3954.	securityIdentity

The EmailInput node Retry properties are described in the following table. For more information about configuring the EmailInput node Retry properties, see "Receiving an email" on page 1801.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Retry mechanism	Yes	No	Short and Long Retry	How the EmailInput node handles a message flow failure. Valid values are `Failure`, `Short Retry`, or `Short and Long Retry`.	
Retry threshold	Yes	Yes	0	The number of times to try the message flow transaction again when the `Retry mechanism` property value is set to `Short Retry`.	retryThreshold
Short retry interval (in seconds)	No	Yes	0	The interval, in seconds, between each retry if the `Retry threshold` property value is not set to zero.	shortRetryInterval
Long retry interval (in seconds)	No	Yes	300	The interval, in seconds, between each retry, if the `Retry mechanism` property value is `Short and Long Retry` and the retry threshold has been exhausted.	longRetryInterval
Action on failing email	Yes	No	Delete Email	The action that the EmailInput node takes with the input data source after all attempts to process the contents fail.	emailFailureAction

The EmailInput node Transactions properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Transaction mode	No	Yes	No	The transaction mode on the EmailInput node determines if the rest of the nodes in the message flow are run under sync point. Valid values are `Yes` or `No`.	

The EmailInput node Instances properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Additional instances pool	No	Yes	Use Pool Associated with Message Flow	The pool from which additional instances are obtained. If you select the property value `Use Pool Associated with Message Flow`, additional instances are obtained from the message flow pool. If you select the property value `Use Pool Associated with Node`, additional instances are allocated from the additional instances of the node, based on the number specified in the `Additional instances` property.	componentLevel
Additional instances	No	Yes	0	The number of additional instances that the EmailInput node can start if the `Additional instances pool` property is set to the value `Use Pool Associated with Node`.	additionalInstances

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

"Configurable services" on page 1296
Configurable services are typically runtime properties. You can use them to define properties that are related to external services on which the broker relies; for example, an SMTP server or a JMS provider.

"MIME parser and domain" on page 1117
Use the MIME domain if your messages use the MIME standard for multipart messages.

"Manipulating messages in the MIME domain" on page 2612
A MIME message does not need to be received over a particular transport. For example, a message can be received over HTTP by using an HTTPInput node, or over WebSphere MQ by using an MQInput node. The MIME parser is used to process a message if the message domain is set to MIME in the input node properties, or if you are using WebSphere MQ, and the MQRFH2 header has a message domain of MIME.

"Samples" on page 98
The WebSphere Message Broker Toolkit provides samples that show the features that are available in WebSphere Message Broker, and how to use them. This topic provides links to the information about the individual samples.

Related tasks:

"Processing email messages" on page 1786
You can configure the EmailOutput node to deliver an email from a message flow to an email server that supports Simple Mail Transfer Protocol (SMTP). You can also configure the EmailInput node to retrieve an email from an email server that supports Post Office Protocol 3 (POP3) or Internet Message Access Protocol (IMAP).

"Receiving emails" on page 1799
You can configure the EmailInput node to receive an email, with or without an attachment, from an email server that supports Post Office Protocol 3 (POP3) or Internet Message Access Protocol (IMAP).

"Receiving an email" on page 1801
You can receive an email, with or without attachments, from an email server that supports Post Office Protocol 3 (POP3) or Internet Message Access Protocol (IMAP).

"Processing responses from an EmailInput node" on page 1804
The EmailInput node can return different response messages that indicate the success or failure of receiving an email, with or without attachments, from an email server that supports Post Office Protocol 3 (POP3) or Internet Message Access Protocol (IMAP).

"Changing connection information for the EmailInput node" on page 1805
You can create a configurable service that the EmailInput node or message flow refers to at run time for email server connection information, instead of defining the connection properties on the node or the message flow. The advantage being that you can change the host name and security identity values without needing to redeploy your message flow.

"Resolving problems when you use Email nodes" on page 3398
Advice for dealing with common problems that can arise when you develop message flows that contain Email nodes.

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

EmailOutput node

Use the EmailOutput node to send email messages to one or more recipients.

This topic contains the following sections:
- "Purpose"
- "Configuring the EmailOutput node" on page 4401
- "Terminals and properties" on page 4404

Purpose:
The EmailOutput node delivers an email message from a message flow to an SMTP server that you specify.

You can configure the EmailOutput node by using the node properties in the WebSphere Message Broker Toolkit, or dynamically from the local environment and email output header (EmailOutputHeader) that are associated with the message (for more information, see "Producing dynamic email messages" on page 1791). You can configure the EmailOutput node to produce an e-mail with a single attachment. When you produce email messages dynamically, you can specify multiple attachments.

The EmailOutput node is contained in the **Email** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Look at the following sample to see how to use this node:

- Email

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Configuring the EmailOutput node:
When you have put an instance of the EmailOutput node into a message flow, you can configure it. For more information, see "Configuring a message flow node" on page 1503. The properties of the node are displayed in the Properties view.

All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The following is a description of the four levels of configuration of the EmailOutput node:

- Option 1: Configure the EmailOutput node by using the node properties in the WebSphere Message Broker Toolkit to send an email with a statically-defined subject and text to a statically-defined list of recipients. The same email is sent to the same recipients and it has no attachments. This method is useful when you want to test the EmailOutput node, or when notification alone is sufficient. For more details, see "Sending an email" on page 1789.
- Option 2: This option is the same as Option 1 but with the inclusion of an attachment. This option causes the email message to be constructed as a MIME message. The subject, text, and list of recipients remains static, but the content of the attachment is sought dynamically from the message that is passed to the EmailOutput node at run time. The location of the attachment in the message is defined statically. For more details, see "Sending an email with an attachment" on page 1790.
- Option 3: This option allows for those properties in Options 1 and 2 to be optional, and to be overridden at run time by values that are specified in the local environment, the email output header (EmailOutputHeader), or the body of the message. This option allows a dynamic email message to be produced where the SMTP server, list of recipients, subject, text, and multiple attachments are all determined at run time. This option requires previous nodes in the message flow to construct these overrides. Where a text value is not specified in the node properties for the main body of the email, the body of the message that is passed to the EmailOutput node is used. However, content that you set in the `Email message text` property overrides dynamically-generated text in the message body. For more details, see "Producing dynamic email messages" on page 1791.
- Option 4: This option passes a MIME message to the EmailOutput node. The EmailOutput node uses the MIME parser to write the MIME message to a bit stream. This message is then sent to the list of recipients in the SMTP header.

Local environment overrides are not taken into consideration when a MIME message is passed. For more details, see “Sending a MIME message” on page 1795.

Email output header

The email output header (EmailOutputHeader) is a child of root. Values that you specify in this header override equivalent properties that you set on the node. Use the SMTP output header to specify any of the email attributes, such as its recipients.

Location	Description
Root.EmailOutputHeader.To	A comma separated list of email addresses.
Root.EmailOutputHeader.Cc	A comma separated list of email addresses.
Root.EmailOutputHeader.Bcc	A comma separated list of email addresses.
Root.EmailOutputHeader.From	A comma separated list of email addresses.
Root.EmailOutputHeader.Reply-To	A comma separated list of email addresses.
Root.EmailOutputHeader.Subject	The subject of the email.

Local environment

Use the local environment to specify overrides to the SMTP server connection information and attachments.

Local environment	Description
Destination.Email.SMTPServer	The Server:Port of the SMTP server. Port is optional; if you do not specify it, the default value is 25.
Destination.Email.SecurityIdentity	The security identity for authentication with the SMTP server, which can be the name of the userid and password pair that is defined using the **mqsisetdbparms** command, or it can reference an external resource that has a securityIdentity attribute that references a userid and password that are defined using the **mqsisetdbparms** command. In both cases, the value is appended after the string “smtp::”. For example, if you use the **mqsisetdbparms** command to create a userid and password of *smtp::myUseridPassword*, the securityIdentity that is specified on the node, or indirectly in an external resource, is *myUseridPassword*.

Destination.Email.BodyContentType	Identifies that the body of the email message contains HTML rather than plain text. You can set this property to text/plain, text/html, or text/xml; text/plain is the default value.
	
	To set the content type for the body of the message, use the following notation.
	`SET OutputLocalEnvironment.Destination.Email.BodyContentType = "text/html"`
	
	To additionally set the character set (charset) in which the message body is sent, use the following notation.
	`SET OutputLocalEnvironment.Destination.Email.BodyContentType = "text/html; charset=utf-8"`
	
	This example sends a text/HTML email with a charset of UTF-8.

Destination.Email.MultiPartContentType	The type of multipart, including related, mixed, and alternative. You can set any value here.

Local environment	Description
Destination.Email.Attachment.Content	Either the attachment (BLOB/text), or an XPath or ESQL expression that references an element; for example, an element in the message tree or local environment. The value of the referenced element is taken as the content of the attachment. • If the element is a BLOB, it is an attachment. • If the element is text, check to see if it can be resolved to another element in the message tree or local environment. If it can be resolved, use that element. If it cannot be resolved, add this element as the attachment.
Destination.Email.Attachment.ContentType	The type of attachment (also known as Internet Media Type), including text/plain, text/html, and text/xml. You can set any value here.
Destination.Email.Attachment.ContentName	The name of the attachment.
Destination.Email.Attachment.ContentEncoding	The encoding of the attachment: 7bit, base64, or quoted-printable. • 7bit is the default value that is used for ASCII text. • Base64 is used for non ASCII, whether non English or binary data. This format can be difficult to read. • Quoted-printable is an alternative to Base64, and is appropriate when the majority of the data is ASCII with some non-ASCII parts. This format is more readable; it provides a more compact encoding because the ASCII parts are not encoded.

Broker properties

You can also configure the SMTP server, port number, and security identity as a broker external resource property. To do this, use an alias that is specified in the `SMTP Server and Port` property on the EmailOutput node. The security identity references a user ID and password pair that is defined on the broker using the **mqsisetdbparms** command. Use the **mqsicreateconfigurableservice** command to create an SMTP broker external resource for the alias that is specified on the node. Then use the **mqsichangeproperties** command to create an SMTPServer property with the value in the form of *server:port*. The port value is optional; if you do not specify it, the default value is 25. You can also use the **mqsichangeproperties** command to create an SMTPSecurityIdentity property with a value that is the name of a security identity that can be resolved at run time to a user ID and password for authentication with the SMTP server. For example:

```
mqsicreateconfigurableservice MY_BROKER –c SMTP –o SMTP_MyAlias
```

followed by:

```
mqsichangeproperties MY_BROKER –c SMTP –o SMTP_MyAlias –n serverName –v smtp.hursley.ibm.com:25
```

These commands override the SMTP server and port values that are specified on any nodes that also specify an alias of SMTP_MyAlias. If the local environment contains any overrides, they take preference over the broker external resource properties. See also the following example:

```
mqsichangeproperties MY_BROKER –c SMTP –o SMTP_MyAlias –n securityIdentity –v mySecurityIdentity
```

You must also use the **mqsisetdbparms** command to define the security identity at the broker run time.

Connecting the terminals:

Connect the In terminal to the node from which outbound messages bound are routed.

Connect the Out or Failure terminal of this node to another node in this message flow to process the message further, process errors, or send the message to an additional destination.

If you connect one of these output terminals to another node in the message flow, the local environment that is associated with the message is enhanced with the following information for each destination to which the message has been put by this node:

Location	Description
WrittenDestination.Email.smtpServer	The Server:Port of the SMTP server.
WrittenDestination.Email.messageId	The ID of the email sent message.

These values are written in WrittenDestination within the local environment tree structure.

If you do not connect either terminal, the local environment tree is unchanged.

Terminals and properties:
The EmailOutput node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the message is routed if a failure is detected when a message is propagated. Connect the Failure terminal of this node to another node in the message flow to process errors.
Out	The output terminal to which the message is routed if it has been propagated successfully. Connect the Out terminal of this node to another node in the message flow to process the message further or send the message to an additional destination.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file at deployment).

The EmailOutput node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, EmailOutput	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

Use the EmailOutput node Basic properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
SMTP Server and Port	No	Yes		This property defines the SMTP server and port to which emails are sent from this node, and is in the format *server:port*; for example: *my.smtp.server:25*. The port value is optional, but if you do not specify a port value, the default value is 25. You can specify an alias value for this property. If the alias exists at run time, the specified values are used. If the alias does not exist at run time, the broker assumes the value to be a valid SMTP host.	smtpServer

The EmailOutput node Email properties are described in the following table.

Property	M	C	Default	Description
To Addresses	No	No		The main recipient or recipients of the email. This property can include a single email address or a comma-separated list of email addresses.
Cc Addresses	No	No		The carbon copy recipient or recipients of the email. This property can include a single email address or a comma-separated list of email addresses.
Bcc Addresses	No	No		The blind carbon copy recipient or recipients of the email. This property can include a single email address or a comma-separated list of email addresses.
From Address	No	No		The email address of the sender of the email.
Reply-To Address	No	No		The email address to which recipients of the email reply.
Subject of email	No	No		The subject of the email.
Email message text	No	No		The main text of the email. Use this property to provide a static main body of an email. If you use this property, it overrides the content that is provided in the body of the message tree that is passed to the input node. If you do not specify a value for this property, the text of the email is the body of the message tree that is passed to the EmailOutput node.
Body Content Type	No	No	`text/plain`	You can use this property to force the content type for the body of the email message. Valid values are: • `None` • `text/plain` • `text/html` • `text/xml`

The EmailOutput node Security properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Security Identity	No	Yes		A security identifier to retrieve a user ID and password that are configured at the broker run time.	securityIdentity

The EmailOutput node Attachment properties are described in the following table.

Property	M	C	Default	Description
Attachment Content	No	No		An XPath or ESQL expression that references an element; for example, an element in the message tree, or local environment. The content of the attachment is the value of the element that is referenced.
Attachment Content Name	No	No		The name of the attachment that is seen by the recipient of the email. This property is optional. If you do not specify a name, a default name is assigned.
Attachment Content Type	No	No	`text/plain`	The type of the attachment. This property is optional, even if you have specified an attachment. Valid values are: • `text/plain` is simple text. • `text/html` is HTML. • `text/xml` is XML. • `application/octet-stream` is the default type for non-text and HTML (binary data).
Attachment Content Encoding	No	No	`7bit`	The encoding of the attachment. This property is optional. If you do not specify a value, a default encoding is assigned. Valid values are: • `7bit` is the default value for ASCII text. • `base64` is used for non-ASCII data, whether it is non-English or binary data. • `quoted-printable` is a more readable-alternative to base64. Use quoted-printable when the majority of the data is ASCII text with some non-ASCII parts. This option provides a more compact encoding because the ASCII parts are not encoded.
Multipart Content Type	No	No	`Mixed`	The type of multipart. Valid values are: • `Mixed`: each MIME body part is independent of the others. • `Alternative`: Each MIME body part is an alternative to the others. • `Related`: All MIME body parts should be considered in the aggregate only.

The Validation properties of the EmailOutput node are described in the following table.

See “Validation properties” on page 4169 for a full description of these properties.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Validate	Yes	Yes	`Inherit`	This property controls whether validation takes place. Valid values are `None`, `Content and Value`, `Content`, and `Inherit`.	validateMaster
Failure action	Yes	No	`Exception`	This property controls what happens if validation fails. You can set this property only if you set `Validate` to `Content` or `Content and Value`. Valid values are `User Trace`, `Local Error Log`, `Exception`, and `Exception List`.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

EndpointLookup node

Use the EndpointLookup node to retrieve service endpoint information held in the WebSphere Service Registry and Repository (WSRR). The entities that match the specified search criteria are stored in the local environment. Depending on the

node configuration, the Web service URL destination used by the SOAP and HTTP request nodes can also be set. The input message is not modified.

This topic contains the following sections:

Purpose:
The EndpointLookup node retrieves service endpoint information related to a WSRR service described by WSDL. A WSDL definition defines a service in terms of an interface (referred to as a portType) made available at a specified port. The WSDL port defines the endpoint information required to access the service. Endpoints are retrieved according to search criteria defined by node properties, optionally supplemented or overridden by local environment definitions at run time. See "LocalEnvironment overrides" on page 4409 for more details.

The retrieved data is placed in the local environment tree, making it available to subsequent nodes. The input message received by the node is propagated to the output terminal unchanged. In addition, the EndpointLookup node can automatically set up the destination URL to be used by a subsequent SOAPRequest, SOAPAsyncRequest or HTTPRequest node, depending on the value of the `Match Policy` property, see "EndpointLookup node processing." This is done by the node setting the local environment overrides that are used by those nodes.

EndpointLookup node processing:
The EndpointLookup node is contained in the **Web services** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

When the EndpointLookup node receives a message the following steps occur in sequence.

1. The EndpointLookup node retrieves the service data from the WSRR by using the specified search criteria.
2. If one or more matches are found, the EndpointLookup node adds a representation of those endpoints to the local environment tree.
   - If `Match Policy` is set to `One`, a single entity is returned by WSRR and added to the local environment tree. A different entity might be returned each time the query is issued. In addition, the retrieved endpoint value is set as the local environment override for the destination URL used by SOAPRequest, SOAPAsyncRequest, or HTTPRequest nodes. If the registry contains more than one entity that matches the specified search criteria it is not possible to determine which one is returned by WSRR.
   - If `Match Policy` is set to `All`, all matching entities are added to the local environment tree. The order of the entities is determined by WSRR and might vary between queries. The destination URL used by SOAPRequest, SOAPAsyncRequest, or HTTPRequest nodes is not set. Instead, you must add

a compute node to your message flow to select the required address and to set up the local environment settings required by those request nodes.

The input message is propagated unchanged to the Out terminal. The local environment tree is propagated to the Out terminal, where it is available for further processing by transformation nodes. See "EndpointLookup node output" on page 1894 for details of the local environment output tree.

3. If no matches are found, the EndpointLookup node propagates the input message to the NoMatch terminal.
4. If a processing error occurs, for example if the WSRR server configured on the `DefaultWSRR` configurable service object cannot be connected to, or the connection times out, the EndpointLookup node propagates the input message unchanged to the Failure terminal. The ExceptionList is populated with details of the error.

Sample:
Look at the following sample to see how to use this node:

- WebSphere Service Registry and Repository Connectivity

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

LocalEnvironment overrides:
You can override the RegistryLookup node properties by using local environment settings. See "Dynamically defining the search criteria" on page 1891.

Terminals and properties:
When you have put an instance of the EndpointLookup node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

The EndpointLookup node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the message is routed if an error occurs within the node's processing.
Out	The output terminal to which the unmodified input message and updated local environment containing the matched registry data is sent.
NoMatch	The terminal to which the input message is sent if no matching entity is found based on the specified search criteria.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The EndpointLookup node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type: EndpointLookup	The name of the node.
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

The EndpointLookup node Basic properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
PortType Name	No	Yes	None	Name tuple that uniquely identifies a WebSphere Service Registry and Repository defined WSDL service portType. At least one of the properties is required. If you leave all three property values blank, an error message is shown when you try to save.	name
PortType Namespace	No	Yes	None		namespace
PortType Version	No	Yes	None		portVersion
User Properties	No	No	None	Allows a query to specify user-defined properties. Add `User Properties` by clicking **Add**. `User Properties` refer to the Additional Properties that are used to catalog the entities in WSRR. Enter values for `Property Name`, which is the case-sensitive match of the additional property in WSRR, `Property Type`, and `Property Value`. The `Property Type` can be: • a String (the default), in which case the `Property Value` is a character string to be matched with the additional property value present in WSRR • XPATH, or ESQL, in which case the `Property Value` is a XPath or ESQL expression which locates a field in the message tree that contains the character string to be matched with the additional property value present in WSRR. These `User Properties` and `Classification` properties are used in the query to uniquely identify the WSDL service port.	
Classification	No	No	None	The Web Ontology Language (OWL) classification system property. Each classifier is a class in OWL, and has a Uniform Resource Identifier (URI). Using classifications in the registry can help to make objects easier to find and can also add meaning to custom objects that are unique to a particular system. Add a `Classification` by clicking **Add** and typing the complete fully-qualified OWL URI for the OWL classification. For example, it can define a particular service endpoint's lifecycle state. These `User Properties` and `Classification` properties are used in the query to uniquely identify the WSDL service port.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Match Policy	Yes	No	`One`	WSRR can contain multiple entities that match the search criteria specified by the previous properties. If `Match Policy` is set to `One`, at most one matching entity is returned. If `Match Policy` is set to `All`, all matching entities are returned. See "EndpointLookup node output" on page 1894. If you request a single matching entity by setting `Match Policy` to `One`, the retrieved endpoint value is set as the local environment override for the destination URL used by SOAPRequest, SOAPAsyncRequest, or HTTPRequest nodes.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

"Configuring aggregation flows" on page 2721
Use aggregation message flows to generate and fan-out a number of related requests, fan-in the corresponding replies, and compile those replies into a single aggregated reply message, by using the AggregateControl, AggregateRequest, and AggregateReply nodes.

"Editing configurable properties" on page 3227
You can edit configurable properties in the deployment descriptor file (`broker.xml`) of your broker archive.

"Populating Destination in the local environment tree" on page 2467
Use the Destination subtree to set up the target destinations that are used by output nodes, the HTTPRequest node, the SOAPRequest node, the SOAPAsyncRequest node, and the RouteToLabel node. The following examples show how you can create and use an ESQL procedure to perform the task of setting up values for each of these uses.

Related reference:

"RegistryLookup node" on page 4646
Use the RegistryLookup node to retrieve any type of entity held in the WebSphere Service Registry and Repository (WSRR). The entities that match the specified search criteria are stored in the local environment. The input message is not modified.

"SOAPRequest node" on page 4828
Use the SOAPRequest node to send a SOAP request to the remote Web service.

"HTTPRequest node" on page 4488
Use the HTTPRequest node to interact with a web service.

Extract node

Use the Extract node to extract the contents of the input message that you want to be processed by later nodes in the message flow.

Attention: The Extract node is deprecated in WebSphere Message Broker Version 6.0 and later releases. Although message flows that contain an Extract node remain valid, redesign your message flows where possible to replace Extract nodes with Mapping nodes.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow" on page 4413
- "Terminals and properties" on page 4413

Purpose:
Using the Extract node, you can create a new output message that contains only a subset of the contents of the input message. The output message comprises only those elements of the input message that you specify for inclusion when configuring the Extract node, by defining mapping statements.

The Extract node is contained in the **Database** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
You might find this node useful if you require only a subset of the message after initial processing of the whole message. For example, you might want to store the whole message for audit purposes (in the Warehouse node), but propagate only a small part of the message (order information, perhaps) for further processing.

For example, you receive orders from new clients and you want to collect their names and addresses for future promotions. Use the Extract node to get this information from each order, and send it as a new message to head office. These messages are processed at head office so that the customer details can be included in the next marketing campaign.

Terminals and properties:
When you have put an instance of the Extract node into a message flow, you can configure it. For more information, see "Configuring a message flow node" on page 1503. The properties of the node are displayed in the Properties view. (If you double-click the Extract node, you open the New Message Map dialog box.) All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The Extract node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the input message is routed if a failure is detected during extraction.
Out	The output terminal to which the transformed message is routed if the input message is processed successfully.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined), the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Extract node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	Extract	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Extract node Basic properties are described in the following table.

Property	M	C	Default	Description
Mapping module	Yes	No	Extract	The name of the mapping routine that contains the statements to run against the message tree. By default, the name that is assigned to the mapping routine is identical to the name of the mappings file in which the routine is defined. The default name for the file is the name of the message flow concatenated with the name of the node when you include it in the message flow (for example, `MFlow1_Extract.msgmap` for the first Extract node in message flow MFlow1). You cannot specify a value that includes spaces. To work with the mapping routine that is associated with this node, right-click the node and click **Open Mappings**. If the mapping routine does not exist, it is created for you with the default name in the default file. If the file exists already, you can also open file *`flow_name_node_name`*`.msgmap` in the Broker Development view. A mapping routine is specific to the type of node with which it is associated; you cannot use a mapping routine that you have developed for an Extract node with any other node that uses mappings (for example, a DataInsert node). If you create a mapping routine, you cannot call it from any other mapping routine, although you can call it from an ESQL routine. For more information about working with mapping files, and defining their content, see “Using message mappings” on page 2228.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see “Configuring monitoring event sources using monitoring properties” on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Use the DataInsert node to interact with a database in the specified ODBC data source.

FileInput node

Use the FileInput node to process messages that are read from files.

This topic contains the following sections:

Purpose:
One or more messages can be read from a single file, and each message is propagated as a separate flow transaction. The part of a file that generates one message flow transaction is called a record. A file can be a single record, or a series of records. Properties on the node specify how the FileInput node determines the records in a file.

The FileInput node is contained in the **File** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Message structure

The FileInput node handles messages in the following message domains:
- XMLNSC
- DataObject
- JSON
- BLOB
- MIME
- MRM
- JMSMap
- JMSStream
- XMLNS

When the FileInput node propagates a message, it stores information about it in the LocalEnvironment.File message tree. If the input file is empty, an empty

message is propagated (assuming that it is valid). The following table lists the LocalEnvironment.File message tree structure. The elements contain data about the current record.

Element Name	Element Data Type	Description
Directory	CHARACTER	Absolute directory path of the input directory in the form used by the file system of the broker. For example, on Windows systems, this starts with the drive letter prefix (such as `C:`).
Name	CHARACTER	File name and extension.
LastModified	TIMESTAMP	Date and time the file was last modified.
TimeStamp	CHARACTER	Date and time, in the Coordinated Universal Time (UTC) zone, the input node started processing the file as a character string. This data is the string used to create archive and backout file names if a timestamp is included.
The following elements contain data about the current record:		
Offset	INTEGER	The start of the record within the file. The first record starts at offset 0. When Offset is part of the End of Data message tree, this value is the length of the input file.
Record	INTEGER	The number of the record within the file. The first record is record number 1. When Record is part of the End of Data message tree, this value is the number of records.
Delimiter	CHARACTER	The characters used to separate this record from the preceding record, if `Delimited` is specified in `Record detection`. The first record has a null delimiter. When Delimiter is part of the End of Data message tree, this value is the delimiter that follows the last record, if any.
IsEmpty	BOOLEAN	Whether the record that is propagated by the message flow is empty. IsEmpty is set to TRUE if the current record is empty. When IsEmpty is part of the End of Data message tree, this property is always set to TRUE.

Using this node in a message flow:
The FileInput node can be used in any message flow that must accept messages in files. You can also look at the following samples to see how to use this node:

- Batch Processing
- WildcardMatch

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

If you configure a File node to use FTP, your network might need it to connect to an FTP proxy server, instead of directly to the remote FTP server. How you configure the File nodes to use an FTP proxy depends on how that proxy handles requests. For some FTP proxies, you must encode the target FTP server information in the logon credentials that you create with the **mqsisetdbparms** command. For example, some FTP proxies support the following values:

```
Username: FtpTargetHostUsername@ProxyUserName@TargetFtpHostname
Password: TargetFtpUserPassword@ProxyUserPassword
```

Other proxies might require different encodings, or might require external configuration, or you might not be able to use them with the File nodes.

Configuring the FileInput node:

When you have put an instance of the FileInput node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (the properties that do not have a default value defined) are marked with an asterisk.

Configure the FileInput node:

1. Optional: On the **Description** tab, enter a `Short description`, a `Long description`, or both. You can also rename the node on this tab.
2. On the **Basic** tab, enter the directories and files to be processed by the FileInput node, together with what to do with any duplicate files encountered.
   - In `Input directory`, specify the directory from which the FileInput node obtains files. Specify the directory as either an absolute or a relative directory path. If the directory path is relative, it is based on the directory specified in the environment variable MQSI_FILENODES_ROOT_DIRECTORY. An example on Windows systems is `C:\fileinput`. An example on UNIX systems is `/var/fileinput`.

     The FileInput node creates an `mqsitransitin` subdirectory in the specified input directory to hold and lock input files while they are being processed. If an execution group that processes files in this input directory is removed, check the `mqsitransitin` subdirectory for partially processed or unprocessed files. Move any such files back into the input directory (and remove the execution group UUID prefix from the file names) so that they can be processed by a different execution group. For more information about the `mqsitransitin` subdirectory, see "How multiple file nodes share access to files in the same directory" on page 1818.
   - In `File name or pattern`, specify a pattern for the file name. It is either a file name or a character sequence (a pattern) that matches a file name. A pattern is a sequence containing at least one of the following wildcard characters:

Wildcard character	Description	Example
*	Any sequence of zero or more characters	`*.xml` matches all file names with an `xml` extension
?	Any single character	`f??????.csv` matches all file names consisting of the letter f followed by six characters and then the sequence `.csv`.

     For a file to be processed, its name must match the pattern.

     If you specify a file name pattern that contains wildcard characters, the FileInput node copies the characters in the file name matched by wildcards, together with any intermediate characters, to the LocalEnvironment.Wildcard.WildcardMatch element. See "File name patterns" on page 1830 for more information.
   - Select `Action on successful processing` to specify the action that the FileInput node takes after successfully processing the file. The action can be to move the file to the archive subdirectory, to augment the file name with a time stamp and move the source file to the archive subdirectory, or to delete the file.
     – If you select `Move to Archive Subdirectory`, the source file is moved to the archive subdirectory of the input directory. The subdirectory name is `mqsiarchive`. For example, if the input directory is `/var/fileinput`, the

absolute path of the archive subdirectory is /var/fileinput/mqsiarchive. If this directory does not exist, the broker creates it when it first tries to move a file there.

– If you select Add Timestamp and Move to Archive Subdirectory, the current date and time are added to the file name, and the file is then moved to mqsiarchive.

– If you select Delete, the file is deleted after successful processing.

The FileInput node writes a message to the user trace, if user tracing is in operation, whenever it processes a file.

- Select Replace duplicate archive files if you want to replace a file in the archive subdirectory with a successfully processed file of the same name. If you do not set this option, and a file with the same name exists in the archive subdirectory, the node throws an exception when it tries to move the successfully processed file.

3. On the **Input Message Parsing** tab, set values for the properties that the node uses to determine how to parse the incoming message.
   - In Message domain, select the name of the parser that you are using from the supplied list. The default is BLOB. You can choose from the following options:
     – XMLNSC
     – DataObject
     – JSON
     – BLOB
     – MIME
     – MRM
     – JMSMap
     – JMSStream
     – XMLNS

     You can also specify a user-defined parser, if appropriate.
   - If you are using the MRM or IDOC parser, or the XMLNSC parser in validating mode, select the Message set that you want to use. This list is populated with available message sets when you select MRM, XMLNSC, or IDOC as the domain.
   - If you are using the MRM parser, select the correct message type from the list in Message type. This list is populated with available message types when you select the MRM parser.
   - If you are using the MRM or IDOC parser, select the correct message format from the list in Message format. This list is populated with available message formats when you select the MRM or IDOC parser.
   - Specify the message coded character set ID in Message coded character set ID.
   - Select the message encoding from the list in Message encoding or specify a numeric encoding value. For more information about encoding, see "Data conversion" on page 1151.
4. On the **Parser Options** subtab:
   - Parse timing is, by default, set to On Demand, which causes parsing of the message to be delayed. To cause the entire message to be parsed immediately, set this property to Immediate or Complete. See "Parsing on demand" on page 4173 for more details.

- If you are using the XMLNSC parser, set values for the properties that determine how the XMLNSC parser operates. For more information, see "Manipulating messages in the XMLNSC domain" on page 2546.

5. On the **Polling** tab, enter a value for the `Polling interval`. This property controls the frequency with which the FileInput node accesses the file system looking for files to process.

   After the initial scan of the directory when the flow is started, whenever the directory is found to contain no files that match the input pattern, the FileInput node waits for the period defined by this property. This process avoids the need for the FileInput node to be continually accessing the file system, and consuming large amounts of system resource.

   The smaller the value set in this property, the more quickly the FileInput node discovers files that are in the input directory. However, a smaller value increases the use of system resources. A larger value reduces the use of system resource but at the cost of the FileInput node discovering files to process less quickly.

   Do not use this property as a means to regulate work, or to schedule processing. If you want the FileInput node to monitor the input directory for selected periods only, start and stop the message flow at appropriate times.

   If you select the `Remote Transfer` property and set the `Scan delay` property on the FTP tab, the value that you set for `Scan delay` overrides the value set for `Polling interval`.

6. Use the **Retry** tab to define how retry processing is performed when a message flow fails:
   - `Retry mechanism` determines the action that occurs if the flow fails:
     - Select `Failure` for the node to report a failure without any retry attempts.
     - Select `Short retry` for the node to try again before reporting a failure if the condition persists. The number of times that it tries again is specified in `Retry threshold`.
     - Select `Short retry and long retry` for the node to try again, first using the value in `Retry threshold` as the number of attempts it is to make. If the condition persists after the `Retry threshold` value has been reached, the node then uses the value of `Long retry interval` between attempts.
   - Specify a value for the `Retry threshold` property. The number of times the node tries the flow transaction again if the `Retry mechanism` property is set to either `Short retry` or `Short retry and long retry`.
   - Specify a value for the `Short retry interval` property. The length of time, in seconds, to wait between short retry attempts.
   - Specify a value for the `Long retry interval` property. The length of time to wait between long retry attempts until a message is successful, the message flow is stopped, or the message flow is redeployed. The `MinLongRetryInterval` broker property defines the minimum value that the `Long retry interval` can take. If the value is lower than the minimum, the broker value is used.
   - Specify a value for the `Action on failing file` property to determine what the node is to do with the input file after all attempts to process its contents fail:
     - `Move to Backout Subdirectory`. The file is moved to the backout subdirectory of the input directory. The name of this subdirectory is `mqsibackout`. If the input directory is `/var/fileinput`, the absolute path of the backout subdirectory is `/var/fileinput/mqsibackout`. If this subdirectory does not exist, the broker creates it when it first tries to

move a file there. If the file cannot be moved to this subdirectory, perhaps because a file of the same name exists there, the node adds the current date and time to the file name and makes a second attempt to move the file. If this second attempt fails, the node stops processing. Messages BIP3331 and BIP3325 are issued. Resolve the problem with the subdirectory or file before attempting to restart the message flow.

- `Delete`. The file is deleted after processing fails.
- `Add Time Stamp and Move to Backout Subdirectory`. The current date and time are added to the file name, and then the file is moved to the backout subdirectory.

7. Use the **Records and Elements** tab to specify how each file is interpreted as records:
   - Use the `Record detection` property to determine how the file is split into records, each of which generates a single message. Choose from the following options:
     - `Whole File` specifies that the whole file is a single record. A limit of 100 MB applies to the size of the files.
     - `Fixed Length` specifies that each record is a fixed number of bytes in length. Each record contains the number of bytes specified in the `Length` property, except possibly a shorter final record in the file. The value specified in `Length` must be in the range 1 byte through 100 MB. The default is 80 bytes.
     - Select `Delimited` if the records that you are processing are separated, or terminated, by a DOS or UNIX line end or by a sequence of user-defined delimiter bytes. Specify the delimiter and delimiter type in the `Delimiter` and `Delimiter type` properties. A limit of 100 MB applies to the length of the records.
     - Select `Parsed Record Sequence` if the file contains a sequence of one or more records that are serially recognized by the parser specified in `Message domain`. The node propagates each recognized record as a separate message. If you select the `Record detection` option, the parser specified in `Message domain` must be either XMLNSC or MRM (either CWF or TDS physical format).
   -

     If you specify `Parsed Record Sequence` in `Record detection`, the FileInput node does not determine or limit the length of a record. Nodes that are downstream in the message flow might try to determine the record length or process a long record. If you intend to process large records in this way, ensure that your broker has sufficient memory. You might have to apply flow techniques described in the Large Messaging sample to make best use of the available memory.
   - If you specified `Delimited` in `Record detection`, use `Delimiter` to specify the delimiter to be used. Choose from:
     - `DOS or UNIX Line End`, which, on UNIX systems, specifies the line feed character (<LF>, X'0A'), and, on Windows systems, specifies a carriage return character followed by a line feed character (<CR><LF>, X'0D0A'). The node treats both of these strings as delimiters, irrespective of the system on which the broker is running. If they are both in the same file, the node recognizes both as delimiters. The node does not recognize X'15' which, on z/OS systems, is the 'newline' byte; specify a value of `Custom Delimiter` in this property and a value of `15` in the `Custom delimiter` property if your input file is coded using EBCDIC new lines, such as EBCDIC files from a z/OS system.

- Custom Delimiter, which permits a sequence of bytes to be specified in Custom delimiter

- In Custom delimiter, specify the delimiter byte or bytes to be used when Custom delimiter is set in the Delimiter property. Specify this value as an even-numbered string of hexadecimal digits. The default is X'0A' and the maximum length of the string is 16 bytes (represented by 32 hexadecimal digits).
- If you specified Delimited in Record detection, use Delimiter type to specify the type of delimiter. Permitted values are:
  - Infix. If you select this value, each delimiter separates two records. If the file ends with a delimiter, the zero length file content following the final delimiter is still propagated as a message although it contains no data.
  - Postfix. If you specify this value, each delimiter terminates a record. If the file ends with a delimiter, no empty record is propagated after the delimiter. If the file does not end with a delimiter, the file is processed as if a delimiter follows the final bytes of the file. Postfix is the default value.
- The FileInput node considers each occurrence of the delimiter in the input file as either separating (Infix) or terminating (Postfix) each record. If the file begins with a delimiter, the node treats the (zero length) file contents preceding that delimiter as a record and propagates an empty record to the flow. The delimiter is never included in the propagated message.

8. Use the **Validation** tab to provide validation based on the message set for predefined messages. For more information about validation, see "Validating messages" on page 1478. For information about how to complete this tab, see "Validation tab properties" on page 4169.
9. On the **FTP** tab, select the Remote Transfer property if you want the node to read files from an FTP or SFTP server using the following properties:
   - In Transfer Protocol, specify the protocol that is to be used for remote file transfer. Possible values are FTP and SFTP.
   - In Remote server and port, supply the IP address and port number of the FTP or SFTP server to be used. Use one of the following syntaxes:
     - *IP_address_or_URL*
     - *IP_address_or_URL*:*port_number*

     If you specify the IP address in IPv6 format, ensure that you enclose it in square brackets, as in the following examples:
     - [12a::13bd:24cd]
     - [12a::13bd:24cd]:123 where 123 is the port number

     If you are using FTP and you do not specify a port number, 21 is assumed. If you are using SFTP and you do not specify a port number, a port number of 22 is assumed. However, if an FtpServer configurable service is defined, you can enter the name of the configurable service in this field. For information about how an FtpServer configurable service definition and the properties on this tab interact, see "FtpServer configurable service properties" on page 3794.
   - In Security identity, specify the name of a security identity that has been defined using the **mqsisetdbparms** command. The user identifier and password that are to be used to log on to the FTP or SFTP server are obtained from this definition, the name of which must have an ftp:: prefix. The value of this property is overridden by the value in the securityIdentity property of the FtpServer configurable service, if it is set.

- In `Server directory`, specify the directory in the FTP or SFTP server from which to transfer files. The default is a period (`.`) which means the default directory after logon. If you specify a relative path, the directory is based on the default directory after FTP or SFTP logon. Ensure that the syntax of the path conforms to the file system standards in the FTP or SFTP server. The value in this property is overridden by the value in the remoteDirectory property of the FtpServer configurable service, if it is set.
- In `Transfer mode`, specify how files are transferred. Select `Binary` if the file contents are not to be transformed. Select `ASCII` if the file is to be transmitted as ASCII. The value of this property is overridden by the value in the transferMode property of the FtpServer configurable service, if it is set.

  This property is valid only when FTP is selected as the protocol for remote transfer. If you have specified SFTP as the protocol, the `Transfer mode` mode property is ignored and binary encoding is used.
- In `Scan delay`, specify the delay, in seconds, between directory scans. The default is 60 seconds. The value set in this property overrides the value set for the polling interval on the **Polling** tab when the `Remote Transfer` property is selected. The value of this property is overridden by the value in the scanDelay property of the FtpServer configurable service, if it is set.

10. On the **Transactions** tab, set the transaction mode. Although all file operations are non-transactional, the transaction mode on this input node determines whether the rest of the nodes in the flow are to be run under sync point. Select `Yes` if you want the flow updates to be treated transactionally, if possible, or `No` if you do not. The default for this property is `No`.
11. Optional: On the **Instances** tab, set values for the properties that control the additional instances (threads) that are available for a node. For more details, see "Configurable message flow properties" on page 4020.

Terminals and properties:
The FileInput node terminals are described in the following table.

Terminal	Description
Failure	The output terminal to which a message is routed if an error occurs before a message is propagated to the Out terminal. Messages propagated to this terminal are not validated, even if you have specified, using the `Validate` property, that validation is to take place.
Out	The output terminal to which a message is routed if it has been successfully extracted from the input file. If no errors occur within the input node, a message received from an external resource is always sent to the Out terminal first.
End of Data	The output terminal to which the End of Data message is routed after all the messages in a file have been processed. The End of Data message flow transaction is initiated only if this terminal is attached.
Catch	The output terminal to which the message is routed if an exception is thrown downstream and caught by this node. Exceptions are caught only if this terminal is attached.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

Description properties:

Property	M	C	Default	Description
Node name	No	No	FileInput	The name of the node.
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

Basic properties:

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Input directory	Yes	Yes	None	The path of the directory from which input files are processed. The directory must be in a file system to which the broker has access. If the input directory does not exist, no files are processed. The FileInput node checks that the input directory exists at intervals that are defined by the `Scan delay` property. The input directory must exist, even if you are processing files over FTP or SFTP. The FileInput node creates an `mqsitransitin` subdirectory in the specified input directory. The `mqsitransitin` subdirectory holds and locks input files while they are being processed. If an execution group that processes files in this input directory is removed, check the `mqsitransitin` subdirectory for partially processed or unprocessed files. Move any such files back into the input directory (and remove the execution group UUID prefix from the file names) so that they can be processed by a different execution group.	inputDirectory
File name or pattern	Yes	Yes	*	A file name or string containing optional wildcard characters (* or ?) identifying the file or files to process from the input directory.	filenamePattern
Action on successful processing	Yes	No	`Delete`	The action the node takes on the file after successfully processing the contents. Valid options are: • `Move to Archive Subdirectory` • `Add Time Stamp and Move to Archive Subdirectory` • `Delete`	
Replace duplicate archive files	Yes	No	Cleared	This property controls whether the node replaces existing archive files with the same name as the input file. It applies only when `Action on successful processing` is not `Delete`.	

The FileInput node Input Message Parsing properties are described in the following table:

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Message Domain	No	No		The domain that is used to parse the incoming message.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Message Set	No	No		The name or identifier of the message set in which the incoming message is defined. If you set this property, and then update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message Set` property, or restore the reference to this message set project.	
Message Type	No	No		The name of the incoming message.	
Message Format	No	No		The name of the physical format of the incoming message.	
Message coded character set ID	Yes	No	Broker System Default	The ID of the coded character set used to interpret bytes of the file being read.	messageCodedCharSetIdProperty
Message encoding	Yes	No	Broker System Determined	The encoding scheme for numbers and large characters used to interpret bytes of the file being read. Valid values are `Broker System Determined` or a numeric encoding value. For more information about encoding, see "Data conversion" on page 1151.	messageEncodingProperty

Parser Options properties:

Property	M	C	Default	Description
Parse timing	No	No	`On Demand`	This property controls when an input message is parsed. Valid values are: • `On Demand` • `Immediate` • `Complete` For a full description of this property, see "Parsing on demand" on page 4173.
Build tree using XML schema data types	No	No	Cleared	This property controls whether the syntax elements in the message tree have data types taken from the XML schema.
Use XMLNSC compact parser for XMLNS domain	No	No	Cleared	Specifies whether the XMLNSC Compact Parser is used for messages in the XMLNS Domain. If you set this property, the message data is displayed under XMLNSC in nodes that are connected to the output terminal when either of the following items is XMLNS: • The input MQRFH2 header. • The Input Message Parsing property, Message Domain.
Retain mixed content	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree for mixed text in an input message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.

Property	M	C	Default	Description
Retain comments	No	No	Cleared	Specifies whether the XMLNSC parser creates elements in the message tree for comments in an input message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree for processing instructions in an input message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the input message that are to be opaquely parsed by the XMLNSC parser. Opaque parsing is performed only if validation is not enabled (that is, if `Validate` is `None`); entries that are specified in `Opaque Elements` are ignored if validation is enabled.

Polling property:

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Polling interval (seconds)	Yes	Yes	`5`	The polling interval in seconds.	waitInterval

Retry properties:

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Retry mechanism	Yes	No	`Failure`	How the node handles a flow failure. Valid options are: • `Failure` • `Short retry` • `Short and long retry`	
Retry threshold	Yes	Yes	`0`	The number of times to try the flow transaction again when the `Retry mechanism` property value is `Short retry`.	retryThreshold
Short retry interval	No	Yes	`0`	The interval, in seconds, between each retry if `Retry threshold` property is not zero.	shortRetryInterval
Long retry interval	No	Yes	`300`	The interval between retries, if the `Retry mechanism` property is `Short and long retry` and the retry threshold has been exhausted.	longRetryInterval
Action on failing file	Yes	Yes	`Move to Backout Subdirectory`	The action that the node takes with the input file if all attempts to process the contents of the input file fail. Valid options are: • `Move to Backout Subdirectory` • `Delete` • `Add Time Stamp and Move to Backout Subdirectory`	

Records and Elements properties:

Property	M	C	Default	Description
Record detection	Yes	No	`Whole File`	The mechanism used to identify records in the input file. Valid options are: • `Whole File` When you set this property to `Whole File`, files larger than 2 Gb are not supported. • `Fixed Length` • `Delimited` • `Parsed Record Sequence`
Length	Yes	No	`80`	The length of each record, in bytes, when `Fixed Length` record detection is selected.
Delimiter	Yes	No	`DOS or UNIX Line End`	The type of delimiter bytes that separate, or end, each record when `Delimited` record detection is selected. Valid options are: • `DOS or UNIX Line End` • `Custom Delimiter`
Custom delimiter	No	No		The delimiter bytes, expressed in hexadecimal, when `Delimited` record detection and `Custom Delimiter` are selected. This property is mandatory only if the `Delimiter` property is set to `Custom Delimiter`.
Delimiter type	Yes	No	`Postfix`	The position of the delimiter when `Delimited` record detection is selected. Valid options are: • `Postfix` • `Infix` This property is ignored unless the `Delimiter` property is set to `Custom Delimiter`.
Skip first record	Yes	No	FALSE	Skip the first record in the file. The FileInput node will read the first record in the file but not propagate the record to the Out terminal. Records will be propagated as normal, from the second record onwards. Use this option when the first record is a header that does not need to be processed. It is not valid to use this option when using the whole file.

Validation properties:

For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Validate	No	Yes	`None`	This property controls whether validation takes place. Valid values are: • `None` • `Content and Value` • `Content`	validateMaster
Failure action	No	No	`Exception`	This property controls what happens if validation fails. Valid values are: • `User Trace` • `Local Error Log` • `Exception` • `Exception List`	

FTP properties:

Property	M	C	Default	Description	mqsiapplybaroverride command property
Remote Transfer	No	Yes	Cleared	This property defines whether the node uses the remote file transfer properties listed on the **FTP** tab and reads files from either an FTP or SFTP server.	fileFtp
Transfer protocol	No	Yes	FTP	This property specifies the protocol to be used for remote transfer. Valid values are: • `FTP` • `SFTP`	remoteTransferType
Remote server and port	No	Yes	None	This property can have either of the following values: • The IP address or name (and, optionally, the port number) of a remote FTP or SFTP server; for example `ftp.server.com:21` or `sftp.server.com:22` • The name of a configurable service of type FtpServer If a configurable service name is specified, any or all the other remote transfer properties on the FTP tab can be overridden by the configurable service.	fileFtpServer
Security identity	No	Yes		The name of the user identification used to access the FTP or SFTP server. This property is overridden by the securityIdentity property, if set, in the FtpServer configurable service.	fileFtpUser
Server directory	No	Yes	"."	The directory on the FTP or SFTP server from which to transfer files. If you specify this property as a relative path, it is relative to the home directory after logon. This property is overridden by the remoteDirectory property, if set, in the FtpServer configurable service.	fileFtpDirectory
Transfer mode	No	No	`Binary`	The FTP transfer mode for transfer of file data. This property is valid only when FTP is selected as the protocol for remote transfer. Valid values are: • `Binary` • `ASCII` This property is overridden by the transferMode property, if set, in the FtpServer configurable service. If you have specified SFTP as the protocol for remote transfer, the `Transfer mode` property is ignored, and binary encoding is used.	
Scan delay	No	Yes	`60`	The delay, in seconds, between remote directory scans. This property overrides the value set for `Polling interval` when the `Remote Transfer` property is selected. This property is overridden by the scanDelay property, if set, in the FtpServer configurable service.	

Transactions properties:

Property	M	C	Default	Description
Transaction mode	No	Yes	`No`	The transaction mode on this input node determines whether the rest of the nodes in the flow are run under sync point. Valid options are: • `Yes` • `No`

Instances properties. For a full description of these properties, see "Configurable message flow properties" on page 4020.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Additional instances pool	No	Yes	`Use Pool Associated with Message Flow`	The pool from which additional instances are obtained. • If you select `Use Pool Associated with Message Flow`, additional instances are obtained from the message flow pool. • If you select `Use Pool Associated with Node`, additional instances are allocated from the additional instances of the node based on the number specified in the `Additional instances` property.	componentLevel
Additional instances	No	Yes	0	The number of additional instances that the node can start if the `Additional instances pool` property is set to `Use Pool Associated with Node`.	additionalInstances

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

"File name patterns" on page 1830
You can specify a file name pattern, using wildcard characters, to identify a file to be read by the FileInput and FTEInput nodes. You can also specify a file name pattern, using a single wildcard character, to name the file to be created by the FileOutput and FTEOutput nodes.

"How the broker processes files" on page 1814
The broker reads files with the FileInput, FTEInput, and FileRead nodes, and writes files with the FileOutput and FTEOutput nodes.

FileOutput node

Use the FileOutput node to write messages to files.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow" on page 4433
- "Configuring the FileOutput node" on page 4433
- "Terminals and properties" on page 4433

Purpose:
You can write one or more messages from message flow transactions to a file in the file system of the broker. Each message, as it is written to a file, is converted to a sequence of bytes called a *record*. Records are accumulated until a process is triggered that completes the file and places it either in the specified output directory or a remote FTP or SFTP server directory. Properties on the node specify how records are accumulated into files and where the files are placed when they are finished.

The FileOutput node is contained in the **File** drawer of the palette and is represented in the workbench by the following icon:

Record processing

The FileOutput node writes files as a sequence of one or more records. Each record is generated from a single message received on the In terminal of the node.

By default, each file comprises a single record but properties on the FileOutput node can specify that the file comprises multiple records and how these records are accumulated in a file. If multiple records are written, the FileOutput node starts with an empty file and writes records to it until a message is received by the Finish File terminal. The node does not append new records to a file that exists. Multiple records can be accumulated in a file in the following ways:

- Concatenated: The record created from each message is added, unmodified, to the file.
- Padded: Each record is adjusted to be a specific length and padded with a padding byte, if necessary, before being added to the file.
- Delimited: A delimiter is used to separate or terminate the records as they are added to the file.

For each message received, whether on the In terminal or the Finish File terminal, you can modify the output directory and the name of the file to be written (or finished) by using elements of the message. On the node you can specify these elements, which, by default, identify elements in the local environment, on the **Request** properties tab.

File processing

The FileOutput node writes accumulated messages to a file, and places it in a specified directory (the output directory) at either of the following times:

- After each record, if the file is to contain a single record. (Specify this behavior by setting the `Record definition` property to `Record is Whole File` on the **Records and Elements** tab.)
- When the Finish File terminal receives a message.

The name of the output directory and the names of the output files are determined by the node properties that you specify and by elements of the message that is being processed.

The FileOutput node uses subdirectories of the output directory to store files during and after processing. All these subdirectories begin with the prefix `mqsi`, and include subdirectories called `mqsitransit` (the transit directory) and `mqsiarchive` (the archive directory). Records are not accumulated directly into a file in the output directory but are accumulated in a file in the transit directory. Files are moved from the transit directory to the output directory when the file is complete. If a file that is to be moved to the output directory has the same name as a file that is already there, you can choose whether the file in the output directory is deleted, moved to the archive directory (`mqsiarchive`), or renamed before being moved to the archive directory.

You can specify that the FileOutput node transfers files to a remote FTP or SFTP server as part of file processing. If the file is successfully transferred, it can be deleted from the local file system, or, optionally, retained for the rest of the file processing to occur as usual. The server is identified by the `Remote server and port` property on the node. Alternatively, you can override the node property by setting a value in the local environment. You can also use the local environment to specify commands to run before or after an FTP or SFTP transfer finishes. For more information, see “Local environment overrides for the FileOutput node” on page 4443.

During the file transfer operation, the FileOutput creates the destination file. However, the destination file is readable before the file transfer is complete. Therefore, ensure that remote applications do not read the file until the file transfer is complete.

When multiple records are written, no file processing occurs until a message is received on the Finish File terminal of the node. Any message received on the Finish File terminal causes the file to be moved from the transit directory to either the specified output directory or to a remote FTP or SFTP directory.

It is not an error if file processing is initiated when there is no file in the transit directory.

If you set the `Record definition` property to `Record is Whole File` on the **Records and Elements** tab, messages received on the Finish File processing are ignored because the file has already been processed.

The UMASK value for WebSphere Message Broker on UNIX and z/OS systems can be set using the MQSI_SET_DFE_UMASK environment variable as follows:

```
MQSI_SET_DFE_UMASK=nnnn
```

where *nnnn* is the UMASK value that you need to specify. The minimum permissions level required by WebSphere Message Broker is `rwrw_(660)`. If neither of the UMASK environment variable are set, then files are created with a UMASK of `6`.

Message propagation

For every message received on the In terminal and successfully processed by the node, a copy is propagated to the Out terminal for further processing if the terminal is attached.

For every message received on the Finish File terminal and successfully processed by the node, a copy is propagated to the End of Data terminal for further processing if the terminal is attached.

When the FileOutput node propagates a message, either to the Out terminal or to the End of Data terminal, it stores information in the LocalEnvironment.WrittenDestination.File message tree. This table describes the LocalEnvironment.WrittenDestination.File elements:

Element Name	Element Data Type	Description
Directory	CHARACTER	Absolute path of the output directory in the form used by the file system of the broker. For example, on Windows systems, the directory path starts with the drive letter prefix (such as `C:`).
Name	CHARACTER	Name of the output file.
Action	CHARACTER	Possible values are: • `Replace` if an output file of the same name is replaced. • `Create` if a new output file is created. • `Append` if this message is associated with a record that is added to an output file. • `Finish` if a Finish File message is received and no file is found to finish (for example, if `Record is Whole File` is specified and a message is sent to the Finish File terminal). • `Transmit` if the file was transferred by FTP or SFTP and the file was not retained.

Element Name	Element Data Type	Description
Timestamp	CHARACTER	The date and time, in character string form, when the node started to process this file. This value prefixes the names of files that are archived if you set the `Output file action` property to `Time Stamp, Archive and Replace Existing File` on the **Basic** tab.

Multiple instances

Several message flows might write to the same file, which can happen where there are additional instances of the flow, or where multiple flows contain FileOutput nodes. The FileOutput node permits only a single instance, within an execution group and between execution groups, to write to a file at the same time. While a record is being written, all other instances in the execution group must wait. The order in which instances gain access is not defined.

When the file is complete, the first instance to gain access processes it, and other instances do not find the file. The Action element of the LocalEnvironment.WrittenDestination.File message tree is set to `Finish` for all instances that fail to discover the file in the transit directory.

Using this node in a message flow:
The FileOutput node can be used in any message flow that sends messages to files. See "Working with files" on page 1807. You can also look at the following samples to see how to use this node:
- File Output
- Batch Processing
- WildcardMatch

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

If you configure a File node to use FTP, your network might need it to connect to an FTP proxy server, instead of directly to the remote FTP server. How you configure the File nodes to use an FTP proxy depends on how that proxy handles requests. For some FTP proxies, you must encode the target FTP server information in the logon credentials that you create with the **mqsisetdbparms** command. For example, some FTP proxies support the following values:

```
Username: FtpTargetHostUsername@ProxyUserName@TargetFtpHostname
Password: TargetFtpUserPassword@ProxyUserPassword
```

Other proxies might require different encodings, or might require external configuration, or you might not be able to use them with the File nodes.

Configuring the FileOutput node:
When you have put an instance of the FileOutput node into a message flow, you must configure it (for more information, see "Configuring a message flow node" on page 1503). The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those properties that do not have a default value defined) are marked with an asterisk in that view.

Terminals and properties:
The FileOutput node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Finish File	The input terminal that accepts a message that triggers the final processing of a file.
Out	The message received on the In terminal is propagated to this terminal if the record is written successfully. The message is unchanged except for status information in the Local Environment.
End of Data	The message received on the Finish File terminal is propagated to this terminal if the file is processed successfully.
Failure	The output terminal to which the message is routed if a failure is detected when a message is propagated.

The following tables describe the node properties that you can set on a specified tab. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The FileOutput node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	FileOutput	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The FileOutput node Basic properties are described in the following table.

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
Directory	No	Yes	None	Specify the output directory in which the FileOutput node places its files. Specify the directory as an absolute or relative directory path. If the directory path is relative, it is based on the directory specified in the environment variable MQSI_FILENODES_ROOT_DIRECTORY. For example: • On Windows: `C:\fileoutput` • On UNIX: `/var/fileoutput` To write files in the directory that is identified by MQSI_FILENODES_ROOT_DIRECTORY, ensure that you specify a value of `.` (a period) in this property. You can override the output directory path to be used by setting values in the current message. For more information, see the Request tab properties.	outputDirectory

Property	M	C	Default	Description	mqsiapplybaroverride command property
File name or pattern	No	Yes	None	Specify a file name pattern. This property defines the name of the file that is created by the FileOutput node. The value is either a specific file name or a character sequence (pattern) that matches a file name. Only patterns with a single wildcard character (the asterisk, *) are allowed in this property field. The file name to be used is determined in the following way: • If the file name contains no wildcard, the value of this property is the name of the file created. This value must be a valid file name on the file system or the FTP file system that hosts the broker to which the message flow is deployed. • If the file name contains a single wildcard character, the value of the element `LocalEnvironment.Wildcard.WildcardMatch` in the current message replaces the wildcard character, and the resulting value is the name of the file created. This value must be a valid file name on the file system or the FTP file system that hosts the broker to which the message flow is deployed. If the WildcardMatch value is not found, the wildcard character is replaced by an empty string. You can override the name of the file by setting values in the current message. For more information, see the Request tab properties. If the `File name or pattern` property is empty, you must override the name by using the current message. Wildcard substitution occurs only if this property is not overridden in this way. File names are passed to the file system to which the broker has access and must adhere to the conventions of these file systems. For example, file names on Windows systems are not case-sensitive; while on UNIX systems, they are.	outputFilename
Mode for writing to file	Yes	No	Stage in transit directory	Specify if the file must be staged or written to directly. Select one of the following options: • `Stage in transit and move to output directory on Finish File` • `Write directly to the output file`	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Action if file exists	Yes	No	Replace Existing File	Specify how the file is to be processed when it is complete. Select one of the following options: • Replace Existing File (the default value) specifies that if a file of the same name exists in the output directory, the new file replaces it. • Append to Existing File moves the output file to the transit directory and appends the file contents to the file. The file is moved back to the output directory when the append is finished. • Fail if File Exists specifies that a new file is created, and that if a file of the same name exists in the output directory, the new file remains in the transit directory and exception BIP3307 is produced. • Archive and Replace Existing File specifies that if any file of the same name exists in the output directory, it is moved to the archive directory before the new file is placed in the output directory. If any file of the same name exists in the archive directory, an exception is produced. • Time Stamp, Archive and Replace Existing File specifies that if a file of the same name exists in the output directory, its name is augmented with a time stamp (a character-based version of the date and time) before being moved to the archive directory. The format of the time stamp is *yyyyMMdd_HHmmss_SSSUUU*, in UTC time, where *UUU* is an additional ID to ensure that the time stamp is unique.	
Replace duplicate archive files	Yes	No	Cleared	Select the Replace duplicate archive files check box to specify that, in cases where Archive and Replace Existing File or Time Stamp, Archive and Replace Existing File is specified in Output file action, files moved to the archive directory replace files that exist there already with the same name. By default, this check box is cleared. If this check box is not selected, and there is already a file in the archive directory with the same name as a file that is to be moved there, an exception is produced, and the new file remains in the transit directory.	

The FileOutput node Request properties are described in the following table.

These properties specify the location of the data to be written, and control information that overrides the Directory and File name or pattern properties on the **Basic** tab. You can specify the properties on this tab as XPath or ESQL expressions. Content assist is available in the properties pane and also in the XPath Expression Builder, which you can open by using the **Edit** button to the right of each property.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Data location	Yes	No	`$Body`	Specify the input data location, which is the location in the input message tree that contains the record to be written to the output file. The default value is `$Body`, meaning the entire message body (`$InputRoot.Body`). When you specify this property, and the data in the message tree that it identifies is owned by a model-driven parser, such as the MRM parser or XMLNSC parser, consider the following factors. • If you are using MRM CWF format, ensure that the identified message tree exists as a message definition. If this element is defined as a global element only, exceptions BIP5180 and BIP5167 are produced. • If you are using MRM TDS format, serialization of the identified message is successful if the element is defined as a global element or message. However, if the identified field is not found as a global element or message, the following conditions apply: – If the field is a leaf field in the message tree, the field is written as self-defining. No validation occurs even if validation is enabled. – If the field is a complex element, an internal exception is generated (BIP5522), indicating that the logical type cannot be converted to a string. • If you are using MRM XML, the events are similar as for the MRM TDS format except that, if the field is a complex element, it is written as self-defining. • If you use the XMLNSC parser, no validation occurs even if validation is enabled.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Request directory property location	Yes	Yes	`$LocalEnvironment/Destination/File/Directory`	Specify the location of the value to override the `Directory` property on the **Basic** tab. If you do not specify a location, the default value is `$LocalEnvironment/Destination/File/Directory`. If you specify a location but the element is empty or missing, the `Directory` property is used. The element has a data type of CHARACTER and is an absolute or relative directory path. Use the path separator character ('/' or '\') according to the file system on which the broker runs. Trailing path separator characters are ignored. Relative directory paths are based on the value of the MQSI_FILENODES_ROOT_DIRECTORY environment variable.	requestDirectoryLocation
Request file name property location	Yes	Yes	`$LocalEnvironment/Destination/File/Name`	Specify the location of the value to override the `File name or pattern` property on the **Basic** tab. If you do not specify a location, the default value is `$LocalEnvironment/Destination/File/Name`. If you specify a location but the element is empty or missing, the `File name or pattern` property is used. The element has a data type of CHARACTER and is an explicit file name. No wildcard substitution occurs for this value.	requestNameLocation

The FileOutput node Records and Elements properties are described in the following table.

These properties specify how the FileOutput node writes the record derived from the message.

Property	M	C	Default	Description
Record definition	Yes	No	`Record is Whole File`	Specify how the records are placed in the output file. Select one of the following options: • `Record is Whole File` specifies that the file is to contain a single record. The file is finished immediately after the record is written; the FileOutput node does not wait for a message on the Finish File terminal. This value is the default. • `Record is Unmodified Data` specifies that records are accumulated in a file with neither padding or delimiters applied. The file is finished only when a message is received on the Finish File terminal. • `Record is Fixed Length Data` specifies that records are padded to a given length if necessary and accumulated in a file by concatenation. You specify this length in the `Length` property. If the record is longer than the value specified in `Length`, the node produces an exception. Use the `Padding byte` property to specify the byte to be used for padding the message to the required length. Records are added to this file until a message is received on the Finish File terminal. • `Record is Delimited Data` to specify that records are separated by a delimiter and accumulated by concatenation. The delimiter is specified by the `Delimiter`, `Custom delimiter`, and `Delimiter type` properties. Records are added to this file until a message is received on the Finish File terminal.
Length	Yes	No	`80`	Specify the length (in bytes) of records when `Record is Fixed Length Data` is specified in `Record definition`. Records that are longer than this value cause an exception to be produced. This value must be in the range 1 byte through 104857600 bytes (100 MB). The default value is 80 bytes.
Padding byte	Yes	No	`X'20'`	When `Record is Fixed Length Data` is specified in `Record definition`, use the `Padding byte` property to specify the byte to be used when padding records to the specified length if they are shorter than this length. Specify this value as two hexadecimal digits. The default value is `X'20'`.
Delimiter	Yes	No	`Broker System Line End`	Specify the delimiter to be used if you specify `Record is Delimited Data` in `Record definition`. Select one of the following options: • `Broker System Line End` specifies that a line end sequence of bytes is used as the delimiter, as appropriate for the file system on which the broker is to run. For example, on Windows systems, the delimiter is a 'carriage-return, line-feed' pair (X'0D0A'); on UNIX systems, it is a single 'line-feed' byte (X'0A'); on z/OS systems, it is a 'newline' byte (X'15'). This value is the default. • `Custom Delimiter` specifies that the explicit delimiter sequence defined in the `Custom delimiter` property is to be used to delimit records.
Custom delimiter	No	No	None	Specify the delimiter sequence of bytes to be used to delimit records when `Custom Delimiter` is specified in the `Delimiter` property. Specify this value as an even-numbered string of hexadecimal digits. The default value is `X'0A'` and the maximum length of the string is 16 bytes.

Property	M	C	Default	Description
Delimiter type	Yes	No	Postfix	If you set the Record definition property to Record is Delimited Data, use Delimiter type to specify how the delimiter is to separate records. Select one of the following options: • Postfix specifies that the delimiter is added after each record that is written. This value is the default. • Infix specifies that the delimiter is inserted only between any two adjacent records.

The FileOutput node Validation properties are described in the following table.

For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	Yes	Inherit	Specify whether validation takes place. Valid values are: • None • Content and Value • Content • Inherit	validateMaster
Failure action	No	No	Exception	Specifies what happens if validation fails. You can set this property only if you set Validate to Content or Content and Value. Valid values are: • User Trace • Local Error Log • Exception • Exception List	

The FileOutput node FTP properties are described in the following table.

To transfer files to an FTP or SFTP server, select the Remote Transfer property, then set the properties described in this table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Remote transfer	No	Yes	Cleared	To transfer files to an FTP or SFTP server, select Remote Transfer, then set the other properties in this table.	fileFtp
Transfer protocol	No	Yes	FTP	This property specifies the protocol to be used for remote transfer. Valid values are: • FTP • SFTP	remoteTransferType

Property	M	C	Default	Description	mqsiapplybaroverride command property
Remote server and port	No	Yes	None	This property can have either of the following values: • The IP address or name (and, optionally, the port number) of a remote FTP or SFTP server • The name of a configurable service of type FtpServer Specify the IP address and port number of the FTP or SFTP server to be used, by using the following syntax: • *IP_address_or_URL* or • *IP_address_or_URL:port_number* If you specify the IP address in IPv6 format, ensure that you enclose it in square brackets, for example: • `[12a::13bd:24cd]` or • `[12a::13bd:24cd]:123` where `123` is the port number If you are using FTP and you do not specify a port number, 21 is assumed. If you are using SFTP and you do not specify a port number, a port number of 22 is assumed. However, if an FtpServer configurable service is defined, you can enter the name of the configurable service in this field. If a configurable service name is specified, any or all of the other remote transfer properties on the FTP tab can be overridden by the configurable service. For information about how an FtpServer configurable service definition and the properties on this tab interact, see "FtpServer configurable service properties" on page 3794. You can override this property by setting the location of the server in the local environment. For more details, see "Local environment overrides for the FileOutput node" on page 4443.	fileFtpServer
Security identity	No	Yes	None	Specify the name of a security identity that has been defined by using the **mqsisetdbparms** command. The user identifier and password that are to be used to log on to the FTP or SFTP server are obtained from this definition. The name of the definition must have the prefix `ftp::`. The value of this property is overridden by the value in the FtpServer configurable service property securityIdentity, if it is set.	fileFtpUser
Server directory	No	Yes	"."	Specify the directory on the FTP or SFTP server to which to transfer files. The default value is `.` (a period), which indicates the default directory after logon. If you specify a relative path, the directory is based on the default directory after FTP or SFTP logon. Ensure that the syntax of the path conforms to the file system standards in the FTP or SFTP server. The value of this property is overridden by the value in the remoteDirectory property of the FtpServer configurable service, if it is set.	fileFtpDirectory

Property	M	C	Default	Description	mqsiapplybaroverride command property
Transfer mode	No	Yes	Binary	Specify how files are transferred. If the file contents are not transformed, select Binary. If the file is transmitted as ASCII, select ASCII. The value of this property is overridden by the value in the FtpServer configurable service property transferMode, if it is set. This property is valid only when FTP is selected as the protocol for remote transfer. If you have specified SFTP as the protocol, the Transfer mode property is ignored and Binary encoding is used.	
Action if remote file exists	No	No	Replace File	Specify whether to create the file or append to an existing file. Select one of the following options: • Replace Existing File (the default value) specifies that if a file of the same name exists in the output directory, the new file replaces it. The file is replaced by using the FTP put verb. • Append to Existing File moves the output file to the transit directory and appends the file contents to the file. The file is transferred to the remote machine by using the FTP append verb and moved back to the output directory when the append is finished.	
Retain local file after transfer	No	No	Cleared	To retain a local copy of the file after the file transfer process has completed, select the Retain local file after transfer check box. If this check box is selected, the local copies are processed after the transfer is complete, as are other output files, as specified on the **Basic** tab. If the check box is cleared, successfully transferred files are not retained locally.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

"File name patterns" on page 1830
You can specify a file name pattern, using wildcard characters, to identify a file to be read by the FileInput and FTEInput nodes. You can also specify a file name pattern, using a single wildcard character, to name the file to be created by the FileOutput and FTEOutput nodes.

"How the broker processes files" on page 1814
The broker reads files with the FileInput, FTEInput, and FileRead nodes, and writes files with the FileOutput and FTEOutput nodes.

"How multiple file nodes share access to files in the same directory" on page 1818
WebSphere Message Broker controls access to files so that only one file node at a time can read or write to a file.

"Archiving" on page 1833
Files that are successfully processed by the FileInput node or FileOutput node can optionally be moved to the `mqsiarchive` subdirectory of the input or output directory.

"Using local environment variables with file nodes" on page 1820
You can use fields in the local environment to dynamically alter the behavior of the FileInput, FileOutput, FTEInput, and FTEOutput nodes. You can also find what values the output nodes used to process the file.

"Message flow aggregation" on page 2718
Aggregation is the generation and fan-out of related requests that are derived from a single input message, and the fan-in of the corresponding replies to produce a single aggregated reply message.

Related tasks:

"Writing a file" on page 1852
Use the FileOutput, CDOutput, and FTEOutput nodes to write files.

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

"Configuring aggregation flows" on page 2721
Use aggregation message flows to generate and fan-out a number of related requests, fan-in the corresponding replies, and compile those replies into a single aggregated reply message, by using the AggregateControl, AggregateRequest, and AggregateReply nodes.

"Validating messages" on page 1478
The broker provides validation based on the message model for predefined messages.

"Recognizing file records as messages to be parsed" on page 1817
Use the FileInput, FTEInput and FileRead nodes to segment your input file into messages that are to be parsed.

"Local environment overrides for the FileOutput node"
Set values in the local environment to override the location of the remote server specified on the FileOutput node.

"FileInput node" on page 4415
Use the FileInput node to process messages that are read from files.

"FtpServer configurable service properties" on page 3794
Select the properties and values that you want to change for an existing FtpServer configurable service or to create a new service.

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

"FTEOutput node" on page 4466
Use the FTEOutput node to write messages to files by using the WebSphere MQ File Transfer Edition.

Local environment overrides for the FileOutput node:

Set values in the local environment to override the location of the remote server specified on the FileOutput node.

Remote server location

You can set the location of the FTP or SFTP server for the FileOutput node to use in `LocalEnvironment.Destination.File.Remote.Server`. If this field is present in the local environment, it overrides the `Remote server and port` property on the FileOutput node. Set this local environment field to the name of a configurable service, the name of a server, or a server name and port number.

The local environment override works in the same way as the node property. If a configurable service exists with the name specified, all the properties of the configurable service are used instead of the properties on the node. If a configurable service of that name does not exist, the value is used as a server name to which the node connects. The system checks for a value with the format *serverName*:*portNumber* first, then it searches for a server name on its own. When a server name is found, no other properties are overridden. This process is repeated for every message that passes through the node.

Related concepts:

"How the broker processes files" on page 1814
The broker reads files with the FileInput, FTEInput, and FileRead nodes, and writes files with the FileOutput and FTEOutput nodes.

"Local environment tree structure" on page 1056
The local environment tree is a part of the logical message tree in which you can store information while the message flow processes the message.

Related tasks:

"Writing a file to a remote FTP or SFTP server" on page 1855
Use a FileOutput node to write a file to a directory on a remote FTP or SFTP server.

"Accessing the local environment tree" on page 2463
The local environment tree has its own correlation name, LocalEnvironment, and you must use this name in all ESQL statements that refer to or set the content of this tree.

Related reference:

"FileOutput node" on page 4430
Use the FileOutput node to write messages to files.

FileRead node

Use the FileRead node to read one record, or the entire contents of a file, from within a message flow.

This topic contains the following sections:

Purpose:

You can use the FileRead node to read one record, or the entire contents of a file, from within the middle of a message flow, see "Routing or enriching a message based on the contents of a file" on page 1837. The FileRead node is like the FileInput node which reads a file from the start of a message flow, except it is driven to read the file by an incoming message.

The FileRead node is contained in the **File** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
To enable function that becomes available in WebSphere Message Broker fix packs, use the **-f** parameter on the **mqsichangebroker** command. For more information, see "**mqsichangebroker** command" on page 3723.

By using any built-in parser, the FileRead node can parse the contents of the file and propagate the contents as a message tree. The node streams data to parsers which support this function, in an identical way to the FileInput node.

The main properties of the node specify the file and directory to read the file from. The file name is given as a pattern which can include wildcards. Both the directory and file pattern can be overridden by using fields in the local environment.

Terminals and properties:
The FileRead node input terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Finish file in	The input terminal that accepts a request to perform the finish file action, without reading any data. When a message is received by the **Finish file in** terminal, the FileRead node starts the processing that is specified by the `Action` property. When a message is received by the **Finish file in** terminal, no data is read before the action is taken.

The FileRead node output terminals are described in the following table.

Terminal	Description
Failure	The output terminal to which a message is routed if a failure is detected when the message is propagated.
Out	The output terminal to which a message is routed if it is successfully retrieved from an external resource. If no errors occur in the input node, a message received from an external resource is always sent to the **Out** terminal first.
No match	The message received on the **No match** terminal is propagated to this terminal if the file does not exist on the file system or it does exist but no record which matches the filter expression can be found. If the terminal is not connected, the message is not used.
Finish file out	A message arriving on the **Finish file in** terminal is propagated to the **Finish file out** terminal with the content unchanged, but the local environment is updated with details of the action the node has taken.

The following tables describe the node properties that you can set on a specified tab. The column headed M indicates whether the property is *mandatory* (marked in the toolkit with an asterisk if you must enter a value when no default is defined). The column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

When the contents of the file have been successfully propagated down the flow, the file is deleted from the file system. No other file node can access the file when the read node starts reading data from it. If a file does not exist which matches the

pattern, then the original message is propagated to the 'No match' terminal. If the terminal is not connected then an exception is thrown.

At the end of processing, it is possible to configure the node not to delete the file. In this mode, any other file read node can also access the file if running in the same browse only mode.

Description properties

Property	M	C	Default	Description
Node name	No	No	`FileRead`	The name of the node.
Long Description	No	No	None	Text that describes the purpose of the node in the message flow.
Short Description	No	No	None	A brief description of the node.

Basic properties

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Input directory	No	Yes	None	Absolute path of the input directory in the form used by the file system of the broker. For example, on Windows systems, the directory path starts with the drive letter prefix (such as `C:`). Alternatively, the path can be relative to the file nodes root directory (which can be overridden with the same environment variable as used for the File input and output nodes).	inputDirectory
File name or pattern	No	Yes	*	A file name, or a character sequence (pattern) that matches a file name. A pattern contains at least one of the following wildcard characters: • Asterisk (*), representing any sequence of zero or more characters • Question mark (?), representing any single character If more than one file matches the pattern, and the **`Action`** property is set to `No action - do nothing to the file`, an exception is thrown. Select the `Use environment wildcard` option if you want to use part of the file name from the input node in this field.	filenamePattern
Substitute wildcard match	No	No	False	If you select this option, the file pattern is no longer a regular expression. Instead, it must contain only one *. The * is replaced by the **$LocalEnvironment/Wildcard/WildcardMatch** field. This location is normally populated by a previous node, such as the FileInput node.	substituteWildcardMatch

Property	M	C	Default	Description	mqsiapplybaroverride command property
Action	Yes	No	No action	The action performed to the file after either the end of the file is reached, or a message is received by the **Finish file in** terminal. This action occurs in any of the following circumstances: 1. When a file is read, if `Record detection` is set to `Whole File`. 2. When the record read is the last record in the file, if `Record detection` is set to anything other than `Whole File`. 3. When a message is received by **Finish file in**. In this case no data is read before the action is performed. Valid actions are: • `No action` - do nothing to the file. • `Delete` - delete the file. • `Archive` - move the file to an archive directory. • `Archive with timestamp` - move the file to the archive directory and add a timestamp. By default if move to `Archive` is selected the file is moved to the `mqsiarchive` sub directory, but this default can be overridden by setting a local environment variable. When the local environment override for the archive file name is set and the finish file action on the node is set to `Archive with timestamp`, the file name is `timestamp_nameYouSpecified`. Where `timestamp` is the date and time the file is archived and `nameYouSpecified` is the name you give to the file. When the local environment override for the archive name is set and the finish file action on the node is set to `Delete`, the file is deleted. When the local environment override for the archive name is set and the finish file action on the node is set to `No action`, no action is applied to the file.	
Replace duplicate archives	Yes	No	False	By default, an error occurs if a file is archived and a file exists with the same name. Set this property to true to ignore the error and replace the archive file.	

Request properties

Property	M	C	Default	Description	mqsiapplybaroverride command property
Request directory property location	No	No	`$LocalEnvironment/Destination/File/Directory`	The message element location containing the name of the input directory.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Request file name property location	No	No	`$LocalEnvironment/Destination/File/Name`	The message element location containing the name of the input file pattern.	
Offset property location	No	No	`$LocalEnvironment/Destination/File/Offset`	The message element location containing the offset to start searching for records from.	
Length property location	No	No	`$LocalEnvironment/Destination/File/Length`	The message element location containing the length of the record to read if using fixed-length record detection.	

Result properties

Property	M	C	Default	Description	mqsiapplybaroverride command property
Result data location	Yes	No	`$ResultRoot`	The location in the message retrieved from the file to copy to the Output data location field in the outgoing message.	
Output data location	Yes	No	`$OutputRoot`	The location in the outgoing message where the record read from the file is to be copied to. The part of the record that is copied to the output data location is defined in the result data location. By default, the entire record is copied.	
Copy local environment	No	No	Selected	This property specifies whether the local environment is copied to the output message. • If `Copy local environment` is selected, a new copy of the local environment is created in the tree, and it is populated with the contents of the local environment from the preceding node. Therefore, if a node changes the local environment, the upstream nodes are not affected by those changes because they have their own copies. This value is the default. • If `Copy local environment` is cleared, the node does not generate its own copy of the local environment, but uses the local environment that is passed to it by the preceding node. Therefore, if a node changes the local environment, the changes are reflected by the upstream nodes.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Record selection expression	No	No	true()	The expression used to select the correct record from the file. The expression is evaluated for each record in the file until one is found that evaluates to true. That record is then propagated to the **Out** terminal. The expression can be set to any valid XPath expression that returns a Boolean value. The expression is not used when `Whole File` is selected as the `Record Detection` option. The following correlation names are in scope to use in the expression: • `InputRoot` • `InputLocalEnvironment` • `OutputRoot` • `OutputLocalEnvironment` • `ResultRoot`	

Input Message Parsing properties

Property	M	C	Default	Description	mqsiapplybaroverride command property
Message Domain	No	No		The domain that is used to parse the incoming message.	
Message Set	No	No		The name or identifier of the message set in which the incoming message is defined. If you set this property, and then update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message Set` property, or restore the reference to this message set project.	
Message Type	No	No		The name of the incoming message.	
Message Format	No	No		The name of the physical format of the incoming message.	
Message coded character set ID	No	Yes	`Broker System Default`	The ID of the coded character set used to interpret bytes of the file being read.	messageCodedCharSetIdProperty
Message encoding	No	Yes	`Broker System Determined`	The encoding scheme for numbers and large characters used to interpret bytes of the file being read. Valid values are `Broker System Determined` or a numeric encoding value. For more information about encoding, see "Data conversion" on page 1151.	messageEncodingProperty

Parser Options properties

Property	M	C	Default	Description
Parse timing	No	No	`On Demand`	This property controls when an input message is parsed. Valid values are: • `On Demand` • `Immediate` • `Complete` For a full description of this property, see "Parsing on demand" on page 4173.
Build tree using XML schema data types	No	No	Cleared	This property controls whether the syntax elements in the message tree have data types taken from the XML schema.
Use XMLNSC compact parser for XMLNS domain	No	No	Cleared	This property controls whether the XMLNSC Compact Parser is used for messages in the XMLNS Domain. If you set this property, the message data is shown under XMLNSC in nodes that are connected to the output terminal when the input MQRFH2 header or Input Message Parsing property, `Message Domain` is XMLNS.
Retain mixed content	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in an input message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in an input message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in an input message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the input message that are to be opaquely parsed by the XMLNSC parser. Opaque parsing is performed only if validation is not enabled (that is, if `Validate` is `None`); entries that are specified in `Opaque Elements` are ignored if validation is enabled.

Records and Elements properties

Property	M	C	Default	Description
Record detection	Yes	No	`Whole File`	The mechanism used to identify records in the input file. Valid options are: • `Whole File` • `Fixed Length` • `Delimited` • `Parsed Record Sequence`
Length	Yes	No	`80`	The length of each record, in bytes, when `Fixed Length` record detection is selected.

Property	M	C	Default	Description
Delimiter	Yes	No	DOS or UNIX Line End	The type of delimiter bytes that separate, or end, each record when Delimited record detection is selected. Valid options are: • DOS or UNIX Line End • Custom Delimiter You can set the delimiter only when the Record detection property is set to Delimited.
Custom delimiter	No	Yes		The delimiter bytes, expressed in hexadecimal, when Delimited record detection and Custom Delimiter are selected. This property is mandatory only if the Delimiter property is set to Custom Delimiter.
Delimiter type	Yes	No	Postfix	The position of the delimiter when Delimited record detection is selected. Valid options are: • Postfix • Infix This property is ignored unless the Delimiter property is set to Custom Delimiter.

Validation properties

For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	Yes	None	This property controls whether validation takes place. Valid values are: • None • Content and Value • Content	validateMaster
Failure action	No	No	Exception	This property controls what happens if validation fails. Valid values are: • User Trace • Local Error Log • Exception • Exception List

Filter node

Use the Filter node to route a message according to message content.

This topic contains the following sections:

Purpose:
Create a filter expression in ESQL to define the route that the message is to take. You can include elements of the input message or message properties in the filter expression, and you can use data that is held in an external database to complete the expression. The output terminal to which the message is routed depends on whether the expression evaluates to true, false, or unknown.

Connect the terminals that cover all situations that could result from the filter; if the node propagates the message to a terminal that is not connected, the message is discarded even if it is transactional.

The Filter node accepts ESQL statements in the same way as the Compute and Database nodes. The last statement that is executed must be a `RETURN <expression>` statement, whose expression evaluates to a Boolean value. This Boolean value determines the terminal to which the message is routed. In many cases, the routing algorithm is a simple comparison of message field values. The comparison is described by the expression and the RETURN statement is the only statement. If you code RETURN without an expression (`RETURN;`) or with a null expression, the node propagates the message to the Unknown terminal.

If your message flow requires more complex routing options, use the RouteToLabel and Label nodes.

The Filter node is contained in the **Routing** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following samples for examples of how to use this node:
- Airline Reservations
- Scribble
- Error Handler
- Large Messaging

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Consider a situation in which you have produced an online test with ten multiple choice questions. Each message coming in has a candidate name and address

followed by a series of answers. Each answer is checked, and if it is correct, the field SCORE is incremented by one. When all the answers have been checked, the field SCORE is tested to see if it is greater than five. If it is, the Filter node propagates the message to the flow that handles successful candidate input; otherwise, the message is filtered into the rejection process, and a rejection message is created.

Terminals and properties:
When you have put an instance of the Filter node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The Filter node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node
Failure	The output terminal to which the message is routed if a failure is detected during the computation
Unknown	The output terminal to which the message is routed if the specified filter expression evaluates to `unknown` or a null value
False	The output terminal to which the message is routed if the specified filter expression evaluates to `false`
True	The output terminal to which the message is routed if the specified filter expression evaluates to `true`

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default value is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Filter node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type	The name of the node.
Short Description	No	No		A brief description of the node
Long Description	No	No		Text that describes the purpose of the node in the message flow

The Filter node Basic properties are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Data Source	No	Yes		The ODBC data source name of the database that contains the tables to which you refer in the ESQL that is associated with this node (identified by the `Filter Expression` property). This name identifies the appropriate database on the system on which this message flow is to execute. The broker connects to this database with user ID and password information that you have specified on the **mqsicreatebroker**, **mqsichangebroker**, or **mqsisetdbparms** command. z/OS On z/OS systems, the broker uses the broker started task ID, or the user ID and password that are specified on the **mqsisetdbparms** command JCL, BIPSDBP, in the customization data set <hlq>.SBIPPROC. If the ESQL that is associated with this node includes a PASSTHRU statement or SELECT function and a database reference, you must specify a value for the `Data Source` property.	dataSource
Transaction	Yes	No	Automatic	The transaction mode for the node. The values are: • Automatic (the default). The message flow, of which the Filter node is a part, is committed if it is successful. That is, the actions that you define in the ESQL module are performed and the message continues through the message flow. If the message flow fails, it is rolled back. Therefore, if you choose Automatic, the ability to commit or roll back the action of the Filter node on the database depends on the success or failure of the entire message flow. • Commit. To commit any uncommitted actions that are performed in this message flow on the database that is connected to this node, irrespective of the success or failure of the message flow as a whole, select Commit. The changes to the database are committed even if the message flow itself fails.	

Property	M	C	Default	Description	mqsiapplybaroverride command property

Filter Expression	No	No	Filter	The name of the module within the ESQL resource (file) that contains the statements to execute against the message that is received in the node The ESQL file, which by default has the name `<message_flow_name>.esql`, contains ESQL for every node in the message flow that requires it. Each portion of code that is related to a specific node is known as a module. If you want the module name to include one or more spaces, enclose it in double quotation marks in the `Filter Expression` property.
				
				Code ESQL statements to customize the behavior of the Filter node in an ESQL file that is associated with the message flow in which you have included this instance of the Filter node.
				
				If an ESQL file does not already exist for this message flow, double-click the Filter node, or right-click the node and click **Open ESQL** to create and open a new ESQL file in the ESQL editor view.
				
				If the file exists already, click **Browse** beside the `Filter Expression` property to display the Module Selection dialog box, which lists the available Filter node modules defined in the ESQL files that can be accessed by this message flow (ESQL files can be defined in other, dependent, projects). Select the appropriate module and click **OK**; if no suitable modules are available, the list is empty.
				
				If the module that you specify does not exist, that module is created for you, and the editor displays it. If the file and the module exist already, the editor highlights the correct module.
				
				If a module skeleton is created for this node in a new or existing ESQL file, it consists of the following ESQL. The default module name is shown in this example:
				`CREATE FILTER MODULE <flow_name>_Filter`
				`  CREATE FUNCTION Main() RETURNS BOOLEAN`
				`  BEGIN`
				`  RETURN TRUE;`
				`  END;`
				`END MODULE;`
				
				If you create your own ESQL module, you must create this skeleton exactly. You can update the default name, but ensure that the name that you specify matches the name of the corresponding node property `Filter Expression`.
				
				To customize this node, add your own ESQL after the BEGIN statement, and before the RETURN statement. If the expression on the RETURN statement is not TRUE or FALSE, its value is resolved to determine the terminal to which the message is propagated. If the expression resolves to a null value, or you code	

Property	M	C	Default	Description	mqsiapplybaroverride command property
				You can use all the ESQL statements including SET, WHILE, DECLARE, and IF in this module, but (unlike the Compute node) the Filter node propagates the message that it receives at its input terminal to its output terminal unchanged. Therefore, in the Filter node, like the Database node, you have only one message to which to refer. The ESQL correlation names that you use in a Filter node are different from those used for a Compute node. For more information about correlation names refer to the related links. You cannot modify any part of any message, so the assignment statement (the SET statement, not the SET clause of the INSERT statement) can assign values only to temporary variables. The scope of actions that you can take with an assignment statement is therefore limited.	
Treat warnings as errors	Yes	No	Cleared	For database warning messages to be treated as errors, and to propagate the output message from the node to the Failure terminal, select `Treat warnings as errors`. The check box is cleared initially. When you select the check box, the node handles all positive return codes from the database as errors and generates exceptions in the same way as it does for the negative, or more serious, errors. If you do not select the check box, the node treats warnings as normal return codes and does not raise any exceptions. The most significant warning raised is `not found`, which can be handled safely as a normal return code in most circumstances.	
Throw exception on database error	Yes	No	Selected	For the broker to generate an exception when a database error is detected, select `Throw exception on database error`. The check box is selected initially. If you clear the check box, you must include ESQL to check for any database error that might be returned after each database call that you make (you can use SQLCODE and SQLSTATE to do this). If an error has occurred, you must handle the error in the message flow to ensure the integrity of the broker and the database; the error is ignored if you do not handle it through your own processing because you have chosen not to invoke the default error handling by the broker. For example, you can include the ESQL THROW statement to throw an exception in this node, or you can use the Throw node to generate your own exception at a later point.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

"RouteToLabel node" on page 4673
Use the RouteToLabel node in combination with one or more Label nodes to dynamically determine the route that a message takes through the message flow, based on its content.

"RETURN statement" on page 5155
The RETURN statement ends processing. What happens next depends on the programming context in which the RETURN statement is issued.

FlowOrder node

Use the FlowOrder node to control the order in which a message is processed by a message flow.

This topic contains the following sections:

Purpose:
The FlowOrder node propagates the input message to the first output terminal, and the sequence of nodes that is connected to this terminal processes the message. When that message processing is complete, control returns to the FlowOrder node. If the message processing completes successfully, the FlowOrder node propagates the input message to the second output terminal, and the sequence of nodes that is connected to this terminal processes the message.

The message that is propagated through the second output terminal is the input message. It is not modified in any way by the FlowOrder node. If a compute node that is connected to the first terminal modifies the InputRoot, for example by using references, these modifications are made visible in the message that is propagated to the Second terminal.

You can include this node in a message flow at any point where the order of execution of subsequent nodes is important.

If you connect multiple nodes to the first output terminal, the second output terminal, or both, the order in which the multiple connections on each terminal are processed is random and unpredictable. However, the message is propagated to all target nodes that are connected to the first output terminal, which must all complete successfully, before the message is propagated to any node that is connected to the second output terminal.

Your message flow performance can benefit from including the FlowOrder node in a situation where one sequence of processing that is required for a message is significantly shorter than another sequence of processing. If you connect the shorter sequence to the first terminal, any failure is identified quickly and prevents execution of the second longer sequence of processing.

The FlowOrder node is contained in the **Construction** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
For an example of using this node, assume that your company receives orders from customers using the Internet. When the order is received, it is processed by nodes that are connected to the first terminal of a FlowOrder node to debit the stock level in your database and raise an invoice. A check is made to see whether the customer has indicated that his details can be sent to other suppliers. If the customer has indicated that he does not want this information to be divulged, this check fails and no further processing occurs. If the customer is happy for you to share his details with other companies (that is, the test is successful), the input message is propagated to the second terminal so that the customer's details can be added to the mailing list.

Connecting the terminals:
The FlowOrder node has no configurable properties that affects its operation. You determine how it operates by connecting the first and second output terminals to subsequent nodes in your message flow.

1. Connect the First terminal to the first node in the sequence of nodes that provide the first phase of processing this message. This sequence can contain one or more nodes that perform any valid processing. The sequence of nodes can optionally conclude with an output node.
2. Connect the Second terminal to the first node in the sequence of nodes that provide the second phase of processing this message. This sequence can contain one or more nodes that perform any valid processing. The sequence of nodes can optionally conclude with an output node.

   The message that is propagated through the Second terminal is identical to that propagated through the First terminal. Any changes that you have introduced as a result of the first phase of processing are ignored by this node.

   If the first phase of processing fails, the FlowOrder node does not regain control and does not propagate the message through the Second terminal.

Terminals and properties:
When you have put an instance of the FlowOrder node into a message flow, you can configure it. For more information, see “Configuring a message flow node” on page 1503. The properties of the node are displayed in the Properties view.

The FlowOrder node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the message is routed if a failure is detected during the computation.

Terminal	Description
First	The output terminal to which the input message is routed in the first instance.
Second	The output terminal to which the input message is routed in the second instance. The message is routed to this terminal only if routing to First is successful.

The following table describes the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The FlowOrder node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	FlowOrder	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

FTEInput node

Use the FTEInput node to receive files using the WebSphere MQ File Transfer Edition.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow"
- "Terminals and properties"

Purpose:
You can use the FTEInput node to extend WebSphere Message Broker Version 7.0 support for file processing through its integration with WebSphere MQ File Transfer Edition. WebSphere MQ File Transfer Edition is a managed file transfer product that uses WebSphere MQ as the transport.

The FTEInput node is contained in the **File** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
You can use the FTEInput node in any flow that is designed to accept files from a WebSphere MQ File Transfer Edition network. Look at the following sample to see how to use this node:
- Managed File Transfer

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
The FTEInput node terminals are described in the following table.

Terminal	Description
Failure	The output terminal to which a message is routed if an error occurs before a message is propagated to the Out terminal. Messages propagated to this terminal are not validated, even if you have specified, using the `Validate` property, that validation is to take place.
Out	The output terminal to which a message is routed if it has been successfully extracted from the input file. If no errors occur within the input node, a message received from an external resource is always sent to the Out terminal first.
End of Data	The output terminal to which the End of Data message is routed after all the messages in a file have been processed. The End of Data message flow transaction is initiated only if this terminal is attached.
Catch	The output terminal to which the message is routed if an exception is thrown downstream and caught by this node. Exceptions are caught only if this terminal is attached.

The following tables describe the node properties that you can set on a specified tab. The column headed M indicates whether the property is *mandatory* (marked in

the toolkit with an asterisk if you must enter a value when no default is defined). The column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

When the FTEInput node propagates a message, it stores information about it in the LocalEnvironment.FTE and LocalEnvironment.FTE.Transfer message trees. If the input file is empty, an empty message is propagated (assuming that it is valid). If you specify a file name pattern that contains wildcard characters in the `File name filter` property, the FTEInput node copies the characters in the file name matched by wildcards, together with any intermediate characters, to the LocalEnvironment.Wildcard.WildcardMatch message tree. See "Using local environment variables with file nodes" on page 1820 for more information.

Description properties

Property	M	C	Default	Description
Node name	No	No	`FTE Input`	The name of the node.
Short Description	No	No	None	A brief description of the node.
Long Description	No	No	None	Text that describes the purpose of the node in the message flow.

Basic properties

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Directory filter	No	Yes	None	The WebSphere MQ File Transfer Edition destination directory from which input files are processed.	inputDirectory
File name filter	Yes	Yes	*	A file name or string containing optional wildcard characters (* or ?) identifying the file or files to process from the Input directory.	filenamePattern
Action on successful processing	Yes	No	`No Action`	The action the node takes on the file after successfully processing the contents. Valid options are: • `No Action` • `Delete` • `Add Time Stamp`	

Input Message Parsing properties

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Message Domain	No	No	None	The domain that is used to parse the incoming message.	
Message Set	No	No	None	The name or identifier of the message set in which the incoming message is defined. If you set this property, and then update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message Set` property, or restore the reference to this message set project.	
Message Type	No	No	None	The name of the incoming message.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Message Format	No	No	None	The name of the physical format of the incoming message.	
Message coded character set ID	Yes	Yes	`Broker System Default`	The ID of the coded character set used to interpret bytes of the file being read.	messageCodedCharSetIdProperty
Message encoding	Yes	Yes	`Broker System Determined`	The encoding scheme for numbers used to interpret bytes of the file being read. Valid values are `Broker System Determined` or a numeric encoding value. For more information about encoding, see "Data conversion" on page 1151.	messageEncodingProperty

Parser Options properties

Property	M	C	Default	Description
Parse timing	No	No	`On Demand`	Specifies when an input message is parsed. Valid values are: • `On Demand` • `Immediate` • `Complete` For a full description of this property, see "Parsing on demand" on page 4173.
Build tree using XML schema data types	No	No	Cleared	Specifies whether the syntax elements in the message tree have data types taken from the XML schema.
Use XMLNSC compact parser for XMLNS domain	No	No	Cleared	Specifies whether the XMLNSC Compact Parser is used for messages in the XMLNS Domain. If you set this property, the message data appears under XMLNSC in nodes that are connected to the output terminal when either of the following items is XMLNS: • The input MQRFH2 header. • The Input Message Parsing property, Message Domain.
Retain mixed content	No	No	Cleared	Specifies whether the XMLNSC parser creates elements in the message tree for mixed text in an input message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	No	No	Cleared	Specifies whether the XMLNSC parser creates elements in the message tree for comments in an input message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	Specifies whether the XMLNSC parser creates elements in the message tree for processing instructions in an input message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.
Opaque elements	No	No	Blank	Specifies a list of elements in the input message that are to be opaquely parsed by the XMLNSC parser. Opaque parsing is performed only if validation is not enabled (that is, if `Validate` is `None`); entries that are specified in `Opaque Elements` are ignored if validation is enabled.

Retry properties

Property	M	C	Default	Description	mqsiapplybaroverride command property
Retry mechanism	Yes	No	Failure	How the node handles a flow failure. Valid options are: • Failure • Short retry • Short and long retry	
Retry threshold	Yes	Yes	0	The number of times to try the flow transaction again when the Retry mechanism property value is Short retry.	retryThreshold
Short retry interval (seconds)	No	Yes	0	The interval, in seconds, between each retry if the Retry threshold property is not zero.	shortRetryInterval
Long retry interval (seconds)	No	Yes	300	The interval between retries, if the Retry mechanism property is Short and long retry and the retry threshold has been exhausted.	longRetryInterval
Action on failing file	Yes	Yes	No Action	The action that the node takes with the input file if all attempts to process the contents of the input file fail. Valid options are: • No Action • Delete • Add Time Stamp	

Records and Elements properties

Property	M	C	Default	Description
Record detection	Yes	No	Whole File	The mechanism used to identify records in the input file. Valid options are: • Whole File • Fixed Length • Delimited • Parsed Record Sequence
Length	Yes	No	80	The length of each record, in bytes, when Fixed Length record detection is selected.
Delimiter	Yes	No	DOS or UNIX Line End	The type of delimiter bytes that separate, or end, each record when Delimited record detection is selected. Valid options are: • DOS or UNIX Line End • Custom Delimiter
Custom delimiter	No	No	None	The delimiter bytes, expressed in hexadecimal, when Delimited record detection and Custom Delimiter are selected. This property is mandatory only if the Delimiter property is set to Custom Delimiter.
Delimiter type	Yes	No	Postfix	The position of the delimiter when Delimited record detection is selected. Valid options are: • Postfix • Infix This property is ignored unless the Delimiter property is set to Custom Delimiter.

Validation properties

For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	Yes	None	This property controls whether validation takes place. Valid values are: • None • Content and Value • Content	validateMaster
Failure action	No	No	Exception	This property controls what happens if validation fails. Valid values are: • User Trace • Local Error Log • Exception • Exception List	

Transactions properties

Property	M	C	Default	Description
Transaction mode	No	No	No	The transaction mode on this input node determines whether the rest of the nodes in the flow are executed under sync point. Valid options are: • Yes • No

Instances properties.

For a full description of these properties, see "Configurable message flow properties" on page 4020.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Additional instances pool	No	Yes	Use Pool Associated with Message Flow	The pool from which additional instances are obtained. • If you select Use Pool Associated with Message Flow, additional instances are obtained from the message flow pool. • If you select Use Pool Associated with Node, additional instances are allocated from the additional instances of the node based on the number specified in the Additional instances property.	componentLevel
Additional instances	No	Yes	0	The number of additional instances that the node can start if the Additional instances pool property is set to Use Pool Associated with Node.	additionalInstances

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

FTEOutput node

Use the FTEOutput node to write messages to files by using the WebSphere MQ File Transfer Edition.

This topic contains the following sections:

Purpose:

You can use the FTEOutput node to extend WebSphere Message Broker Version 7.0 support for file processing through its integration with WebSphere MQ File Transfer Edition. WebSphere MQ File Transfer Edition is a managed file transfer product that uses WebSphere MQ as the transport.

The FTEOutput node is contained in the **File** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
You can use the FTEOutput node in any flow that is designed to send a file across a WebSphere MQ File Transfer Edition network. Look at the following sample to see how to use this node:
- Managed File Transfer

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
The FTEOutput node terminals are described in the following table:

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Finish File	The input terminal that accepts a message that triggers the final processing of a file.
Out	The message received on the In terminal is propagated to this terminal if the record is written successfully. The message is unchanged except for status information in the Local Environment.
End of Data	The message received on the Finish File terminal is propagated to this terminal if the file is processed successfully.
Failure	The output terminal to which the message is routed if a failure is detected when a message is propagated.

The following tables describe the node properties that you can set on a specified tab. The column headed M indicates whether the property is *mandatory* (marked in the toolkit with an asterisk if you must enter a value when no default is defined). The column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

When the FTEOutput node propagates a message, either to the Out terminal or to the End of Data terminal, it stores information about it in the LocalEnvironment.WrittenDestination.FTE message tree. You can override the Destination agent, Destination queue manager, Job name, Destination file directory, Destination file name, and Overwrite files on destination system properties using additions to the LocalEnvironment.Destination.FTE message tree. See "Using local environment variables with file nodes" on page 1820 for more information.

Description properties

Property	M	C	Default	Description
Node name	No	No	`FTE Output`	The name of the node.
Short Description	No	No	None	A brief description of the node.
Long Description	No	No	None	Text that describes the purpose of the node in the message flow.

Basic properties

Property	M	C	Default	Description	mqsiapplybaroverride command property
Job name	No	Yes	None	The name for the transfer that appears in the transfer logs and the metadata.	jobName
Destination agent	No	Yes	None	The name of the destination agent to send the file to. If Destination agent is not specified, and not overridden using the LocalEnvironment tree, it will default to the agent embedded in the Execution Group.	destinationAgent
Destination queue manager	No	Yes	None	The name of the destination queue manager to send the file to.	destinationQMgr
Destination file directory	No	Yes	None	The remote directory that the destination agent writes the file to.	destinationDirectory
Destination file name	Yes	Yes	None	The specific file name or a pattern containing a single wildcard that defines the name of the file to be created by the destination agent.	destinationFileName
Mode	No	Yes	`Binary transfer (no conversion)`	The mode to transfer the file in. Valid values are: • `Binary transfer (no conversion)` • `Text transfer (ASCII/EBCDIC and CR/LF automated)`	transferMode
Disable computation of MD5 check sum	Yes	Yes	`FALSE`	Specifies whether the computation of the MD5 check sum on the transferred file is disabled.	checkSumDisabled
Overwrite files on destination system	Yes	Yes	`FALSE`	Specifies whether files on the destination system can be overwritten when the destination agent moves files of the same name there. If the destination agent fails to overwrite the file, the transfer fails and the transfer logs report the failure. The FTEOutput node does not throw or log any errors.	overwriteDestination

Request properties

Property	M	C	Default	Description
Data location	No	No	`$Body`	The location in the input message tree that contains the record to be written to the output file. The default value, `$Body`, means the entire message.

Records and Elements properties

Property	M	C	Default	Description
Record definition	Yes	No	`Record is Whole File`	Specifies how records are placed in the output file. Valid options are: • `Record is Whole File` • `Record is Unmodified Data` • `Record is Fixed Length Data` • `Record is Delimited Data`
Length (bytes)	Yes	No	`80`	The required length of the output record. The property is available only when `Record is Fixed Length Data` is specified in `Record definition`.
Padding byte (hexadecimal)	Yes	No	`20`	The 2-digit hexadecimal byte to be used to pad short messages. The property is available only when `Record is Fixed Length Data` is specified in `Record definition`.

Property	M	C	Default	Description
Delimiter	Yes	No	`Broker System Line End`	The delimiter to be used. The property is available only when `Record is Delimited Data` is specified in `Record definition`. Valid options are: • `Broker System Line End` • `Custom Delimiter (hexadecimal)`
Custom delimiter (hexadecimal)	Yes	No	None	The delimiter byte sequence to be used. The property is available only when `Record is Delimited Data` is specified in the `Record definition` property, and `Custom Delimiter (hexadecimal)` is specified in the `Delimiter` property.
Delimiter type	Yes	No	`Postfix`	This property specifies how delimiters are to be inserted between records. The property is available only when `Record is Delimited Data` is specified in `Record definition`. Valid options are: • `Postfix` • `Infix`

Validation properties

For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Validate	Yes	Yes	`Inherit`	This property controls whether validation takes place. Valid values are: • `None` • `Content and Value` • `Content` • `Inherit`	validateMaster
Failure action	Yes	No	`Exception`	This property controls what happens if validation fails. The property is available only if you set `Validate` to `Content` or `Content and Value`. Valid values are: • `User Trace` • `Local Error Log` • `Exception` • `Exception List`	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

HTTPHeader node

Use the HTTPHeader node to add, modify, or delete HTTP headers such as HTTPInput, HTTPResponse, HTTPRequest and HTTPReply.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow"
- "Terminals and properties"

Purpose:
The HTTPHeader node provides a toolkit interface to manipulate HTTP headers without any need for coding; it does not modify the message body. You can add or remove a whole header, or selected header properties. You can set the properties to a fixed value, or to a value specified by an XPath expression that accesses a value in one of the message trees. XPath is used to provide a valid location from which a value for a property can be copied. For example, the location can be the body of the message, the local environment tree or exception list.

HTTPInput and HTTPResponse headers can only be deleted or carried forward from the incoming message; their header properties cannot be modified or added to.

The HTTPHeader node is contained in the **HTTP** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following sample for more details about how to use the node:
- HTTPHeader node

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:

When you have put an instance of the node into a message flow, you can configure it; see . This node has no mandatory properties.

HTTPHeader node terminals are described in the following table:

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the input message is routed if a failure is detected during extraction.
Out	The output terminal to which the transformed message is routed if the input message is processed successfully.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The HTTPHeader node Description properties are described in the following table:

Property	M	C	Default	Description
Node name	No	No	HTTPHeader	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

HTTPInput Header properties are described in the following table:

Property	M	C	Default	Description
HTTPInput Header Options	No	Yes	Carry forward header	Options to control the HTTPInputHeader as a whole. Select **Carry forward the header** to carry forward values from incoming message if present. Select **Delete header** to delete the header if present.

HTTPResponse Header properties are described in the following table:

Property	M	C	Default	Description
HTTPResponse Header Options	No	Yes	Carry forward header	Options to control the HTTPResponseHeader as a whole. Select **Carry forward the header** to carry forward values from incoming message if present. Select **Delete header** to delete the header if present.

HTTPRequest Header properties are described in the following table:

Property	M	C	Default	Description
HTTPRequest Header Options	No	Yes	Carry forward header	Configure the HTTPRequest header. These options are available. **Carry forward header** Select this option to carry forward values from an incoming message. **Add header** Select this option to add new properties to the header, or to modify or delete existing properties. **Modify header** Select this option to add properties, or modify and delete existing properties. **Delete header** Select this option to remove the HTTPRequest header and all associated properties from the incoming message.
Clear incoming values	No	Yes	Cleared	This option, which is enabled only if you choose **Modify header**, removes all property names and associated values from the incoming message if present.
HTTPRequest Header	No	Yes	No default value	This field is enabled only if you chose **Add header** or **Modify header** for the **HTTPRequest Header Options**. The screen has no predefined properties; you use it to create custom properties and values. Use the property table to add new properties, or modify or delete existing properties, for the header. There is no limit to the number of properties. Each property must have a name and a type qualifier. The type qualifier can be `Value`, `XPath`, or `Delete`. **Value** Enter a new valid value for the selected property. A null value or empty string is also considered as a valid value. **XPath** Specify a valid XPath expression. WebSphere Message Broker supports XPath definitions that start with an XPath variable such as `$Root` or `$LocalEnvironment`. Only the first occurrence is returned if there are multiple values for the XPath expression. (Examples of valid XPath expressions are: $LocalEnvironment/Host, and $Root/HTTPRequest/Content-Type). **Delete** Specify the property to be deleted from the incoming message. The value associated with the selected property is also deleted.

HTTPReply Header properties are described in the following table:

Property	M	C	Default	Description
HTTPReply Header Options	No	Yes	Carry forward header	Configure the HTTPReply header. These options are available. **Carry forward header** Select this option to carry forward values from an incoming message. **Add header** Select this option to add new properties to the header, or to modify or delete existing properties. **Modify header** Select this option to add properties, or modify and delete existing properties. **Delete header** Select this option to remove the HTTPReply header and all associated properties from the incoming message.
Clear incoming values	No	Yes	Cleared	This option, which is is enabled only if you choose **Modify header**, removes all property names and associated values from the incoming message if present.
HTTPReply Header	No	Yes	No default value	This field is enabled only if you chose **Add header** or **Modify header** for **HTTPRequest Header Options**. The screen has no predefined properties; you use it to create custom properties and values. Use the property table to add new properties, or modify or delete existing properties, for the header. There is no limit to the number of properties. Each property must have a name and a type qualifier. The type qualifier can be `Value`, `XPath`, or `Delete`. **Value** Enter a new valid value for the selected property. A null value or empty string is also considered as a valid value. **XPath** Specify a valid XPath expression. WebSphere Message Broker supports XPath definitions that start with an XPath variable such as `$Root` or `$LocalEnvironment`. Only the first occurrence is returned if there are multiple values for the XPath expression. (Examples of valid XPath expressions are: $LocalEnvironment/Host, and $Root/HTTPRequest/Content-Type). **Delete** Specify the property to be deleted from the incoming message. The value associated with the selected property is also deleted.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

HTTPInput node

Use the HTTPInput node to receive an HTTP message from an HTTP client for processing by a message flow.

This topic contains the following sections:

Purpose:
If you use the HTTPInput node with the HTTPReply and HTTPRequest nodes, the broker can act as an intermediary for web services, and web service requests can be transformed and routed in the same way as other message formats that are supported by WebSphere Message Broker.

Web service requests can be received either in standard HTTP (1.0 or 1.1) format or in HTTP over SSL (HTTPS) format. For more information about web services, see "Processing Web service messages" on page 1601.

The HTTPInput node supports HTTP POST and HTTP GET. For more information about enabling HTTP GET, see "HTTPRequest node" on page 4488.

If your message flows are processing SOAP messages, use the SOAP nodes in preference to the HTTPInput node to take advantage of enhanced features, including WS-Addressing and WS-Security.

The HTTPInput node handles messages in the following message domains:
- MRM
- XMLNSC
- XMLNS
- MIME
- BLOB
- XML (this domain is deprecated; use XMLNSC)
- JSON

HTTP messages are always non-persistent, and have no associated order.

HTTP messages are non-transactional. However, if the message flow interacts with a database or another external resource, such as a WebSphere MQ queue, these interactions are performed in a transaction. The HTTPInput node provides commit or rollback, depending on how the message flow has ended, and how it is configured for error handling (how failure terminals are connected, for example). If

the message flow is rolled back by this node, a fault message is generated and returned to the client. The format of the fault is defined by the `Fault format` property.

If an exception occurs downstream in this message flow, and it is not caught but is returned to this node, the node constructs an error reply to the client. This error is derived from the exception, and the format of the error is defined by the `Fault format` property.

If you include an output node in a message flow that starts with an HTTPInput node, the output node can be any of the supported output nodes (including user-defined output nodes). You can create a message flow that receives messages from web service clients, and generates messages for clients that use all the supported transports to connect to the broker. You can configure the message flow to request the broker to provide any conversion that is necessary.

If you create a message flow to use as a subflow, you cannot use a standard input node; you must use an Input node as the first node to create an In terminal for the subflow.

The HTTPInput node is contained in the **HTTP** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
If you include an HTTPInput node in a message flow, you must either include an HTTPReply node in the same flow, or pass the message to another flow that includes an HTTPReply node (for example, through an MQOutput node to a second flow that starts with an MQInput node). In the latter case, the request from, and reply to, the client are coordinated by the request identifier stored in the local environment by the HTTPInput node.

You cannot use a SOAPReply node to respond to a web service request that is received by an HTTPInput node; the broker generates an exception when the reply is attempted.

When the HTTPInput node receives a message from a web service client, the node starts the appropriate parsers to interpret the headers and the body of the message, and to create the message tree that is used internally by the message flow. The node creates a unique identifier for the input message and stores it as a binary array of 24 bytes in the local environment tree at LocalEnvironment.Destination.HTTP.RequestIdentifier. This value is used by the HTTPReply node, therefore you must not modify it.

By default, HTTP and HTTPS messages are handled by the broker-wide listener, which is started when a message flow that includes an HTTP node is started. All inbound and outbound HTTP messages are routed through this listener, for all HTTP nodes deployed to all message flows in all execution groups on the broker.

You can configure an execution group to use its embedded listener to service the HTTP nodes in all message flows that are deployed to that execution group. The embedded listener, which is always used for the SOAP nodes, communicates directly with the client and the nodes.

If you configure the execution group to use its embedded listener for HTTP nodes, you must deploy the flow that includes the HTTPReply node to the same execution group. If your broker is configured to start the broker-wide listener to support HTTP nodes, you must deploy the reply flow to the same broker, but the execution group is not significant.

For further information about using the embedded listener, see "HTTP listeners" on page 1589.

If a client sends a `gzip` or `deflate` compressed request to the HTTPInput node, it can be extracted using the `Decompress input message` option. This decompression occurs only if the execution group has been configured so that HTTP nodes use the embedded execution group HTTP listener, and not the broker-wide HTTP listener.

Using the HTTPInput and HTTPReply nodes to act as a web server:
A broker can support multiple HTTPInput nodes. When you configure the HTTPInput node, specify the requests to which the node listens in the form of a URL path, excluding the host and port details.

For example, if the broker is listening on address `http://localhost:7080`, and receives the request `http://localhost:7080/Joe/Mary`, the listener removes the HTTP address, leaving the request `Joe/Mary`. The listener then matches this request with the information that is specified in the URL property of the HTTPInput node or nodes.

The match is done from the most specific to the most generic data; you can use a wildcard (an asterisk) to satisfy less specific matches. For example, if you have configured an HTTPInput node to accept requests that match `/Joe/Mary`, that node receives the message. However if the request is `http://localhost:7080/Joe/Sally`, the match is not made with this node. It can match with a node that has a more generic URL, such as one of the following values:

```
/Joe/*
/*
```

If the request does not match any URL property, and you do not have an input node with /* specified, the HTTPInput node returns a response to the originator.

You can use a URL of /* to catch all requests that failed to match the URLs in the HTTPInput nodes, so that you can send a reply message and take other actions as appropriate.

This example uses port `7080`, which is the default HTTP port for the broker-wide listener. The default port numbers for the embedded execution group listener are `7800` for HTTP and `7843` for HTTPS. You can change these port numbers, and port ranges used by the execution group listeners, by using the **mqsichangeproperties** command.

If you choose to handle HTTP messages by using the execution group listener, you must carefully check the URL specifications in your HTTPInput and SOAPInput nodes. If both URL specifications match an incoming message, the wrong type of node might get the message, and processing might fail or produce unexpected results. This situation occurs if you specify identical values for the Path suffix for URL properties of the HTTPInput node and the SOAPInput node. It can also occur if you use wildcards in either or both specifications, and an incoming message matches both properties.

If you want to use the broker listener for HTTP and HTTPS traffic, check that the broker properties for the listener ports for HTTP and HTTPS are suitable. The default port for HTTP is `7080`; the default port for HTTPS is `7083`.

If you want to use the execution group listener, you must configure the execution group by using the **mqsichangeproperties** command to activate the listener for HTTP and HTTPS messages. The default port for HTTP is `7800`; the default port for HTTPS is `7843`. You can change these port numbers, and the ranges from which the ports are allocated, by using the **mqsichangeproperties** command.

If you want to collect trace information about HTTP message processing, see "Resolving problems when you use HTTP and SOAP nodes" on page 3407.

Connecting the terminals:
The HTTPInput node routes each message that it retrieves successfully to the Out terminal. If message validation fails, the message is routed to the Failure terminal; you can connect nodes to this terminal to handle this condition. If you have not connected the Failure terminal, the message is discarded, the `Maximum client wait time` expires, and an error is returned to the client. No other situations exist in which the message is routed to the Failure terminal.

If the message is caught by this node after an exception has been thrown further on in the message flow, the message is routed to the Catch terminal. If you have not connected the Catch terminal, the message is discarded, the `Maximum client wait time` expires, and an error is returned to the client.

If the `Maximum client wait time` expires, by default, the listener returns a fault message to the client to indicate that the timeout has expired. If the HTTP Timeout terminal is connected and the execution group is configured such that the HTTP nodes use the embedded listener, this timeout fault message is propagated to the timeout terminal. In this scenario the listener waits again for the interval defined by the `Maximum client wait time` (sec) property, or for 10 seconds, whichever is the shorter interval:

- If a response is received before this second interval expires, the listener propagates the response to the client.
- If a response is not received before this second interval expires, the listener sends a fault message to the client, indicating that its timeout has expired.

Because the listener waits for only a brief interval after the message has been propagated through the HTTP Timeout terminal, you must ensure that the sequence of nodes that you connect to the HTTP Timeout terminal includes an HTTPReply node, which sends a response before this interval expires.

Terminals and properties:
When you have put an instance of the HTTPInput node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

The terminals of the HTTPInput node are described in the following table.

Terminal	Description
Failure	The output terminal to which the message is routed if an error occurs.
Out	The output terminal to which the message is routed if it is successfully retrieved.

Terminal	Description
HTTPTimeout	The output terminal to which a timeout fault message is routed if the HTTPReply node that is connected to the Out terminal does not respond within the time interval specified by the Maximum client wait time property. This terminal is used only if the execution group has been configured so that HTTP nodes use the embedded execution group listener.
Catch	The output terminal to which the message is routed if an exception is thrown downstream and caught by this node.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The HTTPInput node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, HTTPInput	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The HTTPInput node Basic properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Path suffix for URL	Yes	Yes		This property identifies the location from where web service requests are retrieved. Do not use the full URL. If the URL that you want is `http://`*`hostname`*`[:`*`port`*`]/[`*`path`*`]`, specify either */path* or */path fragment*`/*` where * is a wildcard that you can use to mean match any.	URLSpecifier
Use HTTPS	No	Yes	Cleared	This property identifies whether the node is to accept secure HTTP. If the node is to accept secure HTTP, select the check box.	useHTTPS

The HTTPInput node Advanced properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Set destination list	No	No	Selected	This property specifies whether to add the method binding name to the route to label destination list. If you select this check box, the method binding name is added so that you can use a RouteToLabel node in the message flow after the HTTPInput node.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Label prefix	No	No	None	The prefix to add to the method name when routing to label. Add a label prefix to avoid a clash of corresponding label nodes when you include multiple WebSphere Message Broker input nodes in the same message flow. By default, there is no label prefix, therefore the method name and label name are identical.	

Parse Query String	No	No	False	This property causes any query string that is present with an incoming message to be parsed and decoded (according to `http://tools.ietf.org/html/rfc3986`) into the following location in the local environment as a series of name-value elements that match the names and values present in the query string:
				
				`LocalEnvironment.HTTP.Input.QueryString`
				
				For example, for this query string:
				
				`?myParam1=my%22Value%221&myParam2=my%22Value%222`
				the following elements are placed into the local environment under the QueryString folder:
				
				`myParam1` with a value of `my"Value"1`
				`myParam2` with a value of `my"Value"2`
				
				If the `QueryString` uses a character set that is not UTF-8, you can use the *MQSI_HTTP_QUERY_STRING_CCSID* environment variable to specify the CCSID of the `QueryString`. For example, if your HTTPRequest node has a `QueryStringCCSID` of 943, you can set *MQSI_HTTP_QUERY_STRING_CCSID* to 943 to convert the query string parameters to the 943 code page.	

Decompress input message	No	Yes	Cleared	This property indicates whether an inbound HTTP request is decompressed or not. This property is used only if the execution group has been configured so that HTTP nodes use the embedded execution group HTTP listener. If this option is selected, and the HTTP header Content-Encoding field is "`gzip`" or "`deflate`", the input message is decompressed and propagated to the Out terminal, and the Content-Encoding field is removed.	decompressInputMessage

The HTTPInput node Input Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	BLOB	The domain that is used to parse the incoming message. If you leave this field blank, the default value is BLOB. Select the name of the parser that you are using from the list: • MRM • XMLNSC • XMLNS • MIME • BLOB • XML (this domain is deprecated; use XMLNSC) • JSON You can also specify a user-defined parser, if appropriate.
Message set	No	No		The name or identifier of the message set in which the incoming message is defined. All available message sets are in the list. If you are using the MRM parser or the XMLNSC parser in validating mode, select the Message set that you want to use. This list is populated with available message sets when you select MRM or XMLNSC as the domain. If you set this property, then later update the project dependencies to remove this message set reference, a warning is issued. Either update the Message set property, or restore the reference to this message set project.
Message type	No	No		The name of the incoming message. If you are using the MRM parser, select the type of message from the list in Message type. This list is populated with messages that are defined in the Message set that you have selected.
Message format	No	No		The name of the physical format of the incoming message. If you are using the MRM parser, select the format of the message from the list in Message format. This list includes all the physical formats that you have defined for this Message set.

The properties of the Parser Options for the HTTPInput node are described in the following table.

Property	M	C	Default	Description
Parse timing	No	No	On Demand	This property controls when an input message is parsed. Valid values are On Demand, Immediate, and Complete. By default, this property is set to On Demand, which causes parsing of the message to be delayed. To cause the message to be parsed immediately, see “Parsing on demand” on page 4173.
Build tree using XML schema data types	No	No	Cleared	This property controls whether the XMLNSC parser creates syntax elements in the message tree with data types taken from the XML schema. You can select this property only if you set the Validate property on the **Validation** tab to Content or Content and Value.
Use XMLNSC compact parser for XMLNS domain	No	No	Cleared	This property controls whether the XMLNSC Compact Parser is used for messages in the XMLNS Domain. If you set this property, the message data is displayed under XMLNSC in nodes that are connected to the output terminal when the input MQRFH2 header or the input message Parsing property Message domain is XMLNS.

Property	M	C	Default	Description
Retain mixed content	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in an input message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in an input message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in an input message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the input message that are to be opaquely parsed by the XMLNSC parser. Opaque parsing is performed only if validation is not enabled (that is, if `Validate` is `None`); entries that are specified in `Opaque Elements` are ignored if validation is enabled.

The HTTPInput node Error handling properties are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Maximum client wait time (sec)	Yes	Yes	`180`	The length of time, in seconds, for which the TCP/IP listener that received the input message from the web service client waits for a response from the HTTPReply node in the message flow. The valid range is zero (which means a short wait) through (2^{31})-1. If a response is received within this time, the listener propagates the response to the client. If a response is not received in this time, a fault message is generated indicating that the timeout has expired. This fault message is either sent by the listener or timeout terminal processing. For more details about the HTTP Timeout terminal, see "Connecting the terminals" on page 4477 and "Terminals and properties" on page 4477.	
Fault format	No	Yes	`SOAP 1.1`	The format of any HTTP errors that are returned to the client. Valid values are `SOAP 1.1`, `SOAP 1.2`, and `HTML`.	faultFormat

The Validation properties of the HTTPInput node are described in the following table. If a message is propagated to the Failure terminal of the node, it is not validated. For more details, see "Validating messages" on page 1478 and "Validation properties" on page 4169.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Validate	No	Yes	`None`	This property controls whether validation takes place. Valid values are `None`, `Content and Value`, and `Content`.	validatemaster

Property	M	C	Default	Description	mqsiapplybaroverride command property
Failure action	No	No	Exception	This property controls what happens if validation fails. You can set this property only if you set Validate to Content or Content and Value. Valid values are User Trace, Local Error Log, Exception, and Exception List.	

The Security properties of the HTTPInput node are described in the following table. Set values for the properties that control the extraction of an identity from a message when a security profile is associated with the node. For more information about these properties, see "Identity" on page 390, "Configuring the extraction of an identity or security token" on page 447, "Message flow security overview" on page 383, and "Setting up message flow security" on page 431

Property	M	C	Default	Description
Identity token type	No	No	None	This property specifies the type of identity token that is present in the incoming message. Valid values are: • Transport Default • Username • Username + Password • SAML Assertion • X.509 Certificate If this property is not specified, the identity is retrieved from the Basic-Auth transport header and the type is set to Username + Password.
Identity token location	No	No	None	This property specifies where, in the message, the identity can be found. The location is specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotation marks and must not contain a period (.), If this property is not specified, the identity is retrieved from the Authorization Transport headers.
Identity password location	No	No	None	This property specifies where, in the message, the password can be found. The location is specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotation marks and must not contain a period (.), If you do not specify a value for this property, the password is retrieved from the Authorization Transport headers. You can set this property only if the Identity type is set to Username + Password.
Identity IssuedBy location	No	No	None	This property specifies a string or path expression that describes the issuer of the identity. The location is specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotation marks and must not contain a period (.), The value specifies the Issuer that is passed to a WS-Trust v1.3 STS provider. If you do not specify a value for this property, the default value is the name of the User Agent, or, if this name is not set, the string HTTP.
Treat security exceptions as normal exceptions	No	No	False	This property specifies whether to treat security exceptions (such as Access Denied) as normal exceptions, and propagate them to the Failure terminal (if wired). This option is turned off by default, which ensures that security exceptions cause the message to be backed out even if the Failure terminal is wired.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

"HTTPReply node"
Use the HTTPReply node to return a response from the message flow to an HTTP client. This node generates the response to an HTTP client from which the input message was received by the HTTPInput node, and waits for confirmation that it has been sent.

"HTTPRequest node" on page 4488
Use the HTTPRequest node to interact with a web service.

"Input node" on page 4511
Use the Input node as an In terminal for an embedded message flow (a subflow).

"SecurityPEP node" on page 4729
Use the SecurityPEP node in a message flow to invoke the message flow security manager at any point in the message flow.

HTTPReply node

Use the HTTPReply node to return a response from the message flow to an HTTP client. This node generates the response to an HTTP client from which the input message was received by the HTTPInput node, and waits for confirmation that it has been sent.

This topic contains the following sections:
- "Purpose"
- "Connecting the output terminals to another node" on page 4485
- "Terminals and properties" on page 4485

Purpose:
The HTTPReply node can be used in a message flow that sends a response to an inbound HTTP or HTTPS messages. The most common example of this scenario is a message flow that implements a Web service.

For more information about Web services, see "Processing Web service messages" on page 1601.

By default, HTTP messages are handled by the broker-wide listener, which is started when a message flow that includes HTTP nodes is started. All inbound and outbound HTTP messages are routed through this listener, for all HTTP nodes deployed to all message flows in all execution groups on the broker.

You can configure the execution group to use its embedded listener to service the HTTP nodes in all message flows that are deployed to that execution group. The embedded listener, which is always used for the SOAP nodes, communicates directly with the client and the nodes.

For further information about using the embedded listener, see "HTTP listeners" on page 1589.

You cannot use an HTTPReply node to respond to a Web service request that is received by a SOAPInput node; the broker generates an exception when the reply is attempted.

If you have configured the execution group to use its embedded listener for HTTP nodes, you must deploy the flow that includes the HTTPReply node to the same execution group as the message flow that includes the HTTPInput node. If your broker is configured to start the broker-wide listener to support HTTP nodes, you must deploy the reply flow to the same broker, but the execution group is not significant, because the listener is shared.

The HTTPReply node constructs a reply message for the Web service client from the entire input message tree, and returns it to the requester. If the message was initially received by an HTTPInput node in another message flow, the response is associated with the reply by a request identifier that is stored in the local environment of the message by the HTTPInput node.

The HTTPReply node is contained in the **HTTP** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Connecting the output terminals to another node:
Connect the Out or Failure terminal of this node to another node in this message flow if you want to process the message further, process errors, or send the message to an additional destination.

Terminals and properties:
When you have put an instance of the HTTPReply node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The HTTPReply node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the message is routed if a failure is detected when the message is propagated.

Terminal	Description
Out	The output terminal to which the message is routed if it has been propagated successfully, and if further processing is required in this message flow.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file for deployment).

The HTTPReply node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	HTTPReply	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The HTTPReply node Basic properties are described in the following table.

Property	M	C	Default	Description
Ignore transport failures	Yes	No	Selected	Select `Ignore transport failures` if you want transport-related failures to be ignored (for example, if the client is disconnected). If you clear the check box, and a transport-related error occurs, the input message is propagated to the Failure terminal. If you clear the check box, you must supply a value for `Reply send timeout (sec)`.
Reply send timeout (sec)	Yes	No	`120`	Set the `Reply send timeout (sec)` value if you are not ignoring transport failures. This property specifies the length of time, in seconds, that the node waits for an acknowledgment that the client has received the reply. If the acknowledgment is received within this time, the input message is propagated through the Out terminal to the rest of the message flow, if it is connected. If an acknowledgment is not received within this time, the input message is propagated through the Failure terminal, if it is connected. If the Failure terminal is not connected, and an acknowledgment is not received in time, an exception is generated. The valid range is zero (which means an indefinite wait) to (2^{31})-1. This property is valid only if `Ignore transport failures` is cleared.
Generate default HTTP headers from reply or response	Yes	No	Selected	Select `Generate default HTTP headers from reply or response` if you want the default Web service headers to be created using values from the HTTPReplyHeader or the HTTPResponseHeader. If the appropriate header is not present in the input message, default values are used. The node always includes, in the HTTPReplyHeader, a Content-Length header, which is set to the correct calculated value, even if this header was not included in the original request.

The Validation properties of the HTTPReply node are described in the following table.

If a message is propagated to the Failure terminal of the node, it is not validated. For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	Yes	Inherit	This property controls whether validation takes place. Valid values are None, Content and Value, Content, and Inherit.	validateMaster
Failure action	No	No	Exception	This property controls what happens if validation fails. You can set this property only if you set Validate to Content or Content and Value. Valid values are User Trace, Local Error Log, Exception, and Exception List.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Use the HTTPInput node to receive an HTTP message from an HTTP client for processing by a message flow.

"HTTPRequest node"
Use the HTTPRequest node to interact with a web service.

HTTPRequest node

Use the HTTPRequest node to interact with a web service.

This topic contains the following sections:

Purpose:
The HTTPRequest node interacts with a web service, using all or part of the input message as the request that is sent to that service. You can also configure the node to create an output message from the contents of the input message, augmented by the contents of the web service response, before you propagate the message to subsequent nodes in the message flow.

Depending on the configuration, this node constructs an HTTP or an HTTP over SSL (HTTPS) request from the specified contents of the input message, and sends this request to the web service. The node receives the response from the web service, and parses the response for inclusion in the output tree. The node generates HTTP headers if they are required by your configuration.

You can use this node in a message flow that does or does not contain an HTTPInput or HTTPReply node.

The HTTPRequest node handles messages in the following message domains:
- XMLNSC
- JSON
- BLOB
- MIME
- MRM
- XMLNS

The HTTPRequest node is contained in the **HTTP** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using the HTTPRequest node to issue a request to a web service:
An HTTP request has two parts:

1. The URL of a service.
2. A stream of data that the remote server processes, then sends back a response, which is often a SOAP or other web service message in XML.

The URL is of the format `http://<address>[:<port>]/<function>`; for example, `http://localhost:7080/request`. This URL can be specified statically in the HTTPRequest node parameters as a field in the message itself, or as a field in the local environment. The data to be sent to the web service can be the whole, or a portion of, the message tree, as specified in the HTTPRequest node properties.

The data must be in CCSID 1208 format for most requests. The reply can replace the input message, or be inserted into the message tree; the location is specified in the HTTPRequest node parameters. The domain for the reply is XMLNS. If the request is successful, the HTTPResponse is inserted into the front of the message tree, the reply placed in the specified location in the tree, and the request propagated to the Out terminal. If the HTTPRequest node is not able to issue the request, an ExceptionList is inserted into the message tree and the tree is propagated to the Failure terminal.

If the request is sent successfully by the HTTPRequest node, but the web service is not successful, the HTTPResponse is inserted into the message tree, and propagated to the Error terminal. The error message location parameter on the HTTPRequest node specifies where in the tree the response is placed, for example `OutputRoot.XMLNS.error`. You might have to use a Compute node to cast this response to an appropriate code page to be able to display the data, for example:

```
Set OutputRoot.XMLNS.error850 = CAST(InputRoot.XMLNS.error.BLOB as CHAR CCSID 850);
```

For information about HTTP, see Hypertext Transfer Protocol - HTTP/1.1. For more information about HTTP return codes, see HTTP Response codes.

You can specify a timeout interval, so that if the request takes longer than the specified duration, the request is propagated to the Failure terminal with an appropriate message. For each request that the HTTPRequest node processes, it opens a connection, and then closes it when the response is returned. If the timeout interval is specified, the socket is closed after the interval. This closure ensures that a request gets only the correct response, and any response data for a request that has timed out is discarded.

You can use the HTTP proxy to route a request through an intermediate site. You can run tools as a proxy to see the request and the response, and therefore debug your flows. The HTTP destination is as seen by the proxy; if you specify the HTTP destination of localhost, and the HTTP proxy is running on a different computer, the request is routed to the remote proxy computer, not the computer from which the original request was issued.

Using the HTTPRequest node in a message flow:
The HTTPRequest node can be used in any message flow that must send an HTTP request. The most common example is a message flow that calls a web service.

For more information about web services, see “Processing Web service messages” on page 1601.

Handling errors

The node interacts directly with an external service using TCP/IP; it can, therefore, experience the following types of error:

- Errors that are generated by TCP/IP, for example `no route to host` or `connection refused`.

  If the node detects these errors, it generates an exception, populates the exception list with the error information that is received, and routes the input message unchanged to the Failure terminal.
- Errors that are returned by the web server. These errors are represented by HTTP status codes that are outside the range 100 - 299. If the node detects these errors, it routes the reply to the Error terminal while following the properties specified on the **Error** tab.

The reply is produced as a BLOB message because the node cannot determine in what format the reply will be. If you have not configured this node to handle redirection, messages with a redirection status code (3xx) are also handled in the same way.

HTTP Response Codes

The HTTPRequest node treats the 100 series status codes as a 'continue' response, discards the current response, and waits for another response from the web server.

The 200 series status codes are treated as success, the settings on the various tabs on the node determine the format of the output message that is generated, and the response is routed to the Out terminal of the node.

The 300 series status codes are for redirection. If the Follow HTTP(s) Redirection property is selected, the node resends the request to the new destination that is specified in the response that is received. If the Follow HTTP(s) Redirection property is not selected, the codes are treated as an error, as described in "Using the HTTPRequest node to issue a request to a web service" on page 4488. For more information about HTTP return codes, see HTTP Response codes.

The 400 and 500 series status codes are errors, and are treated as described in "Using the HTTPRequest node to issue a request to a web service" on page 4488. For more information about HTTP return codes, see HTTP Response codes.

Manipulating headers

If you select Replace input message with web-service response or Replace input with error, the header for the input message (the header that belongs to the message when it arrives at the In terminal of the HTTPRequest node) is not propagated with the message that leaves the HTTPRequest node. However, if one of the properties that specify a location in the message tree is specified, the input message headers are propagated.

The HTTPResponse header, which contains the headers that are returned by the remote web service, is the first header in the message (after Properties) that is propagated from the node. This action is taken regardless of the options that are selected. Therefore, for the reply from the HTTPRequest node to be put to a WebSphere MQ queue, manipulate the headers so that an MQMD is the first header (after Properties).

If you are replacing the input message with a response, you can copy the input message MQMD to the Environment tree before the HTTPRequest node, and then copy it back into the message tree after the HTTPRequest node. If you are specifying a location for the response, in order to maintain existing input message headers, you must move or remove the HTTP Response header so that the MQMD is the first header.

The following example contains ESQL that removes the HTTPHeader:

```
SET OutputRoot = InputRoot;
SET OutputRoot.HTTPResponseHeader = NULL;
```

The following example contains ESQL for moving the HTTPHeader, and therefore preserving the information that it provides:

```
SET OutputRoot = InputRoot;
DECLARE HTTPHeaderRef REFERENCE TO OutputRoot.HTTPResponseHeader;
DETACH HTTPHeaderRef;
ATTACH HTTPHeaderRef TO OutputRoot.MQMD AS NEXTSIBLING;
```

Configuring the HTTPRequest node:
When you have put an instance of the HTTPRequest node into a message flow, you can configure the node; see . The properties of the node are displayed in the Properties view.

All mandatory properties, for which you must enter a value, are marked with an asterisk.

Configure the HTTPRequest node:

1. Optional: On the **Description** tab, enter a `Short description`, a `Long description`, or both. You can also rename the node on this tab.
2. On the **Basic** tab:
   a. The HTTPRequest node determines the URL for the web service to which it sends a request. Select one of the following three options; the node checks these in the order shown (that is, the first always overrides the second, the second overrides the third):
      1) X-Original-HTTP-URL in the HTTPRequest header in the input message
      2) LocalEnvironment.Destination.HTTP.RequestURL in the input message
      3) The `Web service URL` property

      The first two options provide dynamic methods to set a URL for each input message as it passes through the message flow. To use either of these options, include a Compute node in the message flow, before the HTTPRequest node, to create and initialize the required value.

      The third option provides a value that is fixed for every message that is received in this node. Set this property to contain a default setting that is used if the other fields have not been created, or contain a null value. If either field contains a value, the setting of this property is ignored. The `Web service URL` property must contain a valid URL or the deployment fails. Ensure that the value that you set in X-Original-HTTP-URL or the LocalEnvironment.Destination.HTTP.RequestURL is also a valid URL; if it is not, the node uses the default setting from the `Web service URL` property.

      If a URL begins `http://`, the request node makes an HTTP request to the specified URL. If the URL begins `https://`, the request node makes an HTTP over SSL (HTTPS) request to the specified URL, using the parameters that are specified on the **SSL** tab for the node.
   b. Set the value of the `Request timeout (sec)` property, which is the length of time, in seconds, that the node waits for a response from the web service. If a response is received within this time, the reply is propagated through the Out terminal to the rest of the message flow. If a response is not received within this time, the input message is propagated through the Failure terminal, if it is connected. If the Failure terminal is not connected, and a response is not received in this time, an exception is generated.
3. On the **HTTP Settings** tab:
   a. In `HTTP(S) proxy location`, set the location of the proxy server to which requests are sent.
   b. Select `Follow HTTP(S) redirection` to specify how the node handles web service responses that contain an HTTP status code of 300 to 399:

- If you select the check box, the node follows the redirection that is provided in the response, and reissues the web service request to the new URL (included in the message content).
- If you clear the check box, the node does not follow the redirection provided. The response message is propagated to the Error terminal.

c. Select one of the options for the `HTTP version` property. Valid values are: `1.0` or `1.1`.

   If you select the `HTTP version` property value `1.1`, you can also select `Enable HTTP/1.1 keep-alive`.

d. Select one of the options for the `HTTP method` property. Valid values are: `POST`, `GET`, `PUT`, `DELETE`, and `HEAD`.

e. Select one of the options for the `Use compression` property to specify the compression of the content of the HTTP request. You can select `gzip`, `zlib (deflate)`, `deflate` or `none`. The value `zlib (deflate)` represents RFC 1950 and RFC 1951 combined, and `deflate` represents RFC 1951 only. The default value is `none`, meaning that the content of the request is not compressed.

4. On the **SSL** tab, if you want to use HTTP over SSL (HTTPS) requests, set the values for HTTPS requests:

   a. Specify the `Protocol` property that you want to use to make the request. Both ends of an SSL connection must agree on the protocol to use. Therefore, the selected protocol must be one that the remote server can accept. The following options are available:
      - `SSL`. This option is the default. This option tries to connect using the SSLv3 protocol first, but enables the handshake to fall back to the SSLv2 protocol where the SSLv2 protocol is supported by the underlying JSSE provider.
      - `SSLv3`. This option tries to connect with the SSLv3 protocol only. Fallback to SSLv2 is not possible.
      - `TLS`. This option tries to connect with the TLS protocol only. Fallback to SSLv3 or SSLv2 is not possible.
      - `TLSv1.0`. This option attempts to connect with the TLS v1.0 protocol only. Fallback to SSLv3 or SSLv2 is not allowed.
      - `TLSv1.1`. This option attempts to connect with the TLS v1.1 protocol only. Fallback to SSLv3, SSLv2, or TLSv1.0 is not allowed.
      - `TLSv1.2`. This option attempts to connect with the TLS v1.2 protocol only. Fallback to SSLv3, SSLv2, TLSv1.0, or TLSv1.1 is not allowed.
      - `SSL_TLS`. This option enables all SSL v3.0 and TLS v1.0 protocols. Fallback to SSLv2 is not allowed.
      - `SSL_TLSv2`. This option enables all SSL v3.0 and TLS v1.0, v1.1, and v1.2 protocols. Fallback to SSLv2 is not allowed.

   b. Set the `Allowed SSL ciphers` property. Use this setting to specify a single cipher (such as SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA) or a list of ciphers that are the only ones used by the connection. This set of ciphers must include one or more that are accepted by the remote server. A comma is used as a separator between the ciphers. The default value is an empty string, which enables the node to use any, or all, of the available ciphers during the SSL connection handshake. This method gives the greatest scope for making a successful SSL connection.

5. On the **Response Message Parsing** tab, set values for the properties that describe the message domain, message set, message type, and message format that the node uses to determine how to parse the response message returned

by the web service. If an error message is returned by the web service, the values of these properties are ignored, and the message is parsed by the BLOB parser.

a. In `Message domain`, select the name of the parser that you are using from the list. If the field is blank, the default value is `BLOB`. Choose from the following options:
   - XMLNSC
   - JSON
   - BLOB
   - MIME
   - MRM
   - XMLNS

   You can also specify a user-defined parser, if appropriate.

b. If you are using the MRM or IDOC parser, or the XMLNSC parser in validating mode, select the `Message set` that you want to use. This list is populated with available message sets when you select MRM, XMLNSC, or IDOC as the domain.

c. If you are using the MRM parser, select the correct message type from the list in `Message type`. This list is populated with available message types when you select the MRM parser.

d. If you are using the MRM or IDOC parser, select the correct message format from the list in `Message format`. This list is populated with available message formats when you select the MRM or IDOC parser.

6. On the **Parser Options** subtab:

   a. `Parse timing` is, by default, set to `On Demand`, which causes parsing of the message to be delayed. To cause the message to be parsed immediately, see "Parsing on demand" on page 4173.

   b. If you are using the XMLNSC parser, set values for the properties that determine how the XMLNSC parser operates. For more information, see "Manipulating messages in the XMLNSC domain" on page 2546.

7. On the **Error Handling** tab, set values for the properties that determine how an error message returned by the web service is handled:

   a. For the whole web service error message to be propagated as the output message, leave `Replace input with error` selected (the default setting).

      For the web service error message to be included in the output message with part of the input message content, clear `Replace input with error` and set the `Error message location` property. If you clear this property, the node copies the input message to the output message and writes the web service error message over the output message content at the specified location (the input message itself is not modified).

   b. In the `Error message location` field, enter the start location (within the output message tree) at which the parsed elements from the web service error message bit stream are stored. This property is required only if you have cleared `Replace input with error`.

      You can enter any valid ESQL field reference, including expressions within the reference and new field references (to create a node in the message tree for the response). For example, enter:

      ```
      OutputRoot.XMLNSC.ABC.DEF
      ```

      or

      ```
      Environment.WSError
      ```

      If you select `Replace input with error`, this property is ignored.

8. On the **Advanced** tab, set values for the Advanced properties that describe the structure and content of the web service request and response:
   a. Specify the content of the request message that is sent to the web service:
      - For the request message to be the whole input message body, leave `Use whole input message as request` selected (the default setting).

        For the request message to contain a subset of the input message, clear `Use whole input message as request` and set the Request message location in tree property.
      - In the Request message location in tree field, enter the start location from which the content of the input message tree is copied to the request message. This property is required only if you have cleared Use whole input message as request. The node creates a request message and copies the specified parts of the input message (the input message itself is not modified).

        You can enter any valid ESQL field reference, including expressions within the reference. For example, enter:

        ```
        InputRoot.XMLNSC.ABC
        ```

        If you select Use whole input message as request, this property is ignored.

      When the appropriate message tree content is parsed to create a bit stream, the message properties (`Message domain`, `Message set`, `Message type`, and `Message format`) that are associated with the input message body and stored in the Properties folder are used.
   b. Specify the content of the output message that is propagated to the next node in the message flow:
      - For the whole web service response message to be propagated as the output message, leave `Replace input message with web-service response` selected (the default setting).

        For the web service response message to be included in the output message with part of the input message content, clear `Replace input message with web-service response` and set the `Response message location in tree` property. If you clear this property, the node copies the input message to the output message and writes the web service response message over the output message content at the specified location (the input message itself is not modified).
      - In the `Response message location in tree` field, enter the start location (within the output message tree) at which the parsed elements from the web service response message bit stream are stored. This property is required only if you have cleared `Replace input message with web-service response`.

        You can enter any valid ESQL field reference, including expressions within the reference, and including new field references (to create a node in the message tree for the response). For example, enter:

        ```
        OutputRoot.XMLNSC.ABC.DEF
        ```

        or

        ```
        Environment.WSReply
        ```

        If you select `Replace input message with web-service response`, this property is ignored.

When the response bit stream is parsed to create message tree contents, the message properties (`Message domain`, `Message set`, `Message type`, and `Message format`), that you have specified in the Response Message Parsing properties of the node, are used.

c. For the node to generate an HTTPRequestHeader for the request message, leave `Generate default HTTP headers from input` selected (the default setting).

   If you do not want the node to generate an HTTPRequestHeader for the request message, clear `Generate default HTTP headers from input`. To control the contents of the HTTPRequestHeader that is included in the request message, include a Compute node that adds an HTTPRequestHeader to the input message before this HTTPRequest node in the message flow, and clear this check box.

   - If you have selected `Generate default HTTP headers from input` and the input message includes an HTTPRequestHeader, the HTTPRequest node extracts web service headers from the input HTTPRequestHeader and adds any unique web service headers, except Host (see the following table), that are present in an HTTPInputHeader, if one exists in the input message. (An HTTPInputHeader might be present if the input message has been received from a web service by the HTTPInput node.)

     The HTTPRequest node also adds the web service headers shown in the following table, with default values, if these are not present in the HTTPRequestHeader or the HTTPInputHeader.

Header	**Default value**
SOAPAction	"" (empty string)
Content-Type	`text/xml; charset=`*`ccsid of the message body`* Unless the input message is in the JSON domain, where the default is: `application/json; charset=`*`ccsid of the message body`*
Host	The host name to which the request is to be sent.

     The HTTPRequest node also adds the optional header Content-Length with the correct calculated value, even if this value is not present in the HTTPRequestHeader or the HTTPInputHeader.

   - If you have selected `Generate default HTTP headers from input` and the input message does not include an HTTPRequestHeader, the HTTPRequest node extracts web service headers, except Host, from the HTTPInputHeader (if it is present in the input message). The HTTPRequest node adds the required web service headers with default values, if these values are not present in the HTTPInputHeader.
   - If you have cleared Generate default HTTP headers from input and the input message includes an HTTPRequestHeader, the node extracts all web service headers present in the input HTTPRequestHeader. The node does not check for the presence of an HTTPInputHeader in the input message, and it does not add the required web service headers if they are not supplied by the input HTTPRequestHeader.
   - If you have cleared Generate default HTTP headers from input and the input message does not include an HTTPRequestHeader, no web service headers are generated. The HTTPRequest node does not check for the presence of an HTTPInputHeader in the input message and does not add any required web service header. The request message is propagated to

the web service without an HTTPRequestHeader. This action typically causes an error to be generated by the web service, unless the web service is configured to handle the message contents.

If you have selected `Use compression` or `Accept compressed responses by default`, the Content-Encoding and Accept-Encoding HTTP header fields are populated regardless of whether you have selected `Generate default HTTP headers from input`:

- If the value of `Use compression` is not the default of `None`, the Content-Encoding HTTP header is populated with this value, and the bit stream is compressed. If the Content-Encoding header is already present in an existing HTTP header, this field is updated with the value of the `Use compression` property. If the existing Content-Encoding header already starts with the named compression function, then no further compression takes place. If the Content-Encoding header starts with `deflate`, then no compression takes place irrespective of whether `ZLIB (deflate)`or `deflate` is selected.
- If you have selected `Accept compressed responses`, the Accept-Encoding field is populated. If this field is already present in an existing HTTP header, the existing value overrides the property on the node. However, if a compressed response is received, it is not decompressed.

d. Select the `Accept compressed responses by default` property to indicate whether the request accepts compressed responses. If you select this option, the request can receive responses with a Content-Encoding of `gzip` or `deflate`. If such a response is received, the content is decoded and the Content-Encoding header is removed. If the Request Header does not contain an Accept-Encoding header then selecting this option sets the Accept-Encoding header to "gzip, deflate".

9. On the **Validation** tab, set Validation properties if you want the parser to validate the body of response messages against the `Message set`. (If a message is propagated to the Failure terminal of the node, it is not validated.) These properties do not cause the input message to be validated. It is expected that, if such validation is required, the validation has already been performed by the input node or a preceding validation node.

   For more details see “Validating messages” on page 1478 and “Validation properties” on page 4169.

Connecting the output terminals to another node

Connect the Out, Error, or Failure terminal of this node to another node in this message flow to process the message further, to process errors, or to send the message to an additional destination. If you do not connect the Error terminal, the message is discarded. If you do not connect the Failure terminal, the broker provides default error processing, see “Handling errors in message flows” on page 2823.

Terminals and properties:
The HTTPRequest node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the message is routed if a failure is detected during processing in the node.
Out	The output terminal to which the message is routed if it represents successful completion of the web service request, and if further processing is required within this message flow.

Terminal	Description
Error	The output terminal to which messages that include an HTTP status code that is not in the range 200 through 299, including redirection codes (3xx) if you have not set the property `Follow HTTP(s) redirection` property, is routed.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk on the panel if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the broker archive file to deploy it).

The HTTPRequest node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, HTTPRequest	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The HTTPRequest node Basic properties are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Web service URL	Yes	Yes		The URL for the web service. You must provide this in the form `http://`*`hostname`*`[:`*`port`*`]/[`*`path`*`]` where • `http://`*`hostname`* must be specified. • *`port`* has a default of `80`. If you specify a value, you must include the : before the port number. • *`path`* has a default of `/`. If you specify a value, you must include the / before the path.	URLSpecifier
Request timeout (sec)	Yes	Yes	`120`	The time in seconds that the node waits for a response from the web service. The valid range is 1 through (2^{31})-1. You cannot enter a value that represents an unlimited wait. The timeout might take up to one second longer than the specified value.	timeoutForServer

The HTTPRequest node HTTP Settings properties are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
HTTP(S) proxy location	No	Yes		The proxy server to which requests are sent. This value must be in the form `hostname:port`.	httpProxyLocation
Follow HTTP(S) redirection	No	No	Cleared	If you select the check box, redirections are followed. If you clear this check box, redirections are not followed.	
HTTP version	No	Yes	`1.0`	The HTTP version to use for requests. Valid values are `1.0` and `1.1`.	httpVersion

Property	M	C	Default	Description	mqsiapplybaroverride command property
Enable HTTP/1.1 keep-alive	No	Yes	Selected (if HTTP version is 1.1)	Use HTTP/1.1 Keep-Alive.	enableKeepAlive
HTTP method	No	No	POST	The HTTP method. Valid values are POST, GET, PUT, DELETE, and HEAD. By default, the HTTPRequest node uses the HTTP POST method when it connects to the remote web server. HEAD is used to determine whether a service is available - for example, by a Network Dispatcher trying to work out which servers are available - and sends back the correct headers (including content-length) but no body data.	
Use compression	No	Yes	None	This property controls whether the content of the HTTP request is compressed. You can choose a value from none, gzip, zlib (deflate), and deflate. If the request is compressed, the Content-Encoding header is set to indicate that the content is compressed. zlib (deflate) represents RFC 1950 + RFC 1951 combined. deflate represents RFC 1951 only.	requestCompressionType

The HTTPRequest node SSL properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Protocol	No	Yes	SSL	The SSL protocol to use when making an HTTPS request.	protocol
Allowed SSL ciphers	No	Yes		A comma-separated list of ciphers to use when making an SSL request. The default value of an empty string means use all available ciphers.	allowedCiphers
Perform hostname checking	No	Yes	No	This property specifies whether the host name of the server that is receiving the request must match the host name in the SSL certificate.	hostnameChecking

The HTTPRequest node Response Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	BLOB	The domain that is used to parse the message that is received from the web service. If the field is blank then the default is BLOB.
Message set	No	No		The name or identifier of the message set in which the response message is defined. If you set this property, and then update the project dependencies to remove this message set reference, a warning is issued. Either update the Message set property, or restore the reference to this message set project.
Message type	No	No		The name of the response message.

Property	M	C	Default	Description
Message format	No	No		The name of the physical format of the response message.

The HTTPRequest node Parser Options properties are described in the following table.

Property	M	C	Default	Description
Parse timing	No	No	`On Demand`	This property controls when a response message is parsed. Valid values are `On Demand`, `Immediate`, and `Complete`. For a full description of this property, see "Parsing on demand" on page 4173.
Build tree using XML schema data types	No	No	Cleared	This property controls whether the XMLNSC parser creates syntax elements in the message tree with data types taken from the XML schema. You can select this property only if you set the `Validate` property on the **Validation** tab to `Content` or `Content and Value`.
Use XMLNSC compact parser for XMLNS domain	No	No	Cleared	This property controls whether the XMLNSC Compact Parser is used for messages in the XMLNS Domain. If you set this property, the response message data is displayed under XMLNSC in nodes that are connected to the output terminal when the input MQRFH2 header or Response Message Parsing properties Domain is XMLNS.
Retain mixed content	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in a response message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in a response message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in a response message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the response message that are to be opaquely parsed by the XMLNSC parser. Opaque parsing is performed only if validation is not enabled (that is, if the `Validate` property is set to `None`); entries that are specified in `Opaque Elements` are ignored if validation is enabled.

The HTTPRequest node Error Handling properties are described in the following table.

Property	M	C	Default	Description
Replace input with error	No	No	Selected	If you select this check box, the input message content is replaced by the error message content. If you clear this check box, you must specify `Error message location`.

Property	M	C	Default	Description
Error message location	Yes	No	`OutputRoot`	The start location at which the parsed elements from the web service error bit stream are stored. This property takes the form of an ESQL field reference.

The HTTPRequest node Advanced properties are described in the following table.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Use whole input message as request	No	No	Selected	If you select this check box, the whole input message body is to be passed to the web service. If you clear this check box, you must select `Request message location in tree`.	
Request message location in tree	Yes	No	`InputRoot`	The start location from which the bit stream is created for sending to the web service. This property takes the form of an ESQL field reference.	
Replace input message with web-service response	No	No	Selected	If you select this check box, the web service response message replaces the copy of the input message as the content of the output message that is created. If you clear this check box, you must select `Response message location in tree`.	
Response message location in tree	Yes	No	`OutputRoot`	The start location at which the parsed elements from the web service response bit stream are stored. This property takes the form of an ESQL field reference.	
Generate default HTTP headers from input	No	No	Selected	If you select this check box, an HTTPRequestHeader is generated. If you clear this check box, a valid HTTPRequestHeader must exist in the input message.	
Accept compressed responses by default	No	Yes	Cleared	This property indicates whether the request node handles compressed responses by default. If the request header does not contain an Accept-Encoding header and this option is selected, the node sets the Accept-Encoding header to "gzip, deflate", and any compressed response that is received is decompressed by the node. If the message propagated to the Request node includes an Accept-Encoding header, the message flow or client application should handle any compressed response. Therefore selecting this option has no effect in that case.	acceptCompressedResponses

The HTTPRequest node Validation properties are described in the following table.

For a full description of these properties see "Validation properties" on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	Yes	None	This property controls whether validation takes place. Valid values are None, Content and Value, Content, and Inherit.	validateMaster
Failure action	No	No	Exception	This property controls what happens if validation fails. You can set this property only if you set Validate to Content or Content and Value. Valid values are User Trace, Local Error Log, Exception, and Exception List.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Local environment overrides:
You can dynamically override set values in the local environment in the same way as setting values in other elements of a message. The following values can be set under LocalEnvironment.Destination.HTTP.

Setting	Description
RequestURL	Overrides the Web service URL property on the node. For example: `SET OutputLocalEnvironment.Destination.HTTP.RequestURL = 'http://ibm.com/abc/';`
Timeout	Overrides the Request timeout (sec) property on the node. For example: `SET OutputLocalEnvironment.Destination.HTTP.Timeout = 42;`
TimeoutMillis	Overrides the Request timeout (sec) property on the node. For example: `SET OutputLocalEnvironment.Destination.HTTP.TimeoutMillis = 5000;` This property defines the timeout in milliseconds. The value of TimeoutMillis overrides the value for Timeout if both values are set.
ProxyURL	Overrides the HTTP(S) proxy location property on the node. For example: `SET OutputLocalEnvironment.Destination.HTTP.ProxyURL = 'my.proxy';`
RequestLine.RequestURI	Overrides the RequestURI, which is the path after the URL and port. For example: `SET OutputLocalEnvironment.Destination.HTTP.RequestLine.RequestURI = '/abc/def';`
RequestLine.HTTPVersion	Overrides the HTTP version property on the node. For example: `SET OutputLocalEnvironment.Destination.HTTP.RequestLine.HTTPVersion = 'HTTP/1.1';`
KeepAlive	Overrides the Enable HTTP/1.1 keep-alive property on the node. For example: `SET OutputLocalEnvironment.Destination.HTTP.KeepAlive = TRUE;`
RequestLine.Method	Overrides the HTTP method property on the node. For example: `SET OutputLocalEnvironment.Destination.HTTP.RequestLine.Method = 'GET';`

Setting	Description
SSLProtocol	Overrides the SSLProtocol. For example: `SET OutputLocalEnvironment.Destination.HTTP.SSLProtocol = 'TLS';` Valid values are: SSL, SSLv3, TLS, TLSv1, TLSv1.1, TLSv1.2, SSL_TLS, and SSL_TLSv2

SSLCiphers	Overrides the Allowed SSL Ciphers property on the node. For example:
	`SET OutputLocalEnvironment.Destination.HTTP.SSLCiphers =`
	`'SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA';`

ProxyConnectHeaders	Specifies additional headers that are used if the outbound request is an SSL connection through a proxy. These additional headers are sent with the initial CONNECT request to the proxy. For example, you can send proxy authentication information to a proxy server when you are using SSL. You can send multiple headers but each one must be separated by a carriage return and a line feed (ASCII 0x0D 0x0A), in accordance with RFC2616; for example:
	`DECLARE CRLF CHAR CAST(X'0D0A' AS CHAR CCSID 1208);`
	`SET OutputLocalEnvironment.Destination.HTTP.ProxyConnectHeaders =`
	`'Proxy-Authorization: Basic Zm5lcmJsZTpwYXNzd29yZA==' || CRLF ||`
	`'Proxy-Connection: Keep-Alive' || CRLF;`
	
	This setting is used only if the request is an SSL request through a proxy server. To send proxy authentication information for a non-SSL request, specify the individual headers in the HTTPRequestHeader folder, as shown in the following example:
	`SET OutputRoot.HTTPRequestHeader."Proxy-Authorization" =`
	`'Basic Zm5lcmJsZTpwYXNzd29yZA==';`
	`SET OutputRoot.HTTPRequestHeader."Proxy-Connection" = 'Keep-Alive';`

UseFolderMode	Sets the UseFolderMode. Use for bitstream generation; for certain parsers this changes the output bitstream. For example: `SET OutputLocalEnvironment.Destination.HTTP.UseFolderMode = TRUE;`

QueryString	Allows the setting of outbound query string parameters. Each parameter must be set individually. For example:
	`SET OutputLocalEnvironment.Destination.HTTP.QueryString.param1 = 'my"Value"1';`
	`SET OutputLocalEnvironment.Destination.HTTP.QueryString.param2 = 'my"Value"2';`
	
	The above ESQL results in the following query string being encoded (according to http://tools.ietf.org/html/rfc3986) and sent with the outbound request:
	`?param1=my%22Value%221&param2= my%22Value%222`
	
	If the destination URL already has one or more query parameters, additional parameters specified here are appended to the existing list.

QueryStringCCSID	Specifies that, before encoding, the query string parameters must be converted into a character set other than the default, which is UTF-8. Any query string parameters are first converted into the specified CCSID before the resulting string is encoded, according to RFC3986. For example: `SET OutputLocalEnvironment.Destination.HTTP.QueryStringCCSID = 943;` The above ESQL results in any QueryString parameters being converted to the 943 code page before they are encoded. Note: Any query string parameters must contain the data in unicode.

Compression	Overrides the Use compression property on the node. For example:
	`SET OutputLocalEnvironment.Destination.HTTP.Compression =`
	`'gzip';`

Working with WrittenDestination data

After the request has been made, the WrittenDestination folder in the local environment is updated with the URI to which the request was sent and compression details (if used). A WrittenDestination for an HTTPRequest node has the following format, with Compression present only if it is used:

```
WrittenDestination = (
   HTTP  = (
      RequestURL = 'http://127.0.0.1:7800/HTTPFLOW' (CHARACTER)
      Compression = (
        OriginalSize = 53 (INTEGER)
        CompressedSize = 71 (INTEGER)
      )
   )
)
```

Use a security profile to configure HTTP basic authentication in the HTTPRequest or SOAPInput nodes.

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

"Editing configurable properties" on page 3227
You can edit configurable properties in the deployment descriptor file (`broker.xml`) of your broker archive.

"Accessing the local environment tree" on page 2463
The local environment tree has its own correlation name, LocalEnvironment, and you must use this name in all ESQL statements that refer to or set the content of this tree.

"Validating messages" on page 1478
The broker provides validation based on the message model for predefined messages.

Related reference:

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

"Compute node" on page 4340
Use the Compute node to construct one or more new output messages.

"HTTPInput node" on page 4474
Use the HTTPInput node to receive an HTTP message from an HTTP client for processing by a message flow.

"HTTPReply node" on page 4484
Use the HTTPReply node to return a response from the message flow to an HTTP client. This node generates the response to an HTTP client from which the input message was received by the HTTPInput node, and waits for confirmation that it has been sent.

"SOAPRequest node" on page 4828
Use the SOAPRequest node to send a SOAP request to the remote Web service.

"ASBITSTREAM function" on page 5224
The ASBITSTREAM field function generates a bit stream for the subtree of a given field according to the rules of the parser that owns the field.

"EndpointLookup node" on page 4407
Use the EndpointLookup node to retrieve service endpoint information held in the WebSphere Service Registry and Repository (WSRR). The entities that match the specified search criteria are stored in the local environment. Depending on the node configuration, the Web service URL destination used by the SOAP and HTTP request nodes can also be set. The input message is not modified.

IMSRequest node

Use the IMSRequest node to send a request to run a transaction on a local or remote IMS system, and wait for a response. IMS Connect must be configured and running on the IMS system.

This topic contains the following sections:
- "Purpose"
- "Using the IMSRequest node in a message flow" on page 4505
- "Terminals and properties" on page 4506

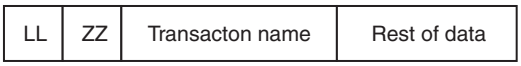
Purpose:
The following example illustrates a situation in which you would use an IMSRequest node.

WebSphere Message Broker can be used to expose an existing target IMS banking application as a Web Service. For example, the IMS application provides transactions that operate on a database that contains information about customers' bank accounts. In this example, the Web service consumer sends a SOAP message across HTTP to WebSphere Message Broker and synchronously waits for the response. The WebSphere Message Broker message flow transforms the SOAP message to IMS format (including the LLZZ and transaction code fields), then sends that bit stream to IMS. The message flow waits for a response. IMS schedules the destination program and queues the request data for that program. The target program accesses the customer account database, builds a response

message that consists of the account statement, and returns it to the WebSphere Message Broker message flow. The message flow transforms the IMS format to a SOAP format and sends that SOAP response back across HTTP to the Web service consumer.

The IMSRequest node is contained in the **IMS** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using the IMSRequest node in a message flow:
The IMSRequest node sends requests to IMS by using IMS Connect. The node takes the incoming message's bit stream and sends it to IMS. It then receives a bit stream, which it passes to the response parser. The bit stream that is sent to IMS must conform to the format that is shown in the following diagram:



The message flow that contains the IMSRequest node ensures that the message that is received by the IMSRequest node has this structure where:

- *LLZZ* is a four-byte field. The first two bytes indicate the length of the bit stream, and the other two bytes are reserved for use by IMS.
- For request segments, the transaction code must follow. The transaction code can contain up to eight characters; if it contains less than eight characters, the transaction code must be delimited by a space. The response segments do not need to have the transaction name, but an IMS program can add it.
- The rest of the data comprises anything else that the IMS program needs.

The IMS program produces many messages. You can receive all messages as a single transmission bit stream, or you can receive them separately. Each message can contain multiple segments; all segments for each message are returned at the same time.

The IMSRequest node has two modes of operation, which you specify by selecting or clearing the `Use connection properties defined on node` check box. If you select the check box, all properties are taken from the node by using the following properties in the node connection details section:

- `Hostname`
- `Port number`
- `Data store name`

If you clear the `Use connection properties defined on node` check box, all connection details are retrieved from the configurable services. However, if the `Security identity` property is set, the security identity on the configurable service is ignored and the value of the node property is used instead.

The IMSRequest node can also use an identity that is present on an input message, and propagate it to IMS, by using the `Propagate` property on the security profile that is defined for the node. For more information, see “Propagating security credentials to IMS” on page 2144.

View the following sample to see how to use this node:

- IMS Synchronous Request

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Using configurable services for IMS nodes

You can configure IMS nodes to get connection details from a configurable service. For details about creating, changing, reporting, and deleting the configurable services, see "Changing connection information for the IMSRequest node" on page 732.

Terminals and properties:
When you have put an instance of the IMSRequest node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The IMSRequest node terminals are described in the following table.

Terminal	Description
In	The input terminal that receives the message that triggers the node.
Out	The output terminal to which the node sends a message after it has been received from the external resource. The message is sent to the terminal unchanged, except for some added status information.
Failure	If an error occurs in the IMSRequest node, the message is sent to the Failure terminal.
Timeout	The output terminal to which the message is sent if a timeout occurs. The input message is propagated to this terminal with an exception list that describes the timeout. If the Timeout terminal is not connected and a timeout occurs, the message is routed to the Failure terminal. A timeout can occur in either of the following situations: • The IMS program has not responded by the time the execution timeout has expired. The execution timeout is configured by using the `Timeout waiting for a transaction to be executed` property on the IMSRequest node. • WebSphere Message Broker has not received the response across the TCP/IP network by the time the socket timeout expires. You can configure the socket timeout on the configurable service.

The following tables describe the node properties. The columns headed M indicate whether the property is *mandatory* (marked with an asterisk on the panel if you must enter a value when no default is defined); the columns headed C indicate whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The IMSRequest node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, IMSRequest	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The IMSRequest node Basic properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Use connection properties defined on node	No	Yes	Selected	If you select this check box, the connection properties that are defined on the node are used instead of a configurable service and security identity that are defined on the broker. If you clear this check box, you must set the `Configurable service` and `Security identity` properties.	
Hostname	Yes	Yes		The IP address or host name of the computer that is running the target IMS Connect system. This property is mandatory if the `Use connection properties defined on node` check box is selected and can be set only if the `Use connection properties defined on node` check box is selected.	hostname
Port number	Yes	Yes	`0`	The port number on which IMS Connect is listening for TCP/IP connections. You can obtain the port number from the IMS Connect job log on the IMS system. This property is mandatory only if the `Use connection properties defined on node` check box is selected and can be set only if the `Use connection properties defined on node` check box is selected.	portNumber
Data store name	Yes	Yes		The name of the data store that IMS Connect is using. This value must match the ID parameter of the Datastore statement that is specified in the IMS Connect configuration member. This name also serves as the XCF member name for IMS during internal XCF communications between IMS Connect and IMS OTMA. You can obtain the data store name from the IMS Connect job log on the IMS system. This property is mandatory only if the `Use connection properties defined on node` check box is selected and can be set only if the `Use connection properties defined on node` check box is selected.	dataStoreName
Timeout waiting for a transaction to be executed	No	No	`60`	The time (in seconds) that the node waits for IMS to process a transaction. If IMS fails to process a transaction in this time, the node issues an exception, but the connection is not closed. You can set this property only if the `Use connection properties defined on node` check box is selected. If the check box is cleared, the `ExecutionTimeoutSec` property on the configurable service is used.	
Configurable service	Yes	Yes		The configurable service from which to get the connection details. All connection details are obtained from the configurable service, except for security information, which is obtained from the `Security identity` property. This property is mandatory if the `Use connection properties defined on node` check box is cleared, and can be set only if the `Use connection properties defined on node` is cleared.	configurableService

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Security identity	No	Yes	An empty string	The security identity to look up in the broker to get the user name and password to use. You use the **mqsisetdbparms** command to set the security identity on the broker. The default value for this property is an empty string, which signifies that the user ID and password are not passed to IMS Connect.	securityIdentity

The IMSRequest node Advanced properties are described in the following table.

Property	M	C	Default	Description
Commit mode	Yes	No	`1: SEND_THEN_COMMIT`	The commit mode to use when processing IMS transactions. Available values are: • `1: SEND_THEN_COMMIT`: (the default value) The transaction is processed using commit mode 1 in IMS. The request transaction is run and data is sent back to the node. After the node acknowledges that it has received the response, the transaction is committed. You cannot process the response before it is committed. The node sends the response after the acknowledgment is sent to IMS. • `0: COMMIT_THEN_SEND`: The transaction is processed using commit mode 0 in IMS. The request transaction is run and committed before data is sent back to the node. The node waits for all response messages to be returned before it continues processing.
Sync level	Yes	No	`1: CONFIRM`	The synchronization level to use when processing IMS transactions. If `Commit mode` is set to 0, the `Sync level` is automatically set to `1: CONFIRM`. If `Commit mode` is set to 1, the `Sync level` property can have either of the following values: • `1: CONFIRM`: (the default value) The node sends an acknowledgment to IMS after it receives the replies. The node then sends the response after the acknowledgment is sent to IMS. If you set the `Sync level` to `1: CONFIRM`, the IMS program is blocked until the IMSRequest node acknowledges the transaction output, which might affect performance. • `0: NONE`: The node does not send any acknowledgments. This value is applicable only when `Commit mode` is set to 1. Typically, `Sync level` can be set to `0: NONE` for read-only types of interactions, such as queries, which do not need an acknowledgment. However, for critical transactions that involve updates and deletions, it is important to be able to acknowledge the output from IMS. If the acknowledgment is not received (for example, because of a connection failure between WebSphere Message Broker and IMS Connect), the transaction is backed out, avoiding the need for a compensation transaction.

The IMSRequest node Request properties are described in the following table.

Property	M	C	Default	Description
Data Location	Yes	No	`$Body`	The location in the incoming message tree from which data is retrieved to form the request that is sent from the IMSRequest node to IMS. The default value, `$Body`, represents the incoming message body. You can enter any XPath or ESQL expression that defines the location of the message tree to serialize and send to IMS.

The IMSRequest node Result properties are described in the following table.

Property	M	C	Default	Description
Output data location	No	No	`$OutputRoot`	The message tree location to which the IMSRequest node copies the response message tree in the outgoing message assembly. The default value, `$OutputRoot`, replaces the incoming message with the response.
Copy local environment	No	No	Selected	This property controls whether to copy the incoming local environment or propagate the incoming local environment. By default, this check box is selected, which signifies that the local environment is copied so that the incoming local environment is preserved. The additions to the local environment are visible only to nodes downstream of this node. If this check box is cleared, the incoming local environment is used for the outgoing message. Any modifications that are made to the local environment by this node are visible to both downstream and upstream nodes after this node has completed.

The IMSRequest node Response Message Parsing properties are described in the following table.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Message domain	No	No		The domain to use to parse the message from the external resource's supplied bit stream.	
Message set	No	No	Set automatically	The name of the message set in which the incoming message is defined. If you set this property, then subsequently update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project.	
Message type	No	No		The name of the response message.	
Message format	No	No		The name of the physical format of the response message.	
Message coded character set ID	Yes	No	`EBCDIC (500)`	The ID of the coded character set that is used to interpret bytes of the data that is being read. Valid values are `EBCDIC (500)` and `Broker System Default`.	messageCodedCharSetIdProperty
Message encoding	Yes	No	`Big Endian, with S390 Floating Point (785)`	The encoding scheme for numbers and large characters that is used to interpret bytes of the data that is being read. Valid values are: • Little Endian, with IEEE Floating Point (546) • Big Endian, with IEEE Floating Point (273) • Big Endian, with S390 Floating Point (785) • Broker System Determined For more information about encoding, see “Data conversion” on page 1151.	messageEncodingProperty

The IMSRequest node Parser Options properties are described in the following table.

Property	M	C	Default	Description
Parse timing	Yes	No	On Demand	This property controls when a response message is parsed. Valid values are On Demand, Immediate, and Complete. For a full description of this property, see "Parsing on demand" on page 4173.
Build tree using XML schema data types	Yes	No	Cleared	This property controls whether the XMLNSC parser creates syntax elements in the message tree with data types taken from the XML Schema. You can select this property only if you set the Validate property on the **Validation** tab to Content or Content and Value.
Use XMLNSC compact parser for XMLNS domain	Yes	No	Cleared	This property controls whether the XMLNSC Compact Parser is used for messages in the XMLNS Domain. If you set this property, the response message data appears under XMLNSC in nodes that are connected to the output terminal when the input MQRFH2 header or Response Message Parsing properties Domain is XMLNS.
Retain mixed content	Yes	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in a response message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	Yes	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in a response message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	Yes	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in a response message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the response message that are to be opaquely parsed by the XMLNSC parser. Opaque parsing is performed only if validation is not enabled (that is, if Validate is None); entries that are specified in Opaque Elements are ignored if validation is enabled.

The IMSRequest node Validation properties are described in the following table.

For a full description of these properties see "Validation properties" on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	Yes	Yes	None	This property controls whether validation takes place. Valid values are None, Content and Value, Content, and Inherit.	validateMaster

Property	M	C	Default	Description	mqsiapplybaroverride command property
Failure action	Yes	No	Exception	This property controls what happens if validation fails. You can set this property only if you set Validate to Content or Content and Value. Valid values are User Trace, Local Error Log, Exception, and Exception List.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

Use the **mqsisetdbparms** command to associate a specific user ID and password (or SSH identity file) with one or more resources that are accessed by the broker.

Input node

Use the Input node as an In terminal for an embedded message flow (a subflow).

This topic contains the following sections:

Purpose:
You can use a subflow for a common task that can be represented by a sequence of message flow nodes. For example, you can create a subflow to increment or decrement a loop counter, or to provide error processing that is common to a number of message flows.

You must use an Input node to provide the In terminal to a subflow; you cannot use a standard input node (a built-in input node such as MQInput, or a user-defined input node).

When you have started your subflow with an Input node, you can connect it to any In terminal on any message flow node, including an Output node.

You can include one or more Input nodes in a subflow. Each Input node that you include provides a terminal through which to introduce messages to the subflow. If you include more than one Input node, you cannot predict the order in which the messages are processed through the subflow.

The Input node is contained in the **Construction** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

When you select and include a subflow in a message flow, it is represented by the following icon:

When you include the subflow in a message flow, this icon shows a terminal for each Input node that you include in the subflow, and the name of the terminal (which you can see when you hold the mouse pointer over it) matches the name of that instance of the Input node. Give your Input nodes meaningful names that you can recognize easily when you use their corresponding terminal on the subflow node in your message flow.

Using this node in a message flow:
Look at the following sample to see how to use this node:
- Error Handler

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
When you have put an instance of the Input node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

The Input node terminals are described in the following table.

Terminal	Description
Out	The input terminal that delivers a message to the subflow.

The following table describes the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Input node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, Input.	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"MQInput node" on page 4594
Use the MQInput node to receive messages from clients that connect to the broker by using the WebSphere MQ Enterprise Transport, and that use the MQI and AMI application programming interfaces.

"Output node" on page 4626
Use the Output node as an out terminal for an embedded message flow (a subflow).

JavaCompute node

Use the JavaCompute node to work with messages by using the Java language.

This topic contains the following sections:

Purpose:
By using this node, you can complete the following tasks:

- Use Java to examine an incoming message and, depending on its content, propagate it unchanged to one of the two output terminals of the node. The node behaves in a similar way to a Filter node, but uses Java instead of ESQL to determine which output terminal to use.
- Use Java to change part of an incoming message and propagate the changed message to one of the output terminals.
- Use Java to create and build a new output message that is totally independent of the input message.

The Java code that is used by the node is stored in an Eclipse Java project.

The JavaCompute node is contained in the **Transformation** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
The JavaCompute node uses the same execution model as Java user-defined nodes and therefore the restrictions and assumptions associated with Java user-defined nodes also apply to Java code developed for JavaCompute nodes; see "Creating a message processing or output node in Java" on page 3062. Only one instance of the JavaCompute node is created regardless of the number of threads running against the flow (either as a result of additional instances or multiple input nodes). Therefore all of your user Java code must be threadsafe and reentrant. For more information, see "User-defined extensions execution model" on page 2981 and "Threading considerations for user-defined extensions" on page 2978.

Double-click the JavaCompute node to open the New Java Compute Node Class wizard. The wizard guides you through the creation of a new Java project and a Java class that contains some skeleton code. This skeleton code is displayed in a Java editor. For more information about creating Java code for a JavaCompute node, and for examples of the skeleton code or template that are provided, see "Creating Java code for a JavaCompute node" on page 2629. If it is not the first time that you have double-clicked the node, the Java code is displayed.

The MbJavaComputeNode class contains two methods that you can override: `onInitialize()` and `onDelete()`. If you want the node to perform cleanup operations, for example closing sockets, include an implementation of the onDelete method:

```
public void onDelete()
{
  // perform node cleanup if necessary
}
```

The `onInitialize()` method is called either during deployment or on broker startup. During deployment, the method is called before deployment has been committed. Other nodes can throw exceptions during their initialization; therefore, the flow will fail to deploy, even if the `onInitialize()` method for this node works. If your `onInitialize()` method throws an exception, the flow either fails to deploy, or fails to start. Therefore, complete tasks that will always work or always fail during the `onInitialize()` method. The broker does not try to start the flow again until the broker is restarted. If you need to initialize an external connection that might need to be retried, do so on the first message through the flow so that the flow can retry the transaction as necessary.

Look at the following sample to see how to use this node.

- JavaCompute Node

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

For instructions about the tasks that you can complete with a JavaCompute node, see the following topics:

- Manipulating message body data
- Manipulating other parts of the message tree

Specifying Java:
Code Java statements to customize the behavior of the JavaCompute node. For example, you can customize the node to create a new output message or messages, using input message or database content (unchanged or modified), or new data. For example, you might want to modify a value in the input message by adding a value from a database, and store the result in a field in the output message.

Code the Java statements that you want in a Java file that is associated with the JavaCompute node.

If a Java file does not already exist for this node, right-click the JavaCompute node and click **Open Java** to create and open a new Java file in the Editor view. If the file exists already, click **Browse** beside the `Java Class` property to display the JavaCompute Node Type Selection window. When you type at least one character in the **Select** field, matching Java classes are listed. You can use the asterisk (*) to represent any character as part of a search string; for example, *a*b*. Select the appropriate Java class and click **OK**.

Restriction: Do not try to create another instance of a JavaCompute node from Java code; this is not supported.

Terminals and properties:
When you have put an instance of the JavaCompute node into a message flow, you can configure it; see . To associate an instance of a JavaCompute node with a Java class, configure the node's properties. The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The JavaCompute node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the input message is routed if a failure is detected during the computation. (Even if the `Validate` property is set, messages that are propagated to the Failure terminal of the node are not validated.)
Out	The output terminal to which the transformed message is routed.
Alternate	An alternative output terminal to which the transformed message can be routed, instead of to the Out terminal.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the JavaCompute node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type: JavaCompute	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties for the JavaCompute node are described in the following table.

Property	M	C	Default	Description
Java class	Yes	No	None	The name of the Java class that is used in this node. This name must be displayed in the list of Java classes that are available in the project references for the message flow project. To select a file that already exists, click **Browse**. When you type at least one character in the **Select** field, matching Java classes are listed. You can use the asterisk (*) to represent any character as part of a search string; for example, *a*b*. Select the appropriate Java class and click **OK**.

Property	M	C	Default	Description
Java classloader service	No	Yes	None	The name of the JavaClassLoader configurable service that is used in this node. If no name is specified, and a if JavaClassLoader configurable service with the same name as the execution group exists, it is used in this node. Otherwise, no JavaClassLoader configurable service is used. All the nodes in an execution group that specify the same JavaClassLoader configurable service use the same instance of the classloader. Consequently all the nodes use the same in-memory version of the classes, including access to the same static variables. For more information, see "JavaCompute node classloading" on page 2635.

The Parser Options properties for the JavaCompute node are described in the following table.

Property	M	C	Default	Description
Use XMLNSC Compact Parser for XMLNS Domain	No	No	Cleared	Setting this property causes the outgoing MQRFH2 to specify the XMLNS instead of XMLNSC parser, allowing an external application to remain unchanged. If outgoing messages do not contain MQRFH2 headers, this property has no effect.

The Validation properties of the JavaCompute node are described in the following table.

Set the validation properties to define how the message that is produced by the JavaCompute node is validated. These properties do not cause the input message to be validated. It is expected that, if such validation is required, the validation has already been performed by the input node or a preceding validation node. For more details, see "Validating messages" on page 1478 and "Validation properties" on page 4169.

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
Validate	No	Yes	None	This property controls whether validation takes place, and what part of the message is validated. Valid values are None, Content and Value, Content, and Inherit.	validateMaster
Failure action	No	No	Exception	This property controls what happens if a validation failure occurs. You can set this property only if `Validate` is set to Content or Content and Value. Valid values are User Trace, Local Error Log, Exception, and Exception List.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

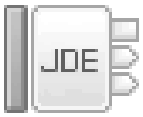
JDEdwardsInput node

Use the JDEdwardsInput node to interact with a JD Edwards EnterpriseOne server.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow"
- "Terminals and properties" on page 4520

Purpose:
Use the JDEdwardsInput node to interact with JD Edwards EnterpriseOne applications. For example, a JDEdwardsInput node monitors a JD Edwards EnterpriseOne server for a specified event. When that event occurs, the JDEdwardsInput node generates a message tree that represents the business object with the new event details. The message tree is propagated to the Out terminal so that the rest of the message flow can use the data to update other systems, or audit the changes.

The JDEdwardsInput node is contained in the **WebSphere Adapters** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:



Using this node in a message flow:
To enable function that becomes available in WebSphere Message Broker fix packs, use the **-f** parameter on the **mqsichangebroker** command. For more information, see "**mqsichangebroker** command" on page 3723.

Before you can develop message flows that use WebSphere Adapters nodes, you must add prerequisite files to the runtime environment (as described in "Adding external software dependencies for JD Edwards EnterpriseOne" on page 2090).

To function correctly, the JDEdwardsInput node needs an adapter component (see "Connecting to an EIS by using the Adapter Connection wizard" on page 2037), which you set by using the `Adapter component` node property, and business object definitions, which are stored in the message set that you reference from the node. For this reason, you must provide a message set. By default, the message that is propagated from the JDEdwardsInput node is in the DataObject domain, therefore the `Message domain` property is set to DataObject. You cannot specify a different domain. The message type is detected automatically by the node.

The JDEdwardsInput node populates the route to label destination list with the name of the method binding. If you add a RouteToLabel node to the message flow after the JDEdwardsInput node, the RouteToLabel node can use the name of the method binding to route the message to the correct part of the message flow for processing.

You can deploy only one input node that uses a particular adapter component to an execution group, but you can deploy many input nodes that use different adapter components to an execution group.

You can use the **mqsisetdbparms** command in the following format to configure an account name with a user name and password for the Adapter for JD Edwards EnterpriseOne.

```
mqsisetdbparms broker name -n adapter name -u user name -p password
```

For example:

```
mqsisetdbparms BRK1 -n eis::JDEdwardsCustomerInbound.inadapter -u jdedwardsuid -p ********
```

Using configurable services for JD Edwards nodes

JD Edwards nodes can get JD Edwards connection details from either the adapter component or a configurable service. By using a configurable service, you can change the connection details for an adapter without the need to redeploy the adapter. For more details about creating, changing, reporting, and deleting the configurable services for JD Edwards, see "Changing connection details for JD Edwards adapters" on page 724.

Terminals and properties:
When you have put an instance of the JDEdwardsInput node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. If you double-click a JDEdwardsInput node, you open the Adapter Connection wizard. All mandatory properties for which you must enter a value (those properties that do not have a default value defined) are marked with an asterisk.

The SiebelInput node terminals are described in the following table.

Terminal	Description
Out	Business object events from the adapter are sent to the Out terminal.
Failure	If an error happens in the JDEdwardsInput node, the message is propagated to the Failure terminal. Information about the error, and business object events can also be propagated to the Failure terminal.
Catch	Business object events are sent to the Catch terminal if they cause an uncaught exception in the message flow. If the Catch terminal is not connected, the retry process is activated to handle the business object.

The following table describes the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The JDEdwardsInput node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, JDEdwardsInput.	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The JDEdwardsInput node Basic properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Primary adapter component	Yes	Yes		The name of the adapter component that contains configuration properties for the adapter. Either enter a name of an adapter file or click **Browse** to select an adapter file from the list of files that are available in referenced message set projects. When theJDEdwardsInput node receives data from the JD Edwards system, it associates that data with a method name, depending on the service operation name that is assigned to that type of data when you run the Adapter Connection wizard. The JDEdwardsInput node attempts to handle methods that are defined in the primary adapter. If the type of data that is received does not correspond to any of the methods that are defined in the primary adapter, the node can handle methods that are defined in matching secondary adapters that are deployed to the same execution group.	adapterComponent
Secondary adapter mode	No	Yes	None	Specifies whether the node can handle methods that are defined in secondary adapters. If you set the `Secondary adapter mode` property to `None`, the node handles only methods that are defined in the primary adapter. If the type of data that is received does not correspond to any of the methods that are defined in the primary adapter, a failure occurs. If you set this property to `All adapters in execution group`, the node can handle methods that are defined in any JD Edwards inbound adapters that are deployed to the same execution group.	secondaryAdapterMode

The JDEdwardsInput node Routing properties are described in the following table.

Property	M	C	Default	Description
Set destination list	No	No	Selected	This property specifies whether to add the method binding name to the route to label destination list. If you select this check box, the method binding name is added so that you can use a RouteToLabel node in the message flow after the JDEdwardsInput node.
Label prefix	No	No		The prefix to add to the method name when routing to label. Add a label prefix to avoid a clash of corresponding label nodes when you include multiple WebSphere Adapters input nodes in the same message flow. By default, there is no label prefix, so the method name and label name are identical.

The JDEdwardsInput node Input Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	DataObject	The domain that is used to parse the incoming message. By default, the message that is propagated from the JDEdwardsInput node is in the DataObject domain. You cannot specify a different domain.

Property	M	C	Default	Description
Message set	Yes	No	Set automatically	The name of the message set in which the incoming message is defined. This field is set automatically from the Adapter component property. If you set this property, then subsequently update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project.
Message type	No	No		The name of the incoming message. The node detects the message type automatically. You cannot set this property.
Message format	No	No		The name of the physical format of the incoming message. You cannot set this property.

The JDEdwardsInput node Transactionality properties are described in the following table.

Property	M	C	Default	Description
Transaction mode	No	No	Yes	The transaction mode on this input node determines whether the rest of the nodes in the flow operate under sync point.

The Instances properties of the JDEdwardsInput node are described in the following table. For a full description of these properties, see "Configurable message flow properties" on page 4020.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Additional instances pool	No	Yes	`Use Pool Associated with Message Flow`	The pool from which additional instances are obtained. • If you select `Use Pool Associated with Message Flow`, additional instances are obtained from the message flow value. • If you select `Use Pool Associated with Node`, additional instances are allocated from the additional instances for the node, based on the number specified in the `Additional instances` property.	componentLevel
Additional instances	No	Yes	`0`	The number of additional instances that the node can start if the `Additional instances pool` property is set to `Use Pool Associated with Node`. By default, no additional instances are given to the node.	additionalInstances

The JDEdwardsInput node Retry properties are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Retry mechanism	No	No	Failure	This property specifies how retry processing is handled when a failure is rolled back to the JDEdwardsInput node. • If you select `Failure`, retry processing is not performed so you cannot set the remaining properties. • If you select `Short and long retry`, retry processing is performed first at the interval that is specified by the `Short retry interval` property, and if that is unsuccessful, it is then performed at the interval that is specified by the `Long retry interval` property.	

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Retry threshold	No	Yes	0	The maximum number of times that retry processing is performed for short retry.	retryThreshold
Short retry interval	No	Yes	0	The interval between short retry attempts.	shortRetryThreshold
Long retry interval	No	Yes	0	The interval between long retry attempts.	longRetryThreshold

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

"**mqsisetdbparms** command" on page 3954
Use the **mqsisetdbparms** command to associate a specific user ID and password (or SSH identity file) with one or more resources that are accessed by the broker.

"JDEdwardsRequest node"
Use the JDEdwardsRequest node to interact with a JD Edwards EnterpriseOne server.

JDEdwardsRequest node

Use the JDEdwardsRequest node to interact with a JD Edwards EnterpriseOne server.

This topic contains the following sections:

Purpose:

Use the JDEdwardsRequest node to discover JD Edwards EnterpriseOne business functions and XML lists. For example, a user might want to retrieve address details for a person where the record exists on a JD Edwards server.

The JDEdwardsRequest node can send and receive business data.

The JDEdwardsRequest node is contained in the **WebSphere Adapters** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:

To enable function that becomes available in WebSphere Message Broker fix packs, use the **-f** parameter on the **mqsichangebroker** command. For more information, see "**mqsichangebroker** command" on page 3723.

Before you can develop message flows that use WebSphere Adapters nodes, you must add prerequisite files to the runtime environment (as described in "Adding external software dependencies for JD Edwards EnterpriseOne" on page 2090).

To function correctly, the JDEdwardsRequest node needs an adapter component (see "Connecting to an EIS by using the Adapter Connection wizard" on page 2037), which you set by using the `Adapter component` node property, and business

object definitions, which are stored in the message set that you reference from the node. For this reason, you must provide a message set. By default, the message that is propagated from the JDEdwardsRequest node is in the DataObject domain, therefore the `Message domain` property is set to DataObject. You cannot specify a different domain. The message type is detected automatically by the node.

The JDEdwardsRequest node supports local transactions by using the Local Transaction Manager of the broker, and global transactions by using the external syncpoint coordinator of the broker.

To effectively maintain the pool of connections to JD Edwards, you can set a connection timeout value on a configurable service. For more information, see "Configuring EIS connections to expire after a specified time" on page 726.

You can deploy several WebSphere Adapters request nodes that use the same adapter component to an execution group.

Use the **mqsisetdbparms** command in the following format to configure an account name with a user name and password for the Adapter for JD Edwards EnterpriseOne.

```
mqsisetdbparms broker name -n adapter name -u user name -p password
```

For example:

```
mqsisetdbparms BRK1 -n eis::JDEdwardsCustomerOutbound.outadapter -u jdedwardsuid -p ********
```

Look at the following sample to see how to use this node:

- JD Edwards Connectivity

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Using configurable services for JD Edwards nodes

JD Edwards nodes can get JD Edwards connection details from either the adapter component or a configurable service. By using a configurable service, you can change the connection details for an adapter without the need to redeploy the adapter. For more details about creating, changing, reporting, and deleting the configurable services for JD Edwards, see "Changing connection details for JD Edwards adapters" on page 724.

Terminals and properties:
When you have put an instance of the JDEdwardsRequest node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. If you double-click a JDEdwardsRequest node, you open the Adapter Connection wizard. All mandatory properties for which you must enter a value (those properties that do not have a default value defined) are marked with an asterisk.

The JDEdwardsRequest node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the JDEdwardsRequest node. The JDEdwardsRequest node is driven by a message arriving on the In terminal.

Terminal	Description
Out	The output terminal from which the message tree is propagated.
Failure	If an error happens in the JDEdwardsRequest node, the message is propagated to the Failure terminal.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk on the panel if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The JDEdwardsRequest node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, for example, JDEdwardsRequest	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The JDEdwardsRequest node Basic properties are described in the following table.

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
Primary adapter component	Yes	No		The name of the adapter component that contains configuration properties for the adapter. Either enter a name of an adapter file, or click **Browse** to select an adapter file from the list of files that are available in referenced message set projects. When theJDEdwardsRequest node receives data from the JD Edwards system, it associates that data with a method name. The JDEdwardsRequest node attempts to call methods that are defined in the primary adapter. If the method is not defined in the primary adapter, the node can call methods that are defined in matching secondary adapters that are deployed to the same execution group.	
Secondary adapter mode	No	Yes	None	Specifies whether the node can call methods that are defined in secondary adapters. If you set the `Secondary adapter mode` property to `None`, the JDEdwardsRequest node calls only methods that are defined in the primary adapter. If the method is not defined in the primary adapter, an error occurs. If you set this property to `All adapters in execution group`, the node can call methods that are defined in any JD Edwards outbound adapter that is deployed to the same execution group. For more information, see "Calling new services from a WebSphere Adapters request node without changing existing deployed resources" on page 2042.	secondaryAdapterMode

Property	M	C	Default	Description	mqsiapplybaroverride command property
Default method	Yes	Yes		The default method binding to use. This property lists the methods that are defined by the adapter. You can override this property by setting the method name in the LocalEnvironment.Adapter subtree. For more information, see "Local environment tree structure" on page 1056. The method names correspond to the Service Operation names, which are configured by the Adapter Connection wizard. In most cases, the names are based on the name of the service that is being discovered.	defaultMethod

The JDEdwardsRequest node Response Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	DataObject	The domain that is used to parse the response message. By default, the response message that is propagated from the JDEdwardsRequest node is in the DataObject domain. You cannot specify a different domain.
Message set	No	No	Set automatically	The name of the message set in which the incoming message is defined. This field is set automatically from the Adapter component property. If you set this property, then subsequently update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project.
Message type	No	No		The name of the response message. The node detects the message type automatically. You cannot set this property.
Message format	No	No		The name of the physical format of the response message. You cannot set this property.

The JDEdwardsRequest node Transactionality properties are described in the following table.

Property	M	C	Default	Description
Transaction mode	No	No	No	This property specifies that updates are performed independently, not as part of a local transaction. You cannot change this property.

The JDEdwardsRequest node Request properties are described in the following table.

Property	M	C	Default	Description
Method Location	Yes	No	$LocalEnvironment/ Adapter/MethodName	The location of the business function or XML list method that is used to trigger the JDEdwardsRequest node to perform an action on the external system.
Data Location	Yes	No	$Body	The location in the incoming message tree from which data is retrieved to form the request that is sent from the JDEdwardsRequest node to the EIS. The default value, `$Body`, represents the incoming message body. You can enter any XPath or ESQL expression that defines the location of the message tree to serialize and send.

The JDEdwardsRequest node Result properties are described in the following table.

Property	M	C	Default	Description
Output data location	No	No	$OutputRoot	The message tree location to which the JDEdwardsRequest node sends output. The default value, `$OutputRoot`, replaces the incoming message with the response.
Copy local environment	No	No	Selected	This property controls whether to copy the incoming local environment or propagate the incoming local environment. By default, this check box is selected, which signifies that the local environment is copied so that the incoming local environment is preserved. The additions to the local environment are visible only to nodes downstream of this node. If this check box is cleared, the incoming local environment is used for the outgoing message. Any modifications that are made to the local environment by this node are visible to both downstream and upstream nodes after this node has completed.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Use the **mqsisetdbparms** command to associate a specific user ID and password (or SSH identity file) with one or more resources that are accessed by the broker.

JMSHeader node

Use the JMSHeader node to modify contents of the JMS Header_Values and Application properties so that you can control the node's output without programming.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow"
- "Terminals and properties" on page 4530

Purpose:
Use the node to control the output from a JMSOutput node. A subset of common values can be changed in the JMS Header, and user-chosen properties can be added, changed, or deleted for the Application properties.

For JMS Header_Values properties, the node provides a set of fields that you can modify using predefined values, user-defined values, or XPath expressions. XPath is used to provide a valid location from which a value for a property can be copied. For example, the location can be the body of the message, the local environment tree, or an exception list.

For JMS Application properties, the node provides a way to add, modify, and delete name-value pairs of application properties.

The JMSHeader node is contained in the **JMS** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:

Look at the following sample for more details about how to use the node:

- JMSHeader node

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
When you have put an instance of the node into a message flow, you can configure it; see . This node has no mandatory properties.

JMSHeader node terminals are described in the following table:

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the input message is routed if a failure is detected during extraction.
Out	The output terminal to which the transformed message is routed if the input message is processed successfully.

The following tables describes the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The JMSHeader node Description properties are described in the following table:

Property	M	C	Default	Description
Node name	No	No	JMSHeader	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The JMSHeader node JMS transport header options are described in the following table:

Property	M	C	Default	Description
JMS header options	No	Yes	Carry forward header	Options to control the JMSTransport header as a whole. Select **Carry forward header** to carry forward any values that are present in an incoming message. Select **Add header** to add a new header using the specified property values. If a header already exists, the header is modified using the specified property values. If *Inherit from header* is specified as a property value and the header does not exist, the default value for the property is used. Select **Modify header** to change an existing header using the specified property values. If a header does not exist, a new header is added first. If *Inherit from header* is specified as a property value and the header does not exist, the default value for the property is used. Select **Delete header** to delete the header, if it exists. **Note:** The **Add header** and **Modify header** options both add a header if it does not exist, and change a header if it does exist. However, the default values offered by each option differ, so use the appropriate option.

The JMSHeader node JMSHeader_Value properties are described in the following table:

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
JMS Delivery Mode	No	Yes	Non _Persistent	Filter messages by message delivery mode: • Non_Persistent • Persistent	
JMS Message Expiration(ms)	No	Yes	0	Ask the JMS provider to keep the output JMS message for a specified time. Values are in milliseconds; the default value 0 means that the message should not expire.	
JMS Message Priority	No	Yes	4	Assign relative importance to the message. A receiving JMS client application or a JMSOutput node can use this value. JMS defines a ten-level priority value, with 0 as the lowest priority and 9 as the highest.	
JMS Correlation Identifier	No	Yes	No default value	A client can use the JMS Correlation Identifier header field to link one message with another. A typical use is to link a response message with its request message.	
JMS Reply To	No	Yes	No default value	The JMS Reply To header field contains a destination supplied by a client when a message is sent. It is the destination where a reply message should be sent to.	jmsReplyTo

The JMSHeader node Application properties are described in the following table:

Property	M	C	Default	Description
Application Properties	No	Yes		This screen is enabled only if you chose **Add header** or **Modify header** for JMS Transport header. The screen has no predefined properties; you use it to create custom properties and values. Use the property table to add new properties, or modify or delete existing properties, for the header. There is no limit to the number of properties. Each property must have a name, and a type qualifier. The type qualifier can be `Value`, `XPath`, or `Delete`. **Value** Enter a new valid value for the selected property. A null value or empty string is also considered as a valid value. **XPath** Specify a valid XPath expression. WebSphere Message Broker supports XPath definitions that start with an XPath variable such as `$Root` or `$LocalEnvironment`. Only the first occurrence is returned if there are multiple values for the XPath expression. (Examples of valid XPath expressions are: $LocalEnvironment/Host, and $Root/HTTPRequest/Content-Type). **Delete** Specify the property to be deleted from the incoming message. The value associated with the selected property is also deleted.
Clear incoming values	No	Yes	Cleared	This option, which is is enabled only if you choose **Modify header**, removes all property names and associated values from the incoming message if present.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related tasks:

"Accessing headers" on page 2453
If the input message received by an input node includes message headers that are recognized by the input node, the node invokes the correct parser for each header. You can access these headers using ESQL.

"JMSOutput node" on page 4549
Use the JMSOutput node to send messages to JMS destinations.

JMSInput node

Use the JMSInput node to receive messages from JMS destinations. JMS destinations are accessed through a connection to a JMS provider.

This topic contains the following sections:

Purpose:
The JMSInput node acts as a JMS message consumer and can receive all six message types that are defined in the Java Message Service Specification, version 1.1. Messages are received by using method calls, which are described in the JMS specification.

The JMSInput node is contained in the **JMS** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using the JMSInput node in a message flow:
The following sample contains a message flow in which the JMSInput node is used. This sample is an example of how to use the JMSInput node.

- JMS Nodes

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

The JMSInput node receives and propagates messages with a JMS message tree. You can set the properties of the JMSInput node to control the way in which the JMS messages are received.

The JMSInput node handles messages in the following message domains:
- XMLNSC
- DataObject
- JSON
- BLOB
- MIME
- MRM
- JMSMap
- JMSStream
- XMLNS

Message flows that handle messages that are received from connections to JMS providers must always start with a JMSInput node. If you include an output node in a message flow that starts with a JMSInput node, it can be any of the supported output nodes (including user-defined output nodes); you do not have to include a JMSOutput node. However, if you do not include a JMSOutput node, you must include the JMSMQTransform node to transform the message to the format that is expected by the output node.

If you are propagating JMS messages and creating a message flow to use as a subflow, you cannot use a standard input node; you must use an instance of the JMSInput node as the first node in order to create an In terminal for the subflow.

Restriction: When the JMSInput node receives publication topics, it internally restricts the message flow property Additional Instances to zero to prevent the receipt of duplicate publications.

Making the JMS provider client available to the JMS nodes:
Configurable services are defined for a number of JMS providers. You can choose one of the predefined services, or you can create a service for a new provider, or for one of the existing providers. The predefined services are listed in "Configurable services properties" on page 3766.

- If you want to use the WebSphere MQ JMS provider, and you have installed WebSphere MQ in the default location on the broker system, the properties are already set and you do not have to change them.
- If you want to use the WebSphere MQ JMS provider, and you have installed WebSphere MQ in a different (nondefault) location, or if you want to use one of the other defined services, you must set the `jarsURL` property to identify the location of the service JAR files on the broker system. On Windows, the file location cannot be a mapped network drive on a remote Windows computer; the directory must be local or on a storage area network (SAN) disk.

  Use the **mqsireportproperties** command to view the provider properties, and the **mqsichangeproperties** command to set or modify the properties.
- If no service is defined for your JMS provider, or if you want to create another service for an existing JMS provider, use the **mqsicreateconfigurableservice** command to identify the new service and to set its properties.
- When you configure the node, select the appropriate service from the list of predefined services shown for the JMS provider name property, or type in the name of your required service.
- Some JMS providers provide an alternative interface to the standard JMS specification for particular JMS API calls. In these cases, IBM supplies a Java class to interface with that proprietary API. For example, if the JMS nodes use BEA WebLogic as the JMS provider, and the nodes have to participate in a globally coordinated message flow, you must modify the configurable services properties that are associated with that vendor. For more information, see "Configuring the broker to enable a JMS provider's proprietary API" on page 748.
- Some JMS providers, such as the BEA WebLogic provider, do not update the optional JMSXDeliveryCount field in the JMS message header; therefore, JMSInput node backout processing is not possible. To cope with any failures in the message flow, connect the Failure terminal of the JMSInput node.
- To connect to different versions of a JMS provider, create a JMSProviders configurable service for each version of the JMS provider, then set the **jarsURL** property to a unique path.

Connecting the terminals:
For each message that is received successfully, the JMSInput node routes the message to the Out terminal. If this action fails, the message is retried. If the retry threshold is reached, where the threshold is defined by the `Backout threshold` property of the node, the message is routed to the Failure terminal. You can connect nodes to the Failure terminal to handle this condition.

If an exception occurs in the failure path, the path is tried again until the number of attempts is twice the `Backout threshold`. If that limit is exceeded, the message is put to the `Backout destination`.

If you have not connected nodes to the Failure terminal, the message is written to the `Backout destination`. If you have not specified a `Backout destination`, the node issues a BIP4669 error message and stops processing further input.

If processing is not resumed after you restart the broker or execution group, check the Deployment Log for a cause, such as an incorrect parser being specified in the node properties. Correct the problem and redeploy the message flow. If the message itself is not valid, remove the message from the input queue to resume processing.

If the message is caught by the JMSInput node after an exception has been generated elsewhere in the message flow, the message is routed to the Catch terminal. If you have not connected nodes to the Catch terminal, the node backs out messages for redelivery until the problem is resolved, or the `Backout threshold` is reached. If you do not define a `Backout destination`, the node issues a BIP4669 error message and stops processing further input.

Configuring for coordinated transactions:
When you include a JMSInput node in a message flow, the value that you set for `Transaction mode` defines whether messages are received under sync point. See "Configuring for coordinated JMS transactions" on page 4544.

Configuring for batch acknowledgment:
You can configure the JMSInput node to send a batch acknowledgment for receipt of non-transactional JMS messages. See "Configuring the JMSInput node for batch message processing" on page 751.

Terminals and properties:
When you have put an instance of the JMSInput node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties that do not have a default value defined are marked with an asterisk.

The terminals of the JMSInput node are described in the following table.

Terminal	Description
Failure	The output terminal to which the message is routed if an error occurs. Even if the Validation property is set, messages that are propagated to this terminal are not validated.
Out	The output terminal to which the message is routed if it is retrieved successfully.
Catch	The output terminal to which the message is routed if an exception is generated downstream and caught by this node.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the JMSInput node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, JMSInput	The name of the node.

Property	M	C	Default	Description
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the JMSInput node are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Source queue	No	Yes	Selected	The name of the queue from which the node receives incoming messages. If the node is to read from a queue (point-to-point), select `Source queue` and enter the name of the source queue, which is the JMS queue that is listed in the bindings file. This property is mutually exclusive with `Subscription topic`.	sourceQueueName
Subscription topic	No	Yes	Cleared	The name of the topic to which the node is subscribed. If the node is to read from a `Subscription topic` (publish/subscribe), select `Subscription topic` and enter the name of the subscription topic. • If you select `Subscription topic`, the node operates in the publish/subscribe message domain only. • This property is mutually exclusive with `Source queue`. • The `Subscription topic` name must conform to the standards of the JMS provider that is being used by the node.	topic
Durable subscription ID	No	Yes		The identifier for a durable subscription topic. If the node is to receive publications from a durable subscription topic, enter a `Durable subscription ID`. • Removing a durable subscription is a separate administration task. For information about removing a durable subscription see the JMS provider documentation. • This property is valid only when a `Subscription topic` string has been specified.	durableSubscriptionID

The JMS Connection properties of the JMSInput node are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
JMS provider name	Yes	No	`WebSphere MQ`	Select a JMS vendor name from the list, or enter a name of your choice. When you select a name from the list, the `Initial context factory` property is updated automatically with the relevant Java class. If you enter your own JMS provider name, you must also enter a value for the `Initial context factory` The name must match the name of a configurable service that is defined for the broker to which you deploy the message flow.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Initial context factory	Yes	Yes	com.sun.jndi.fscontext.RefFSContextFactory	The starting point for a JNDI namespace. A JMS application uses the initial context to obtain and look up the connection factory and queue or topic objects for the JMS provider. If you select a JMS provider name from the list in JMS provider name, the Initial context factory property is updated automatically with the relevant Java class. If you enter your own JMS provider name, you must also enter a value for the Initial context factory. The default value is com.sun.jndi.fscontext.RefFSContextFactory, which defines the file-based Initial context factory for the WebSphere MQ JMS provider. If the node is set to use your own JMS Provider, and the corresponding Configurable services property of the **mqsichangeproperties** definition has the InitialContextFactory attribute set, this attribute overrides the setting on the node.	initialContextFactory
Location JNDI bindings	Yes	Yes		The system path or the LDAP location for the bindings file. The bindings file contains definitions for the JNDI administered objects that are used by the JMSInput node. When you enter a value for Location JNDI bindings, ensure that it complies with the following instructions: • Construct the bindings file before you deploy a message flow that contains a JMSInput node. • Do not include the file name of the bindings file in this field. • If you have specified an LDAP location that requires authentication, configure the LDAP principal (user ID) and LDAP credentials (password) separately. These values are configured at broker level. For information about configuring these values, see "**mqsicreatebroker** command" on page 3831 and "**mqsichangebroker** command" on page 3723. • The string value must include a supported URL prefix that has a URL handler that is available on the class path. For information about constructing the JNDI administered objects bindings file, see the JMS provider documentation. If the node is set to use your own JMS Provider, and the corresponding Configurable services property of the **mqsichangeproperties** definition has the jndiBindingsLocation attribute set, this attribute overrides the setting on the node.	locationJndiBindings

Property	M	C	Default	Description	mqsiapplybaroverride command property
Connection factory name	Yes	Yes		The name of the connection factory that is used by the JMSInput node to create a connection to the JMS provider. This name must exist in the bindings file. The `Connection factory name` can be a JMS QueueConnectionFactory or a JMS TopicConnectionFactory, but it must match the message model that is used by the node. You can also specify the generic JMS ConnectionFactory, which can be used for both JMS queue or JMS topic destinations.	connectionFactoryName
Backout destination	No	Yes		The JMSInput node sends input messages to this destination when errors prevent the message flow from processing the message, and the message must be removed from the input destination. The backout destination name must exist in the bindings file.	backoutDestination
Backout threshold	No	Yes	0	The value that controls when a redelivered message is put to the backout destination. For example, if the value is 3, the JMS provider attempts to deliver the message to the input destination three times. After the third attempted delivery, the message is removed from the input destination and is sent to the `Backout destination`. See "Configuring the backout threshold property" on page 4544.	

The JMSInput node Input Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No		The domain that is used to parse the incoming message. • XMLNSC • DataObject • JSON • BLOB • MIME • MRM • JMSMap • JMSStream • XMLNS You can also specify a user-defined parser, if appropriate. The `Message domain` that is set on the node takes precedence except when the `Message domain` is set to blank on the node property. If `Message domain` is left blank, the JMSInput node determines the message domain in one of two ways: • By checking for the presence of data in the JMSType header value of the JMS input message • Based upon the Java Class of the JMS message For more information, see "JMS message payload and appropriate parser" on page 1698.

Property	M	C	Default	Description
Message set	No	No		The name or identifier of the message set in which the incoming message is defined. If you are using the MRM parser or the XMLNSC parser in validating mode, select the `Message set` that you want to use. This list is populated with available message sets when you select MRM or XMLNSC as the `Message domain`. If you set this property, then later update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project.
Message type	No	No		The name of the incoming message. If you are using the MRM parser, select the message that you want from the list in `Message type`. This list is populated with messages that are defined in the `Message set` that you have selected.
Message format	No	No		The name of the physical format of the incoming message. If you are using the MRM parser, select the format of the message from the list in `Message format`. This list includes all of the physical formats that you have defined for this `Message set`.

The properties of the Parser Options for the JMSInput node are described in the following table.

Property	M	C	Default	Description
Parse timing	No	No	`On Demand`	This property controls when an input message is parsed. Valid values are: • `On Demand` • `Immediate` • `Complete` `Parse timing` is, by default, set to `On Demand`, which causes parsing of the message to be delayed. To cause the message to be parsed immediately, see "Parsing on demand" on page 4173.
Build tree using XML schema data types	No	No	Cleared	This property controls whether the XMLNSC parser creates syntax elements in the message tree with data types taken from the XML schema. For more information about how the XMLNSC parser operates, see "Manipulating messages in the XMLNSC domain" on page 2546.
Use XMLNSC compact parser for XMLNS domain	No	No	Cleared	This property controls whether the XMLNSC Compact Parser is used for messages in the XMLNS Domain. If you set this property, the message data is displayed under XMLNSC in nodes that are connected to the output terminal when the input MQRFH2 header or Input Message Parsing properties `Message domain` is XMLNS.
Retain mixed content	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in an input message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in an input message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in an input message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.

Property	M	C	Default	Description
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the input message that are to be opaquely parsed by the XMLNSC parser. Opaque parsing is performed only if validation is not enabled (that is, if `Validate` is `None`); entries that are specified in `Opaque Elements` are ignored if validation is enabled.

The Message Selectors properties of the JMSInput node are described in the following table. Set these properties to filter messages. For a description of how to construct the JMS message selector, see JMS message selector.

Property	M	C	Default	Description
Application property	No	No		The message selector that filters messages according to the application property value. If the JMS provider is required to filter messages, based on message properties that are set by the originating JMS client application, enter a selector string for `Application property`, specifying both the property name and the selection conditions; for example, `OrderValue > 200`. Leave `Application property` blank if you do not want the input node to make a selection based on application property.
Timestamp	No	No		The message selector that filters messages according to the JMSTimestamp. If the JMS provider is required to filter messages that have been generated at specific times, enter a selector string for `Timestamp`, where the value is an unqualified Java millisecond time; for example, `105757642321`. Qualify the selector with operators, such as `=`, `BETWEEN` or `AND`. Leave `Timestamp` blank if you do not want the input node to make a selection based on the JMSTimeStamp.
Delivery mode	No	No	`All`	The message selector that filters messages according to the message delivery mode. If the JMS provider is required to filter messages based on the JMSDeliveryMode header value in the JMS messages, select an option for `Delivery mode` from the list: • Select `Non Persistent` to receive messages that are marked as nonpersistent by the originating JMS client application. • Select `Persistent` to receive messages that are marked as persistent by the originating JMS client application. • Select `All` to receive both persistent and nonpersistent messages. (This value is the default.)
Priority	No	No		The message selector that filters messages according to the message priority. If the JMS provider is required to filter messages based on the JMSPriority header value in the JMS message, enter a selector string for `Priority`. Valid values for `Priority` are from `0` (lowest) to `9` (highest). For example, enter `= 5` to receive messages of priority 5, `> 4` to receive messages with a priority greater than 4, or `BETWEEN 4 AND 8` to receive messages with a priority in the range 4 - 8. Leave `Priority` blank if you do not want the input node to make a selection based on the JMSPriority.

Property	M	C	Default	Description
Message ID	No	No		The message selector that filters messages according to the message ID. If the JMS provider is required to filter messages based on the JMSMessageID header, enter a selector string for `Message ID`. For example, enter `> WMBRK123456` to return messages where the `Message ID` is greater than `WMBRK123456`. Leave `Message ID` blank if you do not want the input node to make a selection based on JMSMessageID.
Redelivered	No	No		If the JMS provider is required to filter messages based on the JMSRedelivered header, enter a selector string for `Redelivered`: • Enter `= FALSE` if the input node accepts only messages that have not been redelivered by the JMS provider. • Enter `= TRUE` if the input node accepts only messages that have been redelivered by the JMS provider. • Leave `Redelivered` blank if you do not want the input node to make a selection based on JMSRedelivered.
Correlation ID	No	No		The message selector that filters messages according to the correlation ID. If the JMS provider is required to filter messages based on the JMSCorrelationID header, enter a selector string for `Correlation ID`. For example, `= WMBRKABCDEFG` returns messages with a `Correlation ID` that matches this value. Leave `Correlation ID` blank if you do not want the input node to make a selection based on JMSCorrelationID.

The Advanced properties of the JMSInput node are described in the following table.

Property	M	C	Default	Description
Transaction mode	Yes	No	`None`	This property controls whether the incoming message is received under external sync point, local sync point, or out of sync point. • Select `None` if the incoming message is to be treated as nonpersistent. If you select this value, the message is received using a non-transacted JMS session that is created using the `Session.AUTO_ACKNOWLEDGE` flag. • Select `Local` if the JMSInput node must coordinate the commit or roll back of JMS messages that are received by the node, along with any other resources such as DB2 or WebSphere MQ that perform work within the message flow. If you select this value, the node uses a transacted JMS session. • Select `Global` if the JMSInput node must participate in a global message flow transaction that is managed by the external sync point coordinator of the Broker. The sync point coordinator is the queue manager of the Broker on distributed systems and RRS (Resource Recovery Services) on z/OS. If you select this value, any messages that are received by the node are globally coordinated using an XA JMS session.

The Validation properties of the JMSInput node are described in the following table. For more details, see “Validating messages” on page 1478 and “Validation properties” on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	Yes	None	This property controls whether validation takes place. Valid values are: • None • Content and Value • Content If you select Content or Content and Value, select an option from the Failure action list.	validateMaster
Failure action	No	No	Exception	This property controls what happens if validation fails. You can set this property only if you set Validate to Content or Content and Value. Valid values are: • User Trace • Local Error Log • Exception (The default value) • Exception List	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Use the MQJMSTransform node to receive messages that have a WebSphere MQ JMS provider message tree format, and transform them into a format that is compatible with messages that are to be sent to JMS destinations.

"Configurable services properties" on page 3766
The supplied configurable services, and the configurable services that you create, are defined by their names and properties. You can use the supplied services.

Related information:

WebSphere MQ Version 7 Information Center online

Configuring the backout threshold property:

You can set the backout threshold property on nodes that use JMS transport to specify how many attempts are made to deliver the message to the input destination.

If the Backout threshold is set to `0` then redelivery is not attempted. If the Backout threshold is 1 or greater, the message will be redelivered the specified number of times.

Set the value of Backout threshold depending on the capabilities of the JMS provider.

If the JMS provider supports `JMSXDeliveryCount`, you can set the Backout threshold to any value.

If the JMS provider does not support `JMSXDeliveryCount`, the Backout threshold must only be set to 0 or 1. If the JMS provider does not support `JMSXDeliveryCount` and the value is set to greater than 1, a redelivered message is repeatedly backed out and reprocessed, and is never delivered to the backout destination.

Related reference:

"JMSInput node" on page 4532
Use the JMSInput node to receive messages from JMS destinations. JMS destinations are accessed through a connection to a JMS provider.

"SOAPInput node" on page 4795
Use the SOAPInput node to process client SOAP messages, so that the broker operates as a SOAP Web Services provider.

"SOAPAsyncRequest node" on page 4750
Use the SOAPAsyncRequest node with the SOAPAsyncResponse node to construct a pair of message flows that call a Web service asynchronously.

Configuring for coordinated JMS transactions:

Configure your message flow to receive or output messages under coordinated transactions.

When you include a node using JMS transport in a message flow, such as the JMSInput or SOAPInput node when using JMS transport, the value that you set for `Transaction mode` defines whether messages are received under sync point.

- If you set this property to `Global`, the message is received under external sync point coordination; that is, within a WebSphere MQ unit of work. Any messages that are sent later, by an output node in the same instance of the message flow, are put under sync point, unless the output node overrides this setting explicitly.
- If you set this property to `Local`, the message is received under the local sync point control of the node. Any messages that are sent later, by an output node in the flow, are not put under local sync point, unless an individual output node specifies that the message must be put under local sync point.
- If you set this property to `None`, the message is not received under sync point. Any messages that are sent later, by an output node in the flow, are not put under sync point, unless an individual output node specifies that the message must be put under sync point.

To receive messages under external sync point, you must take additional configuration steps, which need be applied only the first time that a specific node using JMS transport is deployed to the broker for a particular JMS provider.

- On distributed systems, the external sync point coordinator for the broker is WebSphere MQ. Before you deploy a message flow in which the `Transaction mode` property is set to `Global` or `Yes`, and is intended to use globally coordinated transactions, modify the queue manager `.ini` file to include extra definitions for each JMS provider resource manager that participates in globally coordinated transactions.
  - Windows On Windows:
    1. Start WebSphere MQ Explorer.
    2. Right-click the queue manager name in the left pane and click **Properties**.
    3. Click **XA resource managers** in the left pane.
    4. Click **Add...** .
    5. Set the options as follows:
       - Set `Name` to any value.
       - On Windows on x86 systems, set the `SwitchFile` property to *`install_dir`*`\bin\JMSSwitch.dll`. On Windows on x86-64 systems, set the `SwitchFile` property to `JMSSwitch.dll`.
       - Set the `XAOpenString` property to a string value as follows: *`Initial Context`*`,`*`location JNDI`*`,`*`Optional_parms`*.
       - Set the `ThreadOfControl` property to `Thread`.
    6. On Windows on x86-64 systems only, copy the switch file *JMSSwitch32.dll* to the `\exits` subdirectory in the WebSphere MQ installation directory, and rename it to `JMSSwitch.dll`. Copy the switch file `JMSSwitch.dll` to the `\exits64` subdirectory in the WebSphere MQ installation directory.

    For more information, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.
  - Linux UNIX On Linux and UNIX systems, add a stanza to the queue manager `.ini` file for each JMS provider.

    For example:

    ```
    XAResourceManager:
    Name=Jms_Provider_Name
    SwitchFile=/install_dir/bin/ JMSSwitch.so
    XAOpenString=Initial Context,location JNDI,Optional_parms
    ThreadOfControl=THREAD
    ```

    Where:

    Name is an installation defined name that identifies a JMS provider resource manager.

    SwitchFile
    is the file system path to the JMSSwitch library that is supplied in the `bin` directory of the broker.

  XAOpenString can have the following values:
  - *Initial Context* is the value that is set in the JMSInput node property `Initial context factory`.
  - *location JNDI* is the value that is set in the JMSInput node property `Location JNDI bindings`. This value must include a supported URL prefix that has a URL handler that is available on the class path.

  The following parameters are optional:

– `LDAP Principal` matches the value that is set for the broker by using the **mqsicreatebroker** or **mqsichangebroker** commands.
– `LDAP Credentials` matches the value that is set for the broker by using the **mqsicreatebroker** or **mqsichangebroker** commands.
– `Recovery Connection Factory Name` is the JNDI administered connection factory that is defined in the bindings file. If a value is not specified, you must add a default value for `recoverXAQCF` to the bindings file. In either case, the Recovery Connection Factory must be defined as an XA Queue Connection Factory for the JMS provider that is associated with the `Initial context factory`.

The optional parameters are comma-separated and are positional. Therefore, any parameters that are missing must be represented by a comma. For example:

```
com.sun.jndi.fscontext.RefFSContextFactory,file:/C:/webservices/SOAP/JMS/JNDIXA,,,QCF
```

1. Update the Java CLASSPATH environment variable for the queue manager of the broker to include a reference to `xarecovery.jar`; for example:

   install_dir`/classes/xarecovery.jar`

2. Update the Java PATH environment variable for the queue manager of the broker to point to the bin directory in which the SwitchFile is located; for example:

   install_dir`/bin`

Finally, ensure that you have taken the following configuration steps:

– In the message flow, ensure that the coordinated property is enabled by using the WebSphere Message Broker Archive editor.
– Ensure that each node that must be part of the XA transaction is set to the global transaction mode.
– Ensure that the service ID that is used for the broker and the queue manager is the same user ID.
– Ensure that the JNDI connection factory objects that the JMS nodes use for a global transaction are configured to be of the type MQXAConnectionFactory, MQXAQueueConnectionFactory, or MQXATopicConnectionFactory.
  - If you create the bindings using WebSphere Message Broker Explorer, ensure the `Support XA Transactions` option is checked when you define your connection factory.
  - If you create the bindings using JMSAdmin, use the command **DEF XAQCF** or **DEF XATCF**, instead of **DEF QCF** or **DEF TCF**, when you define your connection factory.

For more information, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

- z/OS On z/OS, the external sync point manager is Resource Recovery Services (RRS). The only JMS provider that is supported on z/OS is WebSphere MQ JMS. The only transport option that is supported for WebSphere MQ JMS on z/OS is the bind option.

  Sync point control for the JMS provider is managed with RRS sync point coordination of the queue manager of the broker. You do not have to modify the `.ini` file.

JMSMQTransform node

Use the JMSMQTransform node to transform a message with a JMS message tree into a message that has a message tree structure that is compatible with the format of messages that are produced by the WebSphere MQ JMS provider.

This topic contains the following sections:
- "Purpose"
- "Using the JMSMQTransform node in a message flow"
- "Terminals and properties"

Purpose:
You can use the JMSMQTransform node to send messages to existing message flows and to work with WebSphere MQ JMS and WebSphere Message Broker publish/subscribe.

The JMSMQTransform node handles messages in all supported message domains.

The JMSMQTransform node is contained in the **JMS** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using the JMSMQTransform node in a message flow:
The following sample contains a message flow in which the JMSMQTransform node is used. Look at this sample for an example of how to use the JMSMQTransform node.
- JMS Nodes

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
When you have put an instance of the JMSMQTransform node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

The terminals of the JMSMQTransform node are described in the following table.

Terminal	Description
Failure	The output terminal to which the message is routed if an error occurs. Even if the Validation property is set, messages that are propagated to this terminal are not validated.
Out	The output terminal to which the message is routed if it is successfully retrieved from the JMS destination.
In	The input terminal that accepts a message for processing by the node.

The following table describes the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The JMSMQTransform node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, JMSMQTransform	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Use the MQJMSTransform node to receive messages that have a WebSphere MQ JMS provider message tree format, and transform them into a format that is compatible with messages that are to be sent to JMS destinations.

JMSOutput node

Use the JMSOutput node to send messages to JMS destinations.

This topic contains the following sections:

Purpose:

The JMSOutput node acts as a JMS message producer, and can publish all six message types that are defined in the Java Message Service Specification, version 1.1. Messages are published by using method calls, which are described in the JMS specification.

The JMSOutput node is contained in the **JMS** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using the JMSOutput node in a message flow:

The following sample contains a message flow in which the JMSOutput node is used. Look at this sample for an example of how to use the JMSOutput node.

- JMS Nodes

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Message flows that handle messages that are received from connections to JMS providers must always start with a JMSInput node. If you include the JMSOutput node in a message flow, you do not need to include a JMSInput node; but if you do not include a JMSInput node, you must include the MQJMSTransform node to transform the message to the format that is expected by the JMSOutput node.

If you are propagating JMS messages and creating a message flow to use as a subflow, use an instance of the JMSOutput node as the last node to create an out terminal for the subflow.

Controlling the type of the JMS output message:

In the JMS message tree, the JMS message type is represented by the PayloadType field of the Message_MetaData subfolder. To control the type of JMS message that is created by the JMSOutput node, use ESQL code to set the Payload value, as shown in the following example:

```
SET OutputRoot.JMSTransport.Transport_Folders.Message_MetaData.PayloadType=Payload value
```

For more information about the JMS message tree and payload values, see "Representation of messages in the JMS Transport" on page 1691.

Sending a JMS message to a destination list:
To send a JMS message to a destination list, ensure that the following conditions are met.

- Select `Send to destination list in local environment` on the **Basic** properties tab of the JMSOutput node.
- Set up the list in the local environment, as shown in the following example.

```
CREATE PROCEDURE CreateJMSDestinationList() BEGIN
  SET OutputLocalEnvironment.Destination.JMSDestinationList.DestinationData[1]  = 'jndi://TestDestQueue1';
  SET OutputLocalEnvironment.Destination.JMSDestinationList.DestinationData[2]  = 'jndi://TestDestQueue2';
  SET OutputLocalEnvironment.Destination.JMSDestinationList.DestinationData[3]  = 'jndi://TestDestQueue3';
END;
```

- Ensure that the message model (point-to-point or publish/subscribe) matches the model that is used by the JMSOutput node. In this case, the model is point-to-point.
- If the destination name in the list is prefixed with the string "jndi://", it indicates to the JMSOutput node that the value represents the name of a JNDI administered object, which needs to be looked up. Alternatively, if the JMS provider-specific format for a destination is known, it can be used; for example, `queue://qmgrname/queuename` for WebSphere MQ. Otherwise, the value is used to create a temporary destination.
- The items to which the JMS destination list refers represent JMS destinations that can be either JMS queues or JMS topics. These destination types must be consistent with the connection factory type that is specified in the JMSOutput node that will process the destination list. For example, a JMS queue destination can be processed by a JMS queue connection factory or a generic JMS connection factory. Similarly, a JMS topic destination can be processed by a JMS topic connection factory or a generic JMS connection factory.

For further information about using local environment variables in a JMSOutput node, see "Using LocalEnvironment variables with JMSOutput and JMSReply nodes" on page 4242.

Making the JMS provider client available to the JMS nodes:
Configurable services are defined for a number of JMS providers. You can choose one of the predefined services, or you can create a new service for a new provider, or for one of the existing providers. The predefined services are listed in "Configurable services properties" on page 3766.

- If you want to use the WebSphere MQ JMS provider, and you have installed WebSphere MQ in the default location on the broker system, the properties are already set and you do not have to make any changes.
- If you want to use the WebSphere MQ JMS provider, and you have installed WebSphere MQ in a different (non-default) location, or if you want to use one of the other defined services, you must set the `jarsURL` property to identify the location of the service JAR files on the broker system. On Windows, the file location cannot be a mapped network drive on a remote Windows computer; the directory must be local or on a Storage Area Network (SAN) disk.

  Use the **mqsireportproperties** command to view the provider properties, and the **mqsichangeproperties** command to set or modify the properties.
- If no service is defined for your JMS provider, or if you want to create another service for an existing JMS provider, use the **mqsicreateconfigurableservice** command to identify the new service and set its properties.

- When you configure the node, select the appropriate service from the list of predefined services shown for the `JMS provider name` property, or type in the name of your new service.
- Some JMS providers provide an alternative interface from the standard JMS specification for particular JMS API calls. In these cases, IBM supplies a Java JAR file to interface with that proprietary API. For example, if the JMS nodes use BEA WebLogic as the JMS provider, and the nodes need to participate in a globally coordinated message flow, you must modify the configurable services properties that are associated with that vendor. For more information, see "Configuring the broker to enable a JMS provider's proprietary API" on page 748.
- To connect to different versions of a JMS provider, create a JMSProviders configurable service for each version of the JMS provider, then set the **`jarsURL`** property to a unique path.

Using the Message Destination Mode:
The JMSOutput node acts as a message producer and supports the following message scenarios:

- "Sending a datagram message"
- "Sending a reply message"
- "Sending a request message" on page 4552

For more information about how to build JMS destination lists, see "Populating Destination in the local environment tree" on page 2467.

Sending a datagram message

A *datagram* is a self-contained, independent entity of data that carries sufficient information to be routed from the source to the destination computer, without reliance on earlier exchanges between the source and destination computer and the transporting network. The following instructions describe how to send a datagram message:

1. On the **Basic** tab, set the message destination depending on the message model that is being used. Set one of the following properties to a valid JNDI administered object name:
   - `Publication Topic`
   - `Destination Queue`
2. Leave the `Reply To Destination` field blank.

The node resolves the name of the JNDI administered object, which is supplied in either the `Publication topic` or `Destination queue` property, and sends the message to that JMS destination.

Sending a reply message

The sender of a message might want the recipient to reply to the message. In this case, the JMSOutput message can treat the outgoing message as a reply, and route it according to the value that is obtained from the `JMSReplyTo` property from the request message. You can modify the value of the `JMSReplyTo` property in the MbMessage; for example, using a Compute node or a JavaCompute node. This action allows dynamic routing of messages from the JMSOutput node. The node sends the message to the JMS destination name that is set in the JMSReplyTo field of the MbMessage Tree.

The JMSReplyTo value in the MbMessage Tree represents the name of the JMS Destination that is resolved from JNDI. For example:

```
queue://QM_mn2/myJMSQueue4
```

In this case, the value is the JMS-provider specific representation of a JMS destination for the WebSphere MQ JMS provider.

If you do not want to specify a resolved JMS destination name, the JMSOutput node can also accept a JNDI administered object name in the `JMSReplyTo` field. However, the node must resolve an administered object name through JNDI before it can route the message to the underlying JMS destination. In this case, the value in the `JMSReplyTo` field must be prefixed with the string: `jndi://`. For example:

```
jndi://jmsQ4
```

where `jmsQ4` is the name of the JNDI-administered object.

Performance might be affected when you use this method because of the need to look up the administered object in JNDI.

Sending a request message

The JMSOutput node can send a message to a JMS destination with the expectation of a response from the message consumer that processes the request. The following instructions describe how to send a request message:

1. On the **Basic** tab, set the message destination depending on the message model that is being used. Set one of the following properties to a valid JNDI-administered object name:
   - `Publication Topic`
   - `Destination Queue`
2. The JMSReplyTo destination in the outgoing message can be derived from the JMSReplyTo field of the MbMessage Tree that is passed to the node. Alternatively, this value can be overridden by a JNDI-administered object name that is set in the `Reply To Destination` node property.

   To allow the JMSOutput node to set the JMSReplyTo property dynamically in the outgoing message, leave the `Reply To Destination` field blank on the **Basic** tab, and set the JMSReplyTo value in the MbMessage using a Compute node or a JavaCompute node.

The node looks first for a value in the JMSReplyTo field of the MbMessage. If the node finds the value, it passes this value into the JMSReplyTo field of the outgoing message. However, if the `Reply To Destination` field of the **Basic** tab has been specified, this value overrides anything that is set previously in the JMSReplyTo property of the outgoing message, after first resolving the name of the JNDI-administered object.

The node resolves the name of the JNDI-administered object that is supplied in either `Publication Topic` or `Destination Queue`, and sends the message to that JMS destination.

Invoking an output message callback function:
The cciOutputMessageCallback function can be registered as a callback and invoked whenever a message is sent by a JMSOutput node. See "cciOutputMessageCallback" on page 6626.

If the user exit state is active, the cciOutputMessageCallback function is invoked for every output message that is sent successfully from a JMSOutput node where the callback is registered.

If the node provides WrittenDestination information in the LocalEnvironment tree, the callback is invoked after this information is created. See "Using LocalEnvironment variables with JMSOutput and JMSReply nodes" on page 4242.

Working with the JMS message ID:
The JMS message ID is generated by the JMS provider when a message is sent by the JMSOutput node. You cannot set the message ID in the message flow, but you can use one of the following methods to obtain the generated ID after the message has been sent:

- Connect a Compute node to the Out terminal.

  Connect a Compute node to the Out terminal of a JMSOutput node and interrogate the WrittenDestination List. For more information, see "Viewing the logical message tree in trace output" on page 1481.

  An entry for a JMSOutput node has the following format:

```
WrittenDestination = (
   JMS = (
      DestinationData = (
        destinationName = 'queue://jmsQueue1'
        initialContext = 'com.sun.jndi.fscontext.RefFSContextFactory'
        JMSMessageID = ID:414d512054657374514d2020202020206ab98b4520017a02'
        JMSCorrelationID = 'ABCDEFGHIJKLMNOPQRSTUVW'
  )
 )
)
```

- Configure a user exit to process an output message callback event. For more information, see "Exploiting user exits" on page 2985.

Configuring for coordinated transactions:
When you include a JMSOutput node in a message flow, the value that you set for `Transaction Mode` defines whether messages are sent under syncpoint.

- If you set the `Transaction Mode` to `Global`, the message is sent under external syncpoint coordination; that is, within a WebSphere MQ unit of work. Any messages that are sent subsequently by an output node in the same instance of the message flow are put under syncpoint, unless the output node overrides this setting explicitly.
- If you set the `Transaction Mode` to `Local`, the message is sent under the local syncpoint control of the JMSOutput node. Any messages that are sent subsequently by an output node in the flow are not put under local syncpoint, unless an individual output node specifies that the message must be put under local syncpoint.
- If you set the `Transaction Mode` to `None`, the message is not sent under syncpoint. Any messages that are sent subsequently by an output node in the flow are not put under syncpoint, unless an individual output node specifies that the message must be put under syncpoint.

When you want to send messages under external syncpoint, you must perform additional configuration steps, which need to be applied only the first time that a JMSOutput or JMSInput is deployed to the broker for a particular JMS provider:

- On distributed systems, the external syncpoint coordinator for the broker is WebSphere MQ. Before you deploy a message flow in which the `Transaction`

Mode is set to Global, modify the queue manager .ini file to include extra definitions for each JMS provider resource manager that participates in globally coordinated transactions:

– Windows On Windows on x86 systems:

1. Start WebSphere MQ Explorer.
2. Right-click the queue manager name in the left pane and click **Properties**.
3. Click **XA resource managers** in the left pane.
4. Set the SwitchFile property to the following value:

```
install_dir/bin/ JMSSwitch.dll
XAOpenString=Initial Context,location JNDI,Optional_parms
ThreadOfControl=THREAD
```

For more information, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

– Windows On Windows on x86-64 systems:

1. Start WebSphere MQ Explorer.
2. Right-click the queue manager name in the left pane and click **Properties**.
3. Click **XA resource managers** in the left pane.
4. Set the SwitchFile property to the following value:

```
JMSSwitch
     XAOpenString=Initial Context,location JNDI,Optional_parms
     ThreadOfControl=THREAD
```

5. Copy the switch file *JMSSwitch32.dll* to the \exits subdirectory in the WebSphere MQ installation directory, and rename it to JMSSwitch.dll. Copy the switch file JMSSwitch.dll to the \exits64 subdirectory in the WebSphere MQ installation directory.

For more information, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

– Linux UNIX On Linux and UNIX systems, add a stanza to the queue manager's .ini file for each JMS provider.

For example:

```
XAResourceManager:
Name=Jms_Provider_Name
SwitchFile=/install_dir/bin/JMSSwitch.so
XAOpenString=Initial Context,location JNDI,Optional_parms
ThreadOfControl=THREAD
```

Where:

Name is an installation-defined name that identifies a JMS provider resource manager.

SwitchFile
is the file system path to the JMSSwitch library that is supplied in the bin directory of the broker.

XAOpenString can have the following values:

- *Initial Context* is the value that is set in the JMSInput node basic property Initial context factory.
- *location JNDI* is the value that is set in the JMSInput node basic property Location of JNDI bindings. This value must include the leading keyword, which is file://, iiop://, or ldap://

The following parameters are optional:

- `LDAP Principal` matches the value that is set for the broker by using the **mqsicreatebroker** or **mqsichangebroker** commands.
- `LDAP Credentials` matches the value that is set for the broker by using the **mqsicreatebroker** or **mqsichangebroker** commands.
- `Recovery Connection Factory Name` is the JNDI administered connection factory that is defined in the bindings file. If a value is not specified, a default value for `recoverXAQCF` must be added to the bindings file. In either case, the Recovery Connection Factory must be defined as an XA Queue Connection Factory for the JMS provider that is associated with the Initial Context Factory.

The optional parameters are comma-separated and are positional. Therefore, any parameters that are missing must be represented by a comma.

1. Update the Java CLASSPATH environment variable for the broker's queue manager to include a reference to `xarecovery.jar`; for example:

   install_dir`/classes/xarecovery.jar`
2. Update the Java PATH environment variable for the broker's queue manager to point to the bin directory, which is where the switch file is located; for example:

   install_dir`/bin`

For more information, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

– z/OS On z/OS, the external syncpoint manager is Resource Recovery Services (RRS). The only JMS provider that is supported on z/OS is WebSphere MQ JMS. The only transport option that is supported for WebSphere MQ JMS on z/OS is the bind option.

Syncpoint control for the JMS provider is managed with RRS syncpoint coordination of the queue manager of the broker. You do not need to modify the `.ini` file.

If the JMSOutput node uses BEA WebLogic as the JMS provider, and the nodes need to participate in a globallyan XA coordinated message flow, see “Making the JMS provider client available to the JMS nodes” on page 4550.

Connecting the terminals:
Connect the In terminal of the JMSOutput node to the node from which outbound messages are routed.

Connect the Out terminal of the JMSOutput node to another node in the message flow to process the message further, to process errors, or to send the message to an additional destination.

Terminals and properties:
When you have put an instance of the JMSOutput node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties that do not have a default value defined are marked with an asterisk.

The terminals of the JMSOutput node are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the message is routed if an error occurs. Even if the Validation property is set, messages that are propagated to this terminal are not validated.

Terminal	Description
Out	The output terminal to which the message is routed if it has been successfully put to the output destination (topic or queue).

The following tables describe the node properties. The column headed M indicates whether the property is mandatory (marked with an asterisk if you must enter a value when no default is defined), the column headed C indicates whether the property is configurable (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the JMSOutput node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, JMSOutput	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the JMSOutput node are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Destination Queue	No	Yes		The name of the queue to which the node publishes outgoing messages. If the JMSOutput node is to be used to send point-to-point messages, enter the `Destination queue` name for the JMS queue name that is listed in the bindings file.	destinationQueueName
Publication Topic	No	Yes		The name of the topic to which the node publishes messages. • If this property is configured, the node operates only in the publish/subscribe message domain. • This property is mutually exclusive with the `Destination queue` property. • The `Publication Topic` name must conform to the standards of the JMS provider that is being used by the node.	topic
Reply to destination	No	Yes		The name of the JMS destination to which the receiving application must send a reply message. For a reply message to be returned to this JMS destination, the JMS destination name must be known to the domain of the JMS provider that is used by the receiving client. You can enter a JMS destination, which can be either a subscription queue or a destination topic. The default value is blank, in which case the JMS output message can be regarded as a datagram. If the field is blank, the JMSOutput node does not expect a reply from the receiving JMS client.	replyToDestination

Property	M	C	Default	Description	mqsiapplybaroverride command property
Send to destination list in local environment	No	Yes	Cleared	When you have built a list of JMS destinations in the local environment, select this check box to use the destination list. If you do not select this check box, the node uses the configured JMS destination. If you select this check box but you have not built a list of JMS destination in the local environment, the node uses the configured JMS destination.	useDistList

The JMS Connection properties of the JMSOutput node are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
JMS provider name	Yes	No	`WebSphere MQ`	Select a JMS vendor name from the list, or enter a name of your choice. When you select a name from the list, the `Initial Context Factory` property is updated automatically with the relevant Java class. If you enter your own JMS provider name, you must also enter a value for the `Initial Context Factory`. The name must match the name of a configurable service defined for the broker to which you deploy the message flow.	
Initial Context Factory	Yes	Yes	`com.sun.jndi.fscontext.RefFSContextFactory`	This property is the starting point for a JNDI namespace. A JMS application uses the initial context to obtain and look up the connection factory and queue or topic objects for the JMS provider. If you select a JMS provider name from the list in `JMS provider name`, the `Initial Context Factory` property is updated automatically with the relevant Java class. If you enter your own JMS provider name, you must also enter a value for the `Initial Context Factory`. The default value is `com.sun.jndi.fscontext.RefFSContextFactory`, which defines the file-based initial context factory for the WebSphere MQ JMS provider. If the node is set to use your own JMS provider, and the corresponding Configurable services property of the **`mqsichangeproperties`** definition has the `InitialContextFactory` attribute set, this overrides the setting on the node.	initialContextFactory

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Location JNDI Bindings	Yes	Yes		The system path or the LDAP location for the bindings file. The bindings file contains definitions for the JNDI-administered objects that are used by the JMSOutput node. When you enter a value for Location JNDI Bindings, ensure that it complies with the following instructions: • Construct the bindings file before you deploy a message flow that contains a JMSOutput node. • Do not include the file name of the bindings file in this field. • If you have specified an LDAP location that requires authentication, configure both the LDAP principal (userid) and LDAP credentials (password) separately. These values are configured at broker level. For information about configuring these values, see "**mqsicreatebroker** command" on page 3831 and "**mqsichangebroker** command" on page 3723. • The string value must include a supported URL prefix that has a URL handler that is available on the class path. For information about constructing the JNDI-administered objects bindings file, see the documentation that is supplied with the JMS provider. If the node is set to use your own JMS provider, and the corresponding Configurable services property of the **mqsichangeproperties** definition has the `jndiBindingsLocation` attribute set, this overrides the setting on the node.	locationJndiBindings
Connection Factory Name	Yes	Yes		The name of the connection factory that is used by the JMSOutput node to create a connection to the JMS provider. This name must already exist in the bindings file. The Connection factory can be a JMS QueueConnectionFactory or a JMS TopicConnectionFactory, but it must match the message model that is used by the node. Alternatively, you can specify the generic JMS ConnectionFactory, which can be used for both JMS queue or JMS topic destinations.	connectionFactoryName

The Advanced properties of the JMSOutput node are described in the following table.

Property	M	C	Default	Description
New Correlation ID	No	Yes		If the JMSOutput node is required to generate a new Correlation ID for the message, select `New Correlation ID`. If you leave the check box cleared, the Correlation ID of the output message is taken from the JMSCorrelationID field in the JMSTransport_Header_Values section of the message tree.
Transaction Mode	Yes	No	`None`	This property controls whether the incoming message is received under syncpoint. • Select `None` if the outgoing message is to be treated as nonpersistent. If you select this value, the message is sent using a non-transacted JMS session that is created using the `Session.AUTO_ACKNOWLEDGE` flag. • Select `Local` if the input node that received the message must coordinate the commit or roll-back of JMS messages that have been sent by the JMSOutput node, along with any other resources, such as DB2 or WebSphere MQ, that perform work within the message flow. If you select this value, the node uses a transacted JMS session. • Select `Global` if the JMSOutput node must participate in a global message flow transaction that is managed by the broker's external syncpoint coordinator. The syncpoint coordinator is the broker's queue manager on distributed systems, and RRS (Resource Recovery Services) on z/OS. If you select this value, any messages that are received by the node are globally coordinated using an XA JMS session.
Delivery Mode	No	Yes	`Non Persistent`	This property controls the persistence mode that a JMS provider uses for a message. Valid values are: • `Automatic`: the mode from the input message is inherited • `Persistent`: the message survives if the JMS provider has a system failure • `Non Persistent`: the message is lost if the JMS provider has a system failure
Message Expiration (ms)	No	Yes	`0`	This property controls the length of time, in milliseconds, for which the JMS provider keeps the output JMS message. The default value, `0`, is used to indicate that the message must not expire. Select `Inherit from header` or enter an integer that represents a number of milliseconds. If you select `Inherit from header`, the property inherits the value of the JMSExpiry field in the JMS message, which is found at the following location: `OutputRoot.JMSTransport.Transport_Folders.Header_Values.JMSExpiration`
Message Priority	No	Yes	`4`	This property assigns relative importance to the message and it can be used for message selection by a receiving JMS client application or a JMSOutput node. Select a value between `0` (lowest priority) and `9` (highest priority) or select `Inherit from header`. The default value is `4`, which indicates medium priority. Priorities in the range `0` to `4` relate to typical delivery. Priorities in the range `5` to `9` relate to graduations of expedited delivery. If you select `Inherit from header`, the property inherits the value of the JMSPriority field in the JMS message, which is found at the following location: `OutputRoot.JMSTransport.Transport_Folders.Header_Values.JMSPriority`

Property	M	C	Default	Description
Message Type	No	Yes	`Determine output message type from the JMS Message Tree`	Select a value from the list to configure the type of JMS message that is produced by the JMSOutput node. If you do not set a value for this property, the node assumes the output type from the metadata PayLoadType field in the JMS message tree, as indicated by the default value, `Determine output message type from the JMS Message Tree`. Valid values are: • Determine output message type from the JMS Message Tree • TextMessage • BytesMessage • MapMessage • StreamMessage • ObjectMessage • Base JMS message with no payload

The Validation properties of the JMSOutput node are described in the following table. For more information about Validation properties, see "Validating messages" on page 1478 and "Validation properties" on page 4169.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Validate	No	Yes	`Inherit`	This property controls whether validation takes place. Valid values are `None`, `Content`, `Content And Value`, and `Inherit`.	validateMaster
Failure Action	No	No	`Exception`	This property controls what happens if validation fails. You can set this property only if you set `Validate` to `Content` or `Content and Value`. Valid values are `User Trace`, `Local Error Log`, `Exception`, and `Exception List`.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related information:

JMSReply node

Use the JMSReply node to send messages to JMS destinations.

This topic contains the following sections:

Purpose:
The JMSReply node has a similar function to the JMSOutput node, but the JMSReply node sends JMS messages only to the reply destination that is supplied in the JMSReplyTo header field of the JMS message tree. Use the JMSReply node when you want to treat a JMS message that is produced from a message flow as a reply to a JMS input message, and where you have no other routing requirements.

The JMSReply node is contained in the **JMS** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using the JMSReply node in a message flow:
Consider a situation in which you create a message flow in which a JMSInput node message obtains point-to-point messages from a JMS destination called MyJMSInputQueue. The message flow updates a database using the contents of the message, then replies to a JMS destination called MyJMSReplyQueue, which is set by the generating application in the JMSReplyTo header of the input message.

In a similar scenario for the publish/subscribe message model, a JMSInput node subscribes to TopicA, and the JMSReply node publishes on the TopicB destination, which was retrieved from the JMSReplyTo header of the input message.

Calling an output message callback function:
The cciOutputMessageCallback function can be registered as a callback and called whenever a message is sent by a JMSReply node. See "cciOutputMessageCallback" on page 6626.

If the user exit state is active, the cciOutputMessageCallback function is called for every output message that is sent successfully from a JMSReply node where the callback is registered.

If the node provides WrittenDestination information in the LocalEnvironment tree, the callback is called after this information is created. See "Using LocalEnvironment variables with JMSOutput and JMSReply nodes" on page 4242.

Working with the JMS message ID:
The JMS message ID is generated by the JMS provider when a message is sent by the JMSReply node. You cannot set the message ID in the message flow, but you can use one of the following methods to obtain the generated ID after the message has been sent:

- Connect a Compute node to the Out terminal.

Connect a Compute node to the Out terminal of a JMSReply node and interrogate the WrittenDestination List. For more information, see “Viewing the logical message tree in trace output” on page 1481.

An entry for a JMSReply node has the following format:

```
WrittenDestination = (
   JMS = (
      DestinationData = (
        destinationName = 'queue://jmsQueue1'
        initialContext = 'com.sun.jndi.fscontext.RefFSContextFactory'
        JMSMessageID = ID:414d512054657374514d2020202020206ab98b4520017a02'
        JMSCorrelationID = 'ABCDEFGHIJKLMNOPQRSTUVW'
  )
 )
)
```

- Configure a user exit to process an output message callback event. For more information, see “Exploiting user exits” on page 2985.

Terminals and properties:
When you have put an instance of the JMSReply node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties that do not have a default value defined are marked with an asterisk.

The terminals of the JMSReply node are described in the following table.

Terminal	Description
Failure	The output terminal to which the message is routed if an error occurs. Even if the Validation property is set, messages that are propagated to this terminal are not validated.
Out	The output terminal to which the message is routed if it is successfully retrieved from the WebSphere MQ queue.

The following tables describe the node properties. The column headed M indicates whether the property is mandatory (marked with an asterisk if you must enter a value when no default is defined), the column headed C indicates whether the property is configurable (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the JMSReply node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the JMSReply node are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Send to destination list in local environment	No	Yes	Cleared	When you have built a list of JMS destinations in the local environment, select this check box to use the destination list. If you do not select this check box, the node uses the configured JMS destination. If you select this check box but you have not built a list of JMS destinations in the local environment, the node uses the configured JMS destination.	useDistList

The JMS Connection properties of the JMSReply node are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
JMS provider name	Yes	No	`WebSphere MQ`	Select a JMS vendor name from the list, or enter a name of your choice. When you select a name from the list, the `Initial Context Factory` property is updated automatically with the relevant Java class. If you enter your own JMS provider name, you must also enter a value for the `Initial Context Factory`. The default value is `WebSphere MQ`.	
Initial Context Factory	Yes	Yes	`com.sun.jndi.fscontext. RefFSContextFactory`	This property is the starting point for a JNDI namespace. A JMS application uses the initial context to obtain and look up the connection factory and queue or topic objects for the JMS provider. If you select a JMS provider name from the list in `JMS provider name`, the `Initial Context Factory` property is updated automatically with the relevant Java class. If you enter your own JMS provider name, you must also enter a value for the `Initial Context Factory`. The default value of `com.sun.jndi.fscontext. RefFSContextFactory` defines the file-based initial context factory for the WebSphere MQ JMS provider. If the node is set to use your own JMS Provider, and the corresponding Configurable services property of the **`mqsichangeproperties`** definition has the `InitialContextFactory` attribute set, this overrides the setting on the node.	initialContextFactory

Property	M	C	Default	Description	mqsiapplybaroverride command property
Location JNDI Bindings	Yes	Yes		This property specifies either the file system path or the LDAP location for the bindings file. The bindings file contains definitions for the JNDI-administered objects that are used by the JMSReply node. When you enter a value for Location JNDI Bindings, ensure that it complies with the following instructions: • Construct the bindings file before you deploy a message flow that contains a JMSReply node. • Do not include the file name of the bindings file in this field. • If you have specified an LDAP location that requires authentication, configure both the LDAP principal (userid) and LDAP credentials (password) separately. These values are configured at broker level. For information about configuring these values, refer to the **mqsicreatebroker** and **mqsichangebroker** commands. • The string value must include a supported URL prefix that has a URL handler that is available on the class path. For information about constructing the JNDI-administered objects bindings file, refer to the documentation that is supplied with the JMS provider. If the node is set to use your own JMS Provider, and the corresponding Configurable services property of the **mqsichangeproperties** definition has the `jndiBindingsLocation` attribute set, this overrides the setting on the node.	locationJndiBindings
Connection Factory Name	Yes	Yes		The name of the connection factory that is used by the JMSReply node to create a connection to the JMS provider. This name must already exist in the bindings file.	connectionFactoryName

The Advanced properties of the JMSReply node are described in the following table.

Property	M	C	Default	Description
New Correlation ID	No	Yes	Cleared	If the JMSReply node is required to generate a new Correlation ID for the message, select the check box. The check box is cleared by default; if you leave the check box cleared, the Correlation ID of the output message is taken from the JMSCorrelationID field in the JMSTransport_Header_Values section of the message tree.
Transaction Mode	No	No	`None`	This property controls whether the incoming message is received under sync point. To define the transactional characteristics of how the message is handled, select one of the following values: • Select `None` if the outgoing message is to be treated as non-persistent. If you select this value, the message is sent using a non-transacted JMS session that is created using the `Session.AUTO_ACKNOWLEDGE` parameter. • Select `Local` if the input node that receives the message should coordinate the commit or roll-back of JMS messages that have been sent by the JMSReply node, along with any other resources, such as DB2 or WebSphere MQ, that perform work within the message flow. If you select this value, the node uses a transacted JMS session. • Select `Global` if the JMSReply node should participate in a global message flow transaction that is managed by the broker's external sync point coordinator. The sync point coordinator is the broker's queue manager on distributed systems, and RRS (Resource Recovery Services) on z/OS. If you select this value, any messages that are received by the node are globally coordinated using an XA JMS session.
Delivery Mode	No	Yes	`Automatic`	This property controls the persistence mode that a JMS provider uses for a message. Valid values are: • `Automatic`: the mode from the input message is inherited • `Persistent`: the message survives if the JMS provider has a system failure • `Non-persistent`: the message is lost if the JMS provider has a system failure
Message Expiration (ms)	Yes	Yes	`0`	This property controls the length of time, in milliseconds, for which the JMS provider keeps the output JMS message. The default value, `0`, is used to indicate that the message must not expire. Select `Inherit from header` or enter an integer that represents a number of milliseconds. If you select `Inherit from header`, the property inherits the value of the JMSExpiry field in the JMS message, which is found at the following location: `OutputRoot.JMSTransport.Transport_Folders.Header_Values.JMSExpiration`
Message Priority	No	Yes	`4`	This property assigns relative importance to the message and it can be used for message selection by a receiving JMS client application or a JMSReply node. Select a value between `0` (lowest priority) and `9` (highest priority) or select `Inherit from header`. The default value is `4`, which indicates medium priority. Priorities in the range `0` to `4` relate to normal delivery. Priorities in the range `5` to `9` relate to graduations of expedited delivery. If you select `Inherit from header`, the property inherits the value of the JMSPriority field in the JMS message, which is found at the following location: `OutputRoot.JMSTransport.Transport_Folders.Header_Values.JMSPriority`

Property	M	C	Default	Description
Message type	No	Yes	`TextMessage`	This property controls the class of the JMS output message. The default value is `TextMessage`. Valid values are: • `TextMessage` • `BytesMessage` • `MapMessage` • `StreamMessage` • `ObjectMessage` • `Base JMS message with no payload` If you do not set this property, the node assumes the output type from the metadata PayLoadType field in the JMS message tree.

The Validation properties of the JMSReply node are described in the following table. Refer to "Validation properties" on page 4169 for a full description of these properties.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Validate	No	Yes	`Inherit`	This property controls whether validation takes place. Valid values are: • `None` • `Content and Value` • `Content` • `Inherit` If a message is propagated to the Failure terminal of the node, it is not validated.	validateMaster
Failure Action	No	No	`Exception`	This property controls what happens if validation fails. You can set this property only if you set `Validate` to `Content` or `Content and Value`. Valid values are: • `User Trace` • `Local Error Log` • `Exception` (default value) • `Exception List`	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

"Using LocalEnvironment variables with JMSOutput and JMSReply nodes" on page 4242
The LocalEnvironment data elements related to the processing of JMS Messages in the JMSOutput and JMSReply nodes.

Label node

Use the Label node to process a message that is propagated by a RouteToLabel node to dynamically determine the route that the message takes through the message flow.

This topic contains the following sections:

Purpose:
Use the Label node in combination with a RouteToLabel node to route a message through the message flow based on message content. The RouteToLabel node interrogates the LocalEnvironment of the message to determine the identifier of the Label node to which the message must be routed next. You can propagate the message by coding ESQL in a Compute node, or by coding Java in a JavaCompute or user-defined node.

Precede the RouteToLabel node in the message flow with a Compute node or JavaCompute node and populate the LocalEnvironment of the message with the identifiers of one or more Label nodes that introduce the next sequence of processing for the message.

Design your message flow so that a Label node logically follows a RouteToLabel node in a message flow, but do not connect it physically to the RouteToLabel node. The connection is made by the broker, when required, according to the contents of LocalEnvironment.

The Label node provides a target for a routing decision, and does not process the message that it handles in any way. Typically, a Label node connects to a subflow that processes each message in a specific way, and either ends in an output node or in another RouteToLabel node.

The Label node can also be used in conjunction with a SOAPExtract node or as the target of a PROPAGATE statement, which is specified in a Compute or Database node.

The Label node is contained in the **Routing** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following sample to see how to use this node:
- Airline Reservations

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online

information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
When you have put an instance of the Label node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The Label node terminals are described in the following table.

Terminal	Description
Out	The output terminal to which the message is routed.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Label node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The Label node Basic properties are described in the following table.

Property	M	C	Default	Description
Label Name	Yes	No		An identifier for the node. It is used as a target for a message that is routed by a RouteToLabel node. `Label Name` must not be the same as the name of the instance of the node itself, and it must be unique in the message flow in which it appears. The name of the instance can be modified by the WebSphere Message Broker Toolkit if the subflow, of which this Label node is a part, is embedded into another message flow.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Mapping node

Use the Mapping node to construct one or more new messages and populate them with various types of information.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow" on page 4572
- "Terminals and properties" on page 4572

Purpose:
You can populate the new messages with the following types of information:
- New information
- Modified information from the input message
- Information taken from a database

You can modify elements of the message body data, and the local environment tree.

When you first open or create a message map for the node, if you select `This map is called from a message flow node and maps properties and message body`, the headers in the input message are always copied to the output message without modification. To modify the message headers in a Mapping node, select `This map is called from a message flow node and maps properties, headers, and message body`. When you select this property, the map that is created allows additional elements, including WebSphere MQ, HTTP, and JMS headers, to be mapped.

These components of the output message can be defined by using mappings that are based on elements of both the input message and data from an external database. You create the mappings that are associated with this node, in the mapping file that is associated with this node, by mapping inputs (message or database) to outputs. You can modify the assignments made by these mappings by using supplied or user-defined functions and procedures; for example, you can convert a string value to uppercase when you assign it to the message output field.

Use the Mapping node to:
- Build a new message
- Copy messages between parsers
- Transform a message from one format to another

The Mapping node is contained in the **Transformation** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following sample to see how to use this node:
- Pager

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
When you have put an instance of the Mapping node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The Mapping node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the input message is propagated if a failure is detected during the computation. If you have selected `Treat Warnings as Errors`, the node propagates the message to this terminal if database warning messages are returned, even though the processing might have completed successfully.

Terminal	Description
Out	The output terminal that propagates the message following completion of the mappings.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Mapping node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The Mapping node Basic properties are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Data Source	No	Yes		The ODBC data source name of the database that contains the tables to which you refer in the mappings that are associated with this node (identified by the `Mapping Module` property). This name identifies the appropriate database on the system on which this message flow is to execute. The broker connects to this database with user ID and password information that you have specified on the **mqsicreatebroker**, **mqsichangebroker**, or **mqsisetdbparms** command. If the name is different from the data source name used in the Mapping Editor, select the **Use data source from flow property** option on the **Override Data Source and Schema** dialog (see "Message mapping tips and restrictions" on page 2314). z/OS On z/OS systems, the broker uses the broker started task ID, or the user ID and password that are specified on the **mqsisetdbparms** command JCL, BIPSDBP in the customization data set hlq>.SBIPPROC.	dataSource

Property	M	C	Default	Description	mqsiapplybaroverride command property
Transaction	Yes	No	Automatic	The transaction mode for the node. The values are: • `Automatic` (the default). The message flow, of which the Mapping node is a part, is committed if it is successful; that is, the actions that you define in the mappings are performed and the message continues through the message flow. If the message flow fails, it is rolled back. If you choose `Automatic`, the ability to commit or rollback the action of the Mapping node on the database depends on the success or failure of the entire message flow. • `Commit`. To commit any uncommitted actions that are performed in this message flow on the database that is connected to this node, irrespective of the success or failure of the message flow as a whole, select `Commit`. The changes to the database are committed even if the message flow fails.	
Mapping Routine	Yes	No	Mapping	The name of the mapping routine that contains the statements to execute against the database or the message tree. By default, the name that is assigned to the mapping routine is identical to the name of the mapping file in which the routine is defined. The default name for the file is the name of the message flow concatenated with the name of the node when you include it in the message flow (for example, `MFlow1_Mapping.msgmap` for the first Mapping node in message flow MFlow1). You cannot specify a value that includes spaces. If you click **Browse** next to this entry field, a dialog box is displayed that lists all available mapping routines that this node can access. Select the routine that you want and click **OK**; the routine name is set in `Mapping Module`. To work with the mapping routine that is associated with this node, double-click the node, or right-click the node and click **Open Mappings**. If the mapping routine does not exist, it is created for you with the default name in the default file. If the file exists already, you can also open file `<flow_name>_<node_name>.msgmap` in the Broker Development view. A mapping routine is specific to the type of node with which it is associated; you cannot use a mapping routine that you have developed for a Mapping node with any other node that uses mappings (for example, a DataInsert node). If you create a mapping routine, you cannot call it from any other mapping routine, although you can call it from an ESQL routine. For more information about working with mapping files, and defining their content, see “Using message mappings” on page 2228.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Mapping Mode	Yes	No	Message	The mode that is used to process information that is passed through the Mapping node. Valid values are: • `Message` (the default): the message is generated or passed through by the Mapping node, as modified within the node. • `LocalEnvironment`: the LocalEnvironment tree structure is generated or passed through by the Mapping node, as modified within the node. • `LocalEnvironment And Message`: the LocalEnvironment tree structure and message are generated or passed through by the Mapping node, as modified by the node. • `Exception`: the ExceptionList is passed through by the Mapping node unchanged. • `Exception And Message`: the ExceptionList is passed through unchanged, and the message is generated or passed through by the Mapping node, as modified by the node. • `Exception And LocalEnvironment`: the ExceptionList is passed through unchanged, and the LocalEnvironment tree is generated or passed through by the Mapping node, as modified by the node. • `All`: the ExceptionList is passed through unchanged, the message and the localEnvironment are generated or passed through by the Mapping node, as modified by the node. You must set this property to reflect accurately the output message format that you need. If you select an option (or accept the default value) that does not include a particular component of the message, that component is not included in any output message that is constructed. You can choose any combination of `Message`, `LocalEnvironment`, and `Exception` components to be generated and modified by the Mapping node. To construct a map that propagates multiple target messages, set this property to `LocalEnvironment And Message` to ensure that the node executes correctly. LocalEnvironment was known as DestinationList in some previous versions; it is retained for compatibility. The Environment component of the message tree is not affected by the mode setting. Its contents, if any, are passed on from this node.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Treat Warnings as Errors	Yes	No	Cleared	For database warning messages to be treated as errors, and the node to propagate the output message to the Failure terminal, select `Treat Warnings as Errors`. The check box is cleared initially. When you select the check box, the node handles all positive return codes from the database as errors and generates exceptions in the same way as it does for the negative, or more serious, errors. If you do not select the check box, the node treats warnings as normal return codes, and does not raise any exceptions. The most significant warning raised is `not found`, which can be handled safely as a normal return code in most circumstances.	
Throw Exception on Database Error	Yes	No	Selected	For the broker to generate an exception when a database error is detected, select `Throw Exception on Database Error`. The check box is selected initially. If you clear the check box, you must handle the error in the message flow to ensure the integrity of the broker and the database. The error is ignored if you do not handle it through your own processing, because you have chosen not to invoke the default error handling by the broker. For example, you could connect the Failure terminal to an error processing subroutine.	

The parser options for the Mapping node are described in the following table.

Property	M	C	Default	Description
Use XMLNSC Compact Parser for XMLNS Domain	No	No	Cleared	If you select this check box, the outgoing MQRFH2 specifies the XMLNS instead of XMLNSC parser, allowing an external application to remain unchanged. If outgoing messages do not contain MQRFH2 headers, this property has no effect.

The Validation properties of Mapping node are described in the following table.

If a message is propagated to the Failure terminal of the node, it is not validated. These properties do not cause the input message to be validated. It is expected that, if such validation is required, the validation has already been performed by the input node or a preceding validation node. For more details about validating messages and validation properties, see “Validating messages” on page 1478 and “Validation properties” on page 4169.

Property	M	C	Default	Description
Validate	No	Yes	None	This property controls whether validation takes place. Valid values are None, Content and Value, Content, and Inherit.
Failure Action	No	No	Exception	This property controls what happens if a validation failure occurs. You can set this property only if Validate is set to Content or Content and Value. Valid values are User Trace, Local Error Log, Exception, and Exception List.

Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

"**mqsicreatebroker** command" on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

"**mqsisetdbparms** command" on page 3954
Use the **mqsisetdbparms** command to associate a specific user ID and password (or SSH identity file) with one or more resources that are accessed by the broker.

MQGet node

Use the MQGet node to receive messages from clients that connect to the broker by using the WebSphere MQ Enterprise Transport, and the MQI and AMI application programming interfaces.

You can also use the MQGet node to retrieve messages that were previously placed in a WebSphere MQ message queue that is defined to the broker queue manager.

This topic contains the following sections:

The topic uses the following terms:

input message
A message that enters the In terminal of the MQGet node.

queue message
A message that the MQGet node reads from the queue.

Purpose:
The MQGet node reads a message from a specified queue, and establishes the processing environment for the message. If appropriate, you can define the input queue as a WebSphere MQ clustered queue or shared queue.

You can use an MQGet node anywhere in a message flow, unlike an MQInput node, which you can use only as the first node in a message flow. The output message tree from an MQGet node is constructed by combining the input tree with the result tree from the MQGET call. You can set the properties of the MQGet node to control the way in which messages are received; for example, you can indicate that a message is to be processed under transaction control, or you can request that, when the result tree is being created, data conversion is performed on receipt of every input message.

The MQGet node handles messages in the following message domains:
- XMLNSC
- DataObject
- JSON
- BLOB
- MIME
- MRM
- JMSMap
- JMSStream
- XMLNS

The MQGet node is contained in the **WebSphere MQ** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using the MQGet node in a message flow:

For information about how to use the MQGet node in a message flow, see "A request-response scenario that uses an MQGet node" on page 1569.

Look at the following sample to see how to browse messages with the MQGet node:

- Browsing WebSphere MQ Queues

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Configuring the MQGet node:
When you have put an instance of the MQGet node into a message flow, you can configure it; for more information, see "Configuring a message flow node" on page 1503. The properties of the node are displayed in the Properties view.

All mandatory properties for which you must enter a value (those properties that do not have a default value defined) are marked with an asterisk.

Configuring for coordinated transactions:
When you include an MQGet node in a message flow, the value that you set for `Transaction mode` defines whether messages are received under sync point.

- If you set the property to `Yes` (the default), the queue message is received under sync point (that is, in a WebSphere MQ unit of work). Any messages that an output node in the same instance of the message flow sends later are put under sync point, unless the output node, or any other subsequent node, overrides this setting explicitly.
- If you set the property to `Automatic`, the queue message is received under sync point if the incoming message is marked as persistent. Otherwise, it is not received under sync point. Any message that is sent later by an output node is put under sync point, as determined by the incoming persistence property, unless the output node, or any other subsequent node, overrides this setting explicitly.
- If you set the property to `No`, the queue message is not received under sync point. Any messages that are sent later by an output node in the message flow are not put under sync point, unless an individual output node, or any other subsequent node, specifies that the message must be put under sync point.

If you set the `Browse only` property, the value that you set for the `Transaction mode` property is ignored because a message cannot be browsed under sync point. However, any derived messages that are propagated later by an output node in the same instance of the message flow follow the behavior that is described previously in accordance with the specified `Transaction mode` value.

Overriding node properties during message processing:
When you include and configure an MQGet node in a message flow, you might want to override its properties under some conditions. For example, you might want to read from a queue that is identified in another part of the message, or that is retrieved from a database record.

To override the values that you set for the MQGet node properties to achieve a more dynamic way to process messages, include a Compute or JavaCompute node in your message flow before the MQGet node. Configure this node to create an

output message, and add fields to the local environment tree to define new values for the properties that you want to change.

For example, add a Compute node into the flow and define a new queue name for the MQGet node to read for messages, by including the following ESQL statement:

```
SET LocalEnvironment.MQ.GET.QueueName = 'new_queue';
```

Use `LocalEnvironment.MQ.GET.` as the correlation name for all fields that relate to the MQGet node.

You can set the following properties under the InputLocalEnvironment.MQ.GET tree. If you have set a value for the `Input MQ parameters location` property on the MQGet node, that tree location is checked instead.

Setting	Description
QueueName	This setting overrides the MQGet node `Queue name` property; for example: `SET InputLocalEnvironment.MQ.GET.QueueName = 'myQueue';`
InitialBufferSize	This setting overrides the MQGet node `Minimum message buffer size` property; for example: `SET InputLocalEnvironment.MQ.GET.InitialBufferSize = 1024;`

MQGMO.*	This setting overrides the MQGET message options used by the MQGet node; for example:
	`SET InputLocalEnvironment.MQ.GET.MQGMO.Options = MQGMO_ACCEPT_TRUNCATED_MSG;`
	`SET InputLocalEnvironment.MQ.GET.MQGMO.WaitInterval = 10000;`
	
	This override is provided for flexibility, but should be used with caution because the MQGMO is used exactly as specified. Node properties and other local environment overrides are not considered.
	
	For more information about the MQGMO structure, see the WebSphere MQ Version 7 Information Center online.

Connecting the terminals:
Connect the Out, Warning, Failure, and No Message output terminals of this node to another node in the message flow to process the message further, process errors, or send the message to an additional destination.

The completion code (CC) that is generated by the MQGET call controls what is propagated to each of the output terminals.

- If the MQGET call is successful, the MQGet node routes each parsed output message to the Out terminal.
- If the MQGET call fails, but with a CC that indicates a warning, an unparsed output message is propagated to the Warning terminal.
- If the MQGET call fails with a CC more severe than a warning, the input message is propagated to the Failure terminal.
- If the MQGET call fails with a reason code of MQRC_NO_MSG_AVAILABLE, the output message is propagated (without a result body) to the No Message terminal. The output message that is propagated to the No Message terminal is constructed from the input message only, according to the values of the `Generate mode`, `Copy message`, and `Copy local environment` properties.
- If you do not connect the Out, Warning, or No Message terminals to another node in the message flow, any message that is propagated to those terminals is discarded.

- If you do not connect the Failure terminal to another node in the message flow, the broker generates an exception when a message is propagated to that terminal.

For more information, see "Connecting failure terminals" on page 2827.

Terminals and properties:
The terminals of the MQGet node are described in the following table.

Terminal	Description
In	The input terminal that accepts the message that is being processed by the message flow.
Warning	The output terminal to which the output tree is propagated if an error (with a CC that indicates a warning) occurs in the node while trying to get a message from the queue. The MQMD part of the message is parsed, but the rest of the message is an unparsed BLOB element. The warning is discarded if the terminal is not connected, and there is no output propagation from the node at all.
Failure	The output terminal to which the input message is routed if an error (with a CC that indicates an error that is more severe than a warning) occurs in the node while trying to get a message from the queue.
Out	The output terminal to which the message is routed if it is retrieved successfully from the WebSphere MQ queue.
No Message	The output terminal to which the input message is routed if no message is available on the queue. The output message that is propagated to the No Message terminal is constructed from the input message only, according to the values of the `Generate mode`, `Copy message`, and `Copy local environment` properties.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the MQGet node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, MQGet	The name of the node.
Short description	No	No	Blank	A brief description of the node.
Long description	No	No	Blank	Text that describes the purpose of the node in the message flow.

The Basic properties of the MQGet node are described in the following table.

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
Queue name	Yes	Yes	None	The name of the WebSphere MQ message queue from which this node retrieves messages. You must predefine this queue to the queue manager that hosts the broker on which the message flow is deployed. If this queue is not a valid queue, the node generates an exception, and the input message is propagated to the Failure terminal.	queueName

The MQGet node Input Message Parsing properties are described in the following table.

If the queue message has an MQRFH2 header, you do not have to set values for the Input Message Parsing properties, because the values can be derived from the <mcd> folder in the MQRFH2 header; for example:

```
<mcd><Msd>MRM</Msd><Set>DHM4UO906S001</Set><Type>receiptmsg1</Type>
<Fmt>XML</Fmt></mcd>
```

If you set values, and the values differ from those values in the MQRFH2 header, the values in the MQRFH2 header take precedence.

Property	M	C	Default	Description
Message domain	No	No	BLOB	The domain that is used to parse the queue message. If the MQRFH2 header does not supply the Message domain value, then you can select a value from the list. If you do not select a value, the default value is BLOB. You can also specify a user-defined parser, if appropriate.
Message set	No	No	None	The name or identifier of the message set in which the queue message is defined. If you are using the MRM or IDOC parser, or the XMLNSC parser in validating mode, select the Message set that you want to use. If you set this property, then later update the project dependencies to remove this message set reference, a warning is issued. Either update the Message set property, or restore the reference to this message set project.
Message type	No	No	None	The name of the queue message. If you are using the MRM parser, select the correct message from the list in Message type. This list is populated with messages that are defined in the Message set that you have selected.
Message format	No	No	None	The name of the physical format of the queue message. If you are using the MRM or IDOC parser, select the format of the message from the list in Message format. This list includes all the physical formats that you have defined for this Message set. If you set the Message domain property to DataObject, you can set this property to XML or SAP ALE IDoc. Set this property to SAP ALE IDoc when you have to parse a bit stream from an external source and generate a message tree.

The Parser Options properties of the MQGet node are described in the following table.

Property	M	C	Default	Description
Parse timing	No	No	On Demand	This property controls when the queue message is parsed. Valid values are On Demand, Immediate, and Complete. By default, this property is set to On Demand, which causes parsing of the message to be delayed. To cause the message to be parsed immediately, see “Parsing on demand” on page 4173.
Use MQRFH2C compact parser for MQRFH2 header	No	No	Cleared	This property controls whether the MQRFH2C compact parser, instead of the MQRFH2 parser, is used for MQRFH2 headers. Select Use MQRFH2C compact parser for MQRFH2 header if you want the MQRFH2C parser to be used. By default, this check box is cleared, which means that the compact parser is not used.
Build tree using XML schema data types	No	No	Cleared	This property controls whether the XMLNSC parser creates syntax elements in the message tree with data types taken from the XML schema. You can select this property only if you set the Validate property on the **Validation** tab to Content or Content and Value. For more information about XMLNSC, see “Manipulating messages in the XMLNSC domain” on page 2546.

Property	M	C	Default	Description
Use XMLNSC compact parser for XMLNS domain	No	No	Cleared	This property controls whether the XMLNSC Compact Parser is used for messages in the XMLNS Domain. If you set this property, the message data is displayed under XMLNSC in nodes that are connected to the output terminal when the input MQRFH2 header or Input Message Parsing properties `Message domain` is XMLNS.
Retain mixed content	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in the queue message message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in the queue message message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in the queue message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the queue message that are to be opaquely parsed by the XMLNSC parser. Opaque parsing is performed only if validation is not enabled (that is, if `Validate` is `None`); entries that are specified in `Opaque Elements` are ignored if validation is enabled.

The Advanced properties of the MQGet node are described in the following table.

Property	M	C	Default	Description
Transaction mode	No	No	`Yes`	This property controls whether the incoming message is received under sync point. Select a value for `Transaction mode` from the list to define the transactional characteristics of how this message is handled: • If you select `Automatic`, the queue message is received under sync point if it is marked as persistent. If the message is not marked as persistent, it is not received under sync point. The persistence or non-persistence of the input message determines the transactionality of any derived messages that are later propagated by an output node, unless the output node, or any other subsequent node in the message flow, overrides the transactionality explicitly. • If you select `Yes`, the queue message is received under sync point. Any derived messages that are later propagated by an output node in the same instance of the message flow are sent transactionally, unless the output node, or any other subsequent node in the message flow, overrides the transactionality explicitly. • If you select `No`, the queue message is not received under sync point. Any derived messages that are later propagated by an output node in the same instance of the message flow are sent non-transactionally, unless the output node, or any other subsequent node in the message flow, has specified that the messages must be put under sync point.

Property	M	C	Default	Description
Generate mode	No	No	`Message`	This property controls which parts of the message from the input tree are copied. Select a value for `Generate mode` from the list to define which components of the output message are generated in the MQGet node, and which components are taken from the input message. • If you select `None`, all the components of the message from the input tree are propagated unchanged. • If you select `Message` (the default), a new Message component is created by the node, but the local environment, environment, and exception list components from the input tree are propagated unchanged. • If you select `LocalEnvironment`, a new local environment component is created by the node, but the message, environment, and exception list components from the input tree are propagated unchanged. • If you select `Message and LocalEnvironment`, new message and local environment components are created by the node, but the environment and exception list components from the input tree are propagated unchanged.
Copy message	No	No	`None`	This property controls which parts of the message from the input tree are copied. If you have set `Generate mode` to either `Message` or `Message And LocalEnvironment`, select a value for `Copy message` from the list to define which parts of the message are generated in the MQGet node, and which parts are taken from the input message. • If you select `None` (the default), no part of the input message from the input tree is propagated. • If you select `Copy Headers`, the headers from the input message in the input tree are copied to the output message. • If you select `Copy Entire Message`, the entire input message from the input tree is copied to the output message.
Copy local environment	No	No	`Copy Entire LocalEnvironment`	This property controls how the local environment is copied to the output message. If you have set `Generate mode` to either `LocalEnvironment` or `Message And LocalEnvironment`, select a value for `Copy Local Environment` from the list to define which parts of the local environment are generated in the MQGet node, and which parts are taken from the input message. • If you select `Copy Entire LocalEnvironment` (the default), at each node in the message flow, a new copy of the local environment is created in the tree, and it is populated with the contents of the local environment from the preceding node. Therefore, if a node changes the local environment, the upstream nodes do not see those changes because they have their own copies. This behavior might be an issue if you are using a FlowOrder node, or if you use the **`propagate`** command on a Compute node. The entire local environment that is defined in the input message is copied to the output message. • If you select `None`, each node does not generate its own copy of the local environment, but it uses the local environment that is passed to it by the previous node. Therefore, if a node changes the local environment, those changes are seen by the upstream nodes.

Property	M	C	Default	Description
Wait interval (ms)	Yes	No	1000	The maximum time, in milliseconds, to wait for the queue message to be obtained from the message queue. Provide a value for the `Wait interval (ms)` property to specify how many milliseconds to wait for a message to be received from the MQGET call. If you select `0`, the wait interval is disabled and there is no wait time for messages. The `Wait interval (ms)` value cannot be negative. If you do not provide a value, the default value of `1000` milliseconds is used.
Minimum message buffer size (KB)	Yes	No	4	The minimum size, in KB, of the get buffer. The minimum value of this property is 1. Provide a value for this property to specify the size of the initial buffer for the MQGET call. The buffer expands automatically to accept a message of any size, but if messages are likely to be large, specify a suitable value to reduce the frequency of the buffer being resized. If you do not provide a value, the size of the buffer is 4 KB.

The Request properties of the MQGet node are described in the following table.

Property	M	C	Default	Description
Input MQMD location	No	No	`InputRoot.MQMD`	The location in the input message assembly where the MQMD that is to be used for the MQGET can be found. The default location is InputRoot.MQMD.
Input MQ parameters location	No	No	`InputLocalEnvironment.MQ.GET`	The location in the input message assembly where the WebSphere MQ parameters (for example, the initial buffer size and the MQGMO overrides) can be found. The default location is InputLocalEnvironment.MQ.GET.
Get by correlation ID	No	No	Cleared	If you select this check box, only messages that have the specified correlation ID are retrieved. If you select `Get by correlation ID`, the `CorrelId` field of the message to be retrieved must match the `CorrelId` field in the `Input MQMD location`. By default, this check box is cleared. Setting the `CorrelId` field to MQCI_NONE has the same effect as not selecting `Get by correlation ID`.
Get by message ID	No	No	Cleared	If you select this check box, only messages that have the specified message ID are retrieved. If you select `Get by message ID`, the `MsgId` field of the message to be retrieved must match the `MsgId` field in the `Input MQMD location`. By default, this check box is cleared.

Property	M	C	Default	Description
Use all input MQMD fields	No	No	Cleared	If you select `Use all input MQMD fields`, all MQMD fields at the `Input MQMD location` are used to retrieve the message. If an MQMD bit stream is present at the `Input MQMD location`, all fields in the bit stream are used. Make sure that the MQMD of the message to be retrieved matches these fields. By default, this check box is cleared. If you do not supply an input MQMD, the default MQMD is used. If you do supply an input MQMD, the default MQMD is used after the following modifications: • If you set the property `Use all input MQMD fields`, all MQMD fields supplied are copied into the default MQMD from the input MQMD. • If you do not set the property `Use all input MQMD fields`, and the properties `Get by Message ID` or `Get by Correlation ID` are selected, the respective IDs are copied into the default MQMD from the input MQMD. For more information about how the MQMD for the MQGET call is constructed, see "A request-response scenario that uses an MQGet node" on page 1569.
Browse only	No	No	Cleared	This property controls whether a message is removed from the queue when it is read. If this check box is selected, the message is not removed from the queue when it is read. Select `Browse only` to specify that the message must be retained on the queue when it is read.
Reset browse cursor	No	No	Cleared	You can set this property only if you have selected `Browse only`. When you select `Reset browse cursor`, the node browses from the start of the MQ queue (that is, the MQGMO_BROWSE_FIRST MQ get option is specified). If you do not select this property, the node browses from the current cursor position in the MQ queue (that is, the MQGMO_BROWSE_NEXT MQ get option is specified).

The Result properties of the MQGet node are described in the following table. Set these properties to determine how the results of the MQGET call are handled.

Property	M	C	Default	Description
Output data location	No	No	`OutputRoot`	This property specifies where the output data is placed. If you leave the field blank, `OutputRoot` is used as a default. Enter the start location in the output message tree at which the parsed elements from the bit string of the queue message are stored. All elements at this location are deleted, and the default behavior is to replace the input tree message with the queue message. You can enter any valid ESQL field reference (this reference can include expressions), including new field references to create a node in the message tree for inserting the response into the message that is propagated from the input tree. For example, `OutputRoot.XMLNS.ABC.DEF` and `Environment.GotReply` are valid field references. For more detailed information, see "A request-response scenario that uses an MQGet node" on page 1569. When the queue message bit string is parsed to create the contents of the message tree, the message properties that you have specified as the Input Message Parsing properties of the node are used.
Result data location	No	No	`ResultRoot`	This property specifies which subtree (of the queue message) to use. If you leave this field blank, `ResultRoot` is used as a default, and the whole queue message is used. If, for example, ResultRoot.MQMD.ReplyToQ is specified, only that subtree is used. Set this property to control which subtree of the queue message is placed in the output message. If, for example, you want only the MQMD from the queue message, use `ResultRoot.MQMD`; this subtree is then placed at the location specified by `Output data location`.
Output MQ parameters location	No	No	`OutputLocalEnvironment.MQ.GET`	This property specifies where the output WebSphere MQ parameters are located. If you leave this field blank, OutputLocalEnvironment.MQ.GET is used as a default. Set `Generate mode` to include `LocalEnvironment` to ensure that the updated values are visible in downstream nodes. The default location is `OutputLocalEnvironment.MQ.GET`. Set this property to control where the CC (completion code), the RC (reason code), the Browsed indicator, and any other WebSphere MQ parameters (for example, the MQMD that is used by the MQGET call) are placed in the output tree.

Property	M	C	Default	Description
Warning data location	No	No	`OutputRoot`	This property specifies where the output data is placed if MQGET returns a warning code. If you leave this field blank, `OutputRoot` is used as a default. Set this property to control where the queue message is placed when the MQGET call returns a warning code. You can enter any valid ESQL field reference (see the description of the `Output data location` property). The data that is placed at this location is always the complete result tree, with the body as a BLOB element. `Result data location` is not used for warning data.
Include message contents in output message assembly	No	No	Selected	This property specifies that no result or warning data is required for the output message assembly. If you select this check box, the node gets or browses the message on the queue without completely reading or parsing its contents. If you select `Include message contents in output message assembly`, the message contents are not guaranteed to be included in the output tree because this inclusion depends on other node properties, such as the `Generate mode` property. Clear `Include message contents in output message assembly` to specify that no result or warning data is required for the output message assembly. This action gets or browses the message on the queue without reading or parsing its contents.

The Validation properties of the MQGet node are described in the following table. For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Validate	No	Yes	`None`	This property controls whether validation takes place. Valid values are `None`, `Content`, `Content and Value`, and `Inherit`.	validateMaster
Failure action	No	No	`Exception`	This property controls what happens if validation fails. You can set this property only if you set `Validate` to `Content` or `Content and Value`. Valid values are `User Trace`, `Local Error Log`, `Exception`, and `Exception List`.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Parsers" on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

"Specifying namespaces in the Message Type property" on page 1208
When using the MRM domain, the *Message Type* property is used to specify the name of the message.

"Multipart messages" on page 1191
A *multipart message* contains one or more other messages within its structure. The contained message is sometimes referred to as an *embedded message*.

MQHeader node

Use the MQHeader node to add, modify, or delete MQ Message Descriptor (MQMD) and MQ Dead Letter Header (MQDLH) headers.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow"
- "Terminals and properties"

Purpose:
You can add or remove a whole header, or you can change only certain fields in a header. You can set these fields to a fixed value, or to a value specified by an XPath expression to access a value in one of the message trees. XPath is used to provide a valid location from which a value for a property can be copied. For example, the location can be the body of the message, the local environment tree, or an exception list.

The MQHeader node is contained in the **WebSphere MQ** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following sample for more details about how to use the node:
- MQHeader node

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
When you have put an instance of the node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. This node has no mandatory properties.

MQHeader node terminals are described in the following table:

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the input message is routed if a failure is detected.

Terminal	Description
Out	The output terminal to which the transformed message is routed if the input message is processed successfully.

The following tables describes the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The MQHeader node Description properties are described in the following table:

Property	M	C	Default	Description
Node name	No	No	MQHeader	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The MQ Message Descriptor properties are described in the following table: Refer to *WebSphere MQ Application Programming Reference* and *WebSphere MQ Application Programming Guide* for full details of each of the MQ property and its supported values.

Property	M	C	Default	Description	mqsiapplybaroverride command property
MQMD header options	No	No	`Carry forward header`	Options to control the MQMD as a whole. Select `Carry forward header` to carry forward any values that are present in an incoming message. Select `Add header` to add a new header using the specified property values. If a header already exists, the header is modified using the specified property values. If `Inherit from header` is specified as a property value and the header does not exist, the default value for the property is used. Select `Modify header` to change an existing header using the specified property values. If a header does not exist, a new header is added first. If `Inherit from header` is specified as a property value and the header does not exist, the default value for the property is used. Select `Delete header` to delete the header, if it exists. **Note:** The `Add header` and `Modify header` options both add a header if it does not exist, and change a header if it does exist. However, the default values offered by each option differ, so use the appropriate option.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Coded Character Set Identifer	No	No	MQCCSI_Q_MGR	The character set identifier of character data in the message. A sample set of custom literals for EBCIDIC and other common Unicode values is given here: MQCCSI_INTL_EBCIDIC : 500 MQCCSI_US_EBCIDIC : 037 MQCCSI_UNICODE_1200 : 1200 MQCCSI_UNICODE_1208 : 1208 MQCCSI_UNICODE_13488 : 13488 MQCCSI_UNICODE_17584 : 17584 Refer to the *WebSphere MQ Application Programming Reference* and *WebSphere MQ Application Programming Guide* for full details.	
Format	No	No	MQFMT_NONE	A name that the sender of the message can use to indicate to the receiver the nature of the data in the message.	
Version Number	No	No	MQMD_VERSION_1	The version ID of the MQMD message.	
Message Type	No	No	MQMT_DATAGRAM	The message type.	
Message Expiry	No	No	MQEI_UNLIMITED	A period of time expressed in tenths of a second, set by the application that puts the message. The message becomes eligible to be discarded if it has not been removed from the destination queue before this period of time elapses.	
Feedback or Reason Code	No	No	MQFB_NONE	Used with a message of type MQMT_REPORT to indicate the nature of the report, and meaningful only with that type of message.	
Message Priority	No	No	MQPRI_PRIORITY_AS_Q_DEF	Message priority. 0 is the lowest value, and 9 is the highest. Custom display literals are as follows: MQPRI_PRIORITY_HIGH : 9 MQPRI_PRIORITY_8 : 8 MQPRI_PRIORITY_7 : 7 MQPRI_PRIORITY_6 : 6 MQPRI_PRIORITY_5 : 5 MQPRI_PRIORITY_MEDIUM : 4 MQPRI_PRIORITY_3 : 3 MQPRI_PRIORITY_2 : 2 MQPRI_PRIORITY_1 : 1 MQPRI_PRIORITY_LOW : 0	
Message Persistence	No	No	MQPER_PERSISTENCE_AS_Q_DEF	Indicates whether the message survives system failures and restarts of the queue manager.	
Message Identifier	No	No	MQMI_NONE	A string that is used to distinguish one message from another.	
Correlation Identifier	No	No	MQCI_NONE	A string that the application can use to relate one message to another, or to relate the message to other work that the application is performing.	
Reply To Queue	No	Yes	<No default value>	The message queue to which the application that issued the get request for the message should send Reply and Report messages.	mqmdReplyToQ
Reply To Queue Manager	No	Yes	<No default value>	The queue manager to which the reply message or report message should be sent.	mqmdReplyToQMgr

The Report properties are described in the following table:

Property	M	C	Default	Description
Inherit from header	No	No	Selected	This property is enabled only when the `Modify header` option is selected. Select this field to inherit any MQMD report property value that is present in an incoming message.
Exception	No	No	No default value	A type of MQ report message. Exception report message is generated.
Expiration	No	No	No default value	A type of MQ report message. Expiration report message is generated.
Confirm on arrival	No	No	No default value	A type of MQ report message. Confirm on arrival report message is generated.
Confirm on delivery	No	No	No default value	A type of MQ report message. Confirm on delivery report message is generated.
Notification	No	No	No default value	A type of MQ report Message. Action notification report message is generated.

The MQDLH header properties are described in the following table:

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
MQDLH header options	No	No	`Carry forward the header`	Options to control the MQMD as a whole. Select `Carry forward header` to carry forward any values that are present in an incoming message. Select `Add header` to add a new header using the specified property values. If a header already exists, the header is modified using the specified property values. If `Inherit from header` is specified as a property value and the header does not exist, the default value for the property is used. Select `Modify header` to change an existing header using the specified property values. If a header does not exist, a new header is added first. If *Inherit from header* is specified as a property value and the header does not exist, the default value for the property is used. Select `Delete header` to delete the header, if it exists. **Note:** The `Add header` and `Modify header` options both add a header if it does not exist, and change a header if it does exist. However, the default values offered by each option differ, so use the appropriate option.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Coded Character Set Identifer	No	No	MQCCSI_UNDEFINED	The character set identifier of character data in the message.	
Format	No	No	MQFMT_NONE	A name that the sender of the message can use to indicate to the receiver the nature of the data in the message.	
Reason	No	No	MQRC_NONE	A code that indicates why the message is sent to the dead letter queue (DLQ).	
Destination Queue Name	No	Yes	No default value	The name of the destination queue.	mqdlhDestQName
Destination Queue Manager Name	No	Yes	No default value	The name of the destination queue manager.	mqdlhDestQMgrName
Save dead letter queue	No	No	Selected	If selected, the dead letter queue name is stored in the local environment.	
Save source queue	No	No	Selected	If selected, the original source queue name is stored in the local environment.	
Put Application Name	No	No	The name of the application that put the message on the dead-letter queue.	This property is set to WebSphereMQIntegrator and appended with the broker major version number, for example: WebSphereMQIntegrator9.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

MQInput node

Use the MQInput node to receive messages from clients that connect to the broker by using the WebSphere MQ Enterprise Transport, and that use the MQI and AMI application programming interfaces.

This topic contains the following sections:

Purpose:
The MQInput node receives a message from a WebSphere MQ message queue that is defined on the queue manager of the broker. The node uses MQGET to read a message from a specified queue, and establishes the processing environment for the message. If appropriate, you can define the input queue as a WebSphere MQ clustered queue or shared queue.

Message flows that handle messages that are received across WebSphere MQ connections must always start with an MQInput node. You can set the properties of the MQInput node to control the way in which messages are received, by causing appropriate MQGET options to be set. For example, you can indicate that a message is to be processed under transaction control. You can also request that data conversion is performed on receipt of every input message.

The MQInput node handles messages in the following message domains:
- XMLNSC
- DataObject
- JSON
- BLOB
- MIME
- MRM
- JMSMap
- JMSStream
- XMLNS

If you include an output node in a message flow that starts with an MQInput node, the output node can be any one of the supported output nodes, including user-defined output nodes; you do not have to include an MQOutput node. You can create a message flow that receives messages from WebSphere MQ clients and generates messages for clients that use any of the supported transports to connect to the broker, because you can configure the message flow to request that the broker provides any conversion that is necessary.

If you create a message flow to use as a subflow, you cannot use a standard input node; you must use an Input node as the first node to create an In terminal for the subflow.

If your message flow does not receive messages across WebSphere MQ connections, you can choose one of the supported input nodes.

The MQInput node is contained in the **WebSphere MQ** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using the MQInput node in a message flow:
Look at the following samples to see how to use the MQInput node:
- Pager
- Airline Reservations
- Error Handler
- Aggregation
- JMS Nodes
- Large Messaging

- Message Routing
- Scribble
- Timeout Processing
- Video Rental
- XSL Transform
- Browsing WebSphere MQ Queues

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Connecting the terminals:
The MQInput node routes each message that it retrieves successfully to the Out terminal. If this action fails, the message is tried again. If the backout count is exceeded (as defined by the BackoutThreshold attribute of the input queue), the message is routed to the Failure terminal; you can connect nodes to this terminal to handle this condition. If you have not connected the Failure terminal, the message is written to the backout queue.

If the message is caught by this node after an exception has been thrown further on in the message flow, the message is routed to the Catch terminal. If you have not connected the Catch terminal, the message loops continually through the node until the problem is resolved.

You must define a backout queue or a dead-letter queue (DLQ) to prevent the message from looping continually through the node.

Configuring for coordinated transactions:
When you include an MQInput node in a message flow, the value that you set for `Transaction mode` defines whether messages are received under sync point:

- If you set the property to `Automatic`, the message is received under sync point if the incoming message is marked as persistent; otherwise, it is not received under sync point. Any message that is sent later by an output node is put under sync point, as determined by the incoming persistence property, unless the output node has overridden this property explicitly.
- If you set the property to `Yes` (the default), the message is received under sync point; that is, within a WebSphere MQ unit of work. Any messages that are sent later by an output node in the same instance of the message flow are put under sync point, unless the output node has overridden this explicitly.
- If you set the property to `No`, the message is not received under sync point. Any messages that are sent later by an output node in the message flow are not put under sync point, unless an individual output node has specified that the message must be put under sync point.

The MQOutput node is the only output node that you can configure to override this option.

If you have set the `Browse Only` property, the value that is set for the `Transaction mode` property is ignored because a message cannot be browsed under sync point. However, any derived messages that are propagated later by an output node in the same instance of the message flow follow the behavior that is described previously in accordance with the specified `Transaction mode` value.

MQGET buffer size:

The MQGET buffer size is implemented internally by the broker and you cannot change it. The following description is provided for information only. You must not rely on it when you develop your message flows, because the internal implementation might change.

When the MQInput node initializes, it sets the size of the default buffer for the first MQGET to 4 KB. The MQInput node monitors the size of messages and increases or reduces the size of the buffer:

1. If an MQGET fails because the message is larger than the size of the buffer, the node immediately increases the size of the buffer to accommodate the message, issues the MQGET again, and zeros a message count.
2. When 10 messages have been counted since the increase in the size of the buffer, the node compares the size of the largest of the 10 messages with the size of the buffer. If the size of the largest message is less than 75% of the size of the buffer, the buffer is reduced to the size of the largest of the 10 messages. If an MQGET fails during the 10 messages because the message is larger than the size of the buffer, the node takes action 1.

For example, if the first message that the node receives is 20 MB, and the next 10 messages are each 14 MB, the size of the buffer is increased from 4 KB to 20 MB and remains at 20 MB for 10 messages. However, after the 10th message the size of the buffer is reduced to 14 MB.

Terminals and properties:
When you have put an MQInput node into a message flow, you can configure the node; see . The properties of the node are displayed in the Properties view. All mandatory properties that do not have a default value defined are marked with an asterisk.

The terminals of the MQInput node are described in the following table.

Terminal	Description
Failure	The output terminal to which the message is routed if an error occurs. Even if the Validation property is set, messages propagated to this terminal are not validated.
Out	The output terminal to which the message is routed if it is successfully retrieved from the WebSphere MQ queue.
Catch	The output terminal to which the message is routed if an exception is thrown downstream and caught by this node.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the MQInput node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, MQInput	The name of the node.
Short description	No	No		A brief description of the node.

Property	M	C	Default	Description
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the MQInput node are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Queue name	Yes	Yes		The name of the WebSphere MQ input queue from which this node retrieves messages (using MQGET) for processing by this message flow. You must predefine this WebSphere MQ queue to the queue manager that hosts the broker to which the message flow is deployed.	queueName

The MQInput node Input Message Parsing properties are described in the following table.

If the incoming message has an MQRFH2 header, you do not have to set values for the Input Message Parsing properties because the values are derived from the `<mcd>` folder in the MQRFH2 header; for example:

```
<mcd><Msd>MRM</Msd><Set>DHM4UO906S001</Set><Type>receiptmsg1</Type>
<Fmt>XML</Fmt></mcd>
```

If you set values, and those values differ from the values in the MQRFH2 header, and the `<Msd>` element is a valid domain, the values in the MQRFH2 header take precedence.

Property	M	C	Default	Description
Message domain	No	No	`BLOB`	The domain that is used to parse the incoming message. If no MQRFH2 header exists to supply the value for the `Message domain`, you can select the property value from the list. You can either select an option or leave the property blank, in which case the default that is used is BLOB. The following options are available: • XMLNSC • DataObject • JSON • BLOB • MIME • MRM • JMSMap • JMSStream • XMLNS You can also specify a user-defined parser, if appropriate.
Message set	No	No		If you use the MRM or IDOC parser, or the XMLNSC parser in validating mode, select the name or identifier of the message set in which the incoming message is defined. The list of message sets consists of the message sets that are available when you select MRM, XMLNSC, or IDOC as the domain. If you set this property, then later update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project.
Message type	No	No		If you use the MRM parser, select the type of message from the list. This list is populated with messages that are defined in the message set that you have selected.

Property	M	C	Default	Description
Message format	No	No		If you are using the MRM or IDOC parser, select the physical format of the incoming message from the list. This list includes all the physical formats that you have defined for this message set. If you set the `Message domain` property to `DataObject`, you can set this property to `XML` or `SAP ALE IDoc`. Set this property to `SAP ALE IDoc` when you have to parse a bit stream from an external source and generate a message tree.

The properties of the Parser Options for the MQInput node are described in the following table.

Property	M	C	Default	Description
Parse timing	No	No	`On Demand`	This property controls when an input message is parsed. Valid values are On Demand, Immediate, and Complete. `Parse timing` is, by default, set to `On Demand`, which causes parsing of the message to be delayed. To cause the message to be parsed immediately, see "Parsing on demand" on page 4173.
Use MQRFH2C compact parser for MQRFH2 header	No	No	Cleared	This property controls whether the MQRFH2C compact parser, instead of the MQRFH2 parser, is used for MQRFH2 headers.
Build tree using XML schema data types	No	No	Cleared	This property controls whether the XMLNSC parser creates syntax elements in the message tree with data types taken from the XML schema. You can select this property only if you set the `Validate` property on the **Validation** tab to `Content` or `Content and Value`.
Use XMLNSC compact parser for XMLNS domain	No	No	Cleared	This property controls whether the XMLNSC compact parser is used for messages in the XMLNS domain. If you set this property, the message data is displayed under XMLNSC in nodes that are connected to the output terminal when the input MQRFH2 header or the Input Message Parsing property `Message domain` is XMLNS. For more information, see "Manipulating messages in the XMLNSC domain" on page 2546.
Retain mixed content	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in an input message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in an input message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in an input message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the input message that are to be opaquely parsed by the XMLNSC parser. Opaque parsing is performed only if validation is not enabled (that is, if `Validate` is `None`); entries that are specified in `Opaque Elements` are ignored if validation is enabled.

The Advanced properties of the MQInput node are described in the following table. Set these properties to determine how the message is processed, such as its transactional characteristics. Many of these properties map to options on the MQGET call.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Transaction mode	Yes	No	`Yes`	This property controls whether the incoming message is received under sync point. Valid values are `Automatic`, `Yes`, and `No`. • If you select `Automatic`, the incoming message is received under sync point if it is marked persistent, otherwise it is not received under sync point. The transactionality of any derived messages that are sent later by an output node is determined by the incoming persistence property, unless the output node has overridden transactionality explicitly. • If you select `Yes`, the incoming message is received under sync point. Any derived messages that are sent later by an output node in the same instance of the message flow are sent transactionally, unless the output node has overridden transactionality explicitly. • If you select `No`, the incoming message is not received under sync point. Any derived messages that are sent later by an output node in the message flow are sent non-transactionally, unless the output node has specified that the messages must be put under sync point.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Order mode	Yes	No	`Default`	The order in which messages are retrieved from the input queue and processed. Messages arriving can be processed in order, or any thread can process any message when it is ready. When ordering is imposed, a thread processes a message only if it is the first unprocessed message available with a unique ordering value.Valid values are `Default`, `By User ID`, `By Queue Order`, and `User Defined`. This property has an effect only if the message flow property `Additional instances` on the **Instances** tab, is set to greater than zero; that is, if multiple threads read the input queue. Valid values are: • `Default`. Messages are retrieved in the order that is defined by the queue attributes, but this order is not guaranteed because the messages are processed by the message flow. • `By User ID`. Messages that have the same UserIdentifier value in the MQMD are retrieved and processed in the order that is defined by the queue attributes; this order is guaranteed to be preserved when the messages are processed. A message that is associated with a particular user identifier that is being processed by one thread, is completely processed before the same thread, or another thread, can start to process another message with the same user identifier. Ensure that each message has a unique message ID in the MQMD of the incoming message. No other ordering is guaranteed to be preserved. • `By Queue Order`. Messages are retrieved and processed by this node in the order that is defined by the queue attributes; this order is guaranteed to be preserved when the messages are processed. This behavior is identical to the behavior that is exhibited if the message flow property `Additional instances` is set to zero. However, if you set `Order mode` to `By Queue Order` then redeploy the message flow, additional instances that are already running are not released. Therefore, when you set `Order mode` to `By Queue Order`, either stop and restart the message flow, or run the **mqsireload** command for the execution group after you redeploy the flow. • ⌂`User Defined`. You can specify a message element using the `Order field location` property. For more details about using this option, see “Optimizing message flow throughput” on page 587 and “Receiving messages in a WebSphere MQ message group” on page 1554.	
Order field location	N	N	""	An XPath or ESQL expression property to control which part of the message is used to impose ordering on incoming messages when `Order mode` is `User Defined`. If the field is missing, an exception is raised, and the message is rolled back. NULL and empty values are processed separately, in parallel.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Logical order	Yes	No	Selected	If you select this check box, messages are received in logical order, as defined by WebSphere MQ. This option maps to the MQGMO_LOGICAL_ORDER option of the MQGMO of the MQI. If you clear the check box, messages that are sent as part of a group are not received in a predetermined order. If a broker expects to receive messages in groups, and you have not selected this check box, either the order of the input messages is not significant, or you must design the message flow to process them appropriately. You must also select `Commit by message group` if you want message processing to be committed only after the final message of a group has been received and processed. More information about the options to which this property maps is available in the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online. For more details about using this option, see "Receiving messages in a WebSphere MQ message group" on page 1554.	
All messages available	Yes	No	Cleared	Select `All messages available` if you want message retrieval and processing to be done only when all messages in a single group are available. This property maps to the MQGMO_ALL_MSGS_AVAILABLE option of the MQGMO of the MQI. Clear this check box if message retrieval does not depend on all of the messages in a group being available before processing starts. More information about the options to which this property maps is available in the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.	
Match message ID	No	No		A message ID that must match the message ID in the MQMD of the incoming message. Enter a message identifier if you want the input node to receive only messages that contain a matching message identifier value in the MsgId field of the MQMD. Enter an even number of hexadecimal digits (characters `0 to 9`, `A to F`, and `a to f` are valid) up to a maximum of 48 digits. If the matching message identifier that you enter is shorter than the size of the MsgId field, `Match message ID` is padded on the right with `X'00'` characters. This property maps to the MQMO_MATCH_MSG_ID option of the MQGMO of the MQI. Leave this property blank if you do not want the input node to check that the message ID matches. More information about the options to which this property maps is available in the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Match correlation ID	No	No		A correlation ID that must match the correlation ID in the MQMD of the incoming message. Enter a message identifier if you want the input node to receive only messages that contain a matching correlation identifier value in the CorrelId field of the MQMD. Enter an even number of hexadecimal digits (characters `0 to 9`, `A to F`, and `a to f` are valid) up to a maximum of 48 digits. If the ID that you enter is shorter than the size of the CorrelId field, it is padded on the right with `X'00'` characters. This property maps to the MQMO_MATCH_CORREL_ID option of the MQGMO of the MQI. Leave this property blank if you do not want the input node to check that the CorrelID matches. More information about the options to which this property maps is available in the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Convert	Yes	No	Cleared	If you select this check box, WebSphere MQ converts data in the message to be received, in conformance with the CodedCharSetId and Encoding values set in the MQMD. Select `Convert` if you want WebSphere MQ to perform data conversion on the message when it is retrieved from the queue. This option is useful if you are handling messages in the BLOB domain, or are using a user-defined parser. Do not select this option if you are parsing messages with the XML or MRM domains, because the parser does the conversion. WebSphere MQ converts the incoming message to the encoding and coded character set that is specified in the MQMD that the input node supplies on the MQGET call to retrieve the message from the input queue. The broker uses the MQGMO_CONVERT option on the MQGET call; typical rules for WebSphere MQ conversion apply. The values that you specify in the `Convert encoding` and `Convert coded character set ID` options are used in the **MsgDesc Encoding** and **CCSID** fields in the MQGET call. WebSphere MQ can convert the incoming message only if the MQMD **Format** field is a built-in WebSphere MQ value that identifies character data, or if a data conversion exit exists in WebSphere MQ. This property maps to the MQGMO_CONVERT option of the MQGMO of the MQI. Clear the check box if you do not want WebSphere MQ to convert the message. If you select this check box, you can also specify values for the `Convert encoding` and `Convert coded character set ID` properties. For more information about WebSphere MQ data conversion, and why you might choose to use this option, see the *Application Programming Guide* section of the WebSphere MQ Version 7 Information Center online.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Convert encoding	No	No		The representation used for numeric values in the message data, expressed as an integer value. This property is valid only if you have selected `Convert`. Enter the number that represents the encoding to which you want to convert numeric data in the message body. Valid values include: • Linux Windows `546` for DOS, all Windows systems, and Linux on x86 • Linux UNIX `273` for Linux on Linux on POWER, Linux on IBM z Systems, and all UNIX systems • z/OS `785` for z/OS messages that use Binary Packed Decimals, and 273 for messages that use IEEE floating point numbers The encoding is used only in the following circumstances: • If a user-defined WebSphere MQ data conversion exit uses the encoding. • If the built-in WebSphere MQ conversion exit uses the encoding to convert messages in any of the predefined WebSphere MQ formats. If you specify an incorrect value, no conversion is done. For further information about the values that you can specify for `Convert encoding`, see "Data conversion" on page 1151 and the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.	
Convert coded character set ID	No	No		The coded character set identifier of character data in the message data, expressed as an integer value. This property is valid only if you have selected `Convert`. Enter the value that represents the character set identifier to which you want to convert character data in the message body. If you specify an incorrect value, no conversion is done. For further information about the values that you can specify for `Convert coded character set ID`, see the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Commit by message group	Yes	No	Cleared	This property controls when a transaction is committed when processing messages that are part of a message group. If you select the check box, the transaction is committed when the message group has been processed. If you leave this check box cleared, a commit is performed after each message has been propagated completely through the message flow. This property is relevant only if you have selected `Logical order`. Set the `Order mode` property to `By Queue Order` if the messages in a group must be retrieved and processed in the order in which they are displayed on the queue.	
z/OS serialization token	No	No		On z/OS only: A user-defined token for serialized application support. The value that is specified must conform to the rules for a valid ConnTag in the WebSphere MQ MQCNO structure. Enter a serialization token if you want to use the serialized access to shared resources that is provided by WebSphere MQ. The value that you provide for the serialization token must conform to the rules described in the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online. For more information about serialization and queue sharing on z/OS, see the *Concepts and Planning Guide* section of the WebSphere MQ Version 7 Information Center online.	serializationToken
Topic	No	Yes		The default topic for the input message. You can associate a message with a publish/subscribe topic by using this property. You can enter any characters as the topic name. When messages pass through the MQInput node, they take on whatever topic name you have entered. (If you are using publish/subscribe, you can subscribe to a topic and see any messages that passed through the MQInput node and were published under that topic name.) If the incoming message has an MQRFH2 header, you do not have to set a value for the `Topic` property because the value can be obtained from the `<psc>` folder in the MQRFH2 header; for example: `<psc><Topic>stockquote</Topic></psc>` If you set a `Topic` property value, and that value differs from the <Topic> value in the MQRFH2 header, the value in the MQRFH2 header takes precedence.	topicProperty
Browse Only	No	No	Cleared	This property controls whether a message is removed from the queue when it is read. If you select this check box, the message is not removed from the queue when it is read. If you select this option, `OutputLocalEnvironment.MQ.GET.Browsed` is set to true when a message is propagated to the output terminal of the MQInput node.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Reset browse timeout (ms)	Yes	Yes	-1	The time, in milliseconds, between the last eligible message being browsed on the input queue and the browse being reset to the beginning of the queue. The default value of -1 indicates that the browse is not reset.	

The Validation properties of the MQInput node are described in the following table. Set these properties if you want the parser to validate the body of messages against the Message set. (If a message is propagated to the Failure terminal of the node, it is not validated.)

For more details, see "Validating messages" on page 1478 and "Validation properties" on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	Yes	None	This property controls whether validation takes place. Valid values are None, Content, and Content and Value.	validateMaster
Failure action	No	No	Exception	This property controls what happens if validation fails. You can set this property only if you set Validate to Content or Content and Value. Valid values are User Trace, Local Error Log, Exception, and Exception List.	

The Security properties of the MQInput node are described in the following table. Set values for these properties to control the extraction of an identity from a message (when a security profile is associated with the node). For more information about these properties, see "Identity" on page 390, "Configuring the extraction of an identity or security token" on page 447, "Message flow security overview" on page 383, and "Setting up message flow security" on page 431.

Property	M	C	Default	Description
Identity token type	No	No	None	This property specifies the type of identity token present in the incoming message. Valid values are: • Transport Default • Username • Username + Password • SAML Assertion • X.509 Certificate If this property is not specified, the identity is retrieved from the transport headers and the type is set to Username.
Identity token location	No	No	None	This property specifies where, in the message, the identity can be found. The location is specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotation marks and must not contain a period (.), If this property is not specified, the identity is retrieved from the MQMD.UserIdentifier transport header.
Identity password location	No	No	None	This property specifies where, in the message, the password can be found. The location is specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotation marks and must not contain a period (.), If it is not specified, the password is not set. This property can be set only if Identity token type is set to Username + Password.

Property	M	C	Default	Description
Identity IssuedBy location	No	No	`None`	This property specifies a string or path expression that describes the issuer of the identity. The location is specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotation marks and must not contain a period (.), The value specifies the Issuer that is passed to a WS-Trust v1.3 STS provider. If this property is not specified, the MQMD.PutApplName value is used. If you leave the `Identity issuedBy location` field blank and the MQMD.PutApplName is also blank, the string `MQ` is used.
Treat security exceptions as normal exceptions	No	No	`False`	This property specifies whether to treat security exceptions (such as "Access Denied") as normal exceptions, and propagate them to the Failure terminal (if wired). This property is turned off by default, which ensures that security exceptions cause the message to be backed out even if the Failure terminal is wired.

The Instances properties of the MQInput node are described in the following table. Set values for these properties to control the additional instances that are available for a node. For a full description of these properties, see "Configurable message flow properties" on page 4020.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Additional instances pool	No	Yes	`Use Pool Associated with Message Flow`	The pool from which additional instances are obtained. • If you select `Use Pool Associated with Message Flow`, additional instances are obtained from the message flow value. • If you select `Use Pool Associated with Node`, additional instances are allocated from the additional instances of the node, based on the number specified in the `Additional instances` property.	componentLevel
Additional instances	No	Yes	`0`	The number of additional instances that the node can start if the `Additional instances pool` property is set to `Use Pool Associated with Node`. By default, no additional instances are given to the node.	additionalInstances

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

MQJMSTransform node

Use the MQJMSTransform node to receive messages that have a WebSphere MQ JMS provider message tree format, and transform them into a format that is compatible with messages that are to be sent to JMS destinations.

This topic contains the following sections:
- "Purpose"
- "Using the MQJMSTransform node in a message flow" on page 4611
- "Terminals and properties" on page 4611

Purpose:
Use the MQJMSTransform node to send messages to existing message flows and to interoperate with WebSphere MQ JMS and WebSphere Message Broker publish/subscribe.

The JMSMQTransform node handles messages in all supported message domains.

The MQJMSTransform node is contained in the **JMS** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using the MQJMSTransform node in a message flow:
The following sample contains a message flow in which the MQJMSTransform node is used. Look at this sample for an example of how to use the MQJMSTransform node.

- JMS Nodes

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
When you have put an instance of the MQJMSTransform node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

The terminals of the MQJMSTransform node are described in the following table.

Terminal	Description
Failure	The output terminal to which the message is routed if an error occurs. Even if the Validation property is set, messages that are propagated to this terminal are not validated.
Out	The output terminal to which the message is routed if it is successfully retrieved from the WebSphere MQ queue.
In	The input terminal that accepts a message for processing by the node.

The following table describes the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The MQJMSTransform node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, MQJMSTransform	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related reference:

"JMSInput node" on page 4532
Use the JMSInput node to receive messages from JMS destinations. JMS destinations are accessed through a connection to a JMS provider.

"JMSOutput node" on page 4549
Use the JMSOutput node to send messages to JMS destinations.

"JMSMQTransform node" on page 4547
Use the JMSMQTransform node to transform a message with a JMS message tree into a message that has a message tree structure that is compatible with the format of messages that are produced by the WebSphere MQ JMS provider.

"WebSphere Broker JMS Transport" on page 1681
The WebSphere Broker JMS Transport is a service that connects applications that send and receive messages that conform to the Java Message Service (JMS) standard.

MQOptimizedFlow node

Use the MQOptimizedFlow node to provide a high-performance publish/subscribe message flow. The node supports publishers and subscribers that use Java Message Service (JMS) application programming interfaces and the WebSphere MQ Enterprise Transport.

Restriction: z/OS You cannot use an MQOptimizedFlow node in message flows that you deploy to z/OS systems.

The MQOptimizedFlow node is deprecated. The node continues to work but is no longer required.

MQOutput node

Use the MQOutput node to send messages to clients that connect to the broker using the WebSphere MQ Enterprise Transport and that use the MQI and AMI application programming interfaces.

This topic contains the following sections:

Purpose:

The MQOutput node delivers an output message from a message flow to a WebSphere MQ queue. The node uses MQPUT to put the message to the destination queue or queues that you specify.

If appropriate, define the queue as a WebSphere MQ clustered queue or shared queue. When you use a WebSphere MQ clustered queue, leave the Queue Manager Name empty.

You can configure the MQOutput node to put a message to a specific WebSphere MQ queue that is defined on any queue manager that is accessible by the queue manager for the broker, or to the destinations identified in the local environment that is associated with the message.

Set other properties to control the way in which messages are sent, by causing appropriate MQPUT options to be set; for example, you can request that a message is processed under transaction control. You can also specify that WebSphere MQ can, if appropriate, break the message into segments in the queue manager.

If you create a message flow to use as a subflow, you cannot use a standard output node; use an instance of the Output node to create an Out terminal for the subflow through which to propagate the message.

If you do not want your message flow to send messages to a WebSphere MQ queue, choose another supported output node.

The MQOutput node checks for the presence of an MQMD (WebSphere MQ message descriptor) header in the message tree. If no MQMD header is present, the MQOutput node creates one in the message tree, and populates it with MQMD default properties. If an MQMD header is found, the MQOutput node checks that it is an WebSphere MQ type header; if it is not, the `Message Context` property is set to `Default`. The MQOutput node treats any other transport headers in the message tree as data. If such headers are not required as part of the message body, use a transformation node to remove them from the message tree before the MQOutput node. If the message tree is sourced from JMS, you can use a JMSMQTransform node to construct a message tree compatible with MQ. For further details, see “JMS message transformation” on page 1684.

The MQOutput node is contained in the **WebSphere MQ** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following samples to see how to use this node:
- Pager
- Airline Reservations
- Error Handler
- Aggregation
- Large Messaging
- Message Routing
- Timeout Processing
- Video Rental
- XSL Transform

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

For an example of how to use this node, assume that you have written a publishing application that publishes stock updates on a regular basis. The application sends the messages to the broker on an MQInput node, and the message flow makes the publications available to multiple subscribers through a Publication node. You configure a Compute node to create a new output message whenever one particular stock is changed, and connect this node to an MQOutput node to record each price change for this stock.

Working with WrittenDestination data

After the message has been put, the WrittenDestination folder in the local environment is updated with the destination information. WrittenDestination data for an MQOutput node has the following format:

```
WrittenDestination = (
   MQ  = (
      z`DestinationData = (
         queueName        = 'OUT'
         queueManagerName = 'MYQUEUEMANAGER'
         replyIdentifier = X'4d...2e'
         msgId           = X'3c...2c'
         correlId        = X'2a...00'
         GroupId         = X'3a...00'
      )
   )
)
```

Connecting the terminals:
Connect the In terminal to the node from which outbound messages bound are routed.

Connect the Out or Failure terminal of this node to another node in this message flow to process the message further, process errors, or send the message to an additional destination.

If you use aggregation in your message flows, you must use the output terminals.

Contents of the WebSphere MQ reply message:
The:

- Values of the following fields in MQMD are set, irrespective of the settings you make:

  ```
  MQMD.Report = 0;
  MQMD.PutApplType = MQAT_BROKER;
  MQMD.PutDate = Taken from current Timestamp
  MQMD.PutTime = Taken from current Timestamp
  MQMD.PutApplName = MsgTree.MQMD.ReplyToQMgr (first 28 chars)
  ```

- Values of the following fields are set from the values in the `Root.MQMD` folder:

  ```
  MQMD.Version
  MQMD.Format
  MQMD.Priority
  MQMD.Persistence
  MQMD.Expiry
  MQMD.Encoding
  MQMD.CodedCharSetId
  MQMD.GroupId
  ```

```
MQMD.MsgSeqNumber
MQMD.Offset
MQMD.MsgFlags
MQMD.OriginalLength
```

- Following values in MQMD are set conditionally, based on values in the MQOutput node and the `Root.MQMD` folder:

```
IF MsgTree.MQMD.MsgType = MQMT_REQUEST THEN
  MQMD.MsgType = MQMT_REPLY;
IF Nodes Message Context is Default, PassAll or PassIdentity THEN
  MQMD.UserIdentifer = MsgTree.MQMD.UserIdentifier;
IF MsgTree.MQMD.Report contains MQRO_PASS_CORREL_ID THEN
  MQMD.CorrelId = MsgTree.MQMD.CorrelId;
ELSE
  MQMD.CorrelId = MsgTree.MQMD.MsgId;
IF MsgTree.MQMD.Report contains MQRO_PASS_MSG_ID THEN
  MQMD.MsgId = MsgTree.MQMD.MsgId;
ELSE
  MQMD.MsgId = MQMI_NONE;
```

- Value of the `MQMD.Persistence` field is set based on the `Persistence` mode on the MQOutput node.

When the output MQMD structure has been constructed, the `Message Context` on the MQOutput node is ignored, and the behavior is as `set All`.

The values that are overridden, are done only in the output MQMD structure; no updates are made to the MQMD folder in the message tree.

Configuring for coordinated transactions:
When you define an MQOutput node, the option that you select for the `Transaction Mode` property defines whether the message is written under sync point:

- If you select `Yes`, the message is written under sync point (that is, within a WebSphere MQ unit of work).
- If you select `Automatic` (the default), the message is written under sync point if the incoming input message is marked as persistent.
- If you select `No`, the message is not written under sync point.

Another property of the MQOutput node, `Persistence Mode`, defines whether the output message is marked as persistent when it is put to the output queue:

- If you select `Yes`, the message is marked as persistent.
- If you select `Automatic` (the default), the message persistence is determined from the properties of the incoming message, as set in the MQMD.
- If you select `No`, the message is not marked as persistent.
- If you select `As Defined for Queue`, the message persistence is set as defined in the WebSphere MQ queue by the MQOutput node specifying the MQPER_PERSISTENCE_AS_Q_DEF option in the MQMD.

Terminals and properties:
When you have put an instance of the MQOutput node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

The MQOutput node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.

Terminal	Description
Failure	The output terminal to which the message is routed if a failure is detected when the message is put to the output queue.
Out	The output terminal to which the message is routed if it has been successfully put to the output queue.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file for deployment).

The MQOutput node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, MQOutput	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The MQOutput node Basic properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Queue Manager Name	No	Yes		Enter the name of the WebSphere MQ queue manager to which this output queue (which is specified by the `Queue Name` property) is defined. The `Queue Manager Name` property is only needed if the queue specified is defined on another queue manager or is a cluster queue. If it is a cluster queue, then `Queue Manager Name` can optionally be specified if you want to be prescriptive about which queue manager receives the message. If the queue is defined on a remote queue manager, the `Queue Manager Name` must be specified and it must match the transmission queue defined on the broker's local queue manager, for that remote queue manager.	queueManagerName
Queue Name	No	Yes		To send the output message to a single destination queue that is defined by this node, enter the name of the WebSphere MQ output queue to which the message flow sends messages. If you set the `Destination Mode` property to `Queue Name`, you must specify a value for the `Queue Name` property. If you set `Destination Mode` to another value, this property is ignored.	queueName

The MQOutput node Advanced properties are described in the following table. These properties define the transactional control for the message and the way in which the message is put to the queue. Many of these properties map to options on the MQPUT call.

Property	M	C	Default	Description
Destination Mode	Yes	No	`Queue Name`	The queues to which the output message is sent. • If you select `Queue Name` (the default), the message is sent to the queue that is named in the `Queue Name` property. If you select this option, you must set the `Queue Manager Name` and `Queue Name` properties. • If you select `Reply To Queue`, the message is sent to the queue that is named in the ReplyToQ field in the MQMD. When you select this value, the MQOutput node constructs a WebSphere MQ reply message. For more information about the settings that are used by the MQOutput node and the `Root.MQMD` folder in this situation, see "Contents of the WebSphere MQ reply message" on page 4614. • If you select `Destination List`, the message is sent to the list of queues that are named in the local environment that is associated with the message. The data that you have provided is used in the DestinationData subtree of the local environment. For more information about the DestinationData subtree, see "Data types for elements in the MQ DestinationData subtree" on page 4240. For more information about destination lists, see "Creating destination lists" on page 1477.
Transaction Mode	Yes	No	`Automatic`	This property controls whether the message is put transactionally. • If you select `Automatic` (the default), the message transactionality is derived from the way that it was specified at the input node. • If you select `Yes`, the message is put transactionally. • If you select `No`, the message is put non-transactionally. For more information, see "Configuring for coordinated transactions" on page 4615.
Persistence Mode	Yes	No	`Automatic`	This property controls whether the message is put persistently. • If you select `Automatic` (the default), the persistence is as specified in the incoming message. • If you select `Yes`, the message is put persistently. • If you select `No`, the message is put non-persistently. • If you select `As Defined for Queue`, the message persistence is set as defined for the WebSphere MQ queue.
New Message ID	Yes	No	Cleared	If you select this check box, WebSphere MQ generates a new message identifier to replace the contents of the **MsgId** field in the MQMD. This property maps to the MQPMO_NEW_MSG_ID option of the MQPMO of the MQI. Clear the check box if you do not want to generate a new ID. A new message ID is still generated if you select the `Request` property on the **Request** tab. For more information about the options to which this property maps, see the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.
New Correlation ID	Yes	No	Cleared	If you select this check box, WebSphere MQ generates a new correlation identifier to replace the contents of the CorrelId field in the MQMD. This property maps to the MQPMO_NEW_CORREL_ID option of the MQPMO of the MQI. Clear the check box if you do not want to generate a new ID. For more information about the options to which this property maps, see the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.

Property	M	C	Default	Description
Segmentation Allowed	Yes	No	Cleared	If you select this check box, WebSphere MQ breaks the message into segments in the queue manager. Clear the check box if you do not want segmentation to occur. For more information about message segmentation, see "Sending message segments in a WebSphere MQ message" on page 1557. For more information about the options to which this property maps, see the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.
Message Context	Yes	No	`Pass All`	This property controls how origin context is handled. • `Pass All` maps to the MQPMO_PASS_ALL_CONTEXT option of the MQPMO of the MQI. • `Pass Identity` maps to the MQPMO_PASS_IDENTITY_CONTEXT option of the MQPMO of the MQI. • `Set All` maps to the MQPMO_SET_ALL_CONTEXT option of the MQPMO of the MQI. • `Set Identity` maps to the MQPMO_SET_IDENTITY_CONTEXT option of the MQPMO of the MQI. • `Default` maps to the MQPMO_DEFAULT_CONTEXT option of the MQPMO of the MQI. • `None` maps to the MQPMO_NO_CONTEXT option of the MQPMO of the MQI. When a security profile is associated with the node and is configured to perform identity propagation, the chosen context can be overridden to ensure that the outgoing identity is set. For more information about the options to which these properties map, see the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.
Alternate User Authority	Yes	No	Cleared	If you select this check box, alternate authority is used when the output message is put and the MQOO_ALTERNATE_USER_AUTHORITY option is set in the open options (MQOO) of the MQI. If you select this check box, this option is specified when the queue is opened for output. The alternative user information is retrieved from the context information in the message. Clear the check box if you do not want to specify alternative user authority. If you clear the check box, the broker service user ID is used when the message is put.

The MQOutput node Request properties are described in the following table. These properties define the characteristics of each output message that is generated.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Request	Yes	No	Cleared	If you select the check box, each output message in the MQMD is generated as a request message (MQMT_REQUEST), and the message identifier field is cleared (and set to MQMI_NONE) so that WebSphere MQ generates a new identifier. Clear the check box to indicate that each output message is not marked as a request message. If you have set `Destination Mode` to `Reply To Queue`, you cannot select this check box. A new message identifier is generated even if the `New Message ID` check box is not selected on the **Advanced** tab.	
Reply-to Queue Manager	No	Yes		The name of the WebSphere MQ queue manager to which the output queue, which is specified in `Reply-to Queue`, is defined. This name is inserted into the MQMD of each output message as the reply-to queue manager.	replyToQMgr
Reply-to Queue	No	Yes		The name of the WebSphere MQ queue to which to put a reply to this request. This name is inserted into the MQMD of each output message as the reply-to queue.	replyToQ

The Validation properties of the MQOutput node are described in the following table.

For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	Yes	`Inherit`	This property controls whether validation takes place. Valid values are `None`, `Content and Value`, `Content`, and `Inherit`.	validateMaster
Failure Action	No	No	`Exception`	This property controls what happens if validation fails. You can set this property only if you set `Validate` to `Content` or `Content and Value`. Valid values are `User Trace`, `Local Error Log`, `Exception`, and `Exception List`.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

MQReply node

Use the MQReply node to send a response to the originator of the input message.

This topic contains the following sections:

Purpose:

The MQReply node is a specialized form of the MQOutput node that puts the output message to the WebSphere MQ queue that is identified by the ReplyToQ field of the input message header. If appropriate, you can define the queue as a WebSphere MQ clustered queue or shared queue.

The MQReply node uses the options that are set in the Report field in the MQMD. By default (if no options are set), the MQReply node generates a new MsgId field in the reply message, and copies the message ID from the input message to the CorrelId field in the reply message. If the receiving application expects other values in these fields, ensure that the application that puts the message to the message flow input queue sets the required report options, or that you set the appropriate options in the MQMD during message processing in the message flow; for example, use a Compute node to set the Report options in the message.

More information about the Report field is available in the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.

The MQReply node is contained in the **WebSphere MQ** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:

Look at the following sample to see how to use this node:

- Airline Reservations

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

You can use this node when you receive an order from a customer. When the order message is processed, a response is sent to the customer acknowledging receipt of the order and providing a possible date for delivery.

Working with data in the WrittenDestination folder

After the message has been put to the reply queue, the WrittenDestination folder in the local environment tree is updated with the destination information. A WrittenDestination folder for an MQOutput node has the following format:

```
WrittenDestination = (
   MQ  = (
      DestinationData = (
         queueName        = 'OUT'
         queueManagerName = 'MYQUEUEMANAGER'
         replyIdentifier = X'4d...2e'
         msgId           = X'3c...2c'
         correlId        = X'2a...00'
         GroupId         = X'3a...00'
      )
   )
)
```

Configuring the MQReply node:
When you have put an instance of the MQReply node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

Configure the MQReply node as follows:

1. Optional: On the **Description** tab, enter a short description, a long description, or both. You can also rename the node on this tab.
2. On the **Advanced** tab:
   a. Select `Segmentation Allowed` if you want WebSphere MQ to break the message into segments in the queue manager, when appropriate. You must also set `MQMF_SEGMENTATION_ALLOWED` in the MsgFlags field in the MQMD for segmentation to occur.

      More information about the options to which this property maps is available in the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.
   b. Choose the persistence mode that you want for the output message.
      - If you select Automatic (the default), the persistence is as specified in the incoming message.
      - If you select Yes, the message is put persistently.
      - If you select No, the message is put non-persistently.
      - If you select As Defined for Queue, the message persistence is set as defined in the WebSphere MQ queue.
   c. Choose the transaction mode that you want for the output message.
      - If you select Automatic (the default), the message transactionality is derived from how it was specified at the MQInput node.
      - If you select Yes, the message is put transactionally.
      - If you select No, the message is put non-transactionally.
3. On the **Validation** tab, set the validation properties; see "Validation properties" on page 4169. If a message is propagated to the Failure terminal of the node, it is not validated.

   For more details, see "Validating messages" on page 1478.

The reply message is put (using MQPUT) to the queue named in the input message MQMD as the ReplyTo queue. You cannot change this destination.

Connecting the output terminals to another node:
Connect the Out or Failure terminal of this node to another node in the message flow to process the message further, process errors, or send the message to an additional destination.

If you use aggregation in your message flows, you must connect these output terminals.

Configuring for coordinated transactions:
When you define an MQReply node, the option that you select for the `Transaction Mode` property defines whether the message is written under sync point:

- If you select Yes, the message is written under sync point (that is, in a WebSphere MQ unit of work).
- If you select Automatic (the default), the message is written under sync point if the incoming input message is marked as persistent.
- If you select No, the message is not written under sync point.

Another property of the MQReply node, `Persistence Mode`, defines whether the output message is marked as persistent when it is put to the output queue:

- If you select Yes, the message is marked as persistent.
- If you select Automatic (the default), the message persistence is determined by the properties of the incoming message, as set in the MQMD (the WebSphere MQ message descriptor).
- If you select No, the message is not marked as persistent.
- If you select As Defined for Queue, the message persistence is set as defined in the WebSphere MQ queue; the MQReply node specifies the MQPER_PERSISTENCE_AS_Q_DEF option in the MQMD.

Terminals and properties:
The MQReply node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the message is routed if a failure is detected when the message is put to the output queue.
Out	The output terminal to which the message is routed if it has been successfully put to the output queue, and if further processing is required in this message flow.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory*; the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file for deployment).

The MQReply node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type.	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The MQReply node Advanced properties are described in the following table.

Property	M	C	Default	Description
Segmentation Allowed	Yes	No	Cleared	If you select this check box, WebSphere MQ breaks the message into segments in the queue manager.
Persistence Mode	Yes	No	Automatic	This property controls whether the message is put persistently. Valid values are Automatic, Yes, No, and As Defined for Queue.
Transaction Mode	Yes	No	Automatic	This property controls whether the message is put transactionally. Valid values are Automatic, Yes, and No.

The Validation properties of the MQReply node are described in the following table.

For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	Yes	Inherit	This property controls whether validation takes place. Valid values are None, Content and Value, Content, and Inherit.	validateMaster
Failure Action	No	No	Exception	This property controls what happens if validation fails. You can set this property only if you set `Validate` to Content or Content and Value. Valid values are User Trace, Local Error Log, Exception, and Exception List.	

The MQReply node also has the following properties that you cannot access or modify through the WebSphere Message Broker Toolkit interface. However, these values are used by the broker when the message is processed in the message flow.

Property	Description
Queue Manager Name	The name of the WebSphere MQ queue manager to which the output queue, identified in `Queue Name`, is defined. This name is retrieved from the ReplyTo field of the MQMD header of the input message.
Queue Name	The name of the WebSphere MQ queue to which the output message is put. This name is retrieved from the ReplyTo field of the MQMD header of the input message.
Destination	This property always has the value reply.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Output node

Use the Output node as an out terminal for an embedded message flow (a subflow).

This topic contains the following sections:

Purpose:

You can use a subflow for a common task that can be represented by a sequence of message flow nodes. For example, you can create a subflow to increment or decrement a loop counter, or to provide error processing that is common to a number of message flows.

You must use an Output node to provide the Out terminal to a subflow; you cannot use a standard output node (a built-in output node such as MQOutput, or a user-defined output node).

You can include one or more Output nodes in a subflow. Each one that you include provides a terminal through which you can propagate messages to subsequent nodes in the message flow in which you include the subflow.

The Output node is contained in the **Construction** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

When you select and include a subflow in a message flow, it is represented by the following icon:

When you include the subflow in a message flow, this icon exhibits a terminal for each Output node that you included in the subflow, and the name of the terminal (which you can see when you move your mouse pointer over it) matches the name of that instance of the Output node. Give your Output nodes meaningful names, you can easily recognize them when you use their corresponding terminal on the subflow node in your message flow.

Using this node in a message flow:

Look at the following sample to see how to use this node:

- Error Handler

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
When you have put an instance of the Output node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

The Output node terminals are described in the following table.

Terminal	Description
In	The output terminal that defines an out terminal for the subflow.

The following table describes the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Output node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, Output	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Subflows" on page 1030
You can include subflows in your message flows in the same way as you include built-in or user-defined nodes. You can also connect subflows to other nodes in the same way.

Related tasks:

"Deciding which nodes to use" on page 1457
WebSphere Message Broker includes many message processing nodes that you can

use in your message flows.

Related reference:

"Input node" on page 4511
Use the Input node as an In terminal for an embedded message flow (a subflow).

"MQOutput node" on page 4612
Use the MQOutput node to send messages to clients that connect to the broker using the WebSphere MQ Enterprise Transport and that use the MQI and AMI application programming interfaces.

Passthrough node

Use the Passthrough node to enable version control of a subflow at run time.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow"
- "Terminals and properties"

Purpose:
Use the Passthrough node to add a label to your message flow or subflow. By combining this label with keyword replacement from your version control system, you can identify which version of a subflow is included in a deployed message flow. You can use this label for your own purposes. If you have included the correct version keywords in the label, you can see the value of the label:

- Stored in the broker archive (BAR) file, using the **mqsireadbar** command
- As last deployed to a particular broker, on the properties of a deployed message flow in the WebSphere Message Broker Toolkit
- At run time, if you enable user trace for that message flow

The Passthrough node does not process the message in any way. The message that it propagates on its Out terminal is the same message that it received on its In terminal.

The Passthrough node is contained in the **Construction** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Use this node to identify a subflow; for example, if you develop an error processing subflow to include in several message flows, you might want to modify that subflow. However, you might want to introduce the modified version initially to just a subset of the message flows in which it is included. Set a value for the instance of the Passthrough node that identifies which version of the subflow you have included.

Terminals and properties:
When you have put an instance of the Passthrough node into a message flow, you can configure it. For more information, see "Configuring a message flow node" on page 1503. The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The Passthrough node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Out	The output terminal that delivers a message to the subflow.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined), the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Passthrough node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	Passthrough	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Passthrough node Basic properties are described in the following table.

Property	M	C	Default	Description
Label	No	No		The label (identifier) of the node. Enter a value that defines a unique characteristic; for example, the version of the subflow in which the node is included.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

PeopleSoftInput node

Use the PeopleSoftInput node to interact with a PeopleSoft application.

This topic contains the following sections:

Purpose:
Use the PeopleSoftInput node to interact with PeopleSoft applications. For example, a PeopleSoftInput node monitors a PeopleSoft system for a specified event. When that event occurs, the PeopleSoftInput node generates a message tree that represents the business object with the new event details. The message tree is propagated to the Out terminal so that the rest of the message flow can use the data to update other systems, or audit the changes.

The PeopleSoftInput node is contained in the **WebSphere Adapters** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
To function correctly, the PeopleSoftInput node needs an adapter component, which you set using the `Adapter component` node property, and business object definitions, which are stored in the message set that you reference from the node. For this reason, you must provide a message set. By default, the message that is propagated from the PeopleSoftInput node is in the DataObject domain, so the `Message domain` property is set to DataObject. You cannot specify a different domain. The message type is detected automatically by the node.

The PeopleSoftInput node populates the route to label destination list with the name of the method binding. If you add a RouteToLabel node to the message flow after the PeopleSoftInput node, the RouteToLabel node can use the name of the method binding to route the message to the correct part of the message flow for processing.

You can deploy only one input node that uses a particular adapter component to an execution group, but you can deploy many input nodes that use different adapter components to an execution group.

You can use the **mqsisetdbparms** command in the following format to configure an account name with a user name and password for the Adapter for PeopleSoft Enterprise.

```
mqsisetdbparms broker name -n adapter name -u user name -p password
```

For example:

```
mqsisetdbparms BRK1 -n eis::PeopleSoftCustomerInbound.inadapter -u peoplesoftuid -p ********
```

Using configurable services for PeopleSoft nodes

PeopleSoft nodes can get PeopleSoft connection details from either the adapter component or a configurable service. By using a configurable service, you can change the connection details for an adapter without the need to redeploy the adapter. For more details about creating, changing, reporting, and deleting the configurable services for PeopleSoft, see “Changing connection details for PeopleSoft adapters” on page 722.

Terminals and properties:
When you have put an instance of the PeopleSoftInput node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. If you double-click a PeopleSoftInput node, you open the Adapter Connection wizard. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The PeopleSoftInput node terminals are described in the following table.

Terminal	Description
Out	Business object events from the adapter are sent to the Out terminal.
Failure	If an error happens in the PeopleSoftInput node, the message is propagated to the Failure terminal. Information about the error, and business object events can also be propagated to the Failure terminal.
Catch	Business object events are sent to the Catch terminal if they cause an uncaught exception in the message flow. If the Catch terminal is not connected, the retry process is activated to handle the business object.

The following table describes the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The PeopleSoftInput node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, PeopleSoftInput.	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The PeopleSoftInput node Basic properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Primary adapter component	Yes	Yes		The name of the adapter component that contains configuration properties for the adapter. Either enter a name of an adapter file or click **Browse** to select an adapter file from the list of files that are available in referenced message set projects. When the PeopleSoftInput node receives data from the PeopleSoft system, it associates that data with a method name, depending on the service operation name that is assigned to that type of data when you run the Adapter Connection wizard. The PeopleSoftInput node attempts to handle methods that are defined in the primary adapter. If the type of data that is received does not correspond to any of the methods that are defined in the primary adapter, the node can handle methods that are defined in matching secondary adapters that are deployed to the same execution group.	adapterComponent
Secondary adapter mode	No	Yes	None	Specifies whether the node can handle methods that are defined in secondary adapters. If you set the `Secondary adapter mode` property to `None`, the node handles only methods that are defined in the primary adapter. If the type of data that is received does not correspond to any of the methods that are defined in the primary adapter, a failure occurs. If you set this property to `All adapters in execution group`, the node can handle methods that are defined in any PeopleSoft inbound adapters that are deployed to the same execution group.	secondaryAdapterMode

The PeopleSoftInput node Routing properties are described in the following table.

Property	M	C	Default	Description
Set destination list	No	No	Selected	This property specifies whether to add the method binding name to the route to label destination list. If you select this check box, the method binding name is added so that you can use a RouteToLabel node in the message flow after the PeopleSoftInput node.
Label prefix	No	No		The prefix to add to the method name when routing to label. Add a label prefix to avoid a clash of corresponding label nodes when you include multiple WebSphere Adapters input nodes in the same message flow. By default, there is no label prefix, so the method name and label name are identical.

The PeopleSoftInput node Input Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	DataObject	The domain that is used to parse the incoming message. By default, the message that is propagated from the PeopleSoftInput node is in the DataObject domain. You cannot specify a different domain.

Property	M	C	Default	Description
Message set	Yes	No	Set automatically	The name of the message set in which the incoming message is defined. This field is set automatically from the Adapter component property. If you set this property, then subsequently update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project.
Message type	No	No		The name of the incoming message. The node detects the message type automatically. You cannot set this property.
Message format	No	No		The name of the physical format of the incoming message. You cannot set this property.

The PeopleSoftInput node Transactionality properties are described in the following table.

Property	M	C	Default	Description
Transaction mode	No		Yes	The transaction mode on this input node determines whether the rest of the nodes in the flow operate under sync point.

The Instances properties of the PeopleSoftInput node are described in the following table. For a full description of these properties, refer to "Configurable message flow properties" on page 4020.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Additional instances pool	No	Yes	`Use Pool Associated with Message Flow`	The pool from which additional instances are obtained. • If you select `Use Pool Associated with Message Flow`, additional instances are obtained from the message flow value. • If you select `Use Pool Associated with Node`, additional instances are allocated from the node's additional instances based on the number specified in the `Additional instances` property.	componentLevel
Additional instances	No	Yes	`0`	The number of additional instances that the node can start if the `Additional instances pool` property is set to `Use Pool Associated with Node`. By default, no additional instances are given to the node.	additionalInstances

The PeopleSoftInput node Retry properties are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Retry mechanism	No	No	Failure	This property specifies how retry processing is handled when a failure is rolled back to the PeopleSoftInput node. • If you select `Failure`, retry processing is not performed so you cannot set the remaining properties. • If you select `Short and long retry`, retry processing is performed first at the interval that is specified by the `Short retry interval` property, and if that is unsuccessful, it is then performed at the interval that is specified by the `Long retry interval` property.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Retry threshold	No	Yes	0	The maximum number of times that retry processing is performed for short retry.	retryThreshold
Short retry interval	No	Yes	0	The interval between short retry attempts.	shortRetryInterval
Long retry interval	No	Yes	0	The interval between long retry attempts.	longRetryInterval

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Use the **mqsisetdbparms** command to associate a specific user ID and password (or SSH identity file) with one or more resources that are accessed by the broker.

PeopleSoftRequest node

Use the PeopleSoftRequest node to interact with a PeopleSoft application.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow"
- "Terminals and properties" on page 4636

Purpose:
Use the PeopleSoftRequest node to interact with PeopleSoft applications. For example, a PeopleSoftRequest node requests information from a PeopleSoft Enterprise Information System (EIS). A customer business object is sent to PeopleSoft, causing PeopleSoft to retrieve information about a customer, such as an address and account details. The response information that is retrieved by the PeopleSoftRequest node can then be used by the rest of the message flow. The PeopleSoftRequest node can send and receive business data.

The PeopleSoftRequest node is contained in the **WebSphere Adapters** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
To function correctly, the PeopleSoftRequest node needs an adapter component, which you set using the `Adapter component` node property, and business object definitions, which are stored in the message set that you reference from the node. For this reason, you must provide a message set. By default, the message that is propagated from the PeopleSoftRequest node is in the DataObject domain, so the `Message domain` property is set to DataObject. You cannot specify a different domain. The message type is detected automatically by the node.

The PeopleSoftRequest node supports local transactions using the broker's Local Transaction Manager, and global transactions using the broker's external syncpoint coordinator.

To effectively maintain the pool of connections to PeopleSoft, you can set a connection timeout value on a configurable service. For more information, see "Configuring EIS connections to expire after a specified time" on page 726.

You can deploy several WebSphere Adapters request nodes that use the same adapter component to an execution group.

You can use the **mqsisetdbparms** command in the following format to configure an account name with a user name and password for the Adapter for PeopleSoft Enterprise.

```
mqsisetdbparms broker name -n adapter name -u user name -p password
```

For example:

```
mqsisetdbparms BRK1 -n eis::PeopleSoftCustomerOutbound.outadapter -u peoplesoftuid -p ********
```

Using configurable services for PeopleSoft nodes

PeopleSoft nodes can get PeopleSoft connection details from either the adapter component or a configurable service. By using a configurable service, you can change the connection details for an adapter without the need to redeploy the adapter. For more details about creating, changing, reporting, and deleting the configurable services for PeopleSoft, see "Changing connection details for PeopleSoft adapters" on page 722.

Terminals and properties:
When you have put an instance of the PeopleSoftRequest node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. If you double-click a PeopleSoftRequest node, you open the Adapter Connection wizard. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The PeopleSoftRequest node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts the request business object.
Out	The output terminal to which the response business object is sent if it represents successful completion of the request, and if further processing is required within this message flow.
Failure	If an error happens in the PeopleSoftRequest node, the message is propagated to the Failure terminal. Information about the error, and business object events can also be propagated to the Failure terminal.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk on the panel if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The PeopleSoftRequest node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, PeopleSoftRequest	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The PeopleSoftRequest node Basic properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Primary adapter component	Yes	No		The name of the adapter component that contains configuration properties for the adapter. Either enter a name of an adapter file, or click **Browse** to select an adapter file from the list of files that are available in referenced message set projects. When thePeopleSoftRequest node receives data from the PeopleSoft system, it associates that data with a method name. The PeopleSoftRequest node attempts to call methods that are defined in the primary adapter. If the method is not defined in the primary adapter, the node can call methods that are defined in matching secondary adapters that are deployed to the same execution group.	
Secondary adapter mode	No	Yes	None	Specifies whether the node can call methods that are defined in secondary adapters. If you set the `Secondary adapter mode` property to `None`, the PeopleSoftRequest node calls only methods that are defined in the primary adapter. If the method is not defined in the primary adapter, an error occurs. If you set this property to `All adapters in execution group`, the node can call methods that are defined in any PeopleSoft outbound adapter that is deployed to the same execution group.	secondaryAdapterMode
Default method	Yes	Yes		The default method binding to use.	defaultMethod

The PeopleSoftRequest node Response Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	DataObject	The domain that is used to parse the response message. By default, the response message that is propagated from the PeopleSoftRequest node is in the DataObject domain. You cannot specify a different domain.
Message set	Yes	No	Set automatically	The name of the message set in which the response message is defined. This field is set automatically from the Adapter component property. If you set this property, then subsequently update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project.
Message type	No	No		The name of the response message. The node detects the message type automatically. You cannot set this property.
Message format	No	No		The name of the physical format of the response message. You cannot set this property.

The PeopleSoftRequest node Transactionality properties are described in the following table.

Property	M	C	Default	Description
Transaction mode	No	No	No	This property specifies that updates are performed independently, not as part of a local transaction. You cannot change this property.

The PeopleSoftRequest node Request properties are described in the following table.

Property	M	C	Default	Description
Method Location	Yes	No	$LocalEnvironment/Adapter/MethodName	The location of the business method (such as createPurchaseOrder or deletePurchaseOrder) that is used to trigger the PeopleSoftRequest node to perform an action on the external system.
Data Location	Yes	No	$Body	The location in the incoming message tree from which data is retrieved to form the request that is sent from the PeopleSoftRequest node to the EIS.

The PeopleSoftRequest node Result properties are described in the following table.

Property	M	C	Default	Description
Output data location	No	No	$OutputRoot	The message tree location to which the PeopleSoftRequest node sends output.
Copy local environment	No	No	Selected	This property controls how the local environment is copied to the output message. If you select the check box, at each node in the message flow, a new copy of the local environment is created in the tree, and it is populated with the contents of the local environment from the preceding node. So if a node changes the local environment, the upstream nodes do not see those changes because they have their own copies. This behavior might be an issue if you are using a FlowOrder node, or if you use the propagate command on a Compute node. If you clear the check box, each node does not generate its own copy of the local environment, but it uses the local environment that is passed to it by the previous node. So if a node changes the local environment, those changes are seen by the upstream nodes.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

PHPCompute node

Use the PHPCompute node to route and transform an incoming message, using the PHP scripting language.

Support for the PHP scripting language is available on all operating systems on which WebSphere Message Broker is supported.

This topic contains the following sections:

Purpose:

The PHPCompute node can use the PHP scripting language to route and transform incoming messages.

Using this node, you can achieve the following goals:

- Examine an incoming message and, depending on its content, propagate it unchanged to the node's output terminal.
- Change part of an incoming message and propagate the changed message to the output terminal by using PHP.

- Create and build a new output message that is independent of the input message by using PHP.

The PHPCompute node is contained in the **Transformation** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using the PHPCompute node in a message flow:
Look at the following sample to see how to use this node:

- PHPCompute Node

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Specifying PHP:
Create PHP statements to customize the behavior of the PHPCompute node. For example, you can customize the node to create one or more output messages by using either new data or the content of an input message or database (unchanged or modified). For example, you might want to modify a value in the input message by adding a value from a database, and store the result in a field in the output message.

Create the PHP statements that you want in a PHP script file and ensure that it exists in the workspace before you associate it with the PHPCompute node.

If the required PHP script file exists, import it into the workspace before associating it with the PHPCompute node (see "Importing file systems into the WebSphere Message Broker Toolkit" on page 2931).

If a PHP file does not exist for this node, create one in the project folder with a file extension of `.php` (for example, `myfile.php`). For more information about creating a PHP script file, see "Creating PHP code for a PHPCompute node" on page 2672.

The PHPCompute node provides support for Simple Network Management Protocol (SNMP). The Management Information Base (MIB) files are installed during the installation of WebSphere Message Broker, and their location is specified by the **`MIBDIRS`** environment variable.

Configuring the PHPCompute node:
When you have put an instance of the PHPCompute node into a message flow, you can configure it. For more information about how to configure nodes, see .

The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (the ones that do not have a default value defined) are marked with an asterisk in that view.

To configure the PHPCompute node:

1. Optional: On the **Description** tab, enter a short description, a long description, or both. You can also rename the node on this tab.

2. On the **Basic** tab, use the `PHP script` property to specify the name of the PHP file. Select the `Invoke 'evaluate()' method in PHP class definition` property if the code in your PHP script file includes an evaluate method.
3. On the **Parser options** tab, select the `Use XMLNSC compact parser for the XMLNS domain` property to specify that the XMLNSC Compact Parser is used for messages in the XMLNS Domain.
4. On the **Validation** tab, specify the parser validation properties of the node. For more information about validation, see "Validating messages" on page 1478. For information about how to complete this tab, see "Validation tab properties" on page 4169.

Terminals and properties:
The PHPCompute node terminals are described in the following table.

Terminal	Type	Description
In	Input data	The input terminal that accepts a message for processing by the node.
Out	Output data	The output terminal to which the transformed message is routed.
Failure	Output data	The output terminal to which the message is routed if a failure is detected during the computation. Even if the `Validate` property is set, messages that are propagated to the Failure terminal of the node are not validated.
* (dynamic)	Dynamic output	Zero or more dynamic output terminals can be created to support message routing.

You can define additional dynamic output terminals on the PHPCompute node. Not all dynamic output terminals that are created on a PHPCompute node need to be mapped to an expression in the filter table. If any of the dynamic output terminals are unmapped, they never have messages propagated to them. Several expressions can map to the same single dynamic output terminal. No static output terminal exists to which the message is passed straight through. For more information about using dynamic terminals, see "Using dynamic terminals" on page 1518.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the PHPCompute node are described in the following table:

Property	M	C	Default	Description
Node name	No	No	PHPCompute	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the PHPCompute node are described in the following table:

Property	M	C	Default	Description	mqsiapplybaroverride command property
PHP script	Yes	Yes		A string containing the name of the PHP script file.	ScriptName

The Parser Options properties of the PHPCompute node are described in the following table.

Property	M	C	Default	Description
Use XMLNSC compact parser for XMLNS domain	No	No	False	This property controls whether the XMLNSC Compact Parser is used for messages in the XMLNS Domain. If you set this property, the message data appears under XMLNSC in nodes that are connected to the output terminal when the input MQRFH2 header or Input Message Parsing property, `Message Domain`, is XMLNS.

The Validation properties of the PHPCompute node are described in the following table.

For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	No	`None`	This property controls whether validation takes place. Valid values are: • `None` • `Content and Value` • `Content` • `Inherit`	validateMaster
Failure action	No	No	Exception	This property controls what happens if validation fails. You can set this property only if you set `Validate` to `Content` or `Content and Value`. Valid values are: • `User Trace` • `Local Error Log` • `Exception` • `Exception List`	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

The WebSphere Message Broker PHP API provides classes to represent the message, the message assembly, and the element tree.

Publication node

Use the Publication node to filter output messages from a message flow and transmit them to subscribers who have registered an interest in a particular set of topics.

This information contains the following sections:

- "Purpose"
- "Using this node in a message flow" on page 4644
- "Terminals and properties" on page 4644

Purpose:

Use the Publication node to publish a message through the WebSphere MQ queue manager associated with the broker. Applications that expect to receive publications must register a subscription.

The message being published must be:

- A Publish command message
- A Delete Publication command message, or
- Have at least one topic present in the standard properties of the message.

The Publication node uses the topic, or topics, and any options present in the command message to publish the message. The WebSphere MQ queue manager delivers the publication to all subscribing applications matching the topic, and any other options specified on their subscriptions.

The Publication node is contained in the **Routing** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following samples to see how to use this node:
- Scribble
- JMS Nodes
- Pager

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

For an example of how to use this node, assume that you have written a publishing application that publishes stock updates on a regular basis. The application sends the messages to the broker on an MQInput node, and the message flow provides a conversion from the input currency to a number of output currencies. Include a Publication node for each currency that is supported, and set the `Subscription Point` property to a value that reflects the currency in which the stock price is published by the node; for example, Sterling, or USD.

Terminals and properties:
When you have put an instance of the Publication node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

The Publication node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
NoMatch	If no subscribers are matched on any of the published topics, the original message is propagated here.
Out	If at least one subscriber is matched by WebSphere MQ on at least one of the published topics, the original message is propagated here.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory*; the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Publication node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type: Publication	The name of the node.

Property	M	C	Default	Description
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The Publication node Basic properties are described in the following table.

Property	M	C	Default	Description
Implicit Stream Naming	Yes	No	Cleared	Select `Implicit Stream Naming` to take the name of the WebSphere MQ queue on which the message was received by the message flow as the stream name. This property provides compatibility with earlier versions of WebSphere MQ Publish/Subscribe, and applies to messages with an MQRFH header when MQPSStream is not specified. Clear the check box if you do not want this action to be taken.
Subscription Point	No	No		The subscription point value for the node. If you do not specify a value for this property, the default subscription point is assumed. Set a subscription point for a Publication node to restrict the forwarding of its publications to those subscribers that specify the subscription point in their subscription (as described in the example scenario in "Using this node in a message flow" on page 4644). For more information, see "Subscription points" on page 2222.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Use the MQOutput node to send messages to clients that connect to the broker using the WebSphere MQ Enterprise Transport and that use the MQI and AMI application programming interfaces.

Real-timeInput node

The Real-timeInput node, available in earlier versions of WebSphere Message Broker, is not supported in WebSphere Message Broker Version 7.0. See "Migrating from Version 6.1 products" on page 163 for information about migrating your message flows from WebSphere Message Broker to WebSphere Message Broker Version 7.0.

Real-timeOptimizedFlow node

The Real-timeOptimizedFlow node, available in earlier versions of WebSphere Message Broker, is not supported in WebSphere Message Broker Version 7.0. See "Migrating from Version 6.1 products" on page 163 for information about migrating your message flows from WebSphere Message Broker to WebSphere Message Broker Version 7.0.

RegistryLookup node

Use the RegistryLookup node to retrieve any type of entity held in the WebSphere Service Registry and Repository (WSRR). The entities that match the specified search criteria are stored in the local environment. The input message is not modified.

This topic contains the following sections:

Purpose:

The RegistryLookup node retrieves any type of entity held in WSRR.

Data is retrieved according to search criteria defined by node properties, possibly supplemented or overridden by local environment definitions at run time; see "Local environment overrides" for more details.

The retrieved data is placed in the local environment tree, making it available to subsequent nodes. The input message received by the node is propagated to the output terminal unchanged.

RegistryLookup node processing

The RegistryLookup node is contained in the **Web services** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

When the RegistryLookup node receives a message the following steps occur in sequence.

1. The RegistryLookup node retrieves the data from WSRR using the specified search criteria.
2. If one or more matches are found, the RegistryLookup node adds a representation of those entities to the local environment tree.
   - If `Match Policy` is set to `One`, a single entity is returned by WSRR and added to the local environment tree. If the registry contains more than one entity that matches the specified search criteria it is not possible to determine which one is returned by WSRR. A different one can be returned each time the query is issued.
   - If `Match Policy` is set to `All`, all matching entities are added to the local environment tree. The order of the entities is determined by WSRR and might vary between queries.

   The input message is propagated unchanged to the Output terminal. The local environment tree is propagated to the Out terminal, where it is available for further processing by transformation nodes. The exact representation of an entity in the local environment tree depends on the `Depth Policy` property. See "RegistryLookup node output" on page 1897 for details of the local environment output tree.

   Add a compute node to your message flow to interpret and act on the returned data. For instance, if the local environment tree contains multiple endpoint addresses for use by subsequent request nodes the Compute node should select the required address and set up any transport headers or local environment settings required by those request nodes.
3. If no matches are found, the RegistryLookup node propagates the input message to the NoMatch terminal.
4. If a processing error occurs, for example if the WSRR server configured on the `DefaultWSRR` configurable service object cannot be connected to, or the connection times out, the RegistryLookup node propagates the input message unchanged to the Failure terminal. The ExceptionList is populated with details of the error.

Local environment overrides:
You can override the RegistryLookup node properties by using local environment settings. See "Dynamically defining the search criteria" on page 1891.

Terminals and properties:
When you have put an instance of the RegistryLookup node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

The RegistryLookup node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the message is routed if an error occurs within the node's processing.
Out	The output terminal to which the unmodified input message and updated local environment containing the matched registry data is sent.
NoMatch	The terminal to which the input message is sent if no matching entity is found based on the specified search criteria.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The RegistryLookup node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type (RegistryLookup)	The name of the node
Short description	No	No	None	A brief description of the node
Long description	No	No	None	Text that describes the purpose of the node in the message flow

The RegistryLookup node Basic properties are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Name	No	Yes	None	Enter the string values for one or more of `Name`, `Namespace`, and `Version` for the entities or artifacts that you want to retrieve from WSRR. At least one of the properties is required. If you leave all three property values blank, you will get an error message when you try to save.	name
Namespace	No	Yes	None		namespace
Version	No	Yes	None		serviceVersion

Property	M	C	Default	Description	mqsiapplybaroverride command property
User Properties	No	No	None	Allows a query to specify user-defined properties. Add `User Properties` by clicking **Add**. `User Properties` refer to the Additional Properties that are used to catalog the entities in WSRR. Enter values for `Property Name`, which is the case sensitive match of the additional property in WSRR, `Property Type`, and `Property Value`. The `Property Type` can be: • a String (the default), in which case the `Property Value` is a character string to be matched with the additional property value present in WSRR • XPATH, or ESQL, in which case the `Property Value` is a XPath or ESQL expression which locates a field in the message tree that contains the character string to be matched with the property value present in WSRR.	
Classification	No	No	None	The Web Ontology Language (OWL) classification system property. Each classifier is a class in OWL, and has a Uniform Resource Identifier (URI). Using classifications in the registry can help to make objects easier to find and can also add meaning to custom objects that are unique to a particular system. Add a `Classification` by clicking **Add** and typing the complete fully qualified OWL URI for the OWL classification. For example, it can define a particular service endpoint's lifecycle state.	
Match Policy	Yes	No	`One`	WSRR can contain multiple entities that match the search criteria specified by the properties above. If `Match Policy` is set to `One`, at most one matching entity is returned. If `Match Policy` is set to `All`, all matching entities are returned. See "RegistryLookup node output" on page 1897	

The RegistryLookup node Advanced properties are described in the following table.

Property	M	C	Default	Description
Depth Policy	Yes	No	`Return matched only (Depth = 0)`	Specify the depth of the WSRR query and the contents of the entity data to be returned. The returned entities are stored in the ServiceRegistry message tree in the LocalEnvironment. Select `Return matched only (Depth = 0)` to use a WSRR query depth of 0, and to return only the matched entities. Select `Return matched showing immediate relationships (For compatibility only)` to use a WSRR query depth of 1, and to return only the matched entities. Returned entities include elements listing the bsrURIs of related child entities. This option provides compatibility with versions of WebSphere Message Broker before Version 6.1.0.4, using the output format that was used in those prior versions. This option is deprecated, use one of the other options. Select `Return matched plus immediate related entities (Depth = 1)` to use a WSRR query depth of 1, and to return the matched entities and the immediate related child entities. Select `Return matched plus all related entities (Depth = -1)` to use a WSRR query depth of -1, and to return the matched entities and all the related child entities.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

"EndpointLookup node" on page 4407
Use the EndpointLookup node to retrieve service endpoint information held in the WebSphere Service Registry and Repository (WSRR). The entities that match the specified search criteria are stored in the local environment. Depending on the node configuration, the Web service URL destination used by the SOAP and HTTP request nodes can also be set. The input message is not modified.

"XSLTransform node" on page 4968
Use the XSLTransform node to transform an XML message to another form of message, according to the rules provided by an XSL (Extensible Stylesheet Language) style sheet, and to set the `Message domain`, `Message set`, `Message type`, and `Message format` for the generated message.

Resequence node

Use the Resequence node to control the sequence in which a group (or groups) of incoming messages are propagated in a message flow.

This topic contains the following sections:
- "Purpose"
- "Using the Resequence node in a message flow" on page 4653
- "Configuring the Resequence node" on page 4653
- "Terminals and properties" on page 4655

Purpose:
The Resequence node controls the sequence in which a group (or groups) of incoming messages are propagated through the node in a message flow.

You can use a Resequence node to rearrange groups of messages into sequential order according to a sequence number in the message. Each message must contain a sequence number, which can be any positive or negative integer. The sequence number is calculated by an XPath expression defined in the `Path to sequence number` property on the node, and it can be one that was added to the message by a Sequence node.

The Resequence node can reorder multiple sequence groups independently of each other, but it cannot reorder messages between sequence groups. The group to which a message belongs is determined by the properties of the Resequence node.

Each sequence group can be associated with only one Resequence node. Multiple Resequence nodes can have a sequence group with the same name, but each of those sequence groups is treated as a separate group. The combination of the execution group name, message flow name, node name, and sequence group name is used to differentiate between the sequence groups.

For example, you might have a message flow called *flow1* containing a Resequence node called *node1*, which is deployed to an execution group called *eg1*. A message is sent to it using a sequence group called *group1*. The result is *eg1/flow1/node1/group1*. Exactly the same message flow in a different execution group, for example *eg2*, would result in *eg2/flow1/node1/group1*.

You can configure a Resequence node to use multiple threads for propagating messages, but only if each message that is being propagated belongs to a different sequence group. For messages belonging to the same sequence group, only one thread at a time can be used to propagate messages. As a result, the sequential order of messages in a sequence group is preserved, but no order between groups is maintained.

A transaction break occurs at the Resequence node. Messages arriving at the node are not directly propagated to the output terminal; all messages (including the next message in the sequence) are initially serialized to an internal WebSphere MQ queue. The storing of the message occurs in the current transaction; when it has been stored, the transaction is completed. If a stored message is the next one in the sequence, it is propagated down the message flow under a new transaction. Only the serializable part of the data is propagated from the node; local environment, environment, and exception lists are not preserved.

Any exceptions that occur in nodes following the Resequence node are rolled back to the Catch terminal of the Resequence node. If the Catch terminal is not connected to any other nodes, the messages are re-delivered to the original terminal (Out, Missing, or Expired). The messages are never backed-out or discarded.

The Resequence node stores all received messages onto internal queues before propagating messages downstream, even when they are received in order. The message flow is effectively split into two running flows (one before the Resequence node and one after it. If the part of the message flow before the Resequence node runs significantly faster than the part of the message flow after it, the number of messages on the internal queue can increase more quickly than can be processed. Also, any expiry times given for end of groups or missing messages do not occur in a timely manner. When the queues are full, messages arriving at the Resequence node cause exceptions to be thrown. You can avoid this problem by following these steps:

1. Ensure that the controlling applications send only a finite amount of work at a time, which the message flow can manage.
2. Configure additional instances so that the second part of the message flow has more instances to do work with on. Use the properties on the **Instances** tab to give the Resequence node its own set of additional instances.
3. Structure the message flow so that the part of the flow that places the most demands on the CPU (transformation, for example), comes before the Resequence node.
4. If the large workload is transient, increase the maximum queue depth on the internal queues.
5. Use the Resequence configurable service to partition the queues. This can prevent the situation in which an instance of the Resequence node fills up the queues and stops another instance working.

For information about the various states and state transitions of the Resequence node, see "Resequence node state machines" on page 4658.

The Resequence node is contained in the **Routing** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using the Resequence node in a message flow:
Look at the following sample to see how to use the Resequence node:

- Healthcare

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Configuring the Resequence node:
When you have put an instance of the Resequence node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

All mandatory properties that do not have a default value defined are marked with an asterisk.

Configure the Resequence node:

1. Optional: On the **Description** tab, enter a `Short description`, a `Long description`, or both. You can also rename the node on this tab.
2. On the **Basic** tab, set the properties that determine how the message sequence is controlled.
   - Use the `Path to sequence number` property to specify an XPath expression that is used to calculate the sequence number of the message. The XPath expression can calculate the sequence number or it can point to an integer field in the message. Messages can also contain an optional sequence group identifier. This property is mandatory.

- Use the Path to sequence group identifier property to specify the location of the sequence group identifier. The location is specified as an XPath expression. Messages that have the same group identifier are considered part of the same sequence group.
- Use the Start of sequence definition property to identify the first sequence number in each group.
  - Select Literal to specify a literal sequence number, which can be any positive or negative numeric value. When the message with the specified sequence number arrives, the messages are propagated.
  - Select Predicate to specify an XPath expression that evaluates to either True or False, indicating whether the message is the first in the sequence.

    Messages continue to be collected while the expression evaluates to False. When the expression of a message is evaluated to True, it indicates that the message is the first in the sequence.

    Typically, the XPath expression evaluates to a Boolean; however, if other data types are returned, the predicate is determined in the following way:

Table 252.

Returned data type	True	False
Boolean	True	False
Numeric	Any non-zero value	0 or 0.0
String	Any string matching true (case-insensitive)	Any string not matching true (case insensitive)
NodeSet	Never	Always

    When a message evaluates the expression to True (and is therefore identified as the start of the sequence), the node checks that the message has the smallest sequence number collected up to that point. If messages are found with lower sequence numbers, an exception is thrown.

    When the first message that evaluates to true has been processed successfully, the XPath expressions of subsequent messages are not checked. If a message arrives with a lower sequence number than the message that was identified as the start of the sequence, an exception is thrown.
  - Select Automatic to specify a time limit for gathering messages before using the lowest numbered message.
- Use the End of sequence definition property to specify when each sequence group has been completed.
  - Select Literal to specify a literal sequence number. This value can be any positive or negative numeric value that is equal to or greater than the value of the Start of sequence definition property. When the message with the specified sequence number arrives, the sequence group remains open and waits for missing messages until the Missing message timeout property expires. Any messages that arrive within that time are included in the group (unless they are duplicates or outside the allowed range) until the sequence group is closed. When the sequence group is closed, any new messages arriving for that group are treated as belonging to a new instance of the group.
  - Select Predicate to specify an XPath expression that evaluates to either True or False, to indicate whether the message is the last in the sequence.

Typically, the XPath expression evaluates to a Boolean; however, if other data types are returned, the predicate is determined in the way shown in Table 1.

When the predicate evaluates to True, the sequence number of the message is assigned to the `End of sequence definition` property.

When a message has been received with the end of sequence predicate set to True, the sequence group remains open and waits for missing messages until the `Missing message timeout` property expires. Any messages that arrive within that time are included in the group (unless they are duplicates or outside the allowed range) until the sequence group is closed. When the sequence group is closed, any new messages arriving for that group are treated as belonging to a new instance of the group.

If a message arrives with the end of sequence predicate set to True and with a lower sequence number than a message that has already arrived, an exception is thrown.

- Select `Automatic` to specify the timeout period for the node. This option specifies how long (in seconds) the node waits for messages to arrive in an empty queue, before closing the sequence group. This option is useful for applications that cannot determine the final number in the sequence. The timer starts when there are no messages in the queue waiting to be propagated. If new messages arrive before the timeout period is reached, the timer is canceled. If no new messages arrive before the end of the specified time, the sequence group is closed and any further messages for the group are considered part of a new group.

- Use the `Missing message timeout` property to specify how long (in seconds) the node waits for the next message in the sequence before it moves on to the next message in the sequence. Messages that arrive within the specified time limit are propagated in sequential order to the Out terminal.

  When the specified time limit has been exceeded, the messages are propagated in sequential order to the Expire terminal. Subsequent messages in the sequence group are also routed to the Expire terminal. If the missing message eventually arrives, it is propagated to the Missing terminal.

3. On the **Advanced** tab:
   - Use the `Persistence mode` property to specify whether to store incomplete sequences of messages persistently.
   - Use the `Configurable service` property to specify the name of a Resequence configurable service that overrides specified properties of the Resequence node.
4. Optional: On the **Instances** tab, set values for the properties that show the additional instances (threads) that are available for a node.

   Multiple threads can be used to propagate messages from the same Resequence node, but only if each message that is being propagated belongs to a different sequence group. For messages belonging to the same sequence group, only one thread at a time can be used to propagate messages. As a result, the sequential order of messages in a sequence group is preserved, but no order between groups is maintained.

   For more information about specifying additional instances, see “Configurable message flow properties” on page 4020.

Terminals and properties:
The terminals of the Resequence node are described in the following table.

Terminal	Description
In	The input terminal through which the incoming message assembly arrives at the node.
Failure	The output terminal to which the message is routed if an error occurs. This value includes failures caused by retry processing.
Out	The output terminal to which the output message is propagated by default.
Expire	The output terminal to which the message is routed if a timeout occurs while the node is waiting for the message to arrive. All subsequent messages in the same group are also propagated to this terminal.
Missing	The output terminal to which the missing message (which caused a timeout to occur) is routed if it subsequently arrives at the node.
Catch	The output terminal to which the message is routed if an exception is issued downstream and caught by this node. Exceptions are caught only if this terminal is attached.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file for deployment).

The Description properties of the Resequence node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	Resequence	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the Resequence node are described in the following table.

Property	M	C	Default	Description
Path to sequence number	Yes	No		An XPath expression that calculates the sequence number of the message.
Path to sequence group identifier	No	No		An XPath expression that calculates the sequence group identifier. Messages that have the same group identifier are considered part of the same sequence group. This property functions in the same way as the `Correlation path` property in the Collector node.
Start of sequence definition	Yes	No	`Literal, 0`	Specifies the first sequence number in each group. Valid values are: • `Literal` and *number* • `Predicate` and *XPath* • `Automatic` and *time in seconds* If this property is set to `Automatic`, the associated time is overridden by the value of the `startSequenceSeconds` property, if set, in the Resequence configurable service.

Property	M	C	Default	Description
End of sequence definition	Yes	No	`Automatic`	Specifies when each sequence group has been completed. Valid values are: • `Literal` and *number* • `Predicate` and *XPath* • `Automatic` and *time in seconds* If this property is set to `Automatic`, the associated time is overridden by the value of the `endSequenceSeconds` property, if set, in the Resequence configurable service.
Missing message timeout (seconds)	No	No		Specifies how long (in seconds) the node waits for the next message in the sequence before it moves on to the following one. This property is overridden by the **`Missing message timeout`** property, if set, in the Resequence configurable service.

The Instances properties of the Resequence node are described in the following table. For a full description of these properties, see "Configurable message flow properties" on page 4020.

Property	M	C	Default	Description
Additional instances pool	No	Yes	`Use Pool Associated with Message Flow`	The pool from which additional instances are obtained. • If you select `Use Pool Associated with Message Flow`, additional instances are obtained from the message flow pool. • If you select `Use Pool Associated with Node`, additional instances are allocated from the node's additional instances based on the number specified in the `Additional instances` property.
Additional instances	No	Yes	`0`	The number of additional instances that the node can start if the `Additional instances pool` property is set to `Use Pool Associated with Node`.

The Advanced properties of the Resequence node are described in the following table.

Property	M	C	Default	Description
Persistence mode	Yes	No	`Non-persistent`	Specifies whether to store incomplete sequences of messages persistently. Valid options are: • `Non-persistent` • `Persistent`
Configurable service	No	Yes	None set	This property specifies the name of a Resequence configurable service to be used by the Resequence node. The properties set by the Resequence configurable service override the equivalent properties set on the Resequence node. For more information about the properties than you can set with this configurable service, see "Configurable services properties" on page 3766.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

You cannot use monitoring properties to configure transaction events on the following nodes:

"Collector node" on page 4333

"Resequence node" on page 4651

Use a monitoring profile instead; see "Configuring monitoring event sources using a monitoring profile" on page 762.

Related concepts:

Related reference:

"Sequence node" on page 4736
Use the Sequence node to add a sequence number to one or more groups of input messages.

"Configurable message flow properties" on page 4020
When you add a message flow to a broker archive (BAR) file in preparation for deploying it to a broker, you can set additional properties that influence its run time operation. These properties are available for review and update when you select the **Manage and Configure** tab for the broker archive file.

"Collector node" on page 4333
Use the Collector node to create message collections based on rules that you configure in the node.

Resequence node state machines:

State machine diagrams show the possible actions and states of a system, and the transitions between those states.

The following topics contain state machine diagrams showing the states, transitions, and actions of the Resequence node:

- "Automatic start and end of sequence" on page 4659
- "Literal start and end of sequence" on page 4661

- “Predicate start and end of sequence” on page 4662

In each of the diagrams, the following syntax is used:

```
<action> [ <predicate list> ] / <result list>
```

where the predicate list and result list are separated by commas.

You can use these diagrams to infer the behavior of other combinations of sequence start and end definitions for a sequence group; for example, combinations such as literal start of sequence and automatic end of sequence.

For more information about state machine diagrams, see the Agile Modeling Web site at `http://www.agilemodeling.com/artifacts/stateMachineDiagram.htm`. For information about the Unified Modeling Language (UML), see the Object Management Group (OMG) UML Web site at `http://www.uml.org/`.

ResetContentDescriptor node

Use the ResetContentDescriptor node to request that the message is reparsed by a different parser.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow" on page 4664
- "Configuring the ResetContentDescriptor node" on page 4664
- "Terminals and properties" on page 4666

Purpose:
The node associates the new parser information with the input message bit stream. If the message has been parsed already to create a message tree, and the contents of the tree have been modified (for example, by a Compute node), the ResetContentDescriptor node must re-create the bit stream from the message tree by calling the current parser.

If your message flow has updated the message before it is received by the ResetContentDescriptor node, ensure that the changed message contents are still valid for the current parser. If the contents are not valid, the parser generates an error when it attempts to re-create the bit stream from the message tree, and the ResetContentDescriptor node raises an exception. For example, if you have added a new field to a message in the MRM domain, and the field is not present in the model, the recreation of the bit stream fails.

If you specify MRM as the new parser, you can also specify a different message template (message set, message type, and message format). This node does not reparse the message, but the properties that you set for this node determine how the message is parsed when it is next reparsed by the message flow.

The ResetContentDescriptor node does not:
- Change the message content; it changes message properties to specify the way in which the bit stream is parsed next time that the parser is started.
- Convert the message from one format to another; for example, if the incoming message has a message format of XML and the outgoing message format is binary, the ResetContentDescriptor node does not do any reformatting. It starts the parser to re-create the bit stream of the incoming XML message, which retains the XML tags in the message. When the message is reparsed by a subsequent node, the XML tags are not valid and the parse fails.

The ResetContentDescriptor node is contained in the **Construction** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
For an example of how to use this node, assume that you want to swap between the BLOB and the MRM domains. The format of an incoming message might be unknown when it enters a message flow, therefore the BLOB parser is started. Later on in the message flow, you might decide that the message is predefined as a message in the MRM domain, and you can use the ResetContentDescriptor node to set the correct values to use when the message is parsed by a subsequent node in the message flow.

The following table shows typical ResetContentDescriptor node properties.

Property	Value
Message domain	MRM
Reset message domain	Selected
Message set	MyMessageSet
Reset message set	Selected
Message type	m_MESSAGE1
Reset message type	Selected
Message format	Text1
Reset message format	Selected

The `Message domain` is set to MRM, and the MRM parser is started when the message is next parsed. The `Message set`, `Message type`, and `Message format` are the message template values that define the message model, and all of the reset check boxes are selected because all of the properties need to change.

The ResetContentDescriptor node causes the BLOB parser that is associated with the input message to construct the physical bit stream of the message (not the logical tree representation of it), which is later passed to the MRM parser. The MRM parser then parses the bit stream using the message template (`Message set`, `Message type`, and `Message format`) specified in this ResetContentDescriptor node.

In Version 6.1, you do not need to include a ResetContentDescriptor node after an XSLTransform node in your message flow to set `Message domain`, `Message set`, `Message type`, and `Message format` of the message generated by the XSLTransform node. The XSLTransform node performs this function.

Configuring the ResetContentDescriptor node:
When you have put an instance of the ResetContentDescriptor node into a message flow, you can configure the node. For more information, see . The properties of the node are displayed in the Properties view.

All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

1. Optional: On the **Description** tab, enter a Short description, a Long description, or both. You can also rename the node on this tab.
2. On the **Basic** tab:
   a. To use a different parser associated with the message, specify the new domain in the Message domain property:
      - XMLNSC
      - DataObject
      - JSON
      - BLOB
      - MIME
      - MRM
      - JMSMap
      - JMSStream
      - XMLNS

      You can also specify a user-defined parser if appropriate.

      You must also select the Reset message domain check box.

      If you leave the Message domain property blank and do not select the Reset message domain check box, the domain is not reset. If you leave the Message domain property blank and select the Reset message domain check box, the default value is BLOB.
   b. If the MRM, XMLNSC, or IDOC parser is to reparse the message, specify the other properties of the model that are to be associated with the input message, and select the relevant reset check box beneath each field. If you select a reset check box for a property and you have not specified a value for that property, the value of that property is reset to blank. Alternatively, if you have specified a value for that property, the property is not blank. If you do not select the reset check box for a property, the value for that property is inherited from the incoming message. If the parser is associated with the input message already, specify only the properties that are to change.
      1) Define the Message set. Choose a value from the list of available message models (the name and identifier of the message model are shown), and select the Reset message set check box.
      2) For MRM domains, define the name of the message in Message type. Enter the name and select the Reset message type check box.
      3) For MRM and IDOC, define the Message format. This property specifies the physical format for the parser. You can select one of the formats from the list (which lists the names of those formats that you have defined on the Message set specified previously), and select Reset message format.

      These actions are taken only if suitable headers exist. If the message does not have an MQRFH2 header, the node does not create one.
3. On the **Parser Options** subtab:
   a. Parse timing is, by default, set to On Demand, which causes parsing of the message to be delayed.

      For more details, see "Parsing on demand" on page 4173.
   b. Select Use MQRFH2C compact parser for MQRFH2 header if you want the MQRFH2C parser to be used. By default, this check box is cleared, which means that the compact parser is not used.

c. If you are using the XMLNSC parser, set values for the properties that determine how the XMLNSC parser operates. For more information, see "Manipulating messages in the XMLNSC domain" on page 2546.

4. On the **Validation** tab, set the validation properties if you want the parser to validate the body of messages against the `Message set`. (If a message is propagated to the Failure terminal of the node, it is not validated.)

   For more details, see "Validating messages" on page 1478 and "Validation properties" on page 4169.

Terminals and properties:
The ResetContentDescriptor node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the message is routed if an error is detected by the node.
Out	The output terminal to which the message is routed if a new parser is identified by the properties.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the ResetContentDescriptor node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the ResetContentDescriptor node are described in the following table.

The ResetContentDescriptor node Basic properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	`BLOB`	The message domain that is associated with the message that you want to reparse.
Reset message domain	Yes	No	Cleared	If you select the reset check box, the `Message domain` property is reset. In this case, if you do not select a value for the `Message domain` property, the `Message domain` property value is `BLOB`.

Property	M	C	Default	Description
Message set	No	No		The message set that is associated with the message that you want to reparse. If you set this property, then later update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project.
Reset message set	Yes	No	Cleared	If you select the reset check box, the `Message set` property is reset. In this case, if you do not select a value for the `Message set` property, the `Message set` property value is blank.
Message type	No	No		The message type that is associated with the message that you want to reparse.
Reset message type	Yes	No	Cleared	If you select the reset check box, the `Message type` property is reset. In this case, if you do not select a value for the `Message type` property, the `Message type` property value is blank.
Message format	No	No		The message format that is associated with the message that you want to reparse. If you set the `Message domain` property to `DataObject`, you can set this property to `XML` or `SAP ALE IDoc`. Set this property to `SAP ALE IDoc` when you need to parse a bit stream from an external source and generate a message tree.
Reset message format	Yes	No	Cleared	If you select the reset check box, the `Message format` property is reset. In this case, if you do not select a value for the `Message format` property, the `Message format` property value is blank.

The Parser Options properties of the ResetContentDescriptor node are described in the following table.

Property	M	C	Default	Description
Parse timing	No	No	On Demand	This property controls when the reparsed message is parsed. Valid values are On Demand, Immediate, and Complete. For a full description of this property, see "Parsing on demand" on page 4173.
Use MQRFH2C compact parser for MQRFH2 header	No	No	Cleared	This property controls whether the MQRFH2C compact parser, instead of the MQRFH2 parser, is used for MQRFH2 headers.
Build tree using XML schema data types	No	No	Cleared	This property controls whether the XMLNSC parser creates syntax elements in the message tree with data types taken from the XML Schema. You can select this property only if you set the `Validate` property on the **Validation** tab to `Content` or `Content and Value`.
Use XMLNSC compact parser for XMLNS domain	No	No	Cleared	This property controls whether the XMLNSC Compact Parser is used for messages in the XMLNS Domain. If you set this property, the message data is displayed under XMLNSC in nodes that are connected to the output terminal when the input MQRFH2 header or Domain is XMLNS.
Retain mixed content	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in the reparsed message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.

Property	M	C	Default	Description
Retain comments	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in the reparsed message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in the reparsed message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the reparsed message that are to be opaquely parsed by the XMLNSC parser. Opaque parsing is performed only if validation is not enabled (that is, if the value of the `Validate` property is set to `None`); entries that are specified in `Opaque Elements` are ignored if validation is enabled.

The Validation properties of the ResetContentDescriptor node are described in the following table. For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Validate	No	Yes	None	This property controls whether validation takes place. Valid values are None, Content, Content and Value, and Inherit.	validateMaster
Failure action	No	No	Exception	This property controls what happens if validation fails. You can set this property only if you set `Validate` to Content and Value or Content. Valid values are User Trace, Local Error Log, Exception, and Exception List.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

"Specifying namespaces in the Message Type property" on page 1208
When using the MRM domain, the *Message Type* property is used to specify the name of the message.

"Multipart messages" on page 1191
A *multipart message* contains one or more other messages within its structure. The contained message is sometimes referred to as an *embedded message*.

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Parsers" on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

"Message modeling" on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

Related tasks:

"Validating messages" on page 1478
The broker provides validation based on the message model for predefined messages.

"Manipulating messages in the XMLNSC domain" on page 2546
If you are writing ESQL to process messages in the XMLNSC domain, it is helpful to learn about the structure of the message tree that the XMLNSC parser builds.

"Deciding which nodes to use" on page 1457
WebSphere Message Broker includes many message processing nodes that you can use in your message flows.

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

Related reference:

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

Route node

Use the Route node to direct messages that meet certain criteria down different paths of a message flow.

This topic contains the following sections:

Purpose:
As an example, you can forward a message to different service providers, based on the request details. You can also use the Route node to bypass unnecessary steps. For example, you can check to see if certain data is in a message, and perform a database lookup operation only if the data is missing. If you set the `Distribution Mode` property to `All`, you can trigger multiple events that each require different

conditions. For example, you can log requests that relate to a particular account identifier, and send requests that relate to a particular product to be audited.

You use XPath filter expressions to control processing. A result of a filter expression is cast as Boolean, so the result is guaranteed to be either true or false. For more information about XPath 1.0 query syntax, see W3C XPath 1.0 Specification.

The Route node is contained in the **Routing** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following sample to see how to use this node:

- Simplified Database Routing

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

The Route node has one input terminal and a minimum of three output terminals: Match, Default, and Failure. The Default and Failure output terminals are static, so they are always present on the node. The dynamic Match terminal is created automatically each time a new Route node is selected and used in the Message Flow editor. This behavior means that you do not always have to create the first dynamic output terminal for this node, which is the minimum number of terminals needed for this node to operate. You can rename this dynamic terminal if "Match" is not an appropriate name.

A message is copied to the Default terminal if none of the filter expressions are true. If an exception occurs during filtering, the message is propagated to the Failure terminal. The Route node can define one or more dynamic output terminals. For all terminals, the associated filter expression is applied to the input message and, if the result is true, a copy of the message is routed to the specified terminal. The Route node determines the order in which the terminals are driven. The node always propagates messages to the terminals in the order in which they appear in the filter table.

Each filter expression is applied to the input message in the order that is given in the filter table. If the result is true, a copy of the message is routed to its associated dynamic output terminal. If you set the `Distribution Mode` property to `First`, application of all filter expressions might not occur.

Consider the following example input message:

```
<EmployeeRecord>
 <EmployeeNumber>00001</EmployeeNumber>
 <FamilyName>Smith</FamilyName>
 <Wage>20000</Wage>
</EmployeeRecord>
```

and the following XPath filter expressions:

```
$Root/XMLNSC/EmployeeRecord/EmployeeNumber="00002"|Match
$Root/XMLNSC/EmployeeRecord/EmployeeNumber="00001"|out_exp2
```

In this example, the `Distribution Mode` property is set to `First`. The Route node processes the XPath filter expressions, in the order in which the are displayed, against the input message. Because the `Distribution Mode` property is set to `First`, the unmodified input message is propagated only once to the dynamic output terminal that is mapped to the first filter expression that resolves to true. In the previous example, the first filter expression, which is associated with the Match terminal, is false because the employee number in the input message is not "00002". Therefore no message is propagated to the Match terminal. The second filter expression is true, therefore a copy of the input message is routed to the "out_expr2" dynamic terminal. If the employee number in the input message is "00003", and therefore does not match either filter expression, the message is propagated to the static Default output terminal. If the `Distribution Mode` property is set to `All` for this example, the same outcome is achieved because only one filter expression is true.

Terminals:
The Route node terminals are described in the following table.

Terminal	Description
In	The static input terminal that accepts a message for processing by the node.
Match	A dynamic output terminal to which the original message can be routed when processing completes successfully. You can create additional dynamic terminals; see “Dynamic terminals.”
Default	The static output terminal to which the message is routed if no filter expression resolves to true.
Failure	The static output terminal to which the message is routed if a failure is detected during processing.

Dynamic terminals

The Route node can have further dynamic output terminals. Not all dynamic output terminals that are created on a Route node have to be mapped to an expression in the filter table. Messages are never propagated to unmapped dynamic output terminals. Several expressions can map to the same single dynamic output terminal. No static output terminal exists to which the message is passed straight through. For more information about using dynamic terminals, see “Using dynamic terminals” on page 1518.

Properties:
When you have put an instance of the Route node into a message flow, you can configure it. For more information, see “Configuring a message flow node” on page 1503. The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those properties that do not have a default value defined) are marked with an asterisk.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Route node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, Route	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The Route node Basic properties are described in the following table.

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
Filter table	Yes	No		A table where all rows are expressions and associated terminal names that define the switching that is performed by this node following evaluation of each filter expression. The full expression is in the format *`XPath filter expression`*`,` *`terminal name`* All XPath expressions must start with $Root, $Properties, $LocalEnvironment, $DestinationList, $ExceptionList, or $Environment. If you are creating an expression by hand, you can also start the expression with $Body. However, the XPath Expression Builder and associated validation in the WebSphere Message Broker Toolkit do not support use of the $Body variable. If you are using the XPath Expression Builder, use the $Root variable instead. Expressions are evaluated in the order in which they are displayed in the table. To improve performance, specify the expressions that are satisfied most frequently at the top of the filter table. Typically, you specify a unique terminal name for each XPath expression.	
Distribution Mode	No	Yes	`All`	This property determines the routing behavior of the node when an inbound message matches multiple filter expressions. If you set the `Distribution Mode` property to `First`, the message is propagated to the associated output terminal of the first expression in the table that resolves to true. If you set this property to `All`, the message is propagated to the associated output terminal for each expression in the table that resolves to true. If no output terminal matches, the message is propagated to the Default terminal.	distributionMode

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

"Using nodes for decision making" on page 2209
You can use several built-in nodes in different ways to control the path that a message takes through the message flow.

W3C XPath 1.0 Specification

RouteToLabel node

Use the RouteToLabel node in combination with one or more Label nodes to dynamically determine the route that a message takes through the message flow, based on its content.

This topic contains the following sections:

Purpose:

The RouteToLabel node interrogates the local environment of the message to determine the identifier of the Label node to which to route the message.

You must precede the RouteToLabel node in the message flow with a Compute node that populates the local environment of the message with the identifiers of one or more Label nodes that introduce the next sequence of processing for the message. The destinations are set up as a list of label names in the local environment tree in a specific location. This excerpt of ESQL from the Airline Reservations sample demonstrates how to set up the local environment content in a Compute node:

```
IF InputRoot.XMLNSC.PassengerQuery.ReservationNumber<>'' THEN
   SET OutputLocalEnvironment.Destination.RouterList.DestinationData[1].labelName = 'SinglePassenger';
ELSE
   SET OutputLocalEnvironment.Destination.RouterList.DestinationData[1].labelName = 'AllReservations';
END IF;
```

The label names can be any string value, and can be specified explicitly in the Compute node, taken or cast from any field in the message, or retrieved from a database. A label name in the local environment must match the `Label Name` property of a corresponding Label node.

When you configure the Compute node, you must also select a value for the `Compute Mode` property from the list that includes LocalEnvironment.

Design your message flow so that a RouteToLabel node logically precedes one or more Label nodes in a message flow, but do not physically wire the RouteToLabel node with a Label node. The connection is made by the broker, when required, according to the contents of the local environment.

The RouteToLabel node is contained in the **Routing** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following sample to see how to use this node:

- Airline Reservations

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
When you have put an instance of the RouteToLabel node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value are marked with an asterisk.

The RouteToLabel node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the message is routed if a failure is detected during processing.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The RouteToLabel node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type: RouteToLabel	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The RouteToLabel node Basic properties are described in the following table.

Property	M	C	Default	Description
Mode	Yes	No	Route To Last	This property controls how the RouteToLabel node processes the items in the local environment that is associated with the current message . Valid values are: • `Route To First`: removes the first item from the local environment. The current message is routed to the Label node that is identified by labelName in that list item. • `Route To Last` (the default): removes the last item from the local environment. The current message is routed to the Label node that is identified by labelName in that list item.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

The SET statement assigns a value to a variable.

SAPInput node

Use the SAPInput node to accept input from an SAP application.

This topic contains the following sections:

- "Purpose"
- "Using this node in a message flow"
- "Terminals and properties" on page 4678

Purpose:

Use the SAPInput node to accept input from SAP applications. For example, the SAPInput node might monitor an SAP system for new purchase orders. When a new purchase order is raised, the SAPInput node generates a message tree that represents the business object with the new purchase order details. The message tree is propagated to the Out terminal so that the rest of the message flow can use the data to update other systems, or to audit the changes.

The SAPInput node is contained in the **WebSphere Adapters** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:

The SAPInput node needs an adapter component to function correctly. You set the component by using the `Adapter component` node property and business object definitions, which are stored in the message set that you reference from the node. For this reason, you must provide a message set. By default, the message that is propagated from the SAPInput node is in the DataObject domain, so the `Message domain` property is set to DataObject. You cannot specify a different domain. The message type is detected automatically by the node.

The SAPInput node populates the route-to-label destination list with the name of the method binding. If you add a RouteToLabel node to the message flow after the SAPInput node, the RouteToLabel node can use the name of the method binding to route the message to the correct part of the message flow for processing.

You can deploy only one input node that uses a particular adapter component to an execution group, but you can deploy many input nodes that use different adapter components to an execution group.

You can use the **mqsisetdbparms** command in the following format to configure an account name with a user name and password for the Adapter for SAP Software.

```
mqsisetdbparms broker name -n adapter name -u user name -p password
```

For example:

```
mqsisetdbparms BRK1 -n eis::SAPCustomerInbound.inadapter -u sapuid -p ********
```

The SAP inbound adapter has a property called `Number of listeners`, which configures the adapter to have a particular number of threads listening to the SAP RFC program ID. These threads are not used directly to process messages in a message flow. When a message listener has an event to deliver to the message flow, it requests one of the instances of the flow. In general, it is sensible to keep the number of listeners equal to the number of instances (where instances equals 1 plus additional instances set on the flow or node). For example:

- If the number of listeners is 1, and additional instances is 0, you get a single-threaded message flow that processes one message at a time.
- If the number of listeners is 2, and additional instances is 1, you get two threads that process messages at the same time.
- If the number of listeners is 2, and additional instances is 0, you get two threads that receive data from the EIS, but only one message flow thread will ever run.

The listeners block processing until a message flow instance is available; the listeners do not queue multiple pieces of work. If you leave the number of listeners set to 1 (the default value), the broker ensures that the number of listeners is equal to the number of additional instances plus one. Additional threads can increase the throughput of a message flow, but consider the potential effect on message order.

Using configurable services for SAP nodes

SAP nodes can get SAP connection details from either the adapter component or a configurable service. By using a configurable service, you can change the connection details for an adapter without the need to redeploy the adapter. For more details about creating, changing, reporting, and deleting the configurable services for SAP, see “Changing connection details for SAP adapters” on page 719.

Generic IDoc routing

By using the SAPInput node in passthrough mode, WebSphere Message Broker can receive any IDoc and route it according to IDoc type. For more information, see “Generic IDoc routing” on page 1976. You can use a pattern to process IDocs of various kinds with a single RFC program ID without having to redeploy or rediscover existing message sets and adapters, even when adding new types of IDoc. For more information, look at the pattern: Data distribution SAP to WebSphere MQ: one-way (for IDoc). You can view patterns in the information center by using the links only when you use the information center that is integrated with the WebSphere Message Broker Toolkit, or when you use the online information center.

Look at the following samples to see how to use this node:

- SAP Connectivity
- SAP callout to a synchronous system

- SAP callout to an asynchronous system

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
When you have put an instance of the SAPInput node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. If you double-click an SAPInput node, you open the Adapter Connection wizard. All mandatory properties for which you must enter a value (those properties that do not have a default value defined) are marked with an asterisk.

The SAPInput node terminals are described in the following table.

Terminal	Description
Out	Business object events from the adapter are sent to the Out terminal.
Failure	If an error occurs in the SAPInput node, the message is propagated to the Failure terminal. Information about the error, and business object events can also be propagated to the Failure terminal.
Catch	Business object events are sent to the Catch terminal if they cause an uncaught exception in the message flow. If the Catch terminal is not connected, the retry process is activated to handle the business object.

The following tables describe the node properties. The columns headed M indicate whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the columns headed C indicate whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The SAPInput node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, SAPInput	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The SAPInput node Basic properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Primary adapter component	Yes	Yes		The name of the adapter component that contains configuration properties for the adapter. Either enter a name of an adapter file, or click **Browse** to select an adapter file from the list of files that are available in referenced message set projects. When the SAPInput node receives data from the SAP system, it associates that data with a method name, depending on the service operation name that is assigned to that type of data when you run the Adapter Connection wizard. The SAPInput node attempts to handle methods that are defined in the primary adapter. If the type of data that is received does not correspond to any of the methods that are defined in the primary adapter, the node can handle methods that are defined in matching secondary adapters that are deployed to the same execution group.	adapterComponent
Secondary adapter mode	No	Yes	None	Specifies whether the node can handle methods that are defined in secondary adapters. If you set the `Secondary adapter mode` property to `None`, the node handles only methods that are defined in the primary adapter. If the type of data that is received does not correspond to any of the methods that are defined in the primary adapter, a failure occurs. If you set this property to `All adapters in execution group`, the node can handle methods that are defined in matching SAP inbound adapters that are deployed to the same execution group. For example, if the primary adapter is configured for IDoc messages, matching secondary adapters are IDoc inbound adapters.	secondaryAdapterMode

The SAPInput node Advanced properties are described in the following table.

Property	M	C	Default	Description
Maximum client wait time (secs)	No	Yes	60	The time (in seconds) for the SAP system to wait for a reply to be returned by an SAPReply node. The default value is 60 seconds. If a reply is sent to an SAPReply node after the timeout, the SAPReply node issues an exception. If the broker is stopped while the adapter is waiting for an SAPReply node to provide a reply, a system failure is sent back to the SAP system. If you set this property to zero (0), the SAP system waits indefinitely for a reply to be returned by an SAPReply node. This property is applicable to synchronous callback mode only; it does not apply to asynchronous BAPIs or IDOCs. If you set this property for an SAPInput node that is configured with an adapter that is not for synchronous callback, a warning is issued.

The SAPInput node Routing properties are described in the following table.

Property	M	C	Default	Description
Set destination list	No	No	Selected	Specifies whether to add the method binding name to the route-to-label destination list. If you select this check box, the method binding name is added so that you can use a RouteToLabel node in the message flow after the SAPInput node.
Label prefix	No	No		The prefix to add to the method name when routing to a label. Add a label prefix to avoid a clash of corresponding label nodes when you include multiple WebSphere Adapters input nodes in the same message flow. By default, there is no label prefix, so the method name and label name are identical.

The SAPInput node Input Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	`DataObject`	The domain that is used to parse the incoming message. By default, the message that is propagated from the SAPInput node is in the DataObject domain. You cannot specify a different domain.
Message set	Yes	No	Set automatically	The name of the message set in which the incoming message is defined. This field is set automatically from the Adapter component property. If you set this property, then later update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project.
Message type	No	No		The name of the incoming message. The node detects the message type automatically. You cannot set this property.
Message format	No	No		The name of the physical format of the incoming message. You cannot set this property.

The SAPInput node Transactionality properties are described in the following table.

Property	M	C	Default	Description
Transaction mode	No	No	`Yes`	The transaction mode on this input node determines whether the rest of the nodes in the message flow are executed under sync point.

The Instances properties of the SAPInput node are described in the following table. For a full description of these properties, refer to "Configurable message flow properties" on page 4020. For more information about tuning the SAP adapter, see "Tuning the SAP adapter for scalability and performance" on page 3278.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Additional instances pool	No	Yes	`Use Pool Associated with Message Flow`	The pool from which additional instances are obtained. • If you select `Use Pool Associated with Message Flow`, additional instances are obtained from the message flow value. • If you select `Use Pool Associated with Node`, additional instances are allocated from the additional instances of the node based on the number specified in the `Additional instances` property.	componentLevel
Additional instances	No	Yes	`0`	The number of additional instances that the node can start if the `Additional instances pool` property is set to `Use Pool Associated with Node`. By default, no additional instances are given to the node.	additionalInstances

The SAPInput node Retry properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Retry mechanism	No	No	`Failure`	Specifies how retry processing is handled when a failure is rolled back to the SAPInput node. • If you select `Failure`, retry processing is not performed so you cannot set the remaining properties. • If you select `Short and long retry`, retry processing is performed first at the interval that is specified by the `Short retry interval` property, and if that is unsuccessful, it is then performed at the interval that is specified by the `Long retry interval` property.	
Retry threshold	No	Yes	`0`	The maximum number of times that retry processing is performed for short retry.	retryThreshold
Short retry interval	No	Yes	`0`	The interval between short retry attempts.	shortRetryInterval
Long retry interval	No	Yes	`0`	The interval between long retry attempts.	longRetryInterval

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

SAPReply node

Use the SAPReply node to send a reply to an SAP synchronous callout. Use this node with an SAPInput node to implement a message flow that acts as a remote function call (RFC) destination.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow" on page 4683
- "Terminals and properties" on page 4683

Purpose:
An SAP program can call functions on remote RFC servers. These functions can be called asynchronously or synchronously, where they must provide a reply. A message flow can act as an RFC destination and receives the function call through the SAPInput node. When the function is called synchronously, use the SAPReply node to send a reply back.

The SAPReply node is contained in the **WebSphere Adapters** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
You can use an SAPReply node in the same message flow as an SAPInput node, or in a different flow from an SAPInput node. The SAPReply node must be deployed in the same execution group as the SAPInput node.

Look at the following samples to see how to use this node:

- SAP callout to a synchronous system
- SAP callout to an asynchronous system

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
When you have put an instance of the SAPReply node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. To display the properties of the node in the Properties dialog, either double-click the node, or right-click the node and click **Properties**. All mandatory properties for which you must enter a value (those properties that do not have a default value defined) are marked with an asterisk.

The SAPReply node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the message is routed if a failure is detected when the message is propagated.
Out	The output terminal to which the message is routed if it has been sent to an external resource. The message is unchanged except for the addition of status information.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk in the Properties view) if you must enter a value when no default is defined). The column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The SAPReply node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type: SAPReply	The name of the node.
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

The SAPReply node Basic properties are described in the following table.

Property	M	C	Default	Description
SAP Reply Identifier	No	No	$LocalEnvironment/Destination/Adapter/Reply/ReplyIdentifier	Use this property to specify the location of the SAP reply identifier. The SAPReply node issues an exception in the following circumstances: • The SAPReply node receives a reply for a BAPI that has timed out • The SAPReply node receives a reply for a BAPI when the broker has been restarted or redeployment has occurred after the flow with the SAPInput node has finished, but before the flow with the SAPReply node has started.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

SAPRequest node

Use the SAPRequest node to send requests to an SAP application.

This topic contains the following sections:

Purpose:

Use the SAPRequest node to send requests to SAP applications. For example, the SAPRequest node might request information from an SAP Enterprise Information System (EIS). A customer business object is sent to SAP, causing SAP to retrieve information about a customer, such as an address and account details. The response information that is retrieved by the SAPRequest node can then be used by the rest of the message flow. The SAPRequest node can send and receive business data.

The SAPRequest node is contained in the **WebSphere Adapters** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using the SAPRequest node in a message flow:

The SAPRequest node needs an adapter component to function correctly. You set the component by using the `Adapter component` node property and business object definitions, which are stored in the message set that you reference from the node.

For this reason, you must provide a message set. By default, the message that is propagated from the SAPRequest node is in the DataObject domain, so that the `Message domain` property is set to DataObject. You cannot specify a different domain. The node automatically detects the message type.

The SAPRequest node supports local transactions by using the Local Transaction Manager of the broker.

You can deploy several WebSphere Adapters request nodes that use the same adapter component to an execution group.

The SAPRequest node can use an identity that is present on an input message, and propagate it to SAP, by using the `Propagate` property on the security profile that is defined on the node. For more information, see "Propagating security credentials to an SAP request" on page 2065.

To effectively maintain the pool of connections to SAP, you can set a connection timeout value on a configurable service. By default, the connectionIdleTimeout property is set to zero, indicating that no timeout occurs. However, new connections to SAP are opened with different user IDs, therefore do not set this property to zero if you are using identity propagation. For more information, see "Configuring EIS connections to expire after a specified time" on page 726.

You can use the **mqsisetdbparms** command in the following format to configure an account name with a user name and password for the Adapter for SAP Software. The **mqsisetdbparms** command stores the password in case-sensitive form. However, when the SAP GUI sets a password, it automatically converts the password to uppercase. Therefore, specify an uppercase password to connect to the SAP system.

```
mqsisetdbparms broker name -n adapter name -u user name -p PASSWORD
```

For example:

```
mqsisetdbparms BRK1 -n eis::SAPCustomerOutbound.outadapter -u sapuid -p ********
```

Look at the following sample to see how to use this node:

- SAP Connectivity

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Using configurable services for SAP nodes

SAP nodes can get SAP connection details from either the adapter component or a configurable service. By using a configurable service, you can change the connection details for an adapter without the need to redeploy the adapter. For more details about creating, changing, reporting, and deleting the configurable services for SAP, see "Changing connection details for SAP adapters" on page 719.

Terminals and properties:
When you have put an instance of the SAPRequest node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. If you double-click an SAPRequest node, you open the Adapter Connection

wizard. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The SAPRequest node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts the request business object.
Out	The output terminal to which the response business object is sent if it represents successful completion of the request, and if further processing is required within this message flow.
Failure	If an error occurs in the SAPRequest node, the message is propagated to the Failure terminal. Information about the error, and business object events can also be propagated to the Failure terminal.

The following tables describe the node properties. The columns headed M indicate whether the property is *mandatory* (marked with an asterisk on the panel if you must enter a value when no default is defined); the columns headed C indicate whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The SAPRequest node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, SAPRequest	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The SAPRequest node Basic properties are described in the following table.

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
Primary adapter component	Yes	No		The name of the adapter component that contains configuration properties for the adapter. Either enter a name of an adapter file, or click **Browse** to select an adapter file from the list of files that are available in referenced message set projects. When the SAPRequest node receives data from the SAP system, it associates that data with a method name. The SAPRequest node attempts to call methods that are defined in the primary adapter. If the method is not defined in the primary adapter, the node can call methods that are defined in matching secondary adapters that are deployed to the same execution group.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Secondary adapter mode	No	Yes	None	Specifies whether the node can call methods that are defined in secondary adapters. If you set the `Secondary adapter mode` property to `None`, the SAPRequest node calls only methods that are defined in the primary adapter. If the method is not defined in the primary adapter, an error occurs. If you set this property to `All adapters in execution group`, the node can call methods that are defined in matching SAP outbound adapters that are deployed to the same execution group. For example, if the primary adapter is configured for IDoc messages, matching secondary adapters are IDoc outbound adapters.	secondaryAdapterMode
Default method	Yes	Yes		The default method binding to use. This property lists the methods that are defined by the adapter. You can override this property by setting the method name in the LocalEnvironment.Adapter subtree. For more information, see "Local environment tree structure" on page 1056. The method names correspond to the Service Operation names, which are configured by the Adapter Connection wizard. In most cases, the names are based on the name of the service that is being discovered (for example, a BAPI).	defaultMethod

The SAPRequest node Response Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	`DataObject`	The domain that is used to parse the response message. By default, the message that is propagated from the SAPRequest node is in the DataObject domain. You cannot specify a different domain.
Message set	Yes	No	Set automatically	The name of the message set in which the incoming message is defined. This field is set automatically from the Adapter component property. If you set this property, then subsequently update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project.
Message type	No	No		The name of the response message. The node detects the message type automatically. You cannot set this property.
Message format	No	No		The name of the physical format of the response message. You cannot set this property.

The SAPRequest node Transactionality properties are described in the following table.

Property	M	C	Default	Description
Transaction mode	No	No	`Automatic`	Specifies how updates are handled. • If you select `Yes`, the SAPRequest node takes part in the local transaction that is started by the message flow's input node. • If you select `No`, the SAPRequest node does not take part in the local transaction that is started by the message flow's input node. • If you select `Automatic`, the SAPRequest node uses the value that is set on the input node that drives the message flow. For example, if the message flow is driven by an SAPInput node, the SAPRequest assumes the Transaction mode that is set on the SAPInput node. For more information about transactionality, see "SAP BAPI transaction commit" on page 1928.

The SAPRequest node Request properties are described in the following table.

Property	M	C	Default	Description
Method Location	Yes	No	`$LocalEnvironment/Adapter/MethodName`	The location of the business method (such as createPurchaseOrder or deletePurchaseOrder) that is used to trigger the SAPRequest node to perform an action on the external system.
Data Location	Yes	No	`$Body`	The location in the incoming message tree from which data is retrieved to form the request that is sent from the SAPRequest node to the EIS.

The SAPRequest node Result properties are described in the following table.

Property	M	C	Default	Description
Output data location	No	No	`$OutputRoot`	The message tree location to which the SAPRequest node sends output.
Copy local environment	No	No	Selected	This property controls how the local environment is copied to the output message. If you select this check box, a new copy of the local environment is created in the tree (at each node in the message flow), and it is populated with the contents of the local environment from the preceding node. Therefore, if a node changes the local environment, the previous nodes in the flow do not see those changes because they have their own copies. This behavior might be an issue if you are using a FlowOrder node, or if you use the propagate command on a Compute node. If you clear the check box, each node does not generate its own copy of the local environment, but it uses the local environment that is passed to it by the previous node. Therefore, if a node changes the local environment, those changes are seen by the upstream nodes.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

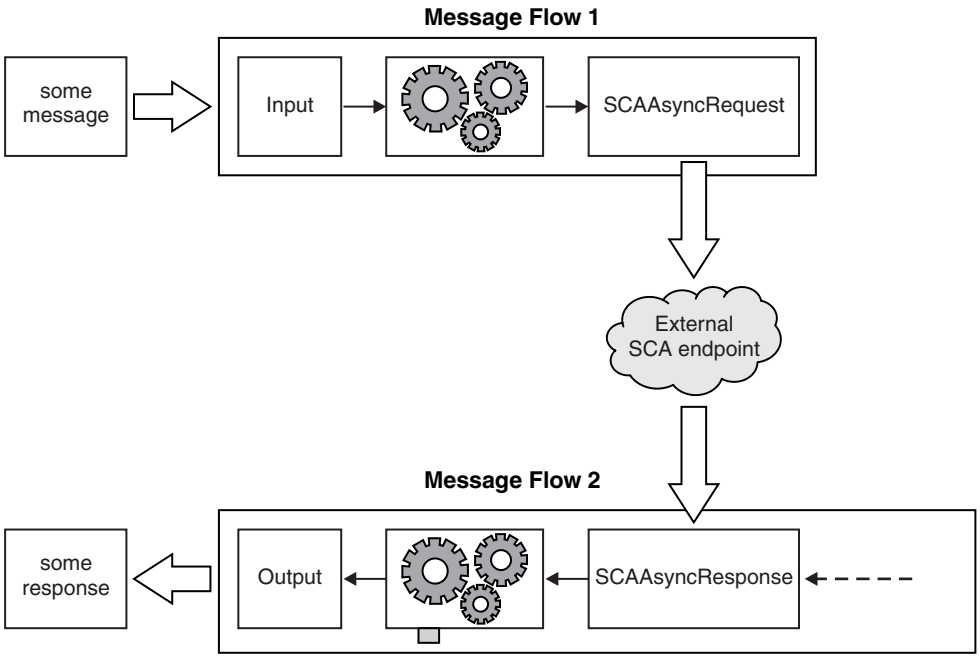
Use the **mqsisetdbparms** command to associate a specific user ID and password (or SSH identity file) with one or more resources that are accessed by the broker.

SCAAsyncRequest node

Use the SCAAsyncRequest node with the SCAAsyncResponse node to construct a pair of message flows that invoke a WebSphere Process Server service component asynchronously.

This topic contains the following sections:

Purpose:
The SCAAsyncRequest node sends a request to a business process that is running on WebSphere Process Server, but the node does not wait for the associated response to be received. However, the SCAAsyncRequest node does wait for an acknowledgment before continuing with the message flow. The response to the Process Server request is received by the SCAAsyncResponse node, which can be in the same message flow or in a separate message flow. The nodes are used as a pair, and correlate responses against the original requests.



The SCAAsyncRequest node is the first half of the asynchronous request and response node pair. The SCAAsyncRequest node sends a request to a business process that is running on WebSphere Process Server. The request is sent by the SCAAsyncRequest node, but the SCAAsyncRequest node does not receive the response. The response is received by a SCAAsyncResponse node that is running on a different thread. The SCAAsyncResponse node is typically at the beginning of a different message flow; however, it must be in the same execution group as the SCAAsyncRequest node.

A Broker SCA definition is required to configure both the SCAAsyncRequest node and the SCAAsyncResponse node. The Broker SCA definition contains specific data related to the Process Server binding.

The SCAAsyncRequest node is contained in the **SCA** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following sample to see how to use the node:

SCA nodes

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

You can change the operation that should be invoked by changing the value in the following location in the local environment:

`LocalEnvironment.Destination.SCA.Request.Operation`

For a Web Services binding, you can change the URL to which the request is sent. Change the value in the following location in the local environment:

`LocalEnvironment.Destination.SCA.Request.Binding.WebServices.Transport.HTTP.WebServiceURL`

For an MQ binding, you can change the Request Queue Manager and Request Queue by changing the values in the following locations:

`LocalEnvironment.Destination.SCA.Request.Binding.MQ.queueManagerName`
`LocalEnvironment.Destination.SCA.Request.Binding.MQ.queueName`

You can store context data in the following location in the local environment. The SCAAysncResponse node can later retrieve this data.

`LocalEnvironment.Destination.SCA.Request.UserContext`

`LocalEnvironment.Destination.SCA.Request.KeyAlias`

Configuring the SCAAsyncRequest node:
Ensure that the message set contains a Broker SCA definition with an extension of .outsca with which to configure the SCAAsyncRequest node.

There are two methods of putting an instance of the SCAAsyncRequest node into a message flow: you can either drag an instance of the node from the node palette, or drag a Broker SCA definition with an extension of .outsca from a message set onto the message flow editor canvas.

`Dragging a node onto the canvas`

If you have dragged an instance of the node from the palette onto the canvas, use one of the following methods to start to configure it:

- Drag a Broker SCA definition with an extension of `.outsca` onto the node.
- Type the file name in the `SCA file name` option in the Properties view of the node.
- Browse to the file (`SCA file name` option in the Properties view of the node.)

`Dragging a .outsca file onto the canvas`

- If the `.outsca` file contains a WSDL that has only a single, one-way operation defined, a SCARequest node is created.
- If the `.outsca` file contains a WSDL that only has request-response operations, you first select the operation, and say whether you want the outbound request to be sent synchronously or asynchronously. For a

synchronous request, a SCARequest node is created and configured. For an asynchronous request, a pair of SCAAsyncRequest and SCAAsyncResponse nodes are created and configured.

- If the `.outsca` file contains a WSDL that has a mixture of one-way and request-response operations defined, and you select a one-way operation, a SCARequest node is created.

The values for many of the node properties are provided in the Broker SCA definition. The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (properties that do not have a default value defined) are marked with an asterisk.

1. Optional: On the **Description** tab, enter a `Short description`, a `Long description`, or both. You can also rename the node on this tab.
2. On the **Basic** tab, set the `Unique identifier` and `Broker SCA definition` properties.
   - `Unique identifier`. You must specify the unique string that is common to your pair of SCAAsyncRequest and SCAAsyncResponse nodes. This property is mandatory.
   - In `Broker SCA definition`, specify the name of the Broker SCA definition that contains configuration properties for the SCAAsyncRequest node. If you have created the node by dragging a Broker SCA definition from a message set onto the Message flow editor canvas, this property is preset to the name of the Broker SCA definition. If you created the node by selecting it from the palette, you can set this property in one of the following ways:
     - If you have a Broker SCA definition, you can select it from the Broker SCA definitions by clicking **Browse**.
     - Type a file name that is relative to the message set project in which the Broker SCA definition exists.
     - If you have Broker SCA definitions, but no message set, you can create a message set:
       a. Click **Browse** to open the Broker SCA Definition Selection pane.
       b. Click **Import/Create New** to open the Import Broker SCA definition wizard.
       c. Enter the message set name and message set project name, then click **Next**.
       d. Choose the relevant option:
          - If your Broker SCA definition exists in your workspace, click **Use resources from the workspace**, and select the Broker SCA definition.
          - If your Broker SCA definition is in the file system, click **Use external resources**, select the Broker SCA definition, click **Next**.
       e. Select the Broker SCA definition to import.
       f. Click **Finish**. A new message set project and message set are created with message definitions. The Broker SCA definition is added to the `Broker SCA Definitions` folder.
       g. Select the Broker SCA definition from the Broker SCA Definition Selection window, then click **OK**.
     - If you have a message set but no Broker SCA definition, generate a Broker SCA definition by following the instructions in "Generating a Broker SCA definition from a message set" on page 2967.
     - Drag a Broker SCA definition from a message set onto the node.

3. On the **Binding** tab, specify properties that relate to the WebSphere Process Server binding. Some of the properties on this tab are derived from the Broker SCA definition.
   - The value of the Binding type property is derived from the binding information in the Broker SCA definition. It is read-only. Possible values are:
     - `WebService`. Requests from WebSphere Process Server are sent as SOAP messages over the HTTP transport. See the WSDL properties table in "Terminals and properties" for details of binding properties that are either supplied by the Broker SCA definition, or that you need to set.
     - `MQ`. Requests from WebSphere Process Server arrive as WebSphere MQ messages. See the MQ properties table and the Transactionality table in "Terminals and properties," for details of binding properties that are either supplied by the Broker SCA definition, or that you need to set.

Terminals and properties:
The SCAAsyncRequest node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message.
Failure	The output terminal to which the message is sent if a failure is detected in the node.
Out	The output terminal to which the message is sent after the node has successfully sent the message to the SCA resource.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the SCAAsyncRequest node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type	The name of the node.
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

The Basic properties of the SCAAsyncRequest node are described in the following table.

Property	M	C	Default	Description
Unique identifier	Yes	Yes	Not set	The property specifies a unique identifier that is common to your pair of SCAAsyncRequest and SCAAsyncResponse nodes.

Property	M	C	Default	Description
Broker SCA definition	Yes	Yes	Not set	The property specifies the name of the Broker SCA definition that contains configuration properties for the SCAAsyncRequest node. You can click Browse to see a list of all relevant Broker SCA definitions in the current workspace.

The Binding property of the SCAAsyncRequest node is described in the following table.

Property	M	C	Default	Description
Binding type	Yes	No	From SCA export	This property is read-only. It is supplied by the toolkit when the SCA export configuration file is parsed. The property describes the binding type that was found in the Broker SCA definition. If the binding is Web Services, only the WSDL properties are shown. If the binding is MQ, only the MQ properties are shown.

The WSDL properties are described in the following table. These properties are shown only if the binding type is Web Services.

Note: The values for the properties must be supplied on the node. They are not marked as mandatory on the node because the Broker SCA definition might not contain all the property values, resulting in node errors being shown. You must supply values for those properties that have not been configured by the Broker SCA definition file.

Property	M	C	Default	Description
WSDL file name	Yes	No	Not set	The WSDL file name is taken from the WSDL file that is referenced by the Broker SCA definition.
Target namespace	No	No	From Broker SCA definition	This property type is String. It is supplied by the toolkit when the WSDL configuration file that is referenced by the Broker SCA definition is parsed.
Port type	Yes	No	By default, the `Port type` that is referenced in the Broker SCA definition.	This property type is String. This property is read-only. Error Conditions: • The selected `Port type` does not contain at least one operation.
Imported binding	Yes	No	From Broker SCA definition	This property type is String. It is supplied by the toolkit when the WSDL that is referenced by the Broker SCA definition is parsed. Error Conditions: • No SOAP bindings (with HTTP transport) in the WSDL file are associated with the `Port type`. • The selected binding does not have any operations.
Operation	Yes	No	From Broker SCA definition	This property type is String. The `Operation` property lists the operations that are defined by the port type. The first two-way operation in the list is selected by default. Only two-way operations are supported.

Property	M	C	Default	Description
Service port	Yes	No	From Broker SCA definition	This property type is String. It is supplied by the toolkit when the WSDL configuration file is parsed. Error Conditions: • No ports point to the selected binding.
Web service URL	Yes	Yes	From Broker SCA definition	This property type is String. This property is automatically derived from the `<soap:address>` element of the selected `Service port`. Whenever the selected port is updated, the `Web service URL` is updated accordingly. However, if you override the value, your value persists and the URL is no longer updated from the service port. If you choose to override this property you must specify it in the form http://<hostname>[:<port>]/[<path>] where: • http://<hostname> must be specified. • <port> has a default of 80. If you specify a value, you must include the : before the port number. • <path> has a default of /. If you specify a value, you must include the / before the path.

The MQ properties are described in the following table. These properties are shown only if the binding type is MQ.

Note: The values for the properties must be supplied on the node. They are not marked as mandatory on the node because the Broker SCA definition might not contain all the property values, resulting in node errors being shown. You must provide values for those properties that have not been configured by the Broker SCA definition file.

Property	M	C	Default	Description
Operation	Yes	No	From the Broker SCA definition	The available operations that are found in the interface of the Broker SCA definition. Only two-way operations are supported.
Queue name	Yes	Yes	From the Broker SCA definition	The name of the queue that receives a request message from WebSphere Message Broker. This is taken from the Broker SCA definition, but can be updated directly in the node. This can be a remote queue; see "How does distributed queuing work?" in the *Intercommunication* section of the WebSphere MQ information center.
Queue manager name	Yes	Yes	From the Broker SCA definition	The name of the queue manager that receives a message from WebSphere Message Broker. It is taken from the Broker SCA definition, but can be updated directly in the node. If a remote queue is used, leave this property blank to allow WebSphere MQ to resolve the queue manager name.
Reply-to queue name	Yes	Yes	From the Broker SCA definition	The name of the queue that receives a response message from WebSphere Process Server. It is taken from the Broker SCA definition, but can be updated directly in the node.

Property	M	C	Default	Description
Reply-to queue manager name	No	Yes	From the Broker SCA definition	The name of the queue manager that receives a response from WebSphere Process Server. It is taken from the Broker SCA definition, but can be updated directly in the node. This queue manager must be local to the broker.
Response message correlation	Yes	No	From the Broker SCA definition	This property indicates how WebSphere Process Server provides correlation ID information in the response message. This correlation information is used by the WebSphere Message Broker to determine which message is a response to which request, and is supplied by the toolkit when the SCA export file is parsed. Select From Message ID if the WebSphere Process Server is expected to copy the MQMD MSGID field in the request to the MQMD CORRELID field in the response. Select From Correl ID if the WebSphere Process Server is expected to copy the MQMD CORRELID field in the request to the MQMD CORRELID field in the response.

The Transactionality property of the SCAAsyncRequest node is described in the following table.

Property	M	C	Default	Description
Transaction mode	No	No	For MQ, 'yes'	This property can be 'automatic', 'no', or 'yes'. The property is enabled only when the Binding type is MQ.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

"SCAAsyncResponse node"
Use the SCAAsyncResponse node with the SCAAsyncRequest node to construct a pair of message flows that start a component asynchronously.

"SCARequest node" on page 4719
Use the SCARequest node to send a request to WebSphere Process Server. The node is a synchronous request and response node, and blocks after sending the request until the response is received. The node can also send one-way requests.

"SCAInput node" on page 4707
Use the SCAInput node with the SCAReply node to process messages from WebSphere Process Server.

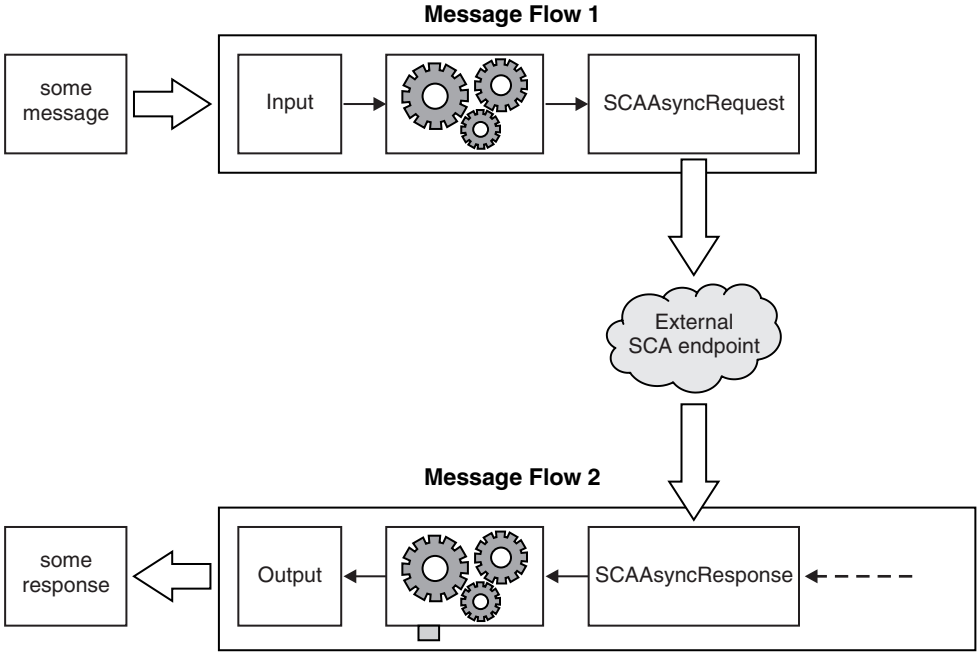
"SCAReply node" on page 4726
Use the SCAReply node to send a message from the broker to the originating client in response to a message received by a SCAInput node.

SCAAsyncResponse node

Use the SCAAsyncResponse node with the SCAAsyncRequest node to construct a pair of message flows that start a component asynchronously.

This topic contains the following sections:

Purpose:
The node allows the broker to receive the response to a previous asynchronous request made from an SCAAsyncRequest node.



The node is contained in the **SCA** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following sample to see how to use the node:

SCA nodes

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

You can retrieve context data that has been stored by the SCAAsyncRequest node from the following location in the local environment:

```
LocalEnvironment.SCA.Response.UserContext
```

You can access the SOAP header and context information in an inbound response in the local environment, at the following locations:

```
LocalEnvironment.SCA.Response.Binding.WebServices.SOAP.Header
LocalEnvironment.SCA.Response.Binding.WebServices.SOAP.Context
```

Configuring the node:
Ensure that the message set contains a Broker SCA definition with an extension of .outsca with which to configure the node.

There are two methods of putting an instance of the node into a message flow: You can either drag an instance of the node from the node palette, or drag a Broker SCA definition with an extension of .outsca from a message set, onto the message flow editor canvas. Dragging a Broker SCA definition with an extension of .outsca onto the canvas creates a pair of SCAAsyncRequest and SCAAsyncResponse nodes.

If you have dragged an instance of the node from the palette onto the canvas, you must then start to configure it by dragging a Broker SCA definition with an extension of .outsca onto the node. The values for many of the node properties are provided in the Broker SCA definition. If you have dragged a Broker SCA definition onto the canvas and created a pair of SCAAsyncRequest and SCAAsyncResponse nodes, many of the values for the node properties have already been supplied from the Broker SCA definition.

The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (properties that do not have a default value defined) are marked with an asterisk.

1. Optional: On the **Description** tab, enter a `Short description`, a `Long description`, or both. You can also rename the node on this tab.
2. On the **Basic** tab, set the `Unique identifier` and `Broker SCA definition` properties.
   - `Unique identifier`. You must specify the unique URL fragment that is common to your pair of SCAAsyncRequest and SCAAsyncResponse nodes. This property is mandatory.
   - In `Broker SCA definition`, specify the name of the Broker SCA definition that contains configuration properties for the node. If you have created the node by dragging a Broker SCA definition from a message set onto the Message flow editor canvas, this property is preset to the name of the Broker SCA definition. If you created the node by selecting it from the palette, you can set this property in one of the following ways:
     – If you have a Broker SCA definition, you can select it from the Broker SCA definitions by clicking **Browse**.
     – If you have Broker SCA definitions, but no message set, you can create a message set:
       a. Click **Browse** to open the Broker SCA Definition Selection pane.
       b. Click **Import/Create New** to open the Import Broker SCA definition wizard.
       c. Enter the message set name and message set project name, then click **Next**.
       d. Choose the relevant option:
          - If your Broker SCA definition exists in your workspace, click **Use resources from the workspace**, and select the Broker SCA definition.
          - If your Broker SCA definition is in the file system, click **Use external resources**, select the Broker SCA definition, then click **Next**.
       e. Select the Broker SCA definition to import.
       f. Click **Finish**. A new message set project and message set are created with message definitions. The Broker SCA definition is added to the `Broker SCA Definitions` folder.
       g. Select the Broker SCA definition from the Broker SCA Definition Selection window, then click **OK**.

- If you have a message set but no Broker SCA definition, generate a Broker SCA definition by following the instructions in "Generating a Broker SCA definition from a message set" on page 2967.
- Drag a Broker SCA definition from a message set onto the node.
- Type a file name that is relative to the message set project in which the Broker SCA definition exists.

3. On the **Binding** tab, specify properties that relate to the binding. Some of the properties on this tab are derived from the Broker SCA definition.

   The value of the Binding type property is derived from the binding information in the Broker SCA definition, and is read-only. Possible values are:

   - `WebService`. Web service responses are sent as SOAP messages over the HTTP transport.
   - `MQ`. MQ responses arrive as messages.

   The `Propagate only SOAP body (owned by XMLNSC domain)` check box is shown only when the Binding type is Web Services. It is not shown when the Binding type is MQ; there are no MQ-specific binding properties.
4. On the **Response Message Parsing** tab, the properties are set automatically from the Broker SCA Definition file.
   - If the Binding type is Web Services, the Message domain is always SOAP. If the Binding type is MQ, you can change the domain to MRM, XMLNSC, XMLNS, MIME, JSON or BLOB.
   - If the Binding type is MQ, the Message domain defaults to XMLNSC if the data bindings for all operations are using XML. Otherwise the default domain is BLOB.
5. On the **Parser Options** sub tab, set properties that are associated with the parser.
   - `Parse timing` is, by default, set to `On Demand`, which causes parsing of the message to be delayed. For information about how to cause the message to be parsed immediately, see "Parsing on demand" on page 4173.
   - `XMLNSC Parser Options`. Set values for the properties that determine how the XMLNSC parser operates. For more information, see "Manipulating messages in the XMLNSC domain" on page 2546.
6. Use the **Validation** tab to provide validation based on the message set for predefined messages. For more information about validation, see "Validating messages" on page 1478. For information about how to complete this tab, see "Validation tab properties" on page 4169.
7. Use the **Instances** tab to specify how additional threads are handled for the message flow.
   - The `Additional instances pool` property specifies whether additional instance threads are allocated from a thread pool for the whole message flow, or from a thread pool for use by that node only. By default, this property is set to `Use Pool Associated with Message Flow`.
   - The `Additional instances` property specifies the number of additional threads that the broker can use to service the message flow and has the default value `0`.

Terminals and properties:
The terminals of the node are described in the following table.

Terminal	Description
Failure	The output terminal to which the message is routed if a failure is detected when the message is propagated.
Out	The output terminal to which the message is routed if it has been propagated successfully, and if further processing is required within this message flow.
Fault	The output terminal to which a SOAP fault message is routed if the Binding type is Web Services. The Fault terminal is not used by any other type of Binding type.
Catch	The output terminal to which the message is routed if an exception is thrown downstream and caught by this node.

When you have put an instance of the node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (properties that do not have a default value defined) are marked with an asterisk.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type: SOAPAsyncResponse	The name of the node.
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

The Basic properties of the node are described in the following table:

Property	M	C	Default	Description
Unique identifier	Yes	No	Not set	Specify the unique identifier that is common to your pair of nodes.
Broker SCA definition	Yes	Yes	Not set	The property specifies the name of the Broker SCA definition that contains configuration properties for the node. You can click Browse to see a list of all relevant Broker SCA definitions in the current workspace.

.

The Binding properties of the node are described in the following table:

Property	M	C	Default	Description
Binding type	Yes	No	Not set	The binding type that was found in the SCA Import.
extractSOAPBody	No	No	Cleared	This option is available if the binding is `Web Services`. If the check box is selected, only the SOAP body is propagated. If it is cleared, the entire SOAP message is propagated.

The Response Message Parsing properties of the node are described in the following table. The node sets these properties automatically; the table describes when you can change them.

Property	M	C	Default	Description
Message domain	No	No	Set automatically according to the binding that is defined in the corresponding node.	The domain that is used to parse the response message. It is determined according to the Binding type. You can change this property if the Binding type is MQ. The property is read-only when the Binding type is Web Services.
Message set	No	No	Picked automatically according to the Broker SCA definition that is chosen in the corresponding node.	The name of the message set in which the response message is defined. `Message set` is set automatically to the message set that contains the SCA file that is configured on the corresponding node. This property is read-only.
Message type	No	No	Not set	The node detects the message type automatically. You can change this property if the Binding type is MQ and the message domain is MRM. You cannot change this property if the Binding type is Web Services.
Message format	No	No	Not set	The name of the physical format of the response message. You can change this property if the Binding type is MQ and the message domain is MRM. You cannot change this property if the Binding type is Web Services.

The Parser Options properties of the node are described in the following table.

Property	M	C	Default	Description
Parse timing	Yes	No	`On Demand`	This property controls when a response message is parsed. Valid values are `On Demand`, `Immediate`, and `Complete`. By default, parse timing is set to `On demand`, which causes parsing of the input message to be delayed. For a full description of this property, see "Parsing on demand" on page 4173.
Build tree using XML schema data types	No	No	Selected	This property controls whether the XMLNSC parser creates syntax elements in the message tree with data types taken from the XML Schema.
Retain mixed content	Yes	No	Cleared	This property controls whether the parser creates elements in the message tree when it encounters mixed text in a response message. If you select the check box, elements are created for mixed text. If the check box is cleared, mixed text is ignored and no elements are created.
Retain comments	Yes	No	Cleared	This property controls whether the parser creates elements in the message tree when it encounters comments in a response message. If you select the check box, elements are created for comments. If the check box is cleared, comments are ignored and no elements are created.
Retain processing instructions	Yes	No	Cleared	This property controls whether the parser creates elements in the message tree when it encounters processing instructions in a response message. If you select the check box, elements are created for processing instructions. If the check box is cleared, processing instructions are ignored and no elements are created.

Property	M	C	Default	Description
Opaque elements	No	No	Not set	This property is used to specify a list of elements in the response message that are to be opaquely parsed. Opaque parsing is performed only if validation is not enabled (that is, if `Validate` is `None`); entries that are specified in `Opaque Elements` are ignored if validation is enabled.

The Validation properties of the node are described in the following table.

If validation fails, the message is propagated to the failure terminal, if this terminal is wired. For more details, see "Validating messages" on page 1478 and "Validation properties" on page 4169.

Property	M	C	Default	Description
Validate	Yes	Yes	`Content and value`	This property controls whether validation takes place. Valid values are `None`, `Content and value`, and `Content`.
Failure action	Yes	Yes	`Exception`	This property controls what happens if validation fails. You can set this property only if you set `Validate` to `Content` or `Content and value`. Valid values are `User trace`, `Exception list`, `Local error log`, and `Exception`.

The Security properties of the node are described in the following table. Set values for these properties to control the extraction of an identity from a message (when a security profile is associated with the node). For more information about these properties, see "Identity" on page 390, "Configuring the extraction of an identity or security token" on page 447, "Message flow security overview" on page 383, and "Setting up message flow security" on page 431.

Property	M	C	Default	Description
Identity token type	No	No	`None`	This property specifies the type of identity token present in the incoming message. Valid values are: `Transport Default`, `Username`, `Username + Password`, `SAML Assertion`, and `X.509 Certificate`. If this property is not specified, the identity is retrieved from the Basic-Auth transport header and the type is set to `Username + Password`.
Identity token location	No	No	`None`	This property specifies where, in the message, the identity can be found. The location is specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotation marks and must not contain a period (.), If this property is not specified, the identity is retrieved from the MQMD.UserIdentifier transport header.
Identity password location	No	No	`None`	This property specifies where, in the message, the password can be found. The location is specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotation marks and must not contain a period (.), If it is not specified, the password is not set. This property can be set only if `Identity token type` is set to `Username + Password`.
Identity IssuedBy location	No	No	`None`	This property specifies a string or path expression that describes the issuer of the identity. The location is specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotation marks and must not contain a period (.), The value specifies the Issuer that is passed to a WS-Trust v1.3 STS provider. If this property is not specified, the MQMD.PutApplName value is used. If you leave the `Identity issuedBy location` field blank and the MQMD.PutApplName is also blank, the string `MQ` is used.

Property	M	C	Default	Description
Treat security exceptions as normal exceptions	No	No	`False`	This property specifies whether to treat security exceptions (such as "Access Denied") as normal exceptions, and propagate them to the Failure terminal (if wired). This property is turned off by default, which ensures that security exceptions cause the message to be backed out even if the Failure terminal is wired.

The Instances properties of the node are described in the following table.

Property	M	C	Default	Description
Additional instances pool	No	Yes	`Flow`	The pool from which additional instances are obtained. • If you select `Flow`, additional instances are obtained from the message flow value. • If you select `Node`, additional instances are allocated from the additional instances pool for that node; how many are allocated is specified in the `Additional instances` property.
Additional instances	No	Yes	`0`	The number of additional instances that the node can start if the `Additional instances pool` property is set to `Node`. By default, no additional instances are given to the node.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see “Configuring monitoring event sources using monitoring properties” on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

“Message modeling” on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

“Parsers” on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

“SOAP parser and domain” on page 1082
You can use the SOAP parser to create a common WSDL-based logical tree format for working with Web services, independent of the physical bitstream format.

“XMLNSC parser” on page 1090
The XMLNSC parser is a flexible, general-purpose XML parser that offers high performance XML parsing and optional XML Schema validation.

Use the SCARequest node to send a request to WebSphere Process Server. The node is a synchronous request and response node, and blocks after sending the request until the response is received. The node can also send one-way requests.

"SecurityPEP node" on page 4729
Use the SecurityPEP node in a message flow to invoke the message flow security manager at any point in the message flow.

SCADAInput node

The SCADAInput node, available in earlier versions of WebSphere Message Broker, is not supported in WebSphere Message Broker Version 7.0. See "Migrating from Version 6.1 products" on page 163 for information about migrating your message flows from WebSphere Message Broker to WebSphere Message Broker Version 7.0.

SCADAOutput node

The SCADAOutput node, available in earlier versions of WebSphere Message Broker, is not supported in WebSphere Message Broker Version 7.0. See "Migrating from Version 6.1 products" on page 163 for information about migrating your message flows from WebSphere Message Broker to WebSphere Message Broker Version 7.0.

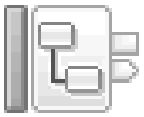
SCAInput node

Use the SCAInput node with the SCAReply node to process messages from WebSphere Process Server.

This topic contains the following sections:

Purpose:
If you use service components in WebSphere Process Server, you can use this node to start a service provided by WebSphere Message Broker. The flow acts as a SCA endpoint for the service component to use through an import binding.

The SCAInput node is contained in the **SCA** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:



Using this node in a message flow:
Look at the following sample to see how to use the node:

- SCA nodes

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

You can access the operation that is being called on an inbound request in the following location in the local environment:

```
LocalEnvironment.SCA.Input.Operation
```

You can access the SOAP Header information that is present in an inbound request from the following location in the local environment:

```
LocalEnvironment.SCA.Input.Binding.WebServices.SOAP.Header
```

You can also access the SOAP context information that is present in an inbound request in the local environment. The SOAP context is stored in the following location:

```
LocalEnvironment.SCA.Input.Binding.WebServices.SOAP.Context
```

Configuring the SCAInput node:
Ensure that the message set contains a Broker SCA definition with an extension of `.insca` with which to configure the SCAInput node.

You can put an instance of the SCAInput node into a message flow in either of the following ways:

- Drag a Broker SCA definition with an extension of `.insca` from a message set onto the message flow editor canvas. If the `.insca` file contains only one-way operations, dragging a `.insca` file onto the canvas creates a SCAInput node.

Otherwise, a pair of SCAInput and SCAReply nodes is created. If you use this method, many of the values for the properties of the node or nodes are supplied by the Broker SCA definition.

- Drag an instance of the node from the node palette onto the canvas. You then configure the node by dragging a Broker SCA definition with an extension of `.insca` onto the node.

The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (properties that do not have a default value defined) are marked with an asterisk.

1. Optional: On the **Description** tab, enter a `Short description`, a `Long description`, or both. You can also rename the node on this tab.
2. On the **Basic** tab, set the `Broker SCA definition` and `Message routing` properties.
   - In `Broker SCA definition`, specify the name of the Broker SCA definition that contains configuration properties for the SCAInput node. If you have created the node by dragging a Broker SCA definition from a message set onto the Message flow editor canvas, this property is preset to the name of the Broker SCA definition. If you created the node by selecting it from the palette, you can set this property in one of the following ways:
     – If you have a Broker SCA definition, you can select it from the Broker SCA definitions by clicking **Browse**.
     – If you have Broker SCA definitions, but no message set, you can create a message set:
       a. Click **Browse** to open the Broker SCA Definition Selection pane.
       b. Click **Import/Create New** to open the Import Broker SCA definition wizard.
       c. Enter the message set name and message set project name, then click **Next**.
       d. Choose the relevant option:
          - If your Broker SCA definition exists in your workspace, click **Use resources from the workspace**, and select the Broker SCA definition.
          - If your Broker SCA definition is in the file system, click **Use external resources**, select the Broker SCA definition, then click **Next**.
       e. Select the Broker SCA definition to import.
       f. Click **Finish**. A new message set project and message set are created with message definitions. The Broker SCA definition is added to the `Broker SCA Definitions` folder.
       g. Select the Broker SCA definition from the Broker SCA Definition Selection window, then click **OK**.
     – If you have a message set but no Broker SCA definition, generate a Broker SCA definition by following the instructions in “Generating a Broker SCA definition from a message set” on page 2967.
     – Drag a Broker SCA definition from a message set onto the node.
     – Type a file name that is relative to the message set project in which the Broker SCA definition exists.
   - Use `Message routing` to specify whether to allow message propagation to dynamic terminals for the operations defined in the SCA message or to the common Out terminal. By default, each operation is routed to its own terminal. You can select:

- `Route each operation to its own terminal`. The default. One terminal is generated on the node for each operation defined in the interface of the Broker SCA definition and messages are propagated to the appropriate terminal.
- `Route to a common out terminal`. One Out terminal is generated on the node. All messages are propagated to this terminal. If you select this option, the `Propagate only SOAP body (owned by XMLNSC domain)` check box is disabled and you cannot select it.

If you specify the `Broker SCA definition` property by typing a file name, or by selecting a Broker SCA definition by using the **Browse** facility, on an SCAInput node that already has dynamic terminals configured on it, the existing dynamic terminals are replaced. If you specify a file name that is not valid, previously existing dynamic terminals are removed and no terminals are added.

If you drag a Broker SCA definition onto an SCAInput node that already has dynamic terminals configured on it, a dialog box is displayed allowing you to confirm whether you want to override the existing dynamic terminals with dynamic terminals that might be generated from the Broker SCA definition. If you choose to override existing dynamic terminals, any existing connections that are configured for these terminals are also deleted. You can specify that this dialog box is not displayed again.

If you drag a Broker SCA definition onto an SCAInput node which already has an Out terminal, no dynamic terminals which be generated from the Broker SCA definition are added and the node continues to operate with its Out terminal.

3. On the **Binding** tab, properties that relate to the WebSphere Process Server binding are specified. Some of the properties on this tab are derived from the Broker SCA definition.
   - The value of the Binding type property is derived from the binding information in the Broker SCA definition. It is read-only. Possible values are:
     - `Web Service`. Requests from WebSphere Process Server are sent as SOAP messages over the HTTP transport. See the WSDL properties table in "Terminals and properties" on page 4710 for details of binding properties that are either supplied by the Broker SCA definition, or that you must set.
     - `MQ`. Requests from WebSphere Process Server arrive as WebSphere MQ messages. See the MQ properties table and the Transactionality table in "Terminals and properties" on page 4710, for details of binding properties that are either supplied by the Broker SCA definition, or that you must set.
4. On the **Input Message Parsing** tab, the properties are set automatically when the WSDL file is configured.
   - If the Binding type is Web Services, the Message domain is always SOAP.
   - If the Binding type is MQ, the Message domain defaults to XMLNSC if the data bindings for all operations are using XML. Otherwise the default domain is BLOB. You can change the domain to MRM, XMLNSC, XMLNS, MIME, JSON, or BLOB.
5. On the **Parser Options** sub tab, set properties that are associated with the parser.
   - `Parse timing` is, by default, set to `On Demand`, which causes parsing of the message to be delayed. For information about how to cause the message to be parsed immediately, see "Parsing on demand" on page 4173.

- `XMLNSC Parser Options`. Set values for the properties that determine how the XMLNSC parser operates. For more information, see "Manipulating messages in the XMLNSC domain" on page 2546.

6. Use the **Validation** tab to provide validation based on the message set for predefined messages. For more information about validation, see "Validating messages" on page 1478. For information about how to complete this tab, see "Validation tab properties" on page 4169.
7. Use the **Instances** tab to specify how additional threads are handled for the message flow.
   - The `Additional instances pool` property specifies whether additional instance threads are allocated from a thread pool for the whole message flow, or from a thread pool for use by that node only. By default, this property is set to `Use Pool Associated with Message Flow`.
   - The `Additional instances` property specifies the number of additional threads that the broker can use to service the message flow and has the default value `0`.
8. Use the **Retry** tab to define how retry processing is carried out when a failure gets rolled back to the input node.
   - The `Retry mechanism` defines the format of the mechanism, and its type is Enumerate. Set the property to either `Failure` or `Short and long retry`.
   - The `Retry threshold` property defines the number of retries to correct the failure, and its type is Integer.
   - The `Short retry interval` property defines the time the client waits in seconds before attempting to correct the failure, and its type is Integer.
   - The `Long retry interval` property defines the time the client waits in seconds before attempting to correct the failure, and its type is Integer.

Terminals and properties:
The following table describes the terminals of the SCAInput node.

Terminal	Description
Failure	The output terminal to which the received message is propagated when a failure (such as a message validation failure) is detected
Out	The output terminal to which the message is routed if you have selected `Route to common out terminal` on the `Message routing` property.
Catch	The output terminal to which the message is routed if an exception is thrown downstream and caught by this node.
* (dynamic)	(Applicable only when the Binding type is Web Services.) A dynamic terminal is generated for each operation that is supported by the port type and implemented by the imported binding. The dynamic operation terminal to which the SCA message is routed depends on the operation that is defined in the SCA message when it is received.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The following table describes the Description properties of the SCAInput node.

Property	M	C	Default	Description
Node name	No	No	The node type	The name of the node.
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

The following table describes the Basic properties of the SCAInput node.

Property	M	C	Default	Description
Broker SCA definition	Yes	No	<None>	This property type is String. The name of the Broker SCA definition that contains configuration properties for the SCAInput node.
Message routing	Yes	No	`Route each operation to its own terminal`	This property determines whether a common Out terminal is to be used, or whether each operation is to be routed to its own terminal. • If the Binding type is MQ, the common out terminal is always used. • If the Binding type is Web Services, you can choose whether to route messages to a dynamic terminal, or to the common Out terminal.

The following table describes the Binding properties of the SCAInput node; the binding that is found in Broker SCA definition is defined here.

Property	M	C	Default	Description
Binding type	Yes	No	Derived from the Broker SCA definition	This property type is String. Its value derives from the Broker SCA definition.

The following table describes the Web Service properties of the SCAInput node. These properties are only relevant if Binding type is Web Services.

Property	M	C	Default	Description
WSDL file name	Yes	No	<None>	This property type is String. A value is given to this property when the WSDL configuration file is parsed.
Target namespace	No	No	Derived from the Broker SCA definition	This property type is String. `Target namespace` displays the namespace of the selected WSDL file.
Port type	Yes	No	The default value is the port type from the Broker SCA definition.	This property type is String. This property is read-only. Error conditions: • Selected `Port type` does not contain at least one operation.

Property	M	C	Default	Description
Imported binding	Yes	No	Derived from the Broker SCA definition.	This property type is String. The `Imported binding` box lists all the SOAP bindings that are associated with the selected port type. Bindings are listed in the order that they are displayed in the WSDL file. By default, the first binding that is pointed to by the port in the Broker SCA definition is selected. This property is updated every time the `Port type` value changes, and an information message is displayed that states that corresponding changes must be made in the WebSphere Process Server system. Error conditions: • No SOAP bindings in the WSDL file are associated with the `Port type`. • Selected binding does not have any operations.
Service port	Yes	No	Derived from the Broker SCA definition	This property type is String. The `Service port` box lists all the service ports that point to the selected binding. The service port that is referenced in the Broker SCA definition is selected by default. This property is updated every time the selected binding value changes, and an information message is displayed that states that corresponding changes must be made in the WebSphere Process Server system. Error conditions: • No ports point to the selected binding.
URL selector	Yes	Yes	Derived from the Broker SCA definition	This property type is String. `URL selector` is the HTTP path selector upon which the node accepts inbound messages.
Use HTTPS	No	Yes	Derived from the Broker SCA definition	This property type is Boolean. Its value is `True` if the HTTP location is an HTTPS; otherwise, its value is `False`.
Propagate only SOAP Body	No	No	True	This property type is Boolean. Select the check box if only the body of the SOAP message is to be propagated.
Use WS-Addressing	No	No	False	This property type is Boolean. Select the check box if WS-Addressing is to be used.

The following table describes the MQ properties of the SCAInput node. These properties are only relevant if the Binding type is MQ.

Property	M	C	Default	Description
Queue name	Yes	Yes	Derived from the Broker SCA definition	This property type is String. The value of this property can be changed directly on the node. If the property is changed, an information message is displayed that states that corresponding changes must be made to the WebSphere Process Server system.

The SCAInput node Input Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	Set automatically according to the binding that is defined in the corresponding node.	The domain that is used to parse the incoming message. The domain is determined according to the Binding type type. You can change this property if the Binding type is MQ. The property is read-only when the Binding type is Web Services.
Message set	No	No	Picked automatically according to the Broker SCA definition that is chosen in the corresponding node.	The name of the message set in which the incoming message is defined. `Message set` is set automatically to the message set that contains the SCA file that is configured on the corresponding node. This property is read-only.
Message type	No	No	Not set	The node detects the message type automatically. You can change this property if the Binding type is MQ and the message domain is MRM. You cannot change this property if the Binding type is Web Services.
Message format	No	No	Not set	The name of the physical format of the incoming message. You can change this property if the Binding type is MQ and the message domain is MRM. You cannot change this property if the Binding type is Web Services.

The following table describes the Parser Options properties of the SCAInput node.

Property	M	C	Default	Description
Parse timing	No	No	`On demand`	This property controls when an input message is parsed. Valid values are `On demand`, `Immediate`, and `Complete`. For a full description of this property, see "Parsing on demand" on page 4173.
Build tree using XML Schema data types	No	No	Selected	This property controls whether the syntax elements in the message tree have data types taken from the XML Schema.
Retain mixed content	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in an input message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in an input message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in an input message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.

Property	M	C	Default	Description
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the input message that are to be opaquely parsed. Opaque parsing is performed only if validation is not enabled (that is, if `Validate` is `None`); entries that are specified in `Opaque Elements` are ignored if validation is enabled.

The following table describes the Validation properties of the SCAInput node. For more information, see "Validation properties" on page 4169.

Property	M	C	Default	Description
Validate	No	Yes	`Content and value`	This property controls whether validation takes place. Valid values are `None`, `Content and value`, and `Content`.
Failure action	No	No	`Exception`	This property controls what happens if validation fails. You can set this property only if you set `Validate` to `Content` or `Content and value`. Valid values are `User Trace`, `Local Error Log`, `Exception`, and `Exception List`.

The Security properties of the node are described in the following table. Set values for these properties to control the extraction of an identity from a message (when a security profile is associated with the node). For more information about these properties, see "Identity" on page 390, "Configuring the extraction of an identity or security token" on page 447, "Message flow security overview" on page 383, and "Setting up message flow security" on page 431.

Property	M	C	Default	Description
Identity token type	No	No	`None`	This property specifies the type of identity token present in the incoming message. Valid values are: `Transport Default`, `Username`, `Username + Password`, `SAML Assertion`, and `X.509 Certificate`. If this property is not specified, the identity is retrieved from the Basic-Auth transport header and the type is set to `Username`.
Identity token location	No	No	`None`	This property specifies where, in the message, the identity can be found. The location is specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotation marks and must not contain a period (.), If this property is not specified, the identity is retrieved from the MQMD.UserIdentifier transport header.
Identity password location	No	No	`None`	This property specifies where, in the message, the password can be found. The location is specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotation marks and must not contain a period (.), If it is not specified, the password is not set. This property can be set only if `Identity token type` is set to `Username + Password`.
Identity IssuedBy location	No	No	`None`	This property specifies a string or path expression that describes the issuer of the identity. The location is specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotation marks and must not contain a period (.), The value specifies the Issuer that is passed to a WS-Trust v1.3 STS provider. If this property is not specified, the MQMD.PutApplName value is used. If you leave the `Identity issuedBy location` field blank and the MQMD.PutApplName is also blank, the string `MQ` is used.

Property	M	C	Default	Description
Treat security exceptions as normal exceptions	No	No	`False`	This property specifies whether to treat security exceptions (such as "Access Denied") as normal exceptions, and propagate them to the Failure terminal (if wired). This property is turned off by default, which ensures that security exceptions cause the message to be backed out even if the Failure terminal is wired.

The following table describes the Instances properties of the SCAInput node.

Property	M	C	Default	Description
Additional instances pool	No	Yes	`Use Pool Associated with Message Flow`	The pool from which additional instances are obtained. • If you select `Use Pool Associated with Message Flow`, additional instances are obtained from the message flow value. • If you select `Use Pool Associated with Node`, additional instances are allocated from the additional instances of the node, based on the number specified in the `Additional instances` property.
Additional instances	No	Yes	`0`	The number of additional instances that the node can start if the `Additional instances pool` property is set to `Use Pool Associated with Node`. By default, no additional instances are given to the node.

The following table describes the Retry properties of the SCAInput node.

Property	M	C	Default	Description
Retry mechanism	No	No	`Failure`	This property specifies how retry processing is handled when a failure is rolled back to the SCAInput node. • If you select `Failure`, retry processing is not performed so you cannot set the remaining properties. • If you select `Short and long retry`, retry processing is performed first at the interval that is specified by the `Short retry interval` property, and if that is unsuccessful, it is then performed at the interval that is specified by the `Long retry interval` property.
Retry threshold	No	Yes	`0`	The maximum number of times that retry processing is performed for short retry.
Short retry interval	No	Yes	`0`	The interval between short retry attempts.
Long retry interval	No	Yes	`0`	The interval between long retry attempts.

The Transactionality property of the SCAInput node is described in the following table.

Property	M	C	Default	Description
Transaction mode	No	No	For MQ, 'yes'	This property can be 'automatic', 'no', or 'yes'.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

"Message domains used by SCA nodes"
Use the `Message domain` property of the SCAInput node to determine which domain to use to parse the incoming message.

"SecurityPEP node" on page 4729
Use the SecurityPEP node in a message flow to invoke the message flow security manager at any point in the message flow.

Message domains used by SCA nodes:

Use the `Message domain` property of the SCAInput node to determine which domain to use to parse the incoming message.

If the Binding type is `MQ`, you must set the message domain. The SCAInput node supports all MQ data formats used by WebSphere Process Server. If the data format in the Service Component Definition Language (SCDL) file is either `com.ibm.websphere.sca.mq.data.impl.MQDataBindingImplXML` or `com.ibm.wbiserver.datahandler.xml.XMLDataHandler`, the default domain is XMLNSC; otherwise the default domain is BLOB.

See the following table for the relationship between the MQ data format and default message domain:

Data format	Description	Default message domain
Delimited MQ	Serializes the business object to and from a delimited format in the message that is sent and received from the MQ client.	BLOB

Data format	Description	Default message domain
Fixed Width MQ	Serializes the business object to and from a fixed width format in the message that is sent and received from the MQ client.	BLOB
JSON	Sends and receives a business object that is based on JavaScript Object Notation (JSON) from the MQ client.	BLOB
JMS adapter language	Needed if your message body contains a message in C, or COBOL, or PL/I.	BLOB
MQ serialized business object XML	Serializes a business object to an XML document, and deserializes an XML document to a business object. Wrapped data objects must be a complex type; they cannot be a simple type.	XMLNSC
MQ serialized Java	Serializes a business object to a Java object and deserializes a Java object to a business object.	BLOB
MQ unstructured binary message	Sets the incoming bytes into a business object property called `value` on the inbound message, and gets the bytes from the business object property called `value`, and sets it in the output stream on the outbound message.	BLOB
MQ unstructured text message	Sets the incoming text message into a business object property called `value` on the inbound message, and gets the text message from the business object property called `value`, and sets it in the output stream on the outbound message.	BLOB
MQRFH header	Contains fixed size and variable sized pieces of information that are specified by the MQRFH header standard.	BLOB
MQRFH2 header	Contains fixed size and variable sized pieces of information that are specified by the MQRFH2 header standard.	BLOB

Data format	Description	Default message domain
WTX	Allows the use of WebSphere Transformation Extender (WTX), a universal validation and transformation engine, to convert business objects to many data formats, and many data formats to business objects.	BLOB

If the Binding type is `Web Service`, the message domain is always `SOAP`.

SCARequest node

Use the SCARequest node to send a request to WebSphere Process Server. The node is a synchronous request and response node, and blocks after sending the request until the response is received. The node can also send one-way requests.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow"
- "Configuring the SCARequest node" on page 4720
- "Terminals and properties" on page 4721

Purpose:
The SCARequest node sends synchronous outbound two-way (request-response) requests, and one-way (request only) operations, to a business process on WebSphere Process Server.

An outbound Broker SCA definition (`.outsca`) file is required to configure the SCARequest node. The Broker SCA definition contains specific data related to the binding that is used by the SCA Export component.

The SCARequest node is contained in the **SCA** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
You can use the node in any message flow that needs to call an application running on WebSphere Process Server.

`LocalEnvironment.Destination.SCA.Request.KeyAlias`

You can change the timeout by changing the value in the following location in the local environment:

`LocalEnvironment.Destination.SCA.Request.Timeout`

You can change the timeout by changing the value in the following location in the local environment:

`LocalEnvironment.Destination.SCA.Request.Timeout`

For a Web Services binding, you can change the URL to which the request is sent. Change the value in the following location in the local environment:

`LocalEnvironment.Destination.SCA.Request.Binding.WebServices.Transport.HTTP.WebServiceURL`

For an MQ binding, you can change the Request Queue Manager and Request Queue by changing the values in the following locations:

```
LocalEnvironment.Destination.SCA.Request.Binding.MQ.queueManagerName
LocalEnvironment.Destination.SCA.Request.Binding.MQ.queueName
```

Configuring the SCARequest node:
Ensure that the message set contains a Broker SCA definition with an extension of `.outsca` with which to configure the SCARequest node.

There are two methods of putting an instance of the SCARequest node into a message flow: You can either drag an instance of the node from the node palette, or drag a Broker SCA definition with an extension of `.outsca` from a message set, onto the message flow editor canvas.

Dragging a node onto the canvas

If you have dragged an instance of the node from the palette onto the canvas, use one of the following methods to start to configure it:

- Drag a Broker SCA definition with an extension of `.outsca` onto the node.
- Type the file name in the `SCA file name` option in the Properties view of the node.
- Browse to the file (`SCA file name` option in the Properties view of the node.)

Dragging a .outsca file onto the canvas

- If the `.outsca` file contains a WSDL that has only a single, one-way operation defined, a SCARequest node is created.
- If the `.outsca` file contains a WSDL that only has request-response operations, you first select the operation, and say whether you want the outbound request to be sent synchronously or asynchronously. For a synchronous request, a SCARequest node is created and configured. For an asynchronous request, a pair of SCAAsyncRequest and SCAAsyncResponse nodes are created and configured.
- If the `.outsca` file contains a WSDL that has a mixture of one-way and request-response operations defined, and you select a one-way operation, a SCARequest node is created.

If the request contains a two-way operation, the node blocks until a response message is received, or for the time defined by the timeout property (120 seconds by default). If the timeout period is exceeded, the message received on the input terminal of the SCARequest is propagated to the Failure terminal.

The SOAP, XMLNSC, XMLNS, MRM, MIME, JSON, and BLOB domains are available to parse the response.

- If the Binding type is `Web Service`, the message domain is SOAP.
- If the Binding type is `MQ`, the default domain is BLOB if any operations have non-XML data bindings. If all operations have XML data binding the default domain is XMLNSC. The data binding is identified as XML if the SCA Export uses `com.ibm.websphere.sca.mq.data.impl.mqdatabindingimplxml` or `com.ibm.wbiserver.datahandler.xml.XMLDataHandler`.

If the request contains a one-way operation, the node sends the request message, then routes the input message through to the Out terminal. In this case, the properties in the Response Message Parsing tab are unavailable.

The values for many of the properties of the node are provided by the Broker SCA definition. The properties of the node are displayed in the Properties view. All

mandatory properties for which you must enter a value (properties that do not have a default value defined) are marked with an asterisk.

Terminals and properties:
The SCARequest node terminals are described in the following table.

Name	Type	Description
In	Input data	The node is driven by a message arriving on the In terminal.
Out	Output data	When a message has been sent to an external resource it is sent to the Out terminal unchanged, except for the addition of status information.
Failure	Output data	A failure in the node is sent to the failure terminal.
Fault	Output data	A SOAP fault from the external system is sent to this terminal. This terminal is only used when the Binding type is Web Services.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the SCARequest node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type	The name of the node.
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

The Basic properties of the SCARequest node are described in the following table.

Property	M	C	Default	Description
Broker SCA Definition	Yes	No	none	The name of the Broker SCA Definition that contains configuration properties for the SCA Request node. Click the browse button to list all relevant Broker SCA Definitions in the current workspace.

The Binding properties of the SCARequest node are described in the following table.

Property	M	C	Default	Description
Binding type	Yes	No	none	The binding type that was found in the SCA Export.
Request Timeout	No	Yes	120	The time in seconds before the request times out waiting for a response from WebSphere Process Server. If the timeout period is exceeded, the message received on the input terminal of the SCARequest is propagated to the Failure terminal. This property is disabled if the Broker SCA definition (inbound) contains only one-way operations.

The Web Services properties are described in the following table. These properties are shown only if the binding type is Web Services.

Property	M	C	Default	Description
WSDL file name	Yes	No	<none>	This property type is String. When you select a WSDL file for the `WSDL file name` field, the WSDL is validated to ensure that it is WS-I compliant. Only Deployable WSDL can be used to configure the SCA nodes. After a valid WSDL file is selected, the message set project to which WSDL file belongs is added as a referenced project to the corresponding flow project, if the reference does not exist.
Port type	Yes	No	From WSDL	This property type is String. The field lists all the `Port types` defined in WSDL file selected in the `WSDL file name` property. Error Conditions: • Selected `Port type` does not contain at least one operation. WSDL properties are disabled when the node is configured to act in gateway mode.
Imported Binding	Yes	No	From WSDL	This property type is String. This property is updated every time that the `Port type` value changes. The field lists the imported SOAP bindings with HTTP or JMS transport associated with the selected `Port type`. When you select a binding, the property tab for the associated transport is enabled; otherwise, it is disabled. Bindings are listed in the same order in which they appear in the WSDL file. The selected binding is the one that has both ports and operations. If there is no such binding, then binding with ports is selected. If no bindings have ports then the first binding in the list is selected. Error Conditions: • No SOAP bindings (with HTTP or JMS transport) in the WSDL file are associated with the `Port type`. • The selected binding does not have any operations. WSDL properties are disabled when the node is configured to act in gateway mode.

Property	M	C	Default	Description
Operation	Yes	No	From WSDL	This property type is String. The `Binding operation` box contains all the operations defined by the selected binding. The first operation in the list is selected by default. This property is updated every time the selected binding value changes WSDL properties are disabled when the node is configured to act in gateway mode.
Service port	Yes	No	From WSDL	This property type is String. This field is updated every time that the selected binding is updated. This field lists all the WSDL ports that point to the selected binding. The first service port for the binding is selected by default. This property is updated every time the selected binding value changes. Error Conditions: • No ports point to the selected binding. WSDL properties are disabled when the node is configured to act in gateway mode.
Target namespace	Yes	No	From WSDL	`Target namespace` is implemented as a read-only field. This hidden property type is String. It is updated with the `Target namespace` of the WSDL file when the `WSDL file name` is configured. WSDL properties are disabled when the node is configured to act in gateway mode.
Web service URL	Yes	Yes	none	The URL of the SOAP address selected. This property is automatically derived from the `<soap:address>` element of the selected `Service port`. Whenever the selected port is updated, the `Web service URL` is updated accordingly. However, if you override the value then your value persists and the URL is no longer updated from the service port. If you choose to override this property you must specify it in the form http://<hostname>[:<port>]/[<path>] where: • http://<hostname> must be specified. • <port> has a default of 80. If you specify a value, you must include the colon : before the port number. • <path> has a default of /. If you specify a value, you must include the / before the path. For more details of how to override this property, see Changing the default URL for a SOAPRequest node or a SOAPAsyncRequest node request.

Property	M	C	Default	Description
Propagate only SOAP Body, owned by XMLNSC domain	No	No	false	If selected, only the SOAP body is propagated, otherwise the entire SOAP message is propagated.
Use WS-Addressing	No	No	false	Select the check box if you want to use WS-Addressing.

The MQ properties are described in the following table. These properties are shown only if the binding type is MQ.

Property	M	C	Default	Description
Operation	Yes	No	From WSDL	The selected operation from the selected binding in the WSDL file. The WSDL is not displayed; the WSDL is in the Broker SCA Definition file.
Queue name	Yes	Yes	none	The queue that receives a request message from WebSphere Message Broker.
Queue manager name	Yes	Yes	none	The Queue Manager that receives a request from WebSphere Message Broker.
Reply-to queue name	Yes	Yes	none	The queue that receives a response message from WebSphere Process Server.
Reply-to queue manager name	No	Yes	none	The Queue Manager that receives a response from WebSphere Process Server.
Response Message Correlation	Yes	No	FromMsgId	This property indicates how WebSphere Message Broker is to complete correlation ID information in the response message.

The Response Message Parsing properties of the node are described in the following table. The node sets these properties automatically; the table describes when you can change them.

Property	M	C	Default	Description
Message domain	No	No	Set automatically according to the binding that is defined in the corresponding node.	The domain that is used to parse the response message. It is determined according to the Binding type. You can change this property if the Binding type is MQ. The property is read-only when the Binding type is Web Services.
Message set	No	No	Picked automatically according to the Broker SCA definition that is chosen in the corresponding node.	The name of the message set in which the response message is defined. `Message set` is set automatically to the message set that contains the SCA file that is configured on the corresponding node. This property is read-only.
Message type	No	No	Not set	The node detects the message type automatically. You can change this property if the Binding type is MQ and the message domain is MRM. You cannot change this property if the Binding type is Web Services.

Property	M	C	Default	Description
Message format	No	No	Not set	The name of the physical format of the response message. You can change this property if the Binding type is MQ and the message domain is MRM. You cannot change this property if the Binding type is Web Services.

The validation properties are described in the following table. For more information, see "Validation properties" on page 4169.

Property	M	C	Default	Description
Validate	No	Yes	`Content and value`	This property controls whether validation takes place. Valid values are `None`, `Content and value`, and `Content`.
Failure action	No	No	`Exception`	This property controls what happens if validation fails. You can set this property only if you set `Validate` to `Content` or `Content and value`. Valid values are `User Trace`, `Local Error Log`, `Exception`, and `Exception List`.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Start here to find out how you can use SCA to allow interoperability with WebSphere Process Server Version 6.2.

"Samples" on page 98
The WebSphere Message Broker Toolkit provides samples that show the features that are available in WebSphere Message Broker, and how to use them. This topic provides links to the information about the individual samples.

Related tasks:

"Validating messages" on page 1478
The broker provides validation based on the message model for predefined messages.

"Manipulating messages in the XMLNSC domain" on page 2546
If you are writing ESQL to process messages in the XMLNSC domain, it is helpful to learn about the structure of the message tree that the XMLNSC parser builds.

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

"Importing from WSDL" on page 2946
You can use the New Message Definition File wizard in the WebSphere Message Broker Toolkit to create a new message definition from WSDL.

Related reference:

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

"SCAAsyncResponse node" on page 4698
Use the SCAAsyncResponse node with the SCAAsyncRequest node to construct a pair of message flows that start a component asynchronously.

"SCAInput node" on page 4707
Use the SCAInput node with the SCAReply node to process messages from WebSphere Process Server.

"SCAReply node"
Use the SCAReply node to send a message from the broker to the originating client in response to a message received by a SCAInput node.

SCAReply node

Use the SCAReply node to send a message from the broker to the originating client in response to a message received by a SCAInput node.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow" on page 4727
- "Terminals and properties" on page 4727

Purpose:
The SCAReply node can be used in a message flow to send a reply back to the client that used an SCAInput node to send an SCA request to the WebSphere Message Broker. The SCAReply node and the SCAInput node must be in the same execution group.

The SCAReply node must use the same transport as the SCAInput node that originated the SCA request.

The SCAReply node is contained in the **SCA** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Look at the following sample to seem how to use the node:

SCA nodes

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

A ReplyIdentifier is created on the SCAInput node and is set in the message context and the local environment.

The value needs to be preserved throughout the flow especially if the SCAInput and SCAReply nodes are in different flows, so that the reply can reach the originating WebSphere Process Server client. The reply identifier is stored in the following location:

```
LocalEnvironment.Destination.SCA.Reply.ReplyIdentifier
```

Terminals and properties:
When you have put an instance of the SCAReply node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (properties that do not have a default value defined) are marked with an asterisk.

The SCAReply node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the message is routed if a failure is detected in this node.
Out	The output terminal to which the message is routed if it has been propagated successfully, and if further processing is required within this message flow. The message is propagated unchanged, except for the addition of status information.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The following table describes the Description properties of the SCAReply node.

Property	M	C	Default	Description
Node name	No	No	The node type: SCAReply	The name of the node.
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

The following table describes the Validation properties of the SCAReply node.

Property	M	C	Default	Description
Validate	Yes	Yes	Inherit	Valid values are `None`, `Content`, `Content and Value`, and `Inherit`.
Failure action	Yes	No	`Exception`	This property controls what happens if validation fails. You can set this property only if you set `Validate` to `Content` or `Content and Value`. Valid values are `User Trace`, `Local Error`, `Exception`, and `Exception List`.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

"SCAAsyncRequest node" on page 4690
Use the SCAAsyncRequest node with the SCAAsyncResponse node to construct a pair of message flows that invoke a WebSphere Process Server service component asynchronously.

"SCAAsyncResponse node" on page 4698
Use the SCAAsyncResponse node with the SCAAsyncRequest node to construct a pair of message flows that start a component asynchronously.

"SCARequest node" on page 4719
Use the SCARequest node to send a request to WebSphere Process Server. The node is a synchronous request and response node, and blocks after sending the request until the response is received. The node can also send one-way requests.

SecurityPEP node

Use the SecurityPEP node in a message flow to invoke the message flow security manager at any point in the message flow.

This topic contains the following sections:
- "Purpose"
- "Using the SecurityPEP node in a message flow" on page 4731
- "Configuring the SecurityPEP node" on page 4731
- "Terminals and properties" on page 4732

Purpose:
The SecurityPEP node enables you to invoke the message flow security manager at any point in the message flow between an input node and an output (or request) node.

Message flow security enables the broker to perform end-to-end processing of an identity or security token carried in a message through a message flow. This capability enables you to configure security for a message flow, allowing you to control access based on the identity or security token associated with the message and providing a security mechanism that is independent of both transport type and message format.

The SecurityPEP node enables you to invoke the security manager even if your message flow input nodes do not support message flow security (for example, TCPIPClientInput or SAPInput nodes). If you use input nodes that do not support message flow security, or you require some processing or routing of the message before the required security operation can be identified, you can use the SecurityPEP node to invoke the message flow security.

The SecurityPEP node also enables you to invoke different aspects of security at different points in the message flow. For example, you might require authentication to occur at a security enabled input node, whereas token mapping and authorization might be required after some logic in the message flow has determined the necessary business operation. Alternatively, you might have a message flow with multiple request nodes that require SecurityPEP nodes to enable one type of security token to be mapped to another type for propagation by the request nodes.

You can use the node properties to specify the location of the security tokens in the message tree. These properties contain an XPath expression or ESQL path that defines the location of the security tokens in the message tree. The message flow security manager extracts this information from the message and sends it to the external Policy Decision Point (PDP), which uses the information for authentication, authorization, or mapping. The PDP to be used is configured by the associated security profile.

Alternatively, you can configure the SecurityPEP node to use the current tokens, which have already been extracted by an upstream input node or SecurityPEP node, and stored in the Properties folder. When the node is configured with the token type as `Current token`, if a mapped token exists, the mapped token is used; otherwise, the source token is used.

The SecurityPEP node must be associated with a security profile, which specifies the security operations to be enforced by the node, including authentication, authorization, and mapping. If no security profile is associated with the node, the node propagates the message to the Output terminal without enforcing any security. Security profiles are configured by the broker administrator before deploying a message flow, and are accessed by the security manager at run time. If a security profile is specified on either a message flow or a node, the profile must be available when the message flow is deployed; otherwise, a deployment error occurs.

The associated security profile also allows you to specify the external security provider to be used (LDAP, WS-Trust V1.3 STS, or TFIM V6.1), and to configure the way in which they are used. The security profile is associated with the SecurityPEP node (or its owning message flow) during deployment, by editing the **`Security Profile`** property with the Broker Archive editor.

For information about the types of security token that are supported by the SecurityPEP node, see “Identity” on page 390.

The SecurityPEP node propagates messages to the Out terminal only if all the configured security operations complete successfully. The input messages are propagated unmodified, apart from the population of the source identity and mapped identity (if one exists).

If any of the configured security operations are unsuccessful, the SecurityPEP node throws a security exception wrapped in a recoverable exception (unlike the security enabled input nodes), which invokes the error handling that is provided by the message flow. This enables the exception to be caught and processed. Alternatively, you can handle SecurityPEP node exceptions by wiring the node's failure terminal into specific security failure processing logic. When a security operation fails, the input messages are unmodified apart from the population of the exception list.

The SecurityPEP node is contained in the **Security** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Message structure

The SecurityPEP node handles messages in the following message domains:
- MRM
- XMLNSC
- DataObject
- XMLNS
- JMSMap
- JMSStream
- MIME
- BLOB
- SOAP
- XML (this domain is deprecated; use XMLNSC)
- IDOC (this domain is deprecated; use MRM)

Using the SecurityPEP node in a message flow:
Look at the following sample to see how to use the SecurityPEP node:
- Security Policy Enforcement Point (PEP)

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Configuring the SecurityPEP node:
When you have put an instance of the SecurityPEP node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

All mandatory properties that do not have a default value defined are marked with an asterisk.

Configure the SecurityPEP node:

1. Optional: On the **Description** tab, enter a `Short description`, a `Long description`, or both. You can also rename the node on this tab.
2. On the **Basic** tab, set values for the properties that control the extraction of an identity or security token from a message (when a security profile is associated with the node).
   - Select an option from the `Identity token type` list to specify the type of identity in the incoming message tree. If you leave this option to the default (`Current token`), the token type that exists in the identity mapped or source field in the Properties folder is used.

     If `Current token` is selected, the `Identity token location` and `Identity password location` fields are disabled.
   - In `Identity token location`, enter the XPath expression, ESQL field reference, or string literal that specifies where, in the message, the identity or token is located. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.),

     This property is disabled if the `Identity token type` property is set to `Current token`.
   - In `Identity password location`, enter the XPath expression, ESQL field reference, or string literal that specifies where, in the message, the password can be found. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.),

This option can be set only if the `Identity token type` is set to `Username + Password`.

This property is disabled if the `Identity token type` property is set to `Current token`.

- In `Identity issuedBy location`, specify an XPath expression, an ESQL field reference, or a string literal that specifies the location in the message of the issuer value. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.),

  If the associated security profile specifies a WS-Trust v1.3 STS provider (for example, TFIM V6.2) and this field is left blank, no WS-Trust Issuer.Address element is included in the WS-Trust request.

3. On the **Advanced** tab, set the properties to override the default settings for a WS-Trust v1.3 STS. These properties can be set only if the security profile associated with the SecurityPEP node specifies a WS-Trust v1.3 STS.
   - Use the `WS-Trust Applies-To Address` property to specify the Address for the **/wst:RequestSecurityToken/wsp:AppliesTo** element of the WS-Trust message. You can use this property to provide the URI of the service for which the security token is to be validated or issued.

     You can specify this value as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.),

     By default, this value is a URI for the fully qualified name of the message flow, in the form *uri:Brokername.Execution Group Name.Message Flow Name*
   - Use the `WS-Trust Applies-To Service` property to specify the Service Name for the **/wst:RequestSecurityToken/wsp:AppliesTo** element of the WS-Trust message. You can use this property to provide the Service Name of the service for which the security token is to be validated or issued.

     You can specify this value as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.),

     By default, this value is left blank, which means that the WS-Trust request will not include this element.
   - Use the `WS-Trust Applies-To PortType` property to specify the Port Type for the **/wst:RequestSecurityToken/wsp:AppliesTo** element of the WS-Trust message. You can use this property to provide the Port Type of the service for which the security token is to be validated or issued.

     You can specify this value as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.),

For more information, see "Message flow security overview" on page 383 and "Setting up message flow security" on page 431.

Terminals and properties:
The terminals of the SecurityPEP node are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing.
Out	The output terminal to which the message is routed if the SecurityPEP node is associated with a security profile and if all the configured security operations complete successfully. The propagated properties folder identity elements are updated by the configured security operations.

Terminal	Description
Failure	The output terminal to which the message is routed if there is a failure in the node; for example, if the configured security operations return an exception.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the bar file to deploy it).

The Description properties of the SecurityPEP node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, SecurityPEP	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the SecurityPEP node are described in the following table. Set values for these properties to control the extraction of an identity from a message (when a security profile is associated with the node). For more information about these properties, see "Identity" on page 390, "Configuring the extraction of an identity or security token" on page 447, "Message flow security overview" on page 383, and "Setting up message flow security" on page 431.

Property	M	C	Default	Description
Identity token type	No	No	`None`	This property specifies the type of identity token present in the incoming message. Valid values are: • `Current token` • `Username` • `Username and password` • `X.509 Certificate` • `SAML assertion` • `Kerberos GSS v5 AP_REQ` • `LTPA v2 token` • `Universal WSSE token` If this property is set to `Current token`, the identity in the Properties folder is used. You can also specify the `Username and password` value to validate a RACF PassTicket using a WS-Trust V1.3 STS such as TFIM V6.2.
Identity token location	No	No	`None`	This property specifies where, in the message, the identity or security token can be found. The location is specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.),

Property	M	C	Default	Description
Identity password location	No	No	`None`	This property specifies where, in the message, the password can be found. The location is specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.), This property can be set only if `Identity token type` is set to `Username and password`.
Identity IssuedBy location	No	No	`None`	This property specifies an XPath expression or ESQL path that describes the issuer of the identity or security token. The location is specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.), This option is used when the associated security profile specifies a WS-Trust V1.3 STS provider (for example, TFIM V6.2) for authentication, mapping or authorization. In this case, when this field is left blank, no WS-Trust Issuer.Address element is sent.

The Advanced properties of the SecurityPEP node are described in the following table. These properties are used only if the security profile specifies a WS-Trust V1.3 STS (for example, TFIM V6.2).

Property	M	C	Default	Description
WS-Trust Applies-To Address	No	Yes	Not set	This property sets the Address for the **`/wst:RequestSecurityToken/wsp:AppliesTo`** element of the WS-Trust message. Use this property to provide the URI of the service for which the security token is to be validated or issued. This value can be specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.), By default, this value is a URI for the fully qualified name of the message flow, in the form *uri:Brokername.Execution Group Name.Message Flow Name*.
WS-Trust Applies-To Service	No	Yes	Not set	This property sets the Service Name for the **`/wst:RequestSecurityToken/wsp:AppliesTo`** element of the WS-Trust message. Use this property to provide the Service Name of the service for which the security token is to be validated or issued. This value can be specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.), By default, this value is left blank, which means that the WS-Trust request does not include this element.

Property	M	C	Default	Description
WS-Trust Applies-To Port Type	No	Yes	Not set	This property sets the Port Type for the **/wst:RequestSecurityToken/wsp:AppliesTo** element of the WS-Trust message. Use this property to provide the Port Type of the service for which the security token is to be validated or issued. This value can be specified as an ESQL field reference, an XPath expression, or a string literal. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.), By default, this value is left blank, which means that the WS-Trust request does not include this element.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

"Message flow security overview" on page 383
WebSphere Message Broker provides a security manager, which enables you to control access to individual messages in a message flow, using the identity of the message.

"Identity" on page 390
In WebSphere Message Broker, an identity is a security token that uniquely identifies an individual, or that provides a set of assertions that can be validated.

"Security profiles" on page 387
A security profile defines the security operations that are to be performed in a message flow at SecurityPEP nodes and security enabled input and output nodes.

"WS-Security" on page 765
Web Services Security (WS-Security) describes enhancements to SOAP messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. WS-Security mechanisms can be used to accommodate a wide variety of security models and encryption technologies.

Related tasks:

Sequence node

Use the Sequence node to add a sequence number to one or more groups of input messages.

This topic contains the following sections:
- "Purpose"
- "Using the Sequence node in a message flow" on page 4737
- "Configuring the Sequence node" on page 4737
- "Terminals and properties" on page 4738

Purpose:
The Sequence node enables you to receive groups of messages from an input source, and preserve the order in which the messages in each group arrived.

Use a Sequence node to generate a monotonically increasing sequence number for each sequence group. As each message in the group arrives at the Sequence node, the sequence number for the group is incremented and stored with the message in a location specified by the node property `Path to store sequence number` (for example, LocalEnvironment, MQRFH2 header, message body).

The sequencing applies to messages within the same sequence group only. You can use properties in the Sequence node to organize messages into groups according to a specified condition; for example, grouping all messages with the same value in a customer number field in the message. If no sequence group is specified, a single default group is used for all messages.

A Sequence node can receive input from multiple input nodes in the message flow or from input nodes that have additional instances. The Sequence node can process multiple sequence groups in parallel, but it processes only one request at a time for sequence numbers from the same sequence group.

The Sequence node allocates a sequence number to each message in a sequence group, and the next sequence number in the group is not allocated until the current message in the group has finished processing (either by being committed or rolled back). Only one thread at a time can process messages in the same sequence group downstream of the Sequence node, which ensures that sequencing is maintained for the group when there are multiple threads in the message flow.

When the Sequence node receives messages from multiple threads, the order in which the messages reach the Sequence node is preserved. However, the order in

which the messages arrive at the Sequence node might be different from the order in which they are taken from the transport by the input node. This situation can occur because messages on one thread might be overtaken by messages on other threads between the input node and Sequence node.

Each sequence group can be associated with only one Sequence node. Multiple Sequence nodes can have a sequence group with the same name, but each of those sequence groups is treated as a separate group. The combination of the execution group name, message flow name, node name, and sequence group name is used to differentiate between the sequence groups.

For example, you might have a message flow called *flow1* containing a Sequence node called *node1*, which is deployed to an execution group called *eg1*. A message is sent to it using a sequence group called *group1*. The result is *eg1/flow1/node1/group1*. Exactly the same message flow in a different execution group, for example *eg2*, would result in *eg2/flow1/node1/group1*.

The Sequence node is contained in the **Routing** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using the Sequence node in a message flow:
Look at the following sample to see how to use the Sequence node:

- Healthcare

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Configuring the Sequence node:
When you have put an instance of the Sequence node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

All mandatory properties that do not have a default value defined are marked with an asterisk.

Configure the Sequence node:

1. Optional: On the **Description** tab, enter a `Short description`, a `Long description`, or both. You can also rename the node on this tab.
2. On the **Basic** tab, set the properties that determine how the message sequence is controlled.
   - Use the `Path to store sequence number` property to specify the location in which to save the sequence number of the message. The location is specified as an XPath expression.
   - Use the `Path to sequence group identifier` property to specify the location of the sequence group identifier. The location is specified as an XPath expression. Messages that have the same group identifier are considered part of the same sequence group.

- Use the Start of sequence definition property to specify the first sequence number in each group. In the Literal field, specify any positive or negative numeric value as the first sequence number in the group. The default value is 0.

  When the first message of a specific sequence group is propagated by the Sequence node, the specified starting sequence number is used to assign the first sequence number; successive messages contain monotonically increasing sequence numbers. This value is overridden by the LocalEnvironment.Sequence.StartOfSequenceNumber variable.
- Use the End of sequence definition property to specify when each sequence group has been completed.
  - Select Literal to specify a literal sequence number. This value can be any positive or negative numeric value that is greater than the value of the Start of sequence definition property. When the message with the specified sequence number arrives, the sequence group is closed.
  - Select Predicate to specify an XPath expression that evaluates to either True or False, indicating whether the message is the last in the sequence. When the first message in the sequence has been determined, messages for that sequence group continue to have sequence numbers assigned to them until the end of sequence predicate evaluates to True.

    If the XPath expression is valid but is not present in the message, it evaluates to False and the next message in the sequence group is assigned a sequence number. When the predicate evaluates to True, the message becomes the last in the sequence and no more messages are assigned to the sequence for that sequence group.

    If the XPath expression is invalid, it fails and the message rolls back
  - Select Automatic to specify the timeout period for the node. This option specifies how long (in seconds) the node waits for messages to arrive in an empty queue, before closing the sequence group. This option is useful for applications that cannot determine the final number in the sequence. The timer starts when there are no messages in the queue waiting to be propagated. If new messages arrive before the timeout period is reached, the timer is canceled. If no new messages arrive before the end of the specified time, the sequence group is closed and any further messages for the group are considered part of a new group.

3. On the **Advanced** tab:
   - Use the Persistence mode property to specify whether to store sequence group state persistently. The default value is Non-persistent.

Terminals and properties:
The terminals of the Sequence node are described in the following table.

Terminal	Description
In	The input terminal through which the incoming message assembly arrives at the node.
Failure	The output terminal to which the message is routed if an error occurs. This value includes failures caused by retry processing.
Out	The output terminal to which the output message is propagated by default.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a

value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file for deployment).

The Description properties of the Sequence node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	Sequence	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the Sequence node are described in the following table.

Property	M	C	Default	Description
Path to store sequence number	No	No	`$OutputLocalEnvironment/Sequence/Number`	An XPath expression that specifies the location in which to save the sequence number of the message.
Path to sequence group identifier	No	No	Not set	An XPath expression that points to the location of the sequence group identifier. Messages that have the same group identifier are considered part of the same sequence group. This property functions in the same way as the `Correlation path` property in the Collector node.
Start of sequence definition	Yes	No	`0`	Specifies the first sequence number in each group. Valid values are positive or negative integers. The default value is 0.
End of sequence definition	Yes	No	`Automatic`	Specifies when each sequence group has been completed. Valid values are: • `Literal` and *number* • `Predicate` and *XPath* • `Automatic` and *time in seconds* The default is `Automatic`.

The Advanced properties of the Sequence node are described in the following table.

Property	M	C	Default	Description
Persistence mode	Yes	No	`Non-persistent`	Specifies whether to store sequence group state persistently. Valid options are: • `Non-persistent` • `Persistent`

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Use the Resequence node to control the sequence in which a group (or groups) of incoming messages are propagated in a message flow.

"Configurable message flow properties" on page 4020
When you add a message flow to a broker archive (BAR) file in preparation for deploying it to a broker, you can set additional properties that influence its run time operation. These properties are available for review and update when you select the **Manage and Configure** tab for the broker archive file.

SiebelInput node

Use the SiebelInput node to interact with a Siebel application.

This topic contains the following sections:

Purpose:

Use the SiebelInput node to interact with Siebel applications. For example, a SiebelInput node monitors a Siebel system for a specified event. When that event occurs, the SiebelInput node generates a message tree that represents the business object with the new event details. The message tree is propagated to the Out terminal so that the rest of the message flow can use the data to update other systems, or audit the changes.

The SiebelInput node is contained in the **WebSphere Adapters** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
To use the SiebelInput node, you must first create the Siebel event table. For instructions, see "Creating the event store manually" on page 2072.

To function correctly, the SiebelInput node needs an adapter component, which you set using the `Adapter component` node property, and business object definitions, which are stored in the message set that you reference from the node. For this reason, you must provide a message set. By default, the message that is propagated from the SiebelInput node is in the DataObject domain, so the `Message domain` property is set to DataObject. You cannot specify a different domain. The message type is detected automatically by the node.

The SiebelInput node populates the route to label destination list with the name of the method binding. If you add a RouteToLabel node to the message flow after the SiebelInput node, the RouteToLabel node can use the name of the method binding to route the message to the correct part of the message flow for processing.

You can deploy only one input node that uses a particular adapter component to an execution group, but you can deploy many input nodes that use different adapter components to an execution group.

You can use the **mqsisetdbparms** command in the following format to configure an account name with a user name and password for the Adapter for Siebel Business Applications.

```
mqsisetdbparms broker name -n adapter name -u user name -p password
```

For example:

```
mqsisetdbparms BRK1 -n eis::SiebelCustomerInbound.inadapter -u siebeluid -p ********
```

Using configurable services for Siebel nodes

Siebel nodes can get Siebel connection details from either the adapter component or a configurable service. By using a configurable service, you can change the connection details for an adapter without the need to redeploy the adapter. For more details about creating, changing, reporting, and deleting the configurable services for Siebel, see "Changing connection details for Siebel adapters" on page 720.

You can also connect to different versions of Siebel by creating a custom EISProviders configurable service and setting the location of the appropriate library files. For more information, see "Connecting to different versions of Siebel" on page 2077.

Terminals and properties:
When you have put an instance of the SiebelInput node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. If you double-click a SiebelInput node, you open the Adapter Connection wizard. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The SiebelInput node terminals are described in the following table.

Terminal	Description
Out	Business object events from the adapter are sent to the Out terminal.

Terminal	Description
Failure	If an error happens in the SiebelInput node, the message is propagated to the Failure terminal. Information about the error, and business object events can also be propagated to the Failure terminal.
Catch	Business object events are sent to the Catch terminal if they cause an uncaught exception in the message flow. If the Catch terminal is not connected, the retry process is activated to handle the business object.

The following table describes the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The SiebelInput node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, SiebelInput.	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The SiebelInput node Basic properties are described in the following table.

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
Primary adapter component	Yes	Yes		The name of the adapter component that contains configuration properties for the adapter. Either enter a name of an adapter file or click **Browse** to select an adapter file from the list of files that are available in referenced message set projects. When theSiebelInput node receives data from the Siebel system, it associates that data with a method name, depending on the service operation name that is assigned to that type of data when you run the Adapter Connection wizard. The SiebelInput node attempts to handle methods that are defined in the primary adapter. If the type of data that is received does not correspond to any of the methods that are defined in the primary adapter, the node can handle methods that are defined in matching secondary adapters that are deployed to the same execution group.	adapterComponent

Property	M	C	Default	Description	mqsiapplybaroverride command property
Secondary adapter mode	No	Yes	None	Specifies whether the node can handle methods that are defined in secondary adapters. If you set the `Secondary adapter mode` property to `None`, the node handles only methods that are defined in the primary adapter. If the type of data that is received does not correspond to any of the methods that are defined in the primary adapter, a failure occurs. If you set this property to `All adapters in execution group`, the node can handle methods that are defined in any Siebel inbound adapters that are deployed to the same execution group.	secondaryAdapterMode

The SiebelInput node Routing properties are described in the following table.

Property	M	C	Default	Description
Set destination list	No	No	Selected	This property specifies whether to add the method binding name to the route to label destination list. If you select this check box, the method binding name is added so that you can use a RouteToLabel node in the message flow after the SiebelInput node.
Label prefix	No	No		The prefix to add to the method name when routing to label. Add a label prefix to avoid a clash of corresponding label nodes when you include multiple WebSphere Adapters input nodes in the same message flow. By default, there is no label prefix, so the method name and label name are identical.

The SiebelInput node Input Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	DataObject	The domain that is used to parse the incoming message. By default, the message that is propagated from the SiebelInput node is in the DataObject domain. You cannot specify a different domain.
Message set	Yes	No	Set automatically	The name of the message set in which the incoming message is defined. This field is set automatically from the Adapter component property. If you set this property, then subsequently update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project.
Message type	No	No		The name of the incoming message. The node detects the message type automatically. You cannot set this property.
Message format	No	No		The name of the physical format of the incoming message. You cannot set this property.

The SiebelInput node Transactionality properties are described in the following table.

Property	M	C	Default	Description
Transaction mode	No	No	Yes	The transaction mode on this input node determines whether the rest of the nodes in the flow operate under sync point.

The Instances properties of the SiebelInput node are described in the following table. For a full description of these properties, see "Configurable message flow properties" on page 4020.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Additional instances pool	No	Yes	`Use Pool Associated with Message Flow`	The pool from which additional instances are obtained. • If you select `Use Pool Associated with Message Flow`, additional instances are obtained from the message flow value. • If you select `Use Pool Associated with Node`, additional instances are allocated from the node's additional instances based on the number specified in the `Additional instances` property.	componentLevel
Additional instances	No	Yes	`0`	The number of additional instances that the node can start if the `Additional instances pool` property is set to `Use Pool Associated with Node`. By default, no additional instances are given to the node.	additionalInstances

The SiebelInput node Retry properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Retry mechanism	No	No	Failure	This property specifies how retry processing is handled when a failure is rolled back to the SiebelInput node. • If you select `Failure`, retry processing is not performed so you cannot set the remaining properties. • If you select `Short and long retry`, retry processing is performed first at the interval that is specified by the `Short retry interval` property, and if that is unsuccessful, it is then performed at the interval that is specified by the `Long retry interval` property.	
Retry threshold	No	Yes	0	The maximum number of times that retry processing is performed for short retry.	retryThreshold
Short retry interval	No	Yes	0	The interval between short retry attempts.	shortRetryThreshold
Long retry interval	No	Yes	0	The interval between long retry attempts.	longRetryThreshold

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

SiebelRequest node

Use the SiebelRequest node to interact with a Siebel application.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow" on page 4746
- "Terminals and properties" on page 4746

Purpose:
Use the SiebelRequest node to interact with Siebel applications. For example, a SiebelRequest node requests information from a Siebel Enterprise Information System (EIS). A customer business object is sent to Siebel, causing Siebel to retrieve information about a customer, such as an address and account details. The response information that is retrieved by the SiebelRequest node can then be used by the rest of the message flow. The SiebelRequest node can send and receive business data.

The SiebelRequest node is contained in the **WebSphere Adapters** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
To function correctly, the SiebelRequest node needs an adapter component, which you set using the `Adapter component` node property, and business object definitions, which are stored in the message set that you reference from the node. For this reason, you must provide a message set. By default, the message that is propagated from the SiebelRequest node is in the DataObject domain, so the `Message domain` property is set to DataObject. You cannot specify a different domain. The message type is detected automatically by the node.

The SiebelRequest node supports local transactions by using the local transaction manager for the broker, and global transactions by using the external syncpoint coordinator for the broker.

To effectively maintain the pool of connections to Siebel, you can set a connection timeout value on a configurable service. For more information, see "Configuring EIS connections to expire after a specified time" on page 726.

You can deploy several WebSphere Adapters request nodes that use the same adapter component to an execution group.

You can use the **mqsisetdbparms** command in the following format to configure an account name with a user name and password for the Adapter for Siebel Business Applications.

```
mqsisetdbparms broker name -n adapter name -u user name -p password
```

For example:

```
mqsisetdbparms BRK1 -n eis::SiebelCustomerOutbound.outadapter -u siebeluid -p ********
```

Using configurable services for Siebel nodes

Siebel nodes can get Siebel connection details from either the adapter component or a configurable service. By using a configurable service, you can change the connection details for an adapter without the need to redeploy the adapter. For more details about creating, changing, reporting, and deleting the configurable services for Siebel, see "Changing connection details for Siebel adapters" on page 720.

You can also connect to different versions of Siebel by creating a custom EISProviders configurable service and setting the location of the appropriate library files. For more information, see "Connecting to different versions of Siebel" on page 2077.

Terminals and properties:
When you have put an instance of the SiebelRequest node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. If you double-click a SiebelRequest node, you open the Adapter Connection wizard. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The SiebelRequest node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts the request business object.
Out	The output terminal to which the response business object is sent if it represents successful completion of the request, and if further processing is required within this message flow.
Failure	If an error happens in the SiebelRequest node, the message is propagated to the Failure terminal. Information about the error, and business object events can also be propagated to the Failure terminal.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk on the panel if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The SiebelRequest node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type, for example, SiebelRequest	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The SiebelRequest node Basic properties are described in the following table.

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
Primary adapter component	Yes	No		The name of the adapter component that contains configuration properties for the adapter. Either enter a name of an adapter file, or click **Browse** to select an adapter file from the list of files that are available in referenced message set projects. When theSiebelRequest node receives data from the Siebel system, it associates that data with a method name. The SiebelRequest node attempts to call methods that are defined in the primary adapter. If the method is not defined in the primary adapter, the node can call methods that are defined in matching secondary adapters that are deployed to the same execution group.	
Secondary adapter mode	No	Yes	None	Specifies whether the node can call methods that are defined in secondary adapters. If you set the `Secondary adapter mode` property to `None`, the SiebelRequest node calls only methods that are defined in the primary adapter. If the method is not defined in the primary adapter, an error occurs. If you set this property to `All adapters in execution group`, the node can call methods that are defined in any Siebel outbound adapter that is deployed to the same execution group.	secondaryAdapterMode

Property	M	C	Default	Description	mqsiapplybaroverride command property
Default method	Yes	Yes		The default method binding to use.	defaultMethod

The SiebelRequest node Response Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	DataObject	The domain that is used to parse the response message. By default, the response message that is propagated from the SiebelRequest node is in the DataObject domain. You cannot specify a different domain.
Message set	Yes	No	Set automatically	The name of the message set in which the incoming message is defined. This field is set automatically from the Adapter component property. If you set this property, then subsequently update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project.
Message type	No	No		The name of the response message. The node detects the message type automatically. You cannot set this property.
Message format	No	No		The name of the physical format of the response message. You cannot set this property.

The SiebelRequest node Transactionality properties are described in the following table.

Property	M	C	Default	Description
Transaction mode	No	No	No	This property specifies that updates are performed independently, not as part of a local transaction. You cannot change this property.

The SiebelRequest node Request properties are described in the following table.

Property	M	C	Default	Description
Method Location	Yes	No	$LocalEnvironment/ Adapter/MethodName	The location of the business method (such as createPurchaseOrder or deletePurchaseOrder) that is used to trigger the SiebelRequest node to perform an action on the external system.
Data Location	Yes	No	$Body	The location in the incoming message tree from which data is retrieved to form the request that is sent from the SiebelRequest node to the EIS.

The SiebelRequest node Result properties are described in the following table.

Property	M	C	Default	Description
Output data location	No	No	$OutputRoot	The message tree location to which the SiebelRequest node sends output.

Property	M	C	Default	Description
Copy local environment	No	No	Selected	This property controls how the local environment is copied to the output message. If you select the check box, at each node in the message flow, a new copy of the local environment is created in the tree, and it is populated with the contents of the local environment from the preceding node. So if a node changes the local environment, the upstream nodes do not see those changes because they have their own copies. This behavior might be an issue if you are using a FlowOrder node, or if you use the propagate command on a Compute node. If you clear the check box, each node does not generate its own copy of the local environment, but it uses the local environment that is passed to it by the previous node. So if a node changes the local environment, those changes are seen by the upstream nodes.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

SOAPAsyncRequest node

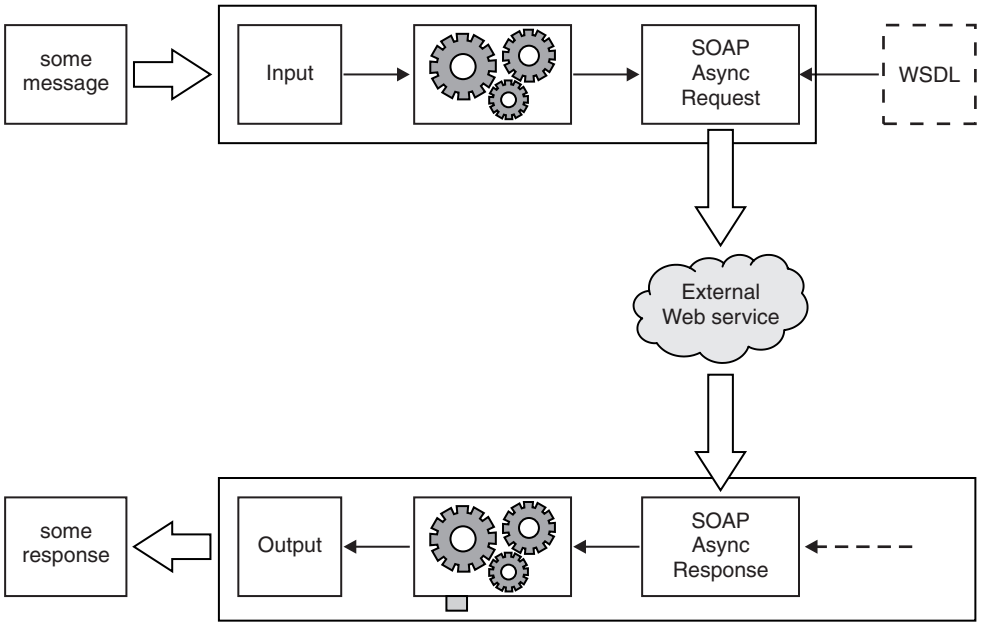
Use the SOAPAsyncRequest node with the SOAPAsyncResponse node to construct a pair of message flows that call a Web service asynchronously.

This topic contains the following sections:

Purpose:

The SOAPAsyncRequest node can use HTTP or JMS transport. It is linked as a pair with a SOAPAsyncResponse using a unique identifier, and WS-Addressing, to correlate response messages with the original request. The SOAPAsyncRequest and SOAPAsyncResponse nodes cannot be used with one-way operations.

The SOAPAsyncRequest node sends a Web service request, but the node does not wait for the associated Web service response to be received. This asynchronous functionality enables multiple outbound requests to be made almost in parallel because the outbound request is not blocked waiting for the response. However, when using HTTP transport, the SOAPAsyncRequest node does wait for the HTTP 202 acknowledgment before continuing with the message flow, and the SOAPAsyncRequest node blocks if the acknowledgment is not received. The Web service response is received by the SOAPAsyncResponse node, which can be in a separate message flow. The nodes are used as a pair, and correlate responses against the original requests.



The SOAPAsyncRequest node is the first half of the asynchronous request and response node pair. The SOAPAsyncRequest node calls a remote SOAP-based Web service. The request is sent by the SOAPAsyncRequest node, but the SOAPAsyncRequest node does not receive the response. The response is received by a SOAPAsyncResponse node that is running on a different thread. The SOAPAsyncResponse node is typically at the beginning of a different message flow; however, it must be in the same execution group as the SOAPAsyncRequest node.

The SOAPAsyncRequest node is WSDL-driven, in a similar manner to the SOAPRequest node.

The SOAPAsyncRequest node is contained in the **Web Services** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
A SOAPAsyncRequest node is linked as a pair with a SOAPAsyncResponse using a unique identifier to correlate request and response messages.

The following sample demonstrates how to use the asynchronous SOAP nodes when you call a Web service. The Web service simulates an order service, and the client shows how existing WebSphere MQ interfaces can be extended to make Web service requests.

- Asynchronous Consumer

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Using WSDL with the SOAPAsyncRequest node:
A SOAPAsyncRequest node must be associated with a WSDL file unless it is operating in gateway mode. For more information about gateway mode, see "Gateway operation mode for SOAP nodes" on page 1645.

In WSDL mode, when you select a WSDL file for the `WSDL file name` field, the WSDL is validated to ensure that it is WS-I compliant. If the WSDL uses a SOAP/JMS transport URI it is not WS-I compliant, but by default no error is shown. To enable strict WS-I validation and display a warning when a SOAP/JMS transport is used, click **Window > Preferences > Broker Development > Message Sets > Validation** and clear the **WS-I BP 1.1: Allow SOAP/JMS as transport URI** check box.

After a valid WSDL file is selected, the message set project to which WSDL file belongs is added as a referenced project to the corresponding flow project, if the reference does not exist. If the WSDL file is not valid, or an incorrect file name is entered, an error message is displayed in the Properties view and all WSDL properties are blank.

If the node was created by dropping a WSDL file from a message set onto the message flow editor, this property is preset to the name of the WSDL file. If the name of the WSDL file is not preset, you can set this property in one of the following ways.

- If you have Deployable WSDL, you can select from the Deployable WSDL files by clicking **Browse**.
- If you have WSDL definitions, but no message set, then you can create a message set:
  1. Click **Browse** to open the WSDL Selection window.
  2. Click **Import/Create New** to open the Import WSDL file wizard.
  3. Enter the message set name and message set project name. Click **Next**.
  4. Select the relevant option:
     - If your WSDL file exists in your workspace, select **Use resources from the workspace**, and select the WSDL file.
     - If your WSDL file is in the file system, select **Use external resources**. Select the WSDL file. Click **Next**.
  5. Select the WSDL bindings to import. Any warnings or errors are displayed in the wizard banner.
  6. Click **Finish**. Result: Creates a new message set project and message set, with message definitions. The WSDL definitions are added to the Deployable WSDL folder.
  7. You can now select the WSDL file from the WSDL Selection window. Click **OK**.
- If you have a message set but no WSDL definition, you must generate a WSDL definition. See "Generating a WSDL definition from a message set" on page 2968.
- Drag a WSDL file from a message set onto the node.
- Type in a file name that is relative to the message set project in which the deployable WSDL file exists.

When you save the flow file, it is validated that the `WSDL file name` exists in the message set. If it is does not, an error is generated, and you will not be able to add a flow that contains this SOAPAsyncRequest node to the broker archive (BAR) file.

Terminals and properties:
The SOAPAsyncRequest node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a SOAP request message for dispatch to the target by the node.
Failure	The output terminal to which the message is routed if a failure is detected when the SOAP request message is dispatched to the target (such as a message validation failure).
Out	The output terminal to which the message is routed if it has been successfully dispatched to the target, and if further processing is required within this message flow. The message that leaves the Out terminal is the same as the message that arrived at the In terminal.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined). The column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

Some SOAPAsyncRequest node properties are initially set from properties in the imported WSDL. These properties are parsed differently depending on which URI format is used by the `address` element in the WSDL. For details, see "WSDL URI formats for JMS" on page 1668.

The SOAPAsyncRequest node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type	The name of the node.
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

The SOAPAsyncRequest node Basic properties are described in the following table.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Unique identifier	Yes	No		This property is the unique identifier that links a pair of SOAPAsyncRequest and SOAPAsyncResponse nodes. When using HTTP transport, this identifier is used as a unique URL fragment to identify incoming response messages for the SOAPAsyncResponse node. When using JMS transport, this property is used as a unique identifier only if the `Get Response By Correl ID` property is checked. If the `Get Response By Correl ID` property is cleared and JMS transport is used, the `Reply To Destination` queue acts as the unique identifier instead, and therefore must be unique to this pair of nodes.	asyncResponseCorrelator

Property	M	C	Default	Description	mqsiapplybaroverride command property
Operation mode	Yes	Yes	`Invoke a specific web service defined by a WSDL interface`	This property allows you to specify the operation mode of the node, which determines whether it acts in WSDL mode or in gateway mode. In WSDL mode, the node performs operations according to the WSDL it is configured with. However, gateway mode allows you to configure your flow to handle generic SOAP request/response and one-way messages, or to act as a façade between multiple web services clients and multiple back-end web services providers. **Invoke a specific web service defined by a WSDL interface** Configure the node with a deployable WSDL by setting the WSDL file name property or by dragging a WSDL onto the node. This is the default option. **Invoke a generic web service** Configure the node to act in gateway mode with no WSDL required. See "Gateway operation mode for SOAP nodes" on page 1645 for a fuller explanation of gateway mode.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
WSDL file name	Yes	No	None	This property indicates the location of the WSDL file that you want to use to configure the node. Enter the full path to the WSDL file, or click **Browse** to locate the WSDL file in your workspace. When you select a WSDL file for the `WSDL file name` property, the WSDL is validated to ensure that it is WS-I compliant. If the WSDL has a binding using SOAP/JMS which is not WS-I compliant, by default no error is shown. To enable strict WS-I validation and display a warning when a SOAP/JMS transport is used, click **Window** > **Preferences** > **Broker Development** > **Message Sets** > **Validation** and clear the **WS-I BP 1.1: Allow SOAP/JMS as transport URI** check box. Only deployable WSDL files can be used to configure the SOAP nodes. After a valid WSDL file is selected, the message set project to which the WSDL file belongs is added as a referenced project to the corresponding message flow project, if the reference does not exist. If the WSDL file is not valid, or an incorrect file name is entered, an error message is displayed in the Properties view and all WSDL properties are blank. If the node was created by dropping a WSDL file from a message set onto the Message Flow editor, this property is preset to the name of the WSDL file. This property takes a string value. The following situations result in an error condition: • The WSDL file does not belong to a message set project, or the WSDL file was not imported correctly; see "Importing from WSDL" on page 2946 and "Importing WSDL definitions from the command line" on page 2948. • The WSDL file contains no HTTP or JMS bindings. • The WSDL file contains no port type. • The WSDL file that is specified in the field does not exist. WSDL properties are disabled when the node is configured to act in gateway mode.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Port type	Yes	No	By default, the first `Port type` found in the WSDL file, that has an associated HTTP or JMS binding with it, is selected.	This property type is String. This field lists all the port types defined by the specified WSDL file. By default, the first port type found in the WSDL file that has an associated HTTP or JMS binding is selected. When you save the flow file, it is validated that the selected `Port type` is valid within the content of the selected WSDL file. If it is not valid, an error is generated, and you will not be able to add a flow that contains this SOAPAsyncRequest node to the broker archive (BAR) file. Error Conditions: • Selected `Port type` does not contain at least one operation. WSDL properties are disabled when the node is configured to act in gateway mode.	
Imported binding	Yes	No		This property type is String. The `Imported binding` box lists all the SOAP bindings associated with the selected port type. Only HTTP or JMS transport is supported. Bindings are listed in the order that they are displayed in the WSDL file. By default, the first binding that implements the operation and has an associated service port is selected. This property is updated every time the `Port type` value changes. Error Conditions: • No SOAP bindings (with HTTP or JMS transport) in the WSDL file are associated with the `Port type`. • Selected binding does not have any operations. WSDL properties are disabled when the node is configured to act in gateway mode.	
Binding operation	Yes	No		This property type is String. The `Binding operation` box contains all the operations defined by the selected binding. The first operation in the list is selected by default. This property is updated every time the selected binding value changes.When you save the flow file, it is validated that the selected `Binding operation` is valid within the content of the selected WSDL file. If it is not valid, an error is generated, and you will not be able to add a flow that contains this SOAPAsyncRequest node to the broker archive (BAR) file. WSDL properties are disabled when the node is configured to act in gateway mode.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Service port	Yes	No		This property type is String. The `Service port` box lists all the service ports that point to the selected binding. The first service port for the binding is selected by default. This property is updated every time the selected binding value changes. When you save the flow file, it is validated that the selected `Service port` is valid within the content of the selected WSDL file. If it is not valid, an error is generated, and you will not be able to add a flow that contains this SOAPAsyncRequest node to the broker archive (BAR) file. Error Conditions: • No ports point to the selected binding. WSDL properties are disabled when the node is configured to act in gateway mode.	
Target namespace	No	No		This property type is String. `Target namespace` displays the namespace of the selected WSDL file. WSDL properties are disabled when the node is configured to act in gateway mode.	
Transport	No	No	HTTP	This property is set automatically when the `Imported binding` property is selected. The value of this property shows the transport used by the selected WSDL binding; for example, `HTTP` or `JMS`. If you choose to switch the transport from `JMS` to `HTTP`, a dialog box displays, which allows you to reset the JMS-specific properties. You must reset the JMS properties to deploy the message flow to a runtime environment version prior to fix pack V7.0.0.1.	

The SOAPAsyncRequest node HTTP Transport properties are described in the following table. These settings are used only when the node uses HTTP transport.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Web service URL	Yes	No		This property type is String. This property is automatically derived from the <soap:address> element of the selected Service port. Whenever the selected port is updated, the Web service URL is updated accordingly. However, if you override the value then your value persists and the URL is no longer updated from the service port. If you choose to override this property you must specify it in the form http://<hostname>[:<port>]/[<path>] where: • http://<hostname> must be specified. • <port> has a default of 80. If you specify a value, you must include the colon (:) before the port number. • <path> has a default of forward slash (/). If you specify a value, you must include the forward slash (/) before the path. For more details of how to override this property, see Changing the default URL for a SOAPRequest node or a SOAPAsyncRequest node request.	webServiceURL
Request timeout (in seconds)	No	Yes	120	This property type is Integer. This property has the value of the wait time for the remote server to respond with an acknowledgment that the message has been received. The time in seconds that the node waits for a response from the Web service. The valid range is 1 to (2^{31})-1. You cannot enter a value that represents an unlimited wait.	requestTimeout
HTTP(S) proxy location	No	Yes		This property type is String. The location of the proxy server to which requests are sent. This value must be in the form hostname:port.	httpProxyLocation

Property	M	C	Default	Description	mqsiapplybaroverride command property
SSL Protocol (if using SSL)	No	Yes	TLS	This property type is Enumerate. The SSL protocol to use when making an HTTPS request. Valid values are: **SSL** This option attempts to connect by using the SSLv3 protocol first, but the handshake can fall back to the SSLv2 protocol where the SSLv2 protocol is supported by the underlying JSSE provider. **SSLv3** This option attempts to connect with the SSLv3 protocol only. The handshake cannot fall back to SSLv2. **TLS** The default. This option attempts to connect with the TLS protocol only. The handshake cannot fall back to SSLv3 or SSLv2. **TLSv1** This option attempts to connect with the TLS v1.0 protocol only. Fallback to SSLv3 or SSLv2 is not allowed. **TLSv1.1** This option attempts to connect with the TLS v1.1 protocol only. Fallback to SSLv3, SSLv2, or TLSv1.0 is not allowed. **TLSv1.2** This option attempts to connect with the TLS v1.2 protocol only. Fallback to SSLv3, SSLv2, TLSv1.0, or TLSv1.1 is not allowed. **SSL_TLS** This option enables all SSL v3.0 and TLS v1.0 protocols. Fallback to SSLv2 is not allowed. **SSL_TLSv2** This option enables all SSL v3.0 and TLS v1.0, v1.1, and v1.2 protocols. Fallback to SSLv2 is not allowed. Both ends of an SSL connection must use the same protocol. The protocol must be one that the remote server can accept.	sslProtocol
Allowed SSL ciphers (if using SSL)	No	Yes	Empty	This property type is String. A comma-separated list of ciphers to use when making an SSL request. This setting enables you to specify a single cipher (such as SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA), or a list of ciphers that are the only ones used by the connection. This list of ciphers must include one or more that are accepted by the remote server. The default value is an empty string, which allows the node to use any, or all, of the available ciphers during the SSL connection handshake. This method enables the greatest scope for making a successful SSL connection.	allowedSSLCiphers

Property	M	C	Default	Description	mqsiapplybaroverride command property
Use compression	No	No	None	This property controls whether the content of the HTTP request is compressed. Valid values are none, gzip, zlib (deflate) and deflate. If the request is compressed, the Content-Encoding header is set to indicate that the content is compressed. zlib (deflate) represents RFC 1950 + RFC 1951 combined. deflate represents RFC 1951 only.	requestCompressionType
Accept compressed responses by default	No	Yes	Cleared	This property indicates whether the request accepts compressed responses. If this option is selected, it is possible for the request to receive responses with a Content-Encoding of gzip or deflate. If such a response is received the content is decoded and the Content-Encoding header is removed. If the Request Header does not contain an Accept-Encoding header then selecting this option sets the Accept-Encoding header to "gzip, deflate".	acceptCompressedResponses
Enable SSL certificate hostname checking	No	Yes	No	This property specifies if the host name of the server that is receiving the request must match the host name in the SSL certificate.	hostnameChecking

The SOAPAsyncRequest node JMS Transport properties are described in the following table. These settings are used only when the node uses JMS transport.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Destination	Yes	Yes	None	The destination to which the node sends outgoing messages. If the SOAPAsyncRequest node is to be used to send point-to-point messages, enter the Destination queue name for the JMS queue name that is listed in the bindings file. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `Destination` is set to the value of `destinationName` found in the WSDL if a W3C-style URI is found, or `destination` if an IBM-style URI is found.	jmsDestination

Property	M	C	Default	Description	mqsiapplybaroverride command property
Reply To Destination	Yes	Yes	None	The name of the JMS destination to which the receiving application must send a reply message. For a reply message to be returned to this JMS destination, the JMS destination name must be known to the domain of the JMS provider that is used by the receiving client. If the `Get Response By Correl ID` property is cleared, this queue uniquely identifies messages destined for the paired SOAPAsyncResponse node. If the `Get Response By Correl ID` property is checked, this queue can then be shared between multiple nodes. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `Reply To Destination` is set to the value of `replyToName` found in the WSDL if a W3C-style URI is found, or to the first of `replyToName`, `replyTo`, `replyToDestination`, or `replyDestination` if an IBM-style URI is found. If any of these other properties are present, they display as a name-value pair in the `User Parameters` table.	jmsReplyToDestination
JMS provider name	Yes	No	`WebSphere MQ`	Select a JMS vendor name from the list, or enter a name of your choice. The name must match the name of a configurable service that is defined for the broker to which you deploy the message flow. When you select a name from the list, the `Initial context factory` property is updated automatically with the relevant Java class. If you enter your own JMS provider name, you must also enter a value for the `Initial context factory`.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Initial context factory	Yes	Yes	com.sun.jndi.fscontext.RefFSContextFactory	The starting point for a JNDI namespace. A JMS application uses the initial context to obtain and look up the connection factory and queue or topic objects for the JMS provider. If you select a JMS provider name from the list in JMS provider name, the Initial context factory property is updated automatically with the relevant Java class. If you enter your own JMS provider name, you must also enter a value for the Initial context factory. The default value is com.sun.jndi.fscontext.RefFSContextFactory, which defines the file-based Initial context factory for the WebSphere MQ JMS provider. This property takes its initial value from a WSDL URI property, depending on whether the WSDL address URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. Initial context factory is set to the value of jndiInitialContextFactory found in the WSDL if a W3C-style URI is found, or initialContextFactory if an IBM-style URI is found.	initialContextFactory

Property	M	C	Default	Description	**mqsiapplybaroverride** command property
JNDI URL bindings location	Yes	Yes		The system path or the LDAP location for the bindings file. The bindings file contains definitions for the JNDI administered objects that are used by the SOAPAsyncRequest node. This property is disabled when the `Initial context factory` is `com.ibm.mq.jms.Nojndi`. When you enter a value for `JNDI URL bindings location`, ensure that it complies with the following instructions: • Construct the bindings file before you deploy a message flow that contains a SOAPAsyncRequest node. • Do not include the file name of the bindings file in this field. • If you have specified an LDAP location that requires authentication, configure the LDAP principal (userid) and LDAP credentials (password) separately. These values are configured at broker level. For information about configuring these values, see "**mqsicreatebroker** command" on page 3831 and "**mqsichangebroker** command" on page 3723. • The string value must include a supported URL prefix that has a URL handler that is available on the class path. For information about constructing the JNDI administered objects bindings file, see the JMS provider documentation. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `JNDI URL bindings location` is set to the value of `jndiURL` found in the WSDL if a W3C-style URI is found, or `jndiProviderURL` if an IBM-style URI is found.	locationJndiBindings

Property	M	C	Default	Description	mqsiapplybaroverride command property
Connection factory name	Yes	Yes		The name of the connection factory that is used by the SOAPAsyncRequest node to create a connection to the JMS provider. This property is initially configured from the imported WSDL. This name must exist in the bindings file. The `Connection factory name` must be a JMS QueueConnectionFactory. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `Connection factory name` is set to the value of `jndiConnectionFactoryName` found in the WSDL if a W3C-style URI is found, or `connectionFactory` if an IBM-style URI is found.	connectionFactoryName
User Parameters	No	No		This table describes user properties that will be sent in the `requestURI` property of the outgoing request message. The properties are name-value pairs that exist in the WSDL and are not used by other properties of the SOAPAsyncRequest node.	
JNDI parameters	No	No		A table mapping JNDI context parameters to their type. These properties take their initial values from any W3C-style WSDL properties starting with `jndi-`. IBM-style WSDL does not support JNDI parameters, but you can set these properties on the node.	
Get Response By Correl ID	No	Yes	Cleared	If this property is checked, the SOAPAsyncRequest node sends the request message with the Correl ID specified in the `Unique identifier` property, and the SOAPAsyncResponse node receives only response messages that match that Correl ID. This allows a single `Reply To Destination` queue to be shared between several pairs of SOAPAsyncRequest and SOAPAsyncResponse nodes, if this property is checked for all those nodes. This functionality works only with web service providers that support reading the Correl ID from the request message and using it as the Correl ID in the response message.	
Backout destination	No	Yes		The SOAPAsyncResponse node sends response messages to this destination when errors prevent the response message flow from processing the response message. The message is removed from the reply to destination. The backout properties are set by the SOAPAsyncRequest node, but used only by its paired SOAPAsyncResponse node.	backoutDestination

Property	M	C	Default	Description	mqsiapplybaroverride command property
Backout threshold	No	Yes	0	This value controls when a message is put to the backout destination. For example, if the value is 3, the JMS provider attempts to deliver the message to the input destination three times. After the third attempted delivery, the message is not rolled back to the reply to destination and is sent to the Backout destination. The backout properties are set by the SOAPAsyncRequest node, but used only by its paired SOAPAsyncResponse node. See "Configuring the backout threshold property" on page 4770.	

The SOAPAsyncRequest node Message Delivery properties are described in the following table. This sub tab is enabled only if the selected binding in the Basic tab uses JMS transport.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Target Service	No	No	None	Used by the SOAPAsyncRequest node when dispatching the service request. This property takes its initial value from the `targetService` WSDL property.	targetService
Delivery mode	No	Yes	Persistent	This property controls the persistence mode that a JMS provider uses for a message. Valid values are: • `Persistent`: the message survives if the JMS provider has a system failure. • `Non Persistent`: the message is lost if the JMS provider has a system failure. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `Delivery mode` is set to the value of `deliveryMode` found in the WSDL if a W3C-style URI is found, or to the first of `deliveryMode` or `persistence` if an IBM-style URI is found. If both these properties are present, the second property displays as a name-value pair in the `User Parameters` table.	deliveryMode

Property	M	C	Default	Description	mqsiapplybaroverride command property
Message Priority	No	Yes	4	This property assigns relative importance to the message and can be used for message selection by a receiving web service. Select a value between 0 (lowest priority) and 9 (highest priority). The default value is 4, which indicates medium priority. Priorities in the range 0 - 4 indicate typical delivery. Priorities in the range 5 - 9 indicate faster delivery. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `Priority` is set to the value of `priority` found in the WSDL if a W3C-style URI is found, or to the first of `priority` or `Priority` if an IBM-style URI is found. If both these properties are present, the second property displays as a name-value pair in the `User Parameters` table.	messagePriority
Message Expiration (ms)	No	Yes	0	This property controls the length of time, in milliseconds, for which the JMS provider keeps the output JMS message. The default value, 0, is used to indicate that the message must not expire. This property takes its initial value from the `timeToLive` WSDL property.	messageExpiration
Message Type	No	Yes	bytes	Select a value from the list to configure the type of JMS message that is produced by the SOAPAsyncRequest node. Valid values are `text` and `bytes`.	messageType

The SOAPAsyncRequest node Transactions properties are described in the following table. This setting does not apply when the node uses HTTP transport.

Property	M	C	Default	Description
Transaction Mode	Yes	No	Automatic	This property controls whether the message is output under a JMS transaction. Valid values are `Yes`, `No`, and `Automatic`. Select `No` to output the message using a non-transactional JMS session. Select `Yes` to output the message using a transactional JMS session. The JMS transaction can be either local or global. To use a global transaction, using an XA JMS session, you must also select the message flow property `Coordinated Transaction` in the BAR file properties. Select `Automatic` if you want the message transactionality to be inherited from the `Transaction mode` setting on the Input node at the start of the flow. See “Configuring for coordinated JMS transactions” on page 4770.

The SOAPAsyncRequest node Advanced properties are described in the following table.

SOAP headers that are part of the must understand headers list are incorporated into the flow rather than causing a SOAP fault. Adding headers to the must understand headers list stops SOAP faults being generated by SOAP headers.

You do not need to add must understand headers for WS-Addressing and WS-Security because these are understood if you configure **WS Extensions**.

The must understand headers list that is configured on this node is applied to the corresponding SOAPAsyncResponse node when the SOAPAsyncResponse node receives the reply from the remote server.

Property	M	C	Default	Description
WSDL-defined SOAP response headers	No	No		The WSDL-defined SOAP response headers table is read-only, and is populated based on the SOAP headers defined in the output part of the selected operations. By default, the check boxes, in the second column of the table, are cleared for all entries in the WSDL-defined SOAP response headers table. You must select the relevant check box to add the header to the must understand headers list. When the node is configured to act in gateway mode, with no WSDL required, this table is cleared. The original values of these fields are restored if the operation mode of the node is changed back to WSDL mode.
User-defined SOAP response headers	No	No		You can add custom headers (headers that are not defined in the WSDL file) in the User-defined SOAP headers table. Use **Add**, **Edit**, and **Delete** for this table. You must select the relevant check box, in the second column of the table, to ensure that the newly added custom header is added to the must understand headers list.

The SOAPAsyncRequest node WS Extensions properties are described in the following table.

Property	M	C	Default	Description	
Use WS-Addressing	No	No	Selected	You cannot edit this property. This property indicates that WS-Addressing is always engaged on the SOAPAsyncRequest node. For more details about WS-Addressing with the SOAPAsyncRequest node, see "WS-Addressing with the SOAPAsyncRequest and SOAPAsyncResponse nodes" on page 1655.	
Allow MTOM	No	Yes	No	This property controls whether MTOM is enabled for the parser. Valid values are Yes, No, and Inherit. For more information about using SOAP MTOM with the SOAPReply, SOAPRequest, and SOAPAsyncRequest nodes; see "Using SOAP MTOM with the SOAPReply, SOAPRequest, and SOAPAsyncRequest nodes" on page 1678. For more information about MTOM, see "SOAP MTOM" on page 6697. MTOM support is disabled when the node is configured to act in gateway mode.	allowMTOM

Property	M	C	Default	Description	
WS-Security	No	No		This table and features two columns: • `Alias` • `XPath Expression` You can add XPath expressions with an associated `Alias` value to the `WS-Security` table. The `Alias` is resolved in a Policy Set that is created by the administrator. The Policy Set resolves the `Alias` to either encrypt or sign the part of the message referred to by the `XPath Expression`. You can **Add**, **Edit**, and **Delete** in this table.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

LocalEnvironment overrides:
You can dynamically override set values in the local environment in the same way as setting values in other elements of a message. For a full list of values you can override in the local environment, see Local environment overrides.

Working with WrittenDestination data:
After the request has been made, the WrittenDestination folder in LocalEnvironment is updated with the WS-Addressing, compression details (if in use), and transport details. A WrittenDestination for a SOAPAsyncRequest node has the following format, with WS-Addressing and Compression present only if it is used:

```
WrittenDestination = (
   SOAP  = (
      Request = (
         WSA = (
            To = 'URI'
            ReplyTo = 'http://server:7800/reply'
            MessageID = 'id'
            Action = 'doAllTheStuff'
         )
         Transport = (
            HTTP = (
               WebServiceURL = 'http://server:8080/service'
               Compression   = (
                  OriginalSize   = 775
                  CompressedSize = 411
               )
            )
      )
   )
)
```

The following example uses JMS transport:

```
WrittenDestination = (
   SOAP  = (
      Request = (
         WSA = (
            To = 'URI'
            ReplyTo = 'http://server:7800/reply'
            MessageID = 'id'
            Action = 'doAllTheStuff'
         )
         Transport = (
            JMS = (
               Destination = 'jms:jndi:B2BQUEUEIN'
            )
         )
      )
   )
)
```

Related concepts:

"Message modeling" on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

"SOAP parser and domain" on page 1082
You can use the SOAP parser to create a common WSDL-based logical tree format for working with Web services, independent of the physical bitstream format.

"SOAP tree overview" on page 1611
This tree format allows you to access the key parts of the SOAP message in a convenient way.

"XMLNSC parser" on page 1090
The XMLNSC parser is a flexible, general-purpose XML parser that offers high performance XML parsing and optional XML Schema validation.

"Using compression with HTTP and SOAP nodes" on page 1597
You can configure HTTP and SOAP nodes to use HTTP compression and decompression when sending and receiving messages.

If you are writing ESQL to process messages in the XMLNSC domain, it is helpful to learn about the structure of the message tree that the XMLNSC parser builds.

"Deciding which nodes to use" on page 1457
WebSphere Message Broker includes many message processing nodes that you can use in your message flows.

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

"Importing from WSDL" on page 2946
You can use the New Message Definition File wizard in the WebSphere Message

Broker Toolkit to create a new message definition from WSDL.

Related reference:

"Configuring the backout threshold property"
You can set the backout threshold property on nodes that use JMS transport to specify how many attempts are made to deliver the message to the input destination.

"Configuring for coordinated JMS transactions" on page 4544
Configure your message flow to receive or output messages under coordinated transactions.

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

"SOAPAsyncResponse node" on page 4777
Use the SOAPAsyncResponse node in conjunction with the SOAPAsyncRequest node to construct a pair of message flows that call a Web service asynchronously.

"WS-Addressing with the SOAPAsyncRequest and SOAPAsyncResponse nodes" on page 1655
The remote Web service must understand WS-Addressing to be able to work with SOAPAsyncRequest and SOAPAsyncResponse nodes.

Configuring the backout threshold property:

You can set the backout threshold property on nodes that use JMS transport to specify how many attempts are made to deliver the message to the input destination.

If the Backout threshold is set to `0` then redelivery is not attempted. If the Backout threshold is 1 or greater, the message will be redelivered the specified number of times.

Set the value of Backout threshold depending on the capabilities of the JMS provider.

If the JMS provider supports `JMSXDeliveryCount`, you can set the Backout threshold to any value.

If the JMS provider does not support `JMSXDeliveryCount`, the Backout threshold must only be set to 0 or 1. If the JMS provider does not support `JMSXDeliveryCount` and the value is set to greater than 1, a redelivered message is repeatedly backed out and reprocessed, and is never delivered to the backout destination.

Configuring for coordinated JMS transactions:

Configure your message flow to receive or output messages under coordinated transactions.

When you include a node using JMS transport in a message flow, such as the JMSInput or SOAPInput node when using JMS transport, the value that you set for `Transaction mode` defines whether messages are received under sync point.

- If you set this property to `Global`, the message is received under external sync point coordination; that is, within a WebSphere MQ unit of work. Any messages that are sent later, by an output node in the same instance of the message flow, are put under sync point, unless the output node overrides this setting explicitly.
- If you set this property to `Local`, the message is received under the local sync point control of the node. Any messages that are sent later, by an output node in the flow, are not put under local sync point, unless an individual output node specifies that the message must be put under local sync point.
- If you set this property to `None`, the message is not received under sync point. Any messages that are sent later, by an output node in the flow, are not put under sync point, unless an individual output node specifies that the message must be put under sync point.

To receive messages under external sync point, you must take additional configuration steps, which need be applied only the first time that a specific node using JMS transport is deployed to the broker for a particular JMS provider.

- On distributed systems, the external sync point coordinator for the broker is WebSphere MQ. Before you deploy a message flow in which the `Transaction mode` property is set to `Global` or `Yes`, and is intended to use globally coordinated transactions, modify the queue manager `.ini` file to include extra definitions for each JMS provider resource manager that participates in globally coordinated transactions.
  - Windows On Windows:
    1. Start WebSphere MQ Explorer.
    2. Right-click the queue manager name in the left pane and click **Properties**.
    3. Click **XA resource managers** in the left pane.
    4. Click **Add...** .
    5. Set the options as follows:
       - Set `Name` to any value.
       - On Windows on x86 systems, set the `SwitchFile` property to *`install_dir`*`\bin\JMSSwitch.dll`. On Windows on x86-64 systems, set the `SwitchFile` property to `JMSSwitch.dll`.
       - Set the `XAOpenString` property to a string value as follows: *`Initial Context`*`,`*`location JNDI`*`,`*`Optional_parms`*.
       - Set the `ThreadOfControl` property to `Thread`.
    6. On Windows on x86-64 systems only, copy the switch file *JMSSwitch32.dll* to the `\exits` subdirectory in the WebSphere MQ installation directory, and rename it to `JMSSwitch.dll`. Copy the switch file `JMSSwitch.dll` to the `\exits64` subdirectory in the WebSphere MQ installation directory.

    For more information, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.
  - Linux UNIX On Linux and UNIX systems, add a stanza to the queue manager `.ini` file for each JMS provider.

    For example:

    ```
    XAResourceManager:
    Name=Jms_Provider_Name
    SwitchFile=/install_dir/bin/ JMSSwitch.so
    XAOpenString=Initial Context,location JNDI,Optional_parms
    ThreadOfControl=THREAD
    ```

    Where:

Name is an installation defined name that identifies a JMS provider resource manager.

SwitchFile
is the file system path to the JMSSwitch library that is supplied in the `bin` directory of the broker.

XAOpenString can have the following values:

– *Initial Context* is the value that is set in the JMSInput node property `Initial context factory`.

– *location JNDI* is the value that is set in the JMSInput node property `Location JNDI bindings`. This value must include a supported URL prefix that has a URL handler that is available on the class path.

The following parameters are optional:

– `LDAP Principal` matches the value that is set for the broker by using the **mqsicreatebroker** or **mqsichangebroker** commands.

– `LDAP Credentials` matches the value that is set for the broker by using the **mqsicreatebroker** or **mqsichangebroker** commands.

– `Recovery Connection Factory Name` is the JNDI administered connection factory that is defined in the bindings file. If a value is not specified, you must add a default value for `recoverXAQCF` to the bindings file. In either case, the Recovery Connection Factory must be defined as an XA Queue Connection Factory for the JMS provider that is associated with the `Initial context factory`.

The optional parameters are comma-separated and are positional. Therefore, any parameters that are missing must be represented by a comma. For example:

```
com.sun.jndi.fscontext.RefFSContextFactory,file:/C:/webservices/SOAP/JMS/JNDIXA,,,QCF
```

1. Update the Java CLASSPATH environment variable for the queue manager of the broker to include a reference to `xarecovery.jar`; for example:

   ```
   install_dir/classes/xarecovery.jar
   ```

2. Update the Java PATH environment variable for the queue manager of the broker to point to the bin directory in which the SwitchFile is located; for example:

   ```
   install_dir/bin
   ```

Finally, ensure that you have taken the following configuration steps:

– In the message flow, ensure that the coordinated property is enabled by using the WebSphere Message Broker Archive editor.

– Ensure that each node that must be part of the XA transaction is set to the global transaction mode.

– Ensure that the service ID that is used for the broker and the queue manager is the same user ID.

– Ensure that the JNDI connection factory objects that the JMS nodes use for a global transaction are configured to be of the type MQXAConnectionFactory, MQXAQueueConnectionFactory, or MQXATopicConnectionFactory.

  - If you create the bindings using WebSphere Message Broker Explorer, ensure the `Support XA Transactions` option is checked when you define your connection factory.
  - If you create the bindings using JMSAdmin, use the command **DEF XAQCF** or **DEF XATCF**, instead of **DEF QCF** or **DEF TCF**, when you define your connection factory.

For more information, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

- z/OS On z/OS, the external sync point manager is Resource Recovery Services (RRS). The only JMS provider that is supported on z/OS is WebSphere MQ JMS. The only transport option that is supported for WebSphere MQ JMS on z/OS is the bind option.

  Sync point control for the JMS provider is managed with RRS sync point coordination of the queue manager of the broker. You do not have to modify the `.ini` file.

Local environment overrides for the SOAPAsyncRequest node:

You can dynamically override values in the local environment in the same way as setting values in other elements of a message. These local environment overrides are used only by the SOAPAsyncRequest node and not by the SOAPAsyncResponse node.

This topic contains the following sections:

Local environment overrides for the SOAPAsyncRequest node:
You can set the following properties under LocalEnvironment.Destination.SOAP.Request:

Setting	Description

TransportType	Overrides the `Transport` property on the node to switch transport. For example, if the node is configured to use the JMS transport, use the following to switch to HTTP transport:
	`SET OutputLocalEnvironment.Destination.SOAP.Request.TransportType = 'http';`
	
	To switch to JMS transport:
	`SET OutputLocalEnvironment.Destination.SOAP.Request.TransportType = 'jms';`
	
	This overrides only the request transport for this message. The response transport is not changed from the property set on the SOAPAsyncResponse node.

Operation	Overrides the `Operation` property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Operation = 'myOperation';`
UserContext	You can store context data in the following location in the local environment. The SOAPAsyncResponse node can later retrieve this data. `SET OutputLocalEnvironment.Destination.SOAP.Request.UserContext = 'myData';`

LocalEnvironment overrides for HTTP transport:
You can set the following properties under LocalEnvironment.Destination.SOAP.Request.Transport.HTTP. These properties apply only when using HTTP transport.

You can switch between HTTP and JMS transport using the `TransportType` override, or the WS-Addressing `To` field; see "WS-Addressing information in the local environment" on page 1656.

Setting	Description
WebServiceURL	Overrides the `Web service URL` property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.WebServiceURL = 'http://ibm.com/abc/';`

Setting	Description
RequestURI	Overrides the RequestURI, which is the path after the URL and port. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.RequestURI = '/abc/def?x=y&g=h';`
Timeout	Overrides the Request timeout (in seconds) property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.Timeout = 42;` This is the time that the node waits to receive the HTTP 202 acknowledgment, rather than the time to wait for the associated Web service response.
ProxyURL	Overrides the HTTP(S) proxy location property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.ProxyURL = 'my.proxy';`
SSLProtocol	Overrides the SSLProtocol property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.SSLProtocol = 'TLS';` Valid values are: SSL, SSLv3, and TLS.
SSLCiphers	Overrides the Allowed SSL Ciphers (if using SSL) property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.SSLCiphers = 'SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA';`
HTTPVersion	Overrides the HTTPVersion. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.HTTPVersion = 'HTTP/1.1';`
Method	Overrides the Method. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.Method = 'GET';`

ProxyConnectHeaders	Specifies additional headers that are used if the outbound request is an SSL connection through a proxy. These additional headers are sent with the initial CONNECT request to the proxy. For example, you can send proxy authentication information to a proxy server when you are using SSL. You can send multiple headers but each one must be separated by a carriage return and a line feed (ASCII 0x0D 0x0A), in accordance with RFC2616; for example:
	`DECLARE CRLF CHAR CAST(X'0D0A' AS CHAR CCSID 1208);`
	`SET OutputLocalEnvironment.Destination.HTTP.ProxyConnectHeaders = 'Proxy-Authorization: Basic Zm5lcmJsZTpwYXNzd29yZA==' || CRLF || 'Proxy-Connection: Keep-Alive' || CRLF;`
	
	This setting is used only if the request is an SSL request through a proxy server. To send proxy authentication information for a non-SSL request, specify the individual headers in the HTTPRequestHeader folder, as shown in the following example:
	`SET OutputRoot.HTTPRequestHeader."Proxy-Authorization" = 'Basic Zm5lcmJsZTpwYXNzd29yZA==';`
	`SET OutputRoot.HTTPRequestHeader."Proxy-Connection" = 'Keep-Alive';`

Compression	Overrides the Use compression property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.Compression = 'gzip';`

Local environment overrides for JMS transport:
You can set the following JMS properties in the SOAPAsyncRequest node under LocalEnvironment.Destination.SOAP.Request.Transport.JMS. These properties apply only when using JMS transport.

You can switch between HTTP and JMS transport using the TransportType override, or the WS-Addressing To field; see "WS-Addressing information in the local environment" on page 1656.

Some JMS local environment overrides for the SOAPAsyncRequest node have equivalent properties in the JMSTransport header. If you specify a local environment override, it takes precedence over any equivalent property set in the JMSTransport header.

Setting	Description
CorrelationID	Sets the request message CorrelID. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.CorrelationID = 'myCorrelID';`
DeliveryMode	Overrides the DeliveryMode property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.DeliveryMode = 'NON_PERSISTENT';` Allowed values for this property are PERSISTENT and NON_PERSISTENT. If the UriFormat is ibm, 1 and 0 are additional allowed values for DeliveryMode.
Destination	Overrides the Destination property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.Destination = 'REPLYTOQ2';`
DestinationURI	You can override multiple JMS properties at the same time in the local environment using the DestinationURI setting. Properties that you set in this way can be overridden by setting local environment overrides for individual JMS properties as shown in the following tables. `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.DestinationURI = 'jms:jndi:INPUTQ1?jndiConnectionFactoryName=QCF& replyToName=REPLYTOQ2& jndiInitialContextFactory=com.sun.jndi.fscontext.RefFSContextFactory& jndiURL=file:/C:/Webservices/SOAP/JMS/JNDI& userParam1=value1& userParam2=value2& timeToLive=30000';` This local environment override can be set with either a W3C-style or IBM-style URI format. For more information, see "WSDL URI formats for JMS" on page 1668.
Expiration	Overrides the Expiration property on the node. This property is specified in milliseconds. For example, to set an expiration of 100 milliseconds: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.Expiration = '100';`
MessagePriority	Overrides the MessagePriority property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.MessagePriority = '7';`
MessageType	Overrides the MessageType property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.MessageType = 'text';` Allowed values for this property are textand bytes.
ProviderName	Overrides the JMS provider name property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.ProviderName = 'WebSphere MQ';`
TargetService	Overrides the TargetService property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.TargetService = 'testService';`

Setting	Description
TransactionMode	Overrides the Transaction mode property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.TransactionMode = 'Yes';` Allowable values for this property are Yes, No and ForceLocal. • No means that no transaction takes place, and is equivalent to None. • Yes means that a local transaction takes place if the flow's Coordinated Transaction is not selected, or a global transaction takes place if the flow's Coordinated Transaction property is selected. • ForceLocal means that a local transaction is always used, even if the flow's Coordinated Transaction property is selected.
UriFormat	Overrides the UriFormat property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.UriFormat = 'w3c';` Allowable values for this property are w3c and ibm.

Local environment overrides for JNDI

You can set the following JMS properties in the SOAPAsyncRequest node under LocalEnvironment.Destination.SOAP.Request.Transport.JMS.JNDI. These properties apply only when using JMS transport.

Setting	Description
BindingsLocation	Overrides the JNDI URL bindings location property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.JNDI.BindingsLocation = 'file:/C:/Webservices/SOAP/JMS/JNDI';`
ConnectionFactoryName	Overrides the Connection factory name property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.JNDI.ConnectionFactoryName = 'QCF';`

ContextParameters	Specify JNDI context parameters in addition to the JNDI context parameters defined on the node. You can define specific JNDI context parameters, for example:
	`SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.JNDI.ContextParameters.property1 = 'value1';`
	`SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.JNDI.ContextParameters.property2 = 'value2';`

InitialContextFactory	Overrides the Initial context factory property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.JNDI.InitialContextFactory = 'com.sun.jndi.fscontext.RefFSContextFactory';`

UserProperties	Specify user context parameters in addition to the user context parameters defined on the node. You can define specific user context parameters, for example:
	`SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.JNDI.UserProperties.property1 = 'value1';`
	`SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.JNDI.UserProperties.property2 = 'value2';`

Local environment overrides for WS-Addressing ReplyTo

You can set the following JMS WS-Addressing ReplyTo properties in the SOAPAsyncRequest node under

LocalEnvironment.Destination.SOAP.Request.Transport.JMS.AsyncReply. Set these properties if you want to override how the remote server locates the JNDI definitions for the response queue.

These properties apply only when using JMS transport. You can switch between HTTP and JMS transport using the TransportType override, or the WS-Addressing To field; see "WS-Addressing information in the local environment" on page 1656.

Setting	Description
BindingsLocation	Overrides the BindingsLocation property in the WS-Addressing ReplyTo. `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.AsyncReply.JNDI.BindingsLocation 'file:/C:/webservices/SOAP/JMS/JNDI';`
ConnectionFactoryName	Overrides the ConnectionFactoryName property in the WS-Addressing ReplyTo. `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.AsyncReply.JNDI.ConnectionFactory 'QCF';`

ContextParameters	Specify JNDI context parameters in the WS-Addressing ReplyTo. You can define specific JNDI context parameters, for example:
	`SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.AsyncReply.JNDI.ContextParameters 'value1';`
	`SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.AsyncReply.JNDI.ContextParameters 'value2';`

InitialContextFactory	Overrides the InitialContextFactory property in the WS-Addressing ReplyTo. `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.AsyncReply.JNDI.InitialContextFac 'com.sun.jndi.fscontext.RefFSContextFactory';`

Setting	Description
OneWay	Instructs the node that the inbound message was a one-way message and that no reply message is needed. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Gateway.OneWay = True` If the inbound message used HTTP transport, the node sends an acknowledgment HTTP 202 message. If the inbound message used JMS transport, no response is expected. The outbound message has no reply-to queue, and the node does not wait for a response. For more information, see "One-way messages in Gateway mode" on page 1648.

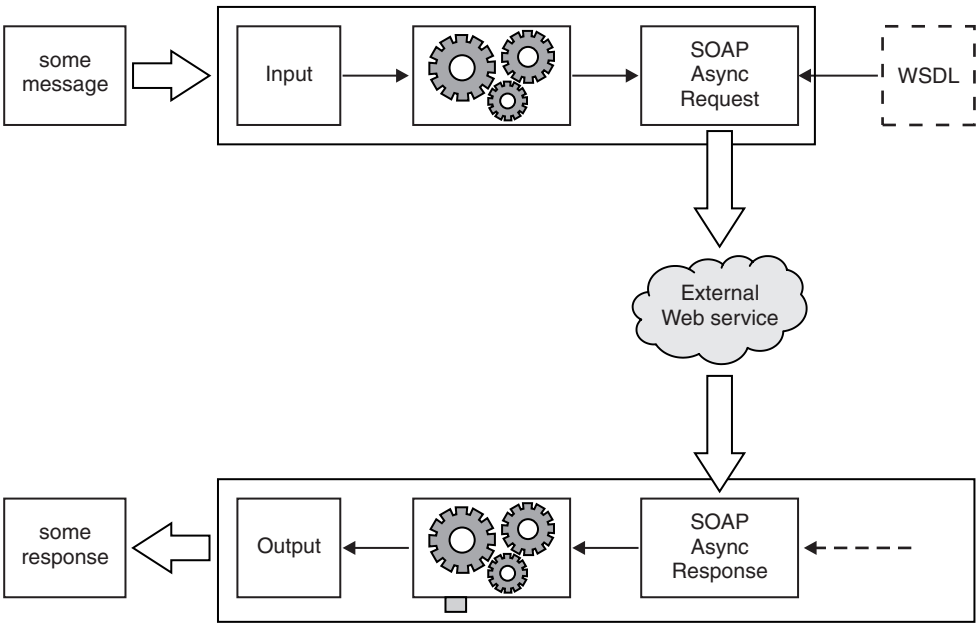
SOAPAsyncResponse node

Use the SOAPAsyncResponse node in conjunction with the SOAPAsyncRequest node to construct a pair of message flows that call a Web service asynchronously.

This topic contains the following sections:

Purpose:
The SOAPAsyncRequest node sends a Web service request, but the node does not wait for the associated Web service response to be received. However, the SOAPAsyncRequest node does wait for the HTTP 202 acknowledgment before continuing with the message flow, and the SOAPAsyncRequest node blocks if the acknowledgment is not received. The Web service response is received by the SOAPAsyncResponse node, which can be in a separate message flow. The nodes

are used as a pair, and correlate responses against the original requests.



The SOAP parser invokes the XMLNSC parser to parse the XML content of the SOAP Web service, and to validate the XML body of the SOAP Web service. The SOAP parser options are passed through to the XMLNSC parser. For more information, see “Manipulating messages in the XMLNSC domain” on page 2546.

The SOAPAsyncResponse node is contained in the **Web Services** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
Configuration of the SOAPAsyncResponse node is not WSDL-driven, although the 'must understand headers' list configured on the corresponding SOAPAsyncRequest node is applicable to the SOAPAsyncResponse node.

Most configuration options for this node are set on its paired SOAPAsyncRequest node, including the `Backout destination` and `Backout threshold` properties. No SOAP fault is sent when the backout threshold is reached.

You can retrieve context data that has been stored by the SOAPAsyncRequest node from the following location in the local environment:

```
LocalEnvironment.SOAP.Response.UserContext
```

The following sample demonstrates how to use the asynchronous SOAP nodes when you call a Web service. The Web service simulates an order service, and the client shows how existing WebSphere MQ interfaces can be extended to make Web service requests.

- Asynchronous Consumer

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

The SOAPAsyncResponse node can receive a response that has a Content-Encoding of gzip or deflate. When such a response is received, the content is decoded and the Content-Encoding header is removed.

Terminals and properties:
When you have put an instance of the SOAPAsyncResponse node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The SOAPAsyncResponse node terminals are described in the following table.

Terminal	Description
Failure	The output terminal to which an asynchronous SOAP response message is routed if a failure is detected when the message received is propagated to the Out flow (such as a message validation failure).
Out	The output terminal to which the asynchronous SOAP response message is routed if it has been successfully received, and if further processing is required in this message flow. If no errors occur in the node, a valid none fault SOAP response message received from an external resource is always sent to the Out terminal first.
Fault	The output terminal to which an asynchronous SOAP fault response is routed if it has been successfully received, and if further processing of the fault is required in this message flow.
Catch	The output terminal to which the message is routed if an exception is thrown downstream and caught by this node.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The SOAPAsyncResponse node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type: SOAPAsyncResponse	The name of the node.
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

The SOAPAsyncResponse node Basic properties are described in the following table.

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
Unique identifier	Yes	No		Specify the unique URL fragment that is common to your pair of SOAPAsyncRequest and SOAPAsyncResponse nodes.	asyncRequestCorrelator

The SOAPAsyncResponse node Transactions property is described in the following table. This setting does not apply when the node uses HTTP transport.

Property	M	C	Default	Description
Transaction mode	Yes	No	No	This property controls whether the message is received under a JMS transaction. Valid values are `Yes` and `No`. Select `No` to receive the message using a non-transactional JMS session. Select `Yes` to receive the message using a transactional JMS session. The JMS transaction can be either local or global. To use a global transaction, using an XA JMS session, you must also select the message flow property `Coordinated Transaction` in the BAR file properties. See "Configuring for coordinated JMS transactions" on page 4784.

The SOAPAsyncResponse node Advanced property is described in the following table.

Property	M	C	Default	Description
Set destination list	No	No	Selected	This property indicates whether to add the incoming SOAP operation to the route to label destination list.
Label prefix	No	No		Use this property to add a prefix to the SOAP Operation name in the destination list. You must add a `Label prefix` if you want to use multiple SOAPAsyncResponse nodes in the same message flow without causing their corresponding Label nodes to clash. By default, the prefix is an empty string so that the operation name and the label name are identical. This property is not available if the `Set destination list` property is cleared.
Place WS-Addressing headers into LocalEnvironment	No	No	Cleared	This property specifies whether the node puts WS-Addressing headers from the response message into the local environment tree. WS-Addressing headers are not accessible to the flow if this check box is cleared because by default, all headers are processed and removed.

The SOAPAsyncResponse node Instances properties are described in the following table.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Additional instances pool	No	Yes	`Use Pool Associated with Message Flow`	The pool from which additional instances are obtained. • If you select `Use Pool Associated with Message Flow`, additional instances are obtained from the message flow value. • If you select `Use Pool Associated with Node`, additional instances are allocated from the node's additional instances based on the number specified in the `Additional instances` property.	componentLevel
Additional instances	No	Yes	`0`	The number of additional instances that the node can start if the `Additional instances pool` property is set to `Use Pool Associated with Node`. By default, no additional instances are given to the node.	additionalInstances

The SOAPAsyncResponse node Response Message Parsing properties are described in the following table. The SOAPAsyncResponse node sets these properties automatically; you cannot set them yourself.

Property	M	C	Default	Description
Message domain	No	No	`SOAP`	The domain that is used to parse the response message. By default, the message that is propagated from the SOAPAsyncResponse node is in the SOAP domain. You cannot specify a different domain. For more information, see "SOAP parser and domain" on page 1082. The Response Message Parsing properties are ignored when the paired SOAPAsyncRequest node is configured to act in gateway mode.
Message set	Yes	No	Set automatically from the `WSDL file name` property that is provided by the SOAPAsyncRequest node.	The name of the message set in which the response message is defined. `Message set` is set automatically to the message set that contains the WSDL file that is configured on the corresponding SOAPAsyncRequest node. If you set this property, and then subsequently update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project. The Response Message Parsing properties are ignored when the paired SOAPAsyncRequest node is configured to act in gateway mode.
Message type	No	No		The name of the response message. The node detects the message type automatically. You cannot set this property.
Message format	No	No		The name of the physical format of the response message. You cannot set this property.

The SOAPAsyncResponse node Parser Options properties are described in the following table. The properties are passed through to the XMLNSC parser.

Property	M	C	Default	Description
Parse timing	No	No	`On Demand`	This property controls when a response message is parsed. Valid values are `On Demand`, `Immediate`, and `Complete`. By default, parse timing is set to `On demand`, which causes parsing of the input message to be delayed. For a full description of this property, see "Parsing on demand" on page 4173.
Build tree using XML schema data types	No	No	Selected	This property controls whether the XMLNSC parser creates syntax elements in the message tree with data types taken from the XML Schema. This property is ignored when the paired SOAPAsyncRequest node is configured to act in gateway mode.
Retain mixed content	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in a response message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in an response message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.

Property	M	C	Default	Description
Retain processing instructions	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in a response message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the response message that are to be opaquely parsed by the XMLNSC parser. Opaque parsing is performed only if validation is not enabled (that is, if `Validate` is `None`); entries that are specified in `Opaque Elements` are ignored if validation is enabled.

The SOAPAsyncResponse node Validation properties are described in the following table. By default, validation is enabled.

If a message is propagated to the Failure terminal of the node, it is not validated. For more details, see "Validating messages" on page 1478 and "Validation properties" on page 4169.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Validate	No	Yes	`Content and value`	This property controls whether validation takes place. Valid values are `None`, `Content and value`, and `Content`. Validation properties are ignored when the paired SOAPAsyncRequest node is configured to act in gateway mode.	validateMaster
Failure action	No	No	`Exception`	This property controls what happens if validation fails. You can set this property only if you set `Validate` to `Content` or `Content and value`. Valid values are `User trace`, `Exception list`, `Local error log`, and `Exception`. Validation properties are ignored when the paired SOAPAsyncRequest node is configured to act in gateway mode.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

LocalEnvironment overrides:
You can retrieve information that was set by the paired SOAPAsyncRequest node from the following property under LocalEnvironment.Destination.SOAP.Response :

Setting	Description
UserContext	You can retrieve context data that was stored by the SOAPAsyncRequest node from the following location in the local environment: `SET myVar = InputLocalEnvironment.Destination.SOAP.Response.UserContext;`

Related concepts:

"Message modeling" on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

"Parsers" on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

"SOAP parser and domain" on page 1082
You can use the SOAP parser to create a common WSDL-based logical tree format for working with Web services, independent of the physical bitstream format.

"XMLNSC parser" on page 1090
The XMLNSC parser is a flexible, general-purpose XML parser that offers high performance XML parsing and optional XML Schema validation.

Configure your message flow to receive or output messages under coordinated transactions.

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

"SOAPAsyncRequest node" on page 4750
Use the SOAPAsyncRequest node with the SOAPAsyncResponse node to construct a pair of message flows that call a Web service asynchronously.

"WS-Addressing with the SOAPAsyncRequest and SOAPAsyncResponse nodes" on page 1655
The remote Web service must understand WS-Addressing to be able to work with SOAPAsyncRequest and SOAPAsyncResponse nodes.

Configuring for coordinated JMS transactions:

Configure your message flow to receive or output messages under coordinated transactions.

When you include a node using JMS transport in a message flow, such as the JMSInput or SOAPInput node when using JMS transport, the value that you set for `Transaction mode` defines whether messages are received under sync point.

- If you set this property to `Global`, the message is received under external sync point coordination; that is, within a WebSphere MQ unit of work. Any messages that are sent later, by an output node in the same instance of the message flow, are put under sync point, unless the output node overrides this setting explicitly.
- If you set this property to `Local`, the message is received under the local sync point control of the node. Any messages that are sent later, by an output node in the flow, are not put under local sync point, unless an individual output node specifies that the message must be put under local sync point.
- If you set this property to `None`, the message is not received under sync point. Any messages that are sent later, by an output node in the flow, are not put under sync point, unless an individual output node specifies that the message must be put under sync point.

To receive messages under external sync point, you must take additional configuration steps, which need be applied only the first time that a specific node using JMS transport is deployed to the broker for a particular JMS provider.

- On distributed systems, the external sync point coordinator for the broker is WebSphere MQ. Before you deploy a message flow in which the `Transaction mode` property is set to `Global` or `Yes`, and is intended to use globally coordinated transactions, modify the queue manager `.ini` file to include extra definitions for each JMS provider resource manager that participates in globally coordinated transactions.
  - Windows On Windows:
    1. Start WebSphere MQ Explorer.
    2. Right-click the queue manager name in the left pane and click **Properties**.
    3. Click **XA resource managers** in the left pane.
    4. Click **Add...** .
    5. Set the options as follows:
       - Set `Name` to any value.
       - On Windows on x86 systems, set the `SwitchFile` property to *`install_dir`*`\bin\JMSSwitch.dll`. On Windows on x86-64 systems, set the `SwitchFile` property to `JMSSwitch.dll`.
       - Set the `XAOpenString` property to a string value as follows: *`Initial Context`*`,`*`location JNDI`*`,`*`Optional_parms`*.
       - Set the `ThreadOfControl` property to `Thread`.
    6. On Windows on x86-64 systems only, copy the switch file *JMSSwitch32.dll* to the `\exits` subdirectory in the WebSphere MQ installation directory, and rename it to `JMSSwitch.dll`. Copy the switch file `JMSSwitch.dll` to the `\exits64` subdirectory in the WebSphere MQ installation directory.

For more information, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

– Linux UNIX On Linux and UNIX systems, add a stanza to the queue manager `.ini` file for each JMS provider.

  For example:

```
XAResourceManager:
Name=Jms_Provider_Name
SwitchFile=/install_dir/bin/ JMSSwitch.so
XAOpenString=Initial Context,location JNDI,Optional_parms
ThreadOfControl=THREAD
```

  Where:

  Name is an installation defined name that identifies a JMS provider resource manager.

  SwitchFile
  is the file system path to the JMSSwitch library that is supplied in the `bin` directory of the broker.

XAOpenString can have the following values:

– *Initial Context* is the value that is set in the JMSInput node property `Initial context factory`.

– *location JNDI* is the value that is set in the JMSInput node property `Location JNDI bindings`. This value must include a supported URL prefix that has a URL handler that is available on the class path.

The following parameters are optional:

– `LDAP Principal` matches the value that is set for the broker by using the **mqsicreatebroker** or **mqsichangebroker** commands.

– `LDAP Credentials` matches the value that is set for the broker by using the **mqsicreatebroker** or **mqsichangebroker** commands.

– `Recovery Connection Factory Name` is the JNDI administered connection factory that is defined in the bindings file. If a value is not specified, you must add a default value for `recoverXAQCF` to the bindings file. In either case, the Recovery Connection Factory must be defined as an XA Queue Connection Factory for the JMS provider that is associated with the `Initial context factory`.

The optional parameters are comma-separated and are positional. Therefore, any parameters that are missing must be represented by a comma. For example:

```
com.sun.jndi.fscontext.RefFSContextFactory,file:/C:/webservices/SOAP/JMS/JNDIXA,,,QCF
```

1. Update the Java CLASSPATH environment variable for the queue manager of the broker to include a reference to `xarecovery.jar`; for example:

   install_dir`/classes/xarecovery.jar`

2. Update the Java PATH environment variable for the queue manager of the broker to point to the bin directory in which the SwitchFile is located; for example:

   install_dir`/bin`

Finally, ensure that you have taken the following configuration steps:

– In the message flow, ensure that the coordinated property is enabled by using the WebSphere Message Broker Archive editor.

– Ensure that each node that must be part of the XA transaction is set to the global transaction mode.

– Ensure that the service ID that is used for the broker and the queue manager is the same user ID.

– Ensure that the JNDI connection factory objects that the JMS nodes use for a global transaction are configured to be of the type MQXAConnectionFactory, MQXAQueueConnectionFactory, or MQXATopicConnectionFactory.
  - If you create the bindings using WebSphere Message Broker Explorer, ensure the `Support XA Transactions` option is checked when you define your connection factory.
  - If you create the bindings using JMSAdmin, use the command **DEF XAQCF** or **DEF XATCF**, instead of **DEF QCF** or **DEF TCF**, when you define your connection factory.

  For more information, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

- z/OS On z/OS, the external sync point manager is Resource Recovery Services (RRS). The only JMS provider that is supported on z/OS is WebSphere MQ JMS. The only transport option that is supported for WebSphere MQ JMS on z/OS is the bind option.

  Sync point control for the JMS provider is managed with RRS sync point coordination of the queue manager of the broker. You do not have to modify the `.ini` file.

SOAPEnvelope node

Use the SOAPEnvelope node to add a SOAP envelope onto an existing message. This node is designed to be used with the SOAPExtract node.

This topic contains the following sections:

Purpose:
The default behavior of the SOAPEnvelope node is to attach the SOAP envelope from a standard location ($LocalEnvironment/SOAP/Envelope) in the local environment tree; you can specify an explicit location by using an XPath expression.

You can also use the node in a flow without a corresponding SOAPExtract node; the node has an option to create a default SOAP envelope.

The SOAPEnvelope node is contained in the **Web Services** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using the SOAPEnvelope node in a message flow:
This node is designed to be used in conjunction with the SOAPExtract node; see "SOAPExtract node" on page 4790.

Configuring the SOAPEnvelope node:
When you have put an instance of the SOAPEnvelope node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

Supported parsers:
This node is designed to work with SOAP messages. Use one of the following parsers:

- XMLNSC
- MRM
- XMLNS

Other XML parsers are not supported because they do not support namespaces. An exception is thrown if a message is received which is not using the correct parser or does not conform to the basic structure of a SOAP message.

Full validation is not done on the SOAP message, which just needs to contain a body element.

As the SOAP domain is not supported by the SOAPEnvelope node, you cannot add the envelope extracted by the SOAPExtract node, from the SOAP domain, back into the message flow again; that is, a flow such as the following example is not supported:

```
SOAPInput node-> SOAPExtract node->SOAPEnvelope node
```

Example SOAP messages:
Incoming SOAP envelope

```
<?xml version="1.0"?>
<soapenv:Envelope
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:tns="http://ws3.st.mqsi.ibm.com/App/DocLiteral1"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
    <soapenv:Header>
        <tns:requestHeader>
            <tns:assessorUrl>header1</tns:assessorUrl>
        </tns:requestHeader>
    </soapenv:Header>
</soapenv:Envelope>
```

Incoming SOAP message body

```
<?xml version="1.0"?>
<tns:requestAvailability
xmlns:tns="http://ws3.st.mqsi.ibm.com/App/DocLiteral1"
xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
    <tns:carDetails>body1</tns:carDetails>
    <tns:claimID>body2</tns:claimID>
    <tns:location>body3</tns:location>
    <tns:reqDate>body4</tns:reqDate>
</tns:requestAvailability>
```

Outgoing SOAP message

```
<?xml version="1.0"?>
<soapenv:Envelope
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:tns="http://ws3.st.mqsi.ibm.com/App/DocLiteral1"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
    <soapenv:Header>
        <tns:requestHeader>
```

```
            <tns:assessorUrl>header1</tns:assessorUrl>
        </tns:requestHeader>
    </soapenv:Header>
    <soapenv:Body>
        <tns:requestAvailability>
            <tns:carDetails>body1</tns:carDetails>
            <tns:claimID>body2</tns:claimID>
            <tns:location>body3</tns:location>
            <tns:reqDate>body4</tns:reqDate>
        </tns:requestAvailability>
    </soapenv:Body>
</soapenv:Envelope>
```

Terminals and properties:
The terminals of the SOAPEnvelope node are described in the following table:

Terminal	Description
In	The input terminal that accepts a SOAP message for processing by the node.
Out	The output terminal that outputs the SOAP message that was constructed from the SOAP message body and a SOAP envelope.
Failure	The output terminal to which the message is routed if a failure is detected during processing.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the SOAPEnvelope node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the SOAPEnvelope node are described in the following table.

Property	M	C	Default	Description
Create new envelope	No	No	Cleared	This property controls whether the node creates a SOAP envelope, or gets an existing one from the message tree. If you select the check box, the node creates a new envelope. If you clear the check box, the node copies the envelope from the value entered in the `Existing Envelope Location` property.

Property	M	C	Default	Description
Existing Envelope Location	No	No	`$LocalEnvironment/SOAP/Envelope`	An XPath expression that represents the location from which the node will copy the SOAP envelope. The following correlation names are available: **`$Root`** The root of the message tree. **`$Body`** The last child of the root of the message tree (equivalent to /). **`$LocalEnvironment`** The root of the local environment tree. **`$Environment`** The root of the global environment tree.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

"SOAP nodes" on page 1609

“Handling errors in message flows” on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

Related reference:

“SOAPExtract node”
Use the SOAPExtract node to remove SOAP envelopes, allowing just the body of a SOAP message to be processed. It can also route a SOAP message based on its operation name. Both functions are optional; they are contained in one node because they are often used together.

“Parsing on demand” on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

SOAPExtract node

Use the SOAPExtract node to remove SOAP envelopes, allowing just the body of a SOAP message to be processed. It can also route a SOAP message based on its operation name. Both functions are optional; they are contained in one node because they are often used together.

This topic contains the following sections:
- “Purpose”
- “Using the SOAPExtract node in a message flow” on page 4791
- “Configuring the SOAPExtract node” on page 4791
- “Supported parsers” on page 4791
- “Terminals and properties” on page 4792
- “Example SOAP messages” on page 4793

Purpose:
The SOAPExtract node can perform two functions:

`Extract function`
The default behavior is to detach the SOAP envelope to a standard location ($LocalEnvironment/SOAP/Envelope) in the LocalEnvironment tree. Alternatively, you can specify an explicit location using an XPath expression. Any existing SOAP envelope at the chosen location is replaced.

`Routing function`
The SOAP message is routed to a Label node in the message flow as identified by the SOAP operation in the message. The SOAP Operation is identified in the SOAP body tag.

Ensure that the message parser options in the properties folder of the outgoing message are correctly set up to parse the message, by copying the message set and message format from the incoming message. The message type is derived from the SOAP envelope message body first child.

Only a single child of the SOAP message body is supported.

The SOAPExtract node is contained in the **Web Services** drawer of the palette, and is represented in the workbench by the following icon:

Using the SOAPExtract node in a message flow:
Look at the following sample to see how to use this node:

- SOAP Nodes

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Configuring the SOAPExtract node:
When you have put an instance of the SOAPExtract node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

1. Optional: On the **Description** tab, enter a `Short description`, a `Long description`, or both. You can also rename the node on this tab.
2. On the **Basic** tab:
   a. Specify in `Remove envelope` whether the node must remove the soap envelope and place it in the location given in `Envelope Destination`, or leave it on the message. The default value is that the node removes the envelope.
   b. In `Envelope Destination`, enter an XPath expression that represents the destination to which the node will copy the envelope. By default, the node copies the envelope to the LocalEnvironment ($LocalEnvironment/SOAP/Envelope).
   c. In `Destination path mode`, specify the behavior of the Envelope Destination property.
      - `Create path`: The node creates the tree if the path specifies a location that does not already exist. Only simple expressions of the form `aaa/bbb/ccc` in `Envelope Destination` are supported. The default.
      - `XPath location of existing element`: If you know that the destination element exists, you can use any valid XPath 1.0 expression in `Envelope Destination`.
   d. In `Route to 'operation' label`, specify whether the node must route the message to the SOAP operation given in the message. The default setting is for the node to send the message to the Out terminal.
   e. In `Label Prefix`, enter the value to prefix to the label used for routing by the node. Entering a prefix allows for name spacing between subflows. By default, no value is prefixed to the label name used for routing the message.

Supported parsers:
This node is designed to work with SOAP messages. Use one of the following parsers:

- SOAP
- XMLNSC
- MRM
- XMLNS

Other XML parsers are not supported because they do not support namespaces. An exception is thrown if a message is received which is not using the correct parser or does not conform to the basic structure of a SOAP message.

Full validation is not done on the SOAP message, which just needs to contain a body element.

Terminals and properties:
The terminals of the SOAPExtract node are described in the following table:

Terminal	Description
In	The input terminal that accepts a SOAP message for processing by the node.
Out	The output terminal that outputs the SOAP message body (without the envelope if the `Remove envelope` check box is selected on the node properties).
Failure	The output terminal to which the message is routed if a failure is detected during processing.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the SOAPExtract node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the SOAPExtract node are described in the following table.

Property	M	C	Default	Description
Remove envelope	No	No	Selected	If you select the check box, the node removes the SOAP header from the message. For a SOAP tree, the node outputs to the Out terminal the first child of SOAP.body from the SOAP tree. It outputs to `Envelope Destination` the full SOAP tree minus the first child of SOAP.body. If you clear the check box, the node leaves the envelope on the message. In the case of a SOAP tree, the full tree is propagated to the Out terminal.

Property	M	C	Default	Description
Envelope Destination	No	No	`$LocalEnvironment/SOAP/Envelope`	An XPath expression that represents the destination to which the node will copy the SOAP envelope. The following correlation names are available: **`$Root`** The root of the message tree. **`$Body`** The last child of the root of the message tree (equivalent to /). **`$LocalEnvironment`** The root of the LocalEnvironment tree. **`$Environment`** The root of the Global Environment tree.
Destination path mode	No	No	`Create path`	This determines the behavior of the `Envelope Destination` property. Set this property: **`Create path`** The default. The tree is created if the path specifies a location that does not exist. Only simple expressions of the form `aaa/bbb/ccc` are supported. **`XPath location of existing element`** If you know that the destination element exists, you can enter any valid XPath 1.0 expression.
Route to 'operation' label	No	No	Cleared	This property determines whether the node must route the message to the SOAP operation given in the message. If you select the check box, the message is routed to a Label node that matches the SOAP operation. An exception is thrown if no Label node matches. The name of the first child element of the SOAP body is used to determine the RouteToLabel name. For the 'RPC literal' and 'wrapped doc literal' WSDL types, this is the 'operation' name. For a SOAP tree, the first child of SOAP.Body supplies the operation name. If you clear the check box, the node sends the message to the Out terminal.
Label Prefix	No	No		The value to prefix to the label that the node uses for routing. Entering a prefix allows for name spacing between subflows.

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Example SOAP messages:

Incoming SOAP message

```
<?xml version="1.0"?>
<soapenv:Envelope
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:tns="http://ws3.st.mqsi.ibm.com/App/DocLiteral1"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
    <soapenv:Header>
    <tns:requestHeader>
        <tns:assessorUrl>header1</tns:assessorUrl>
    </tns:requestHeader>
    </soapenv:Header>
    <soapenv:Body>
        <tns:requestAvailability>
            <tns:carDetails>body1</tns:carDetails>
            <tns:claimID>body2</tns:claimID>
            <tns:location>body3</tns:location>
            <tns:reqDate>body4</tns:reqDate>
        </tns:requestAvailability>
    </soapenv:Body>
</soapenv:Envelope>
```

De-enveloped message

The operation name is requestAvailability. Note that the namespacing is removed from the operation.

```
<?xml version="1.0"?>
<tns:requestAvailability
xmlns:tns="http://ws3.st.mqsi.ibm.com/App/DocLiteral1"
xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
    <tns:carDetails>body1</tns:carDetails>
    <tns:claimID>body2</tns:claimID>
    <tns:location>body3</tns:location>
    <tns:reqDate>body4</tns:reqDate>
</tns:requestAvailability>
```

Removed envelope

```
<?xml version="1.0"?>
<soapenv:Envelope
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:tns="http://ws3.st.mqsi.ibm.com/App/DocLiteral1"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
    <soapenv:Header>
        <tns:requestHeader>
            <tns:assessorUrl>header1</tns:assessorUrl>
        </tns:requestHeader>
    </soapenv:Header>
</soapenv:Envelope>
```

SOAPInput node

Use the SOAPInput node to process client SOAP messages, so that the broker operates as a SOAP Web Services provider.

This topic contains the following sections:

Purpose:

The SOAPInput node is typically used with the SOAPReply node, which can be included in the same message flow, or a different flow in the same execution group.

You can connect a SOAPReply node to the Out terminal to handle successful responses. If you also want your message flow to handle reply processing after a timeout, connect a SOAPReply node to the HTTP Timeout terminal.

You cannot use an HTTPReply node to respond to a Web service request that is received by a SOAPInput node; the broker raises an exception when the reply is attempted.

If you choose to handle HTTP messages by using the execution group listener, you must carefully check the URL specifications in your HTTPInput and SOAPInput nodes. If both URL specifications match an incoming message, the wrong type of node might get the message, and processing might fail or produce unexpected results. This situation occurs if you specify identical values for the Path suffix for URL properties of the HTTPInput node and the SOAPInput node. It can also occur if you use wildcards in either or both specifications, and an incoming message matches both properties.

The SOAPInput node is contained in the **Web Services** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
The SOAPInput node can be used in a message flow that accepts and processes SOAP messages. The node is configured using deployable WSDL. Look at the following sample to see how to use this node:

- SOAP Nodes

A client can send an HTTP GET to the web service endpoint exposed by the SOAPInput node, suffixed with a query string `?wsdl`, and receive a response with the WSDL definition used to configure the flow; see "Using WSDL to configure message flows" on page 1664.

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

A client can send a request that has a Content-Encoding of gzip or deflate. When such a request is received the content is decoded and the Content-Encoding header is removed.

Using port numbers when deploying a SOAPInput node to an execution group:
When processing HTTP messages, you can use either the broker-wide listener or execution group (embedded) listeners for your HTTP message flows. See "HTTP listeners" on page 1589. However, SOAP nodes always use the embedded listener.

Each execution group that contains a SOAPInput node has one listener and two ports, an HTTP port and an HTTPS port. The default SOAP node port numbers are 7800 for HTTP and 7843 for HTTPS. If you deploy the flow to multiple execution groups, the port number is incremented by one for each successive deployment. The message flow that is deployed to the first execution group receives requests on port 7800 (by default), the next one uses port 7801, and so on, up to the specified

limit of 7842. In this scenario, you typically use an intermediary router that listens on one port, then distributes the requests across the range of ports that you are using.

If you do not want the port to be allocated dynamically, you can define a specific port by using the **mqsichangeproperties** command. You can also change the default range of port numbers by using this command.

Connecting the terminals:
The SOAPInput node routes each message that it retrieves successfully to the Out terminal. If message validation fails, the message is routed to the Failure terminal; you can connect nodes to this terminal to handle this condition. If you have not connected the Failure terminal, the message is discarded, the `Maximum client wait time` expires, and an error is returned to the client.

If the message is caught by this node after an exception has been thrown further on in the message flow, the message is routed to the Catch terminal. If you have not connected the Catch terminal, the message is discarded, the `Maximum client wait time` expires, and an error is returned to the client.

If the Maximum client wait time expires, by default, the listener sends a SOAP fault message to the client, indicating that its timeout has expired. If you have connected the HTTP Timeout terminal, and you are using the HTTP transport, the SOAP Fault message is propagated through the HTTP Timeout terminal. You must include a SOAPReply node in the sequence of nodes connected to the HTTP Timeout terminal and this node must send a valid SOAP Fault message. The listener waits again for the interval defined by the `Maximum client wait time (sec)` property, or for 10 seconds, whichever is the shorter interval:

- If a response is received before this second interval expires, the listener propagates the response to the client.
- If a response is not received before this second interval expires, the listener sends a SOAP fault message to the client, indicating that its timeout has expired.

Because the listener waits for only a brief interval after the message has been propagated through the HTTP Timeout terminal, you must ensure that the sequence of nodes that you connect to the HTTP Timeout terminal includes a SOAPReply node, which sends a response before this interval expires. If you have connected the HTTP Timeout terminal, but you are not using the HTTP transport, the message is not propagated through the HTTP Timeout terminal. The listener sends a SOAP fault message to the client, indicating that its timeout has expired.

Terminals and properties:
The SOAPInput node terminals are described in the following table.

Name	Type	Description
Failure	Output data	The output terminal to which a SOAP message is routed if a failure is detected when the message received is propagated to the Out terminal (such as a message validation failure).
Out	Output data	The output terminal to which the SOAP message is routed when it is received successfully and if further processing is required in this message flow. If no errors occur in the input node, a valid SOAP message that is received from an external resource is always sent to the `Out` terminal first.

Name	Type	Description
HTTPTimeout	Output data	The output terminal to which a timeout SOAP fault message is routed if the SOAPReply node that is connected to the Out terminal does not respond within the time interval specified by the Maximum client wait time property. This terminal is used only if the message is sent across the HTTP transport, and WS-RM is not being used.
Catch	Output data	The output terminal to which the message is routed if an exception is thrown downstream and is caught by this node.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

Some SOAPInput node properties are initially set from properties in the imported WSDL. These properties are parsed differently depending on which URI format is used by the `address` element in the WSDL. For details, see "WSDL URI formats for JMS" on page 1668.

The following Retry properties are no longer available on the SOAPInput node:

- Retry mechanism
- Retry threshold
- Short retry interval
- Long retry interval

When a SOAP over HTTP message fails, a SOAP fault is sent back to the client; the message exchange pattern is complete and no message exists to retry. When a SOAP over JMS message fails, retry processing is handled according to the backout properties defined on the JMS Transport tab.

The SOAPInput node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type; SOAPInput	The name of the node.
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

The SOAPInput node Basic properties are described in the following table.

Property	M	C	Default	Description
Operation mode	Yes	Yes	`Specify WSDL interface to expose`	This property allows you to specify the operation mode of the node, which determines whether it acts in WSDL mode or in gateway mode. In WSDL mode, the node performs operations according to the WSDL it is configured with. However, gateway mode allows you to configure your flow to handle generic SOAP request/response and one-way messages, or to act as a façade between multiple web services clients and multiple back-end web services providers. **Specify WSDL interface to expose** Configure the node with a deployable WSDL by setting the WSDL file name property or by dragging a WSDL onto the node. This is the default option. **Operate in gateway mode** Configure the node to act in gateway mode with no WSDL required. See "Gateway operation mode for SOAP nodes" on page 1645 for a fuller explanation of gateway mode.
WSDL file name	Yes	No	None	This property indicates the location of the WSDL file that you want to use to configure the node. Enter the full path to the WSDL file, or click **Browse** to locate the WSDL file in your workspace. When you select a WSDL file for the `WSDL file name` property, the WSDL is validated to ensure that it is WS-I compliant. If the WSDL has a binding using SOAP/JMS which is not WS-I compliant, by default no error is shown. To enable strict WS-I validation and display a warning when a SOAP/JMS transport is used, click **Window** > **Preferences** > **Broker Development** > **Message Sets** > **Validation** and clear the **WS-I BP 1.1: Allow SOAP/JMS as transport URI** check box. Only deployable WSDL files can be used to configure the SOAP nodes. After a valid WSDL file is selected, the message set project to which the WSDL file belongs is added as a referenced project to the corresponding message flow project, if the reference does not exist. If the WSDL file is not valid, or an incorrect file name is entered, an error message is displayed in the Properties view and all WSDL properties are blank. If the node was created by dropping a WSDL file from a message set onto the Message Flow editor, this property is preset to the name of the WSDL file. This property takes a string value. The following situations result in an error condition: • The WSDL file does not belong to a • message set project, or the WSDL file was not imported correctly; for more details, see "Importing from WSDL" on page 2946 and "Importing WSDL definitions from the command line" on page 2948. • The WSDL file contains no HTTP or JMS bindings. • The WSDL file contains no port type. • The WSDL file that is specified in the field does not exist. WSDL properties are disabled when the node is configured to act in gateway mode.

Property	M	C	Default	Description
Port type	Yes	No	The first `Port type` found in the WSDL file (that has an associated HTTP binding with it).	This property lists all the port types that are defined by the specified WSDL file. By default, the first port type found in the WSDL file that has an associated HTTP or JMS binding is selected. This property takes a string value. The following situation causes an error condition: • The selected `Port type` does not contain at least one operation. When you save the message flow file, validation of some of the WSDL-related properties occur to ensure that: • The WSDL file exists in the message set. • The selected `Port type`, `Binding operation`, and `Service port` are all valid in the content of the selected WSDL file. If one or more of these conditions are not met, an error is generated, and you cannot add a message flow that contains this SOAPInput node to a broker archive (BAR) file. WSDL properties are disabled when the node is configured to act in gateway mode.
Imported binding	Yes	No		The `Imported binding` property lists the imported SOAP bindings associated with the selected port type. Only HTTP or JMS transport is supported. When you select a binding, the property tab for the associated transport is enabled; otherwise, it is disabled. Bindings are listed in the order in which they are displayed in the WSDL file. By default, the first imported binding that implements the operation, and has an associated service port, is selected. This property is updated every time the `Port type` value changes. This property type is String. The following situations cause an error condition: • No imported SOAP bindings (with HTTP or JMS transport) in the WSDL file are associated with the `Port type`. • The selected binding does not have any operations. WSDL properties are disabled when the node is configured to act in gateway mode.
Service port	Yes	No		The `Service port` field lists all the service ports that point to the selected binding. By default, the first service port for the binding is selected. This property is updated every time the selected binding value changes. This property type is String. The following situation causes an error condition: • No ports point to the selected binding. WSDL properties are disabled when the node is configured to act in gateway mode.
Target namespace	Yes	No		This property displays the namespace of the selected WSDL file. This property type is String. WSDL properties are disabled when the node is configured to act in gateway mode.

Property	M	C	Default	Description
Transport	No	No		This property is set automatically when the `Imported binding` property is selected. The value of this property shows the transport used by the selected WSDL binding if one is selected; for example, `HTTP` or `JMS`. If you choose to switch the transport from `JMS` to `HTTP`, a dialog box displays, which allows you to reset the JMS-specific properties. You must reset the JMS properties to deploy the message flow to a runtime environment version prior to fix pack V7.0.0.1.

The SOAPInput node HTTP Transport properties are described in the following table. These settings are used only when the node uses HTTP transport.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Path suffix for URL	Yes	Yes	None	`Path suffix for URL` is the HTTP path selector on which the node accepts inbound messages. This property is set automatically from the `<soap:address>` element of the selected `Service port`. Whenever the selected port is updated, `URL Selector` is updated accordingly. However, if you override this value, your value persists, and the URL is no longer updated from the service port. If you choose to override this property, you must specify the [<path>]. If you configure the same HTTP path for nodes in multiple message flows, an inbound request to that endpoint might be processed by any of those message flows. If the message flows are configured differently, they process the message differently and so this can lead to unpredictable behavior. If you require additional resources for a single HTTP path, you can configure additional instances instead of creating multiple message flows. For more information, see “Configurable message flow properties” on page 4020.	urlSelector

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Use HTTPS	No	Yes	Cleared	This property type is Boolean and is configured automatically from the `<soap:address>` element of the selected `Service port`. If the address contains an HTTPS URL, the check box is selected; otherwise it is cleared. However, if you manually override this property value, it is no longer updated from the corresponding service port. To enable the HTTPS protocol when this property is selected, perform the following steps: 1. Create a new key store of type "jks" and choose a password. 2. Create a new self signed certificate with a label of your choice. 3. Run the following command: **mqsichangeproperties** *brokername* `-o BrokerRegistry -n brokerKeystoreFile -v` *keystoreFile* 4. Run the following command: **mqsichangeproperties** *brokername* `-o BrokerRegistry -n brokerTruststoreFile -v` *keystoreFile* 5. Run the following command: **mqsisetdbparms** *brokername* `-n brokerKeystore::password -u na -p` *keystorePassword* 6. Run the following command: **mqsisetdbparms** *brokername* `-n brokerTruststore::password -u na -p` *keystorePassword* 7. Deploy your message flow to the broker. 8. This process uses TLS rather than SSL. To enable SSL, run the following command: **mqsichangeproperties** *brokername* `-e` *executionGroup* `-o HTTPSConnector -n sslProtocol -v SSL`. If your flow uses a SOAPRequest node, you should also change the value of the `Protocol` property on the SOAPRequest node.	useHTTPS

Property	M	C	Default	Description	mqsiapplybaroverride command property
Maximum client wait time (sec)	Yes	Yes	180	The time that the client waits for a remote server to respond with a "message received" acknowledgment. The valid range is zero (which means a short wait) through (2^{31})-1. This property specifies the maximum length of time that the TCP/IP listener that received the input message from the Web service client waits for a response from a SOAPReply node. If a response is received within this time, the listener propagates the response to the client. If a response is not received in this time, a SOAP fault message is generated indicating that the timeout has expired. This fault message is either sent by the listener or when using the HTTP transport, the timeout terminal processing. See the "Connecting the terminals" on page 4797 and "Terminals and properties" on page 4797 sections for more information on the HTTP Timeout terminal.	maxClientWaitTime
Enable support for ?wsdl	N	Y	Cleared	If this property is selected, the broker returns WSDL and XML Schema information relating to this endpoint in response to an HTTP GET request with a `?wsdl` query string. This allows you to control the distribution of your WSDL. For a full description, see "Using WSDL to configure message flows" on page 1664. This property is disabled when the node is configured to act in gateway mode.	

The SOAPInput node JMS Transport properties are described in the following table. These settings are used only when the node uses JMS transport

Property	M	C	Default	Description	mqsiapplybaroverride command property
Source	Yes	No	None	The name of the queue from which the node receives incoming messages. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `Source` is set to the value of `destinationName` found in the WSDL if a W3C-style URI is found, or `destination` if an IBM-style URI is found.	source
JMS provider name	Yes	No	`WebSphere MQ`	Select a JMS vendor name from the list, or enter a name of your choice. When you select a name from the list, the `Initial context factory` property is updated automatically with the relevant Java class. If you enter your own JMS provider name, you must also enter a value for the `Initial context factory`. The name must match the name of a configurable service that is defined for the broker to which you deploy the message flow.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Initial context factory	Yes	Yes	com.sun.jndi.fscontext.RefFSContextFactory	The starting point for a JNDI namespace. A JMS application uses the initial context to obtain and look up the connection factory and queue or topic objects for the JMS provider. If you select a JMS provider name from the list in JMS provider name, the Initial context factory property is updated automatically with the relevant Java class. If you enter your own JMS provider name, you must also enter a value for the Initial context factory. The default value is com.sun.jndi.fscontext.RefFSContextFactory, which defines the file-based Initial context factory for the WebSphere MQ JMS provider. This property takes its initial value from a WSDL URI property, depending on whether the WSDL address URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. Initial context factory is set to the value of jndiInitialContextFactory found in the WSDL if a W3C-style URI is found, or initialContextFactory if an IBM-style URI is found.	initialContextFactory

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
JNDI URL bindings location	Yes	Yes		The system path or the LDAP location for the bindings file. The bindings file contains definitions for the JNDI administered objects that are used by the SOAPInput node. This property is disabled when the `Initial context factory` is `com.ibm.mq.jms.Nojndi`. When you enter a value for `JNDI URL bindings location`, ensure that it complies with the following instructions: • Construct the bindings file before you deploy a message flow that contains a SOAPInput node. • Do not include the file name of the bindings file in this field. • If you have specified an LDAP location that requires authentication, configure the LDAP principal (userid) and LDAP credentials (password) separately. These values are configured at broker level. For information about configuring these values, see "**mqsicreatebroker** command" on page 3831 and "**mqsichangebroker** command" on page 3723. • The string value must include a supported URL prefix that has a URL handler that is available on the classpath. For information about constructing the JNDI administered objects bindings file, see the JMS provider documentation. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `JNDI URL bindings location` is set to the value of `jndiURL` found in the WSDL if a W3C-style URI is found, or `jndiProviderURL` if an IBM-style URI is found.	locationJndiBindings
Connection factory name	Yes	Yes		The name of the connection factory that is used by the SOAPInput node to create a connection to the JMS provider. This property is initially configured from the imported WSDL. This name must exist in the bindings file. The `Connection factory name` must be a JMS QueueConnectionFactory. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `Connection factory name` is set to the value of `jndiConnectionFactoryName` found in the WSDL if a W3C-style URI is found, or `connectionFactory` if an IBM-style URI is found.	connectionFactoryName

Property	M	C	Default	Description	mqsiapplybaroverride command property
Backout destination	No	Yes		The SOAPInput node sends input messages to this destination when errors prevent the message flow from processing the message, and the message must be removed from the input destination. The backout destination name must exist in the bindings file.	backoutDestination
Backout threshold	No	Yes	0	The value that controls when a message is put to the backout destination. For example, if the value is 3, the JMS provider attempts to deliver the message to the input destination three times. After the third attempted delivery, the message is not rolled back to the input destination and is sent to the `Backout destination`. A SOAP fault is sent only when the backout threshold has been reached. See "Configuring the backout threshold property" on page 4816.	
JNDI context parameters	No	No		A table that maps JNDI context parameters to their type. These properties are initially configured from the imported WSDL. These properties take their initial values from any W3C-style WSDL properties starting with `jndi-`. IBM-style WSDL URIs do not support JNDI context parameters, but you can set these properties on the node.	

The SOAPInput node Message Selectors properties are described in the following table. This tab is enabled only if the selected binding in the Basic tab uses JMS transport.

For a description of how to construct the JMS message selector, see JMS message selector.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Application property	No	Yes		The message selector that filters messages according to the application property value. If the JMS provider is required to filter messages, based on message properties that are set by the originating JMS client application, enter a selector string for `Application property`, specifying both the property name and the selection conditions; for example, `OrderValue > 200`. Leave `Application property` blank if you do not want the input node to make a selection based on application property.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Timestamp	No	Yes		The message selector that filters messages according to the JMSTimestamp. If the JMS provider is required to filter messages that have been generated at specific times, enter a selector string for `Timestamp`, where the value is an unqualified Java millisecond time; for example, `105757642321`. Qualify the selector with operators, such as `=`, `BETWEEN` or `AND`. Leave `Timestamp` blank if you do not want the input node to make a selection based on the JMSTimeStamp.	
Delivery mode	No	Yes	`All`	The message selector that filters messages according to the message delivery mode. If the JMS provider is required to filter messages based on the JMSDeliveryMode header value in the JMS messages, select an option for `Delivery mode` from the list: • Select `Non Persistent` to receive messages that are marked as non-persistent by the originating JMS client application. • Select `Persistent` to receive messages that are marked as persistent by the originating JMS client application. • Select `All` to receive both persistent and non-persistent messages. (This value is the default.) This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `Delivery mode` is set to the value of `deliveryMode` found in the WSDL if a W3C-style URI is found, or to the first of `deliveryMode` or `persistence` if an IBM-style URI is found.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Priority	No	Yes		The message selector that filters messages according to the message priority. If the JMS provider is required to filter messages based on the JMSPriority header value in the JMS message, enter a selector string for `Priority`. Valid values for `Priority` are from `0` (lowest) to `9` (highest). For example, enter `= 5` to receive messages of priority 5, `> 4` to receive messages with a priority greater than 4, or `BETWEEN 4 AND 8` to receive messages with a priority in the range 4 - 8. Leave `Priority` blank if you do not want the input node to make a selection based on the JMSPriority. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `Priority` is set to the value of `priority` found in the WSDL if a W3C-style URI is found, or to the first of `priority` or `Priority` if an IBM-style URI is found.	
Message ID	No	Yes		The message selector that filters messages according to the message ID. If the JMS provider is required to filter messages based on the JMSMessageID header, enter a selector string for `Message ID`. For example, enter `> WMBRK123456` to return messages where the `Message ID` is greater than `WMBRK123456`. Leave `Message ID` blank if you do not want the input node to make a selection based on JMSMessageID.	
Redelivered	No	Yes		If the JMS provider is required to filter messages based on the JMSRedelivered header, enter a selector string for `Redelivered`: • Enter `= FALSE` if the input node accepts only messages that have not been redelivered by the JMS provider. • Enter `= TRUE` if the input node accepts only messages that have been redelivered by the JMS provider. • Leave `Redelivered` blank if you do not want the input node to make a selection based on JMSRedelivered.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Correlation ID	No	Yes		The message selector that filters messages according to the correlation ID. If the JMS provider is required to filter messages based on the JMSCorrelationID header, enter a selector string for `Correlation ID`. For example, `= WMBRKABCDEFG` returns messages with a `Correlation ID` that matches this value. Leave `Correlation ID` blank if you do not want the input node to make a selection based on JMSCorrelationID.	
Target service	No	No		This property is configured from the value of the `targetService` property found in the JMS endpoint location URL that is contained in the port section of the WSDL. The SOAP/JMS message will be read from the source queue only if the message has a `targetService` value that matches the value defined on the node. This value is used by the server component to determine the port component to which the request is dispatched. This property takes its initial value from the `targetService` WSDL property.	targetService

The SOAPInput node Transactions properties are described in the following table. This setting does not apply when the node is using HTTP transport.

Property	M	C	Default	Description
Transaction Mode	Yes	No	No	This property controls whether the message is received under a JMS transaction. Valid values are `Yes` and `No`. Select `No` to receive the message using a non-transactional JMS session. Select `Yes` to output the message using a transactional JMS session. The JMS transaction can be either local or global. To use a global transaction, using an XA JMS session, you must also select the message flow property `Coordinated Transaction` in the BAR file properties. See “Configuring for coordinated JMS transactions” on page 4817. The value set for `Transaction mode` on the SOAPInput node is inherited by nodes downstream in the message flow that have their `Transaction mode` set to `Automatic`. Other resources that perform work within the message flow, such as DB2 or WebSphere MQ, use transactions regardless of the node's `Transaction mode` setting, and commit their transaction after the message is processed.

The SOAPInput node Advanced properties are described in the following table.

Property	M	C	Default	Description	
SOAP 1.1 actor (SOAP 1.2 role)	Yes	No	`Ultimate Destination (Ultimate Receiver)`	Use this property to configure the SOAP actor (SOAP 1.1 protocol) or SOAP role (SOAP 1.2 protocol) that is performed by the SOAPInput node. The default value is `Ultimate Destination (Ultimate Receiver)`. (`Ultimate Destination` relates to SOAP 1.1 and `Ultimate Receiver` relates to SOAP 1.2). You can enter any predefined or user-defined value. Predefined roles are specified in the respective SOAP 1.1 or SOAP 1.2 specifications, and are used to process SOAP headers that are targeted at the specific role. If you select `empty`, an error occurs when the message flow is validated. This property takes a string value.	
Set destination list	No	No	Selected	This property specifies whether to add the method binding name to the route-to-label destination list. If you select this check box, the method binding name is added so that you can use a RouteToLabel node in the message flow after the SOAPInput node. This property type is Boolean.	
Label prefix	No	No	None	The prefix to add to the method name when routing to label. Add a `Label prefix` to avoid a clash of corresponding label nodes when you include multiple input nodes in the same message flow. By default, no label prefix exists; therefore, the method name and label name are identical. The default prefix is an empty string so that the operation name and the label name are identical, but the field displays the user instruction: `<enter a prefix if required>`. This property is enabled only if the `setDestinationList` property is enabled.	

Property	M	C	Default	Description	
Route inbound processing failures to failure terminal	No	Yes	Cleared	Select this check box to send any fault to the Failure terminal during inbound SOAP processing. If this property is selected, in a situation during inbound SOAP processing that results in a SOAP fault, instead of immediately sending the SOAP fault back to the client, the fault is sent to the Failure terminal instead to allow logging and recovery processing. In this situation, an exception list is sent to the Failure terminal with the inbound message as a BLOB. By default, this check box is cleared.	sendProcessingFaultsToFailure
WSDL defined SOAP headers	No	No		This table is read-only and is populated by the SOAP headers that are defined in the output part of the selected operations. The table is updated automatically when the selected operation is updated. By default, the check boxes in the second column of the table are cleared for all entries in the WSDL-defined table. You must select the check boxes for those headers that you want to add to the `must understand headers` list. SOAP headers that are part of the must understand headers list are incorporated into the flow rather than causing a SOAP fault. Adding headers to the `must understand headers` list stops SOAP faults being generated by SOAP headers. You do not have to add `must understand headers` for WS-Addressing and WS-Security because these elements are understood if you configure WS Extensions. This property is generated in the CMF file. When the node is configured to act in gateway mode, with no WSDL required, this table is cleared. The original values of these fields are restored if the operation mode of the node is changed back to WSDL mode.	

Property	M	C	Default	Description	
User defined SOAP headers	No	Yes	None	You can add custom headers in this table. Use the **Add**, **Edit** and **Delete** controls to manipulate rows in this table. You must ensure that the check box for the custom header you have added is selected (in the second column of the table), so that the header is added to the `must understand headers` list. This property is generated in the CMF file. When the node is configured to act in gateway mode, with no WSDL required, custom headers in this table have their `Operation` set to `*`. The original values of these fields are restored if the operation mode of the node is changed back to WSDL mode.	

The SOAPInput node WS Extensions properties are described in the following table.

Property	M	C	Default	Description
Use WS-Addressing	No	No	Cleared	This property indicates whether to engage WS-Addressing on the SOAPInput node. By default, this check box is cleared. If this property is selected, a reply can be sent back to a different web service client as specified in the WS-Addressing properties. The reply can be sent using a transport that is different than the one used for the incoming message.
Place WS-Addressing headers into LocalEnvironment	No	No	Cleared	This property specifies whether the node puts WS-Addressing headers received in the message into the local environment tree. WS-Addressing headers are not accessible to the flow if this check box is cleared because, by default, all headers are processed and removed.
WS-Security	No	Yes		This complex property is in the form of a table and consists of two columns: • `Alias` • `XPath Expression` You can add XPath expressions with an associated `Alias` value to the `WS-Security` table. The `Alias` is resolved in a policy set that is created by the administrator. The policy set resolves the `Alias` to either encrypt or sign the part of the message that is referenced by the `XPath Expression`. You can use the **Add**, **Edit** and **Delete** controls in this table.

The SOAPInput node Input Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	SOAP	The domain that is used to parse the incoming message. By default, the message that is propagated from the SOAPInput node is in the SOAP domain. You cannot specify a different domain. Input message parsing properties are disabled when the node is configured to act in gateway mode.
Message set	Yes	No	Set automatically from the WSDL file name property.	The name of the message set in which the incoming message is defined. This value is set automatically to the message set that contains the WSDLfile when the WSDL is associated with the node. If you set this property, then later update the project dependencies to remove this message set reference, a warning is issued. Either update the Message set property, or restore the reference to this message set project. Input message parsing properties are disabled when the node is configured to act in gateway mode.
Message type	No	No		The name of the incoming message. The node detects the message type automatically. You cannot set this property.
Message format	No	No		The name of the physical format of the incoming message. You cannot set this property.

The SOAPInput node Parser Options properties are described in the following table.

Property	M	C	Default	Description
Parse timing	No	No	On demand	This property controls when an input message is parsed. Valid values are On demand, Immediate, and Complete. The default value, On demand, causes parsing of the message to be delayed. For a full description of this property, see "Parsing on demand" on page 4173.
Build tree using XML Schema data types	No	No	Selected	This property controls whether the syntax elements in the message tree have data types taken from the XML Schema. This property is cleared and disabled when the node is configured to act in gateway mode.
Retain mixed content	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in an input message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in an input message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in an input message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.

Property	M	C	Default	Description
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the input message that are to be parsed opaquely. Opaque parsing is performed only if validation is not enabled (that is, if `Validate` is `None`); entries that are specified in `Opaque Elements` are ignored if validation is enabled.

The SOAPInput node Validation properties are described in the following table. See "Validation properties" on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	Yes	`Content and value`	This property controls whether the SOAP parser validates the body of each input message against XML schema generated from the message set. Valid values are `None`, `Content and value`, and `Content`. The SOAP parser invokes the XMLNSC parser to validate the XML body of the SOAP Web Service. If a message is propagated to the Failure terminal of the node, it is not validated. For more details, see "Validating messages" on page 1478 and "Validation properties" on page 4169. Validation properties are disabled, and the `Validate` property is set to `None`, when the node is configured to act in gateway mode.	validateMaster
Failure action	No	No	`Exception`	This property controls what happens if validation fails. You can set this property only if you set `Validate` to `Content` or `Content and value`. Valid values are `User Trace`, `Local Error Log`, `Exception`, and `Exception List`. Validation properties are disabled when the node is configured to act in gateway mode.	

The SOAPInput node Instances properties are described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Additional instances pool	No	Yes	`Use Pool Associated with Message Flow`	This property specifies whether additional instance threads are allocated from a thread pool for the whole message flow, or from a thread pool for use by that node only. • If you select `Use Pool Associated with Message Flow`, additional instances are obtained from the message flow value. • If you select `Use Pool Associated with Node`, additional instances are allocated based on the number specified in the `Additional instances` property.	
Additional instances	No	Yes	`0`	The number of additional instances that the node can start if the `Additional instances pool` property is set to `Use Pool Associated with Node`. By default, no additional instances are given to the node.	additionalInstances

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Identity" on page 390
In WebSphere Message Broker, an identity is a security token that uniquely identifies an individual, or that provides a set of assertions that can be validated.

"What is SOAP?" on page 1604
SOAP is an XML message format used in Web service interactions. SOAP messages are typically sent over HTTP or JMS, but other transport protocols can be used. The use of SOAP in a specific Web service is described by a WSDL definition.

"SOAP parser and domain" on page 1082
You can use the SOAP parser to create a common WSDL-based logical tree format for working with Web services, independent of the physical bitstream format.

"WSDL URI formats for JMS" on page 1668
You must use WSDL to configure SOAP nodes. When using WSDL with a JMS transport, different URI formats can exist in the `address` element in the WSDL, which affect how properties are parsed and applied to the configured nodes.

"SOAP nodes" on page 1609
The SOAP nodes act as points in the flow where Web service processing is configured and applied. Properties on the SOAP nodes control the processing carried out and can be configured by supplying a WSDL definition, or by manually configuring properties, or both.

Related tasks:

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

"Editing configurable properties" on page 3227
You can edit configurable properties in the deployment descriptor file (`broker.xml`) of your broker archive.

"Setting up message flow security" on page 431
Set up security on a message flow to control access based on the identity of a message passing through the message flow.

"Configuring the extraction of an identity or security token" on page 447
You can configure the SecurityPEP node or security enabled input nodes to extract the identity or security token from a message and store it in the properties tree identity fields, enabling it to be processed throughout the message flow and propagated at output or request nodes.

"Importing from WSDL" on page 2946
You can use the New Message Definition File wizard in the WebSphere Message Broker Toolkit to create a new message definition from WSDL.

"Importing WSDL definitions from the command line" on page 2948
WSDL definitions can be imported using the (**mqsicreatemsgdefsfromwsdl**) command.

"Validating messages" on page 1478
The broker provides validation based on the message model for predefined messages.

"Using timeouts with HTTP and SOAP nodes" on page 1595
Connect the HTTP Timeout terminal of the HTTPInput or SOAPInput nodes to further nodes to process timeouts.

Related reference:

"Configuring the backout threshold property"
You can set the backout threshold property on nodes that use JMS transport to specify how many attempts are made to deliver the message to the input destination.

"Configuring for coordinated JMS transactions" on page 4817
Configure your message flow to receive or output messages under coordinated transactions.

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

"WS-Addressing with the SOAPInput node" on page 1651
Various options are available when you use WS-Addressing with the SOAPInput node.

"**mqsichangeproperties** command" on page 3756
Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

"SOAPAsyncResponse node" on page 4777
Use the SOAPAsyncResponse node in conjunction with the SOAPAsyncRequest node to construct a pair of message flows that call a Web service asynchronously.

"SOAPRequest node" on page 4828
Use the SOAPRequest node to send a SOAP request to the remote Web service.

"SOAPReply node" on page 4819
Use the SOAPReply node to send SOAP messages from the broker to the originating client in response to a message received by a SOAPInput node.

"SOAPExtract node" on page 4790
Use the SOAPExtract node to remove SOAP envelopes, allowing just the body of a SOAP message to be processed. It can also route a SOAP message based on its operation name. Both functions are optional; they are contained in one node because they are often used together.

Configuring the backout threshold property:

You can set the backout threshold property on nodes that use JMS transport to specify how many attempts are made to deliver the message to the input destination.

If the Backout threshold is set to `0` then redelivery is not attempted. If the Backout threshold is 1 or greater, the message will be redelivered the specified number of times.

Set the value of Backout threshold depending on the capabilities of the JMS provider.

If the JMS provider supports `JMSXDeliveryCount`, you can set the Backout threshold to any value.

If the JMS provider does not support `JMSXDeliveryCount`, the Backout threshold must only be set to 0 or 1. If the JMS provider does not support `JMSXDeliveryCount` and the value is set to greater than 1, a redelivered message is repeatedly backed out and reprocessed, and is never delivered to the backout destination.

Configuring for coordinated JMS transactions:

Configure your message flow to receive or output messages under coordinated transactions.

When you include a node using JMS transport in a message flow, such as the JMSInput or SOAPInput node when using JMS transport, the value that you set for `Transaction mode` defines whether messages are received under sync point.

- If you set this property to `Global`, the message is received under external sync point coordination; that is, within a WebSphere MQ unit of work. Any messages that are sent later, by an output node in the same instance of the message flow, are put under sync point, unless the output node overrides this setting explicitly.
- If you set this property to `Local`, the message is received under the local sync point control of the node. Any messages that are sent later, by an output node in the flow, are not put under local sync point, unless an individual output node specifies that the message must be put under local sync point.
- If you set this property to `None`, the message is not received under sync point. Any messages that are sent later, by an output node in the flow, are not put under sync point, unless an individual output node specifies that the message must be put under sync point.

To receive messages under external sync point, you must take additional configuration steps, which need be applied only the first time that a specific node using JMS transport is deployed to the broker for a particular JMS provider.

- On distributed systems, the external sync point coordinator for the broker is WebSphere MQ. Before you deploy a message flow in which the `Transaction mode` property is set to `Global` or `Yes`, and is intended to use globally coordinated transactions, modify the queue manager `.ini` file to include extra definitions for each JMS provider resource manager that participates in globally coordinated transactions.
  - Windows On Windows:
    1. Start WebSphere MQ Explorer.
    2. Right-click the queue manager name in the left pane and click **Properties**.
    3. Click **XA resource managers** in the left pane.
    4. Click **Add...** .
    5. Set the options as follows:
       - Set `Name` to any value.

- On Windows on x86 systems, set the SwitchFile property to *install_dir*\bin\JMSSwitch.dll. On Windows on x86-64 systems, set the SwitchFile property to JMSSwitch.dll.
- Set the XAOpenString property to a string value as follows: *Initial Context*,*location JNDI*,*Optional_parms*.
- Set the ThreadOfControl property to Thread.

6. On Windows on x86-64 systems only, copy the switch file *JMSSwitch32.dll* to the \exits subdirectory in the WebSphere MQ installation directory, and rename it to JMSSwitch.dll. Copy the switch file JMSSwitch.dll to the \exits64 subdirectory in the WebSphere MQ installation directory.

For more information, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

– Linux UNIX On Linux and UNIX systems, add a stanza to the queue manager .ini file for each JMS provider.

For example:

```
XAResourceManager:
Name=Jms_Provider_Name
SwitchFile=/install_dir/bin/ JMSSwitch.so
XAOpenString=Initial Context,location JNDI,Optional_parms
ThreadOfControl=THREAD
```

Where:

Name is an installation defined name that identifies a JMS provider resource manager.

SwitchFile
is the file system path to the JMSSwitch library that is supplied in the bin directory of the broker.

XAOpenString can have the following values:

– *Initial Context* is the value that is set in the JMSInput node property Initial context factory.
– *location JNDI* is the value that is set in the JMSInput node property Location JNDI bindings. This value must include a supported URL prefix that has a URL handler that is available on the class path.

The following parameters are optional:

– LDAP Principal matches the value that is set for the broker by using the **mqsicreatebroker** or **mqsichangebroker** commands.
– LDAP Credentials matches the value that is set for the broker by using the **mqsicreatebroker** or **mqsichangebroker** commands.
– Recovery Connection Factory Name is the JNDI administered connection factory that is defined in the bindings file. If a value is not specified, you must add a default value for recoverXAQCF to the bindings file. In either case, the Recovery Connection Factory must be defined as an XA Queue Connection Factory for the JMS provider that is associated with the Initial context factory.

The optional parameters are comma-separated and are positional. Therefore, any parameters that are missing must be represented by a comma. For example:

```
com.sun.jndi.fscontext.RefFSContextFactory,file:/C:/webservices/SOAP/JMS/JNDIXA,,,QCF
```

1. Update the Java CLASSPATH environment variable for the queue manager of the broker to include a reference to xarecovery.jar; for example:

```
install_dir/classes/xarecovery.jar
```

2. Update the Java PATH environment variable for the queue manager of the broker to point to the bin directory in which the SwitchFile is located; for example:

   install_dir/bin

   Finally, ensure that you have taken the following configuration steps:

   – In the message flow, ensure that the coordinated property is enabled by using the WebSphere Message Broker Archive editor.
   – Ensure that each node that must be part of the XA transaction is set to the global transaction mode.
   – Ensure that the service ID that is used for the broker and the queue manager is the same user ID.
   – Ensure that the JNDI connection factory objects that the JMS nodes use for a global transaction are configured to be of the type MQXAConnectionFactory, MQXAQueueConnectionFactory, or MQXATopicConnectionFactory.
     - If you create the bindings using WebSphere Message Broker Explorer, ensure the `Support XA Transactions` option is checked when you define your connection factory.
     - If you create the bindings using JMSAdmin, use the command **DEF XAQCF** or **DEF XATCF**, instead of **DEF QCF** or **DEF TCF**, when you define your connection factory.

   For more information, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

- z/OS On z/OS, the external sync point manager is Resource Recovery Services (RRS). The only JMS provider that is supported on z/OS is WebSphere MQ JMS. The only transport option that is supported for WebSphere MQ JMS on z/OS is the bind option.

  Sync point control for the JMS provider is managed with RRS sync point coordination of the queue manager of the broker. You do not have to modify the `.ini` file.

SOAPReply node

Use the SOAPReply node to send SOAP messages from the broker to the originating client in response to a message received by a SOAPInput node.

This topic contains the following sections:

Purpose:
The SOAPReply node is typically used with the SOAPInput node, which can be included in the same message flow, or a different flow in the same execution group.

You cannot use a SOAPReply node to respond to a Web service request that is received by an HTTPInput node; the broker generates an exception when the reply is attempted.

The SOAPReply node is contained in the **Web Services** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
The SOAPReply node can be used in any message flow that needs to send SOAP messages from the broker to the originating client in response to a message received by a SOAPInput node. If a SOAPReply node is connected in a message flow that receives a one-way message, the message propagates to the Failure terminal of the SOAPReply node, and an exception is raised.

Look at the following sample to see how to use this node:

- SOAP Nodes

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Working with WrittenDestination data:
After the reply has been made, the WrittenDestination folder in the LocalEnvironment is updated if WS-Addressing is in use, and with transport details if WS-Addressing is in non-anonymous mode. A WrittenDestination for a SOAPReply node has the following format:

```
WrittenDestination = (
   SOAP  = (
      Reply = (
         WSA = (
            To = 'URI'
            MessageID = 'id'
            Action = 'doAllTheStuff'
         )      )
   )
)
```

LocalEnvironment overrides:
You can dynamically override set values in the local environment in the same way as setting values in other elements of a message. For a full list of values you can override in the local environment, see Local environment overrides.

Terminals and properties:
When you have put an instance of the SOAPReply node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk.

The SOAPReply node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which the message is routed if a failure is detected when the message is propagated.
Out	The output terminal to which the message is routed if it has been propagated successfully, and if further processing is required within this message flow.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The SOAPReply node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type: SOAPReply	The name of the node.
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

The SOAPReply node Transactions property is described in the following table. This setting does not apply when the node uses HTTP transport.

Property	M	C	Default	Description
Transaction mode	Yes	No	Automatic	This property controls whether the message is sent under a JMS transaction. Valid values are `Yes`, `No`, and `Automatic`. Select `No` to send the message using a non-transactional JMS session. Select `Yes` to output the message using a transactional JMS session. The JMS transaction can be either local or global. To use a global transaction, using an XA JMS session, you must also select the message flow property `Coordinated Transaction` in the BAR file properties. Select `Automatic` if you want the message transactionality to be inherited from the `Transaction mode` setting on the Input node at the start of the flow. See "Configuring for coordinated JMS transactions" on page 4823. The Transactions properties apply only to messages sent using JMS transport.

The SOAPReply node Validation properties are described in the following table. By default, validation is enabled.

If a message is propagated to the Failure terminal of the node, it is not validated. For more details, see "Validating messages" on page 1478 and "Validation properties" on page 4169.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Validate	No	Yes	`Inherit`	This property controls whether validation takes place. Valid values are `None`, `Content and Value`, `Content`, and `Inherit`.	validateMaster
Failure action	No	No	`User trace`	This property controls what happens if validation fails. You can set this property only if you set `Validate` to `Content` or `Content and Value`. Valid values are `User trace`, `Local error log`, `Exception`, and `Exception list`.	

The SOAPReply node WS Extensions property is described in the following table.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Allow MTOM	No	Yes	No	This property controls whether MTOM is enabled for the parser. Valid values are `Yes`, `No`, and `Inherit`. For more information about using SOAP MTOM with the SOAPReply, SOAPRequest, and SOAPAsyncRequest nodes, see "Using SOAP MTOM with the SOAPReply, SOAPRequest, and SOAPAsyncRequest nodes" on page 1678.	allowMTOM

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Use the SOAPRequest node to send a SOAP request to the remote Web service.

Configuring for coordinated JMS transactions:

Configure your message flow to receive or output messages under coordinated transactions.

When you include a node using JMS transport in a message flow, such as the JMSInput or SOAPInput node when using JMS transport, the value that you set for `Transaction mode` defines whether messages are received under sync point.

- If you set this property to `Global`, the message is received under external sync point coordination; that is, within a WebSphere MQ unit of work. Any messages that are sent later, by an output node in the same instance of the message flow, are put under sync point, unless the output node overrides this setting explicitly.
- If you set this property to `Local`, the message is received under the local sync point control of the node. Any messages that are sent later, by an output node in the flow, are not put under local sync point, unless an individual output node specifies that the message must be put under local sync point.
- If you set this property to `None`, the message is not received under sync point. Any messages that are sent later, by an output node in the flow, are not put under sync point, unless an individual output node specifies that the message must be put under sync point.

To receive messages under external sync point, you must take additional configuration steps, which need be applied only the first time that a specific node using JMS transport is deployed to the broker for a particular JMS provider.

- On distributed systems, the external sync point coordinator for the broker is WebSphere MQ. Before you deploy a message flow in which the `Transaction mode` property is set to `Global` or `Yes`, and is intended to use globally coordinated transactions, modify the queue manager `.ini` file to include extra definitions for each JMS provider resource manager that participates in globally coordinated transactions.
  - Windows On Windows:
    1. Start WebSphere MQ Explorer.
    2. Right-click the queue manager name in the left pane and click **Properties**.
    3. Click **XA resource managers** in the left pane.
    4. Click **Add...** .

5. Set the options as follows:
   - Set `Name` to any value.
   - On Windows on x86 systems, set the `SwitchFile` property to *`install_dir`*`\bin\JMSSwitch.dll`. On Windows on x86-64 systems, set the `SwitchFile` property to `JMSSwitch.dll`.
   - Set the `XAOpenString` property to a string value as follows: *`Initial Context`*`,`*`location JNDI`*`,`*`Optional_parms`*.
   - Set the `ThreadOfControl` property to `Thread`.
6. On Windows on x86-64 systems only, copy the switch file *JMSSwitch32.dll* to the `\exits` subdirectory in the WebSphere MQ installation directory, and rename it to `JMSSwitch.dll`. Copy the switch file `JMSSwitch.dll` to the `\exits64` subdirectory in the WebSphere MQ installation directory.

For more information, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

– Linux UNIX On Linux and UNIX systems, add a stanza to the queue manager `.ini` file for each JMS provider.

For example:

```
XAResourceManager:
Name=Jms_Provider_Name
SwitchFile=/install_dir/bin/ JMSSwitch.so
XAOpenString=Initial Context,location JNDI,Optional_parms
ThreadOfControl=THREAD
```

Where:

Name is an installation defined name that identifies a JMS provider resource manager.

SwitchFile
is the file system path to the JMSSwitch library that is supplied in the `bin` directory of the broker.

XAOpenString can have the following values:

– *Initial Context* is the value that is set in the JMSInput node property `Initial context factory`.

– *location JNDI* is the value that is set in the JMSInput node property `Location JNDI bindings`. This value must include a supported URL prefix that has a URL handler that is available on the class path.

The following parameters are optional:

– `LDAP Principal` matches the value that is set for the broker by using the **`mqsicreatebroker`** or **`mqsichangebroker`** commands.

– `LDAP Credentials` matches the value that is set for the broker by using the **`mqsicreatebroker`** or **`mqsichangebroker`** commands.

– `Recovery Connection Factory Name` is the JNDI administered connection factory that is defined in the bindings file. If a value is not specified, you must add a default value for `recoverXAQCF` to the bindings file. In either case, the Recovery Connection Factory must be defined as an XA Queue Connection Factory for the JMS provider that is associated with the `Initial context factory`.

The optional parameters are comma-separated and are positional. Therefore, any parameters that are missing must be represented by a comma. For example:

```
com.sun.jndi.fscontext.RefFSContextFactory,file:/C:/webservices/SOAP/JMS/JNDIXA,,,QCF
```

1. Update the Java CLASSPATH environment variable for the queue manager of the broker to include a reference to `xarecovery.jar`; for example:

install_dir/classes/xarecovery.jar

2. Update the Java PATH environment variable for the queue manager of the broker to point to the bin directory in which the SwitchFile is located; for example:

   install_dir/bin

Finally, ensure that you have taken the following configuration steps:

- In the message flow, ensure that the coordinated property is enabled by using the WebSphere Message Broker Archive editor.
- Ensure that each node that must be part of the XA transaction is set to the global transaction mode.
- Ensure that the service ID that is used for the broker and the queue manager is the same user ID.
- Ensure that the JNDI connection factory objects that the JMS nodes use for a global transaction are configured to be of the type MQXAConnectionFactory, MQXAQueueConnectionFactory, or MQXATopicConnectionFactory.
  - If you create the bindings using WebSphere Message Broker Explorer, ensure the `Support XA Transactions` option is checked when you define your connection factory.
  - If you create the bindings using JMSAdmin, use the command **DEF XAQCF** or **DEF XATCF**, instead of **DEF QCF** or **DEF TCF**, when you define your connection factory.

For more information, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

- z/OS On z/OS, the external sync point manager is Resource Recovery Services (RRS). The only JMS provider that is supported on z/OS is WebSphere MQ JMS. The only transport option that is supported for WebSphere MQ JMS on z/OS is the bind option.

  Sync point control for the JMS provider is managed with RRS sync point coordination of the queue manager of the broker. You do not have to modify the `.ini` file.

Local environment overrides for the SOAPReply node:

You can dynamically override set values in the local environment in the same way as setting values in other elements of a message.

Other local environment overrides are available for WS-Addressing. See "WS-Addressing with the SOAPReply node" on page 1653.

You can set the following HTTP properties in the SOAPReply node under `LocalEnvironment.Destination.SOAP.Request.Transport.HTTP.AsyncReply`. These properties apply only when you make an HTTP reply with WS-Addressing. You can switch between HTTP and JMS transport using the WS-Addressing `To` field; see "WS-Addressing information in the local environment" on page 1656.

Setting	Description
HTTPVersion	Overrides the `HTTPVersion`. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.HTTP.AsyncReply.HTTPVersion = 'HTTP/1.1';`
Method	Overrides the reply message `Method`. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.HTTP.AsyncReply.Method = 'GET';`

Setting	Description

ProxyConnectHeaders	Specifies additional headers that are used if the outbound request is an SSL connection through a proxy. These additional headers are sent with the initial CONNECT request to the proxy. For example, you can send proxy authentication information to a proxy server when you are using SSL. You can send multiple headers but each one must be separated by a carriage return and a line feed (ASCII 0x0D 0x0A), in accordance with RFC2616; for example:
	`DECLARE CRLF CHAR CAST(X'0D0A' AS CHAR CCSID 1208);`
	`SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.HTTP.AsyncReply.ProxyConnectHeaders = 'Proxy-Authorization: Basic Zm5lcmJsZTpwYXNzd29yZA==' || CRLF || 'Proxy-Connection: Keep-Alive' || CRLF;`
	
	This setting is used only if the request is an SSL request through a proxy server. To send proxy authentication information for a non-SSL request, specify the individual headers in the HTTPRequestHeader folder, as shown in the following example:
	`SET OutputRoot.HTTPReplyHeader."Proxy-Authorization" = 'Basic Zm5lcmJsZTpwYXNzd29yZA==';`
	`SET OutputRoot.HTTPReplyHeader."Proxy-Connection" = 'Keep-Alive';`

ProxyURL	Overrides the reply message HTTP(S) proxy location. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.HTTP.AsyncReply.ProxyURL = 'my.proxy';`
RequestURI	Overrides the reply message RequestURI, which is the path after the URL and port. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.HTTP.AsyncReply.RequestURI = '/abc/def?x=y&g=h';`
SSLCiphers	Overrides the reply message Allowed SSL Ciphers (if using SSL). For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.HTTP.AsyncReply.SSLCiphers = 'SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA';`
SSLProtocol	Overrides the reply message SSLProtocol. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.HTTP.AsyncReply.SSLProtocol = 'TLS';` Valid values are SSL, SSLv3, and TLS.
Timeout	Overrides the reply message Request timeout (in seconds). For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.HTTP.AsyncReply.Timeout = 42;`
WebServiceURL	Overrides the reply message Web service URL. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.HTTP.AsyncReply.WebServiceURL = 'http://ibm.com/abc/';`

You can set the following JMS properties in the SOAPReply node under LocalEnvironment.Destination.SOAP.Reply.Transport.JMS. These properties apply only when you make a JMS reply with WS-Addressing. You can switch between HTTP and JMS transport using the WS-Addressing To field; see "WS-Addressing information in the local environment" on page 1656.

Setting	Description
BindingsLocation	Overrides the reply message JNDI URL bindings location. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.JNDI.BindingsLocation = 'file:/C:/mqsi6/Webservices/SOAP/JMS/JNDI';`
ConnectionFactoryName	Overrides the reply message Connection factory name. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.JNDI.ConnectionFactoryName = 'QCF';`

Setting	Description

ContextParameters	Overrides the reply message JNDI context parameters. You can override specific JNDI context parameters, for example:
	`SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.JNDI.ContextParameters.foo = 'bar';`
	`SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.JNDI.ContextParameters.foo2 = 'baz';`

CorrelationID	Sets the reply message CorrelID. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.CorrelationID = 'myCorrelID';`
Destination	Overrides the reply message Destination. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.Destination = 'REPLYTOQ2';`
DeliveryMode	Overrides the reply message DeliveryMode. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.DeliveryMode = 'NON_PERSISTENT';` Allowed values for this property are PERSISTENT and NON_PERSISTENT. If the UriFormat is ibm, 1 and 0 are additional allowed values for DeliveryMode.
Expiration	Overrides the reply message Expiration. This property is specified in milliseconds. For example, to set an expiration of 100 milliseconds: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.Expiration = '100';`
InitialContextFactory	Overrides the reply message Initial context factory. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.JNDI.InitialContextFactory = 'com.sun.jndi.fscontext.RefFSContextFactory';`
MessagePriority	Overrides the reply message MessagePriority. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.MessagePriority = '7';`
MessageType	Overrides the reply message MessageType. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.MessageType = 'text';` Allowed values for this property are text and bytes.
ProviderName	Overrides the reply message JMS provider name. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.ProviderName = 'WebSphere MQ';`
TransactionMode	Overrides the Transaction mode property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.TransactionMode = 'Yes';` Allowable values for this property are Yes, No and ForceLocal. • No means that no transaction takes place, and is equivalent to None. • Yes means that a local transaction takes place if the flow's Coordinated Transaction is not selected, or a global transaction takes place if the flow's Coordinated Transaction property is selected. • ForceLocal means that a local transaction is always used, even if the flow's Coordinated Transaction property is selected.
UriFormat	Overrides the reply message UriFormat. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.UriFormat = 'w3c';` Allowable values for this property are w3c and ibm.

Setting	Description

UserProperties	Overrides the `User Context Parameters` on the node. You can override specific user context parameters, for example:
	`SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.JNDI.UserProperties.property1 = 'value1';`
	`SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.JNDI.UserProperties.property2 = 'value2';`

Setting	Description
OneWay	Instructs the node that the inbound message was a one-way message. The node resources are cleared because no reply message is needed. For example: `SET OutputLocalEnvironment.Destination.SOAP.Reply.Gateway.OneWay = True` Additionally, if the inbound message used HTTP transport, the node sends an acknowledgment HTTP 202 message. For more information, see "One-way messages in Gateway mode" on page 1648.

SOAPRequest node

Use the SOAPRequest node to send a SOAP request to the remote Web service.

This topic contains the following sections:
- "Purpose"
- "Using this node in a message flow"
- "Terminals and properties"
- "Working with WrittenDestination data" on page 4843
- "Local environment overrides" on page 4844

Purpose:
The SOAPRequest node is a synchronous request and response node, which blocks processing after sending the request until the response is received. This node enables the HTTP 1.1 Keep-Alive method by default.

The SOAPRequest node is contained in the **Web Services** drawer of the message flow node palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Using this node in a message flow:
The SOAPRequest node can be used in any message flow that needs to call a Web service. Look at the following sample to see how to use this node:
- SOAP Nodes

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Terminals and properties:
The SOAPRequest node terminals are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Failure	The output terminal to which a message is routed if a failure is detected when the message is propagated to the Out flow (such as a message validation failure). Failures routed to this terminal include failures caused by the retry processing occurring before the retry propagates the message to the Out flow.
Out	The output terminal to which the message is routed if the SOAP request has been sent and responded to successfully, and if further processing is required within this message flow. If no errors occur within the SOAPRequest node and a none fault SOAP response is received from the external resource it is always sent to the Out terminal first.
Fault	SOAP fault messages received in response to the sent request are directed to the Fault terminal. If no connection is provided to the Fault terminal no further processing occurs for a received fault within this message flow.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined; the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

Some SOAPRequest node properties are initially set from properties in the imported WSDL. These properties are parsed differently depending on which URI format is used by the `address` element in the WSDL. For details, see "WSDL URI formats for JMS" on page 1668.

The SOAPRequest node Description properties are described in the following table.

Property	M	C	Default	Description
Node name	No	No	The node type	The name of the node.
Short description	No	No	None	A brief description of the node.
Long description	No	No	None	Text that describes the purpose of the node in the message flow.

The SOAPRequest node Basic properties are described in the following table.

Property	M	C	Default	Description
Operation mode	Yes	Yes	`Invoke a specific web service defined by a WSDL interface`	This property allows you to specify the operation mode of the node, which determines whether it acts in WSDL mode or in gateway mode. In WSDL mode, the node performs operations according to the WSDL it is configured with. However, gateway mode allows you to configure your flow to handle generic SOAP request/response and one-way messages, or to act as a façade between multiple web services clients and multiple back-end web services providers. **Invoke a specific web service defined by a WSDL interface** Configure the node with a deployable WSDL by setting the WSDL file name property or by dragging a WSDL onto the node. This is the default option. **Invoke a generic web service** Configure the node to act in gateway mode with no WSDL required. See “Gateway operation mode for SOAP nodes” on page 1645 for a fuller explanation of gateway mode.
WSDL file name	Yes	No	None	This property indicates the location of the WSDL file that you want to use to configure the node. Enter the full path to the WSDL file, or click **Browse** to locate the WSDL file in your workspace. When you select a WSDL file for the `WSDL file name` property, the WSDL is validated to ensure that it is WS-I compliant. If the WSDL has a binding using SOAP/JMS which is not WS-I compliant, by default no error is shown. To enable strict WS-I validation and display a warning when a SOAP/JMS transport is used, click **Window > Preferences > Broker Development > Message Sets > Validation** and clear the **WS-I BP 1.1: Allow SOAP/JMS as transport URI** check box. Only deployable WSDL files can be used to configure the SOAP nodes. After a valid WSDL file is selected, the message set project to which the WSDL file belongs is added as a referenced project to the corresponding message flow project, if the reference does not exist. If the WSDL file is not valid, or an incorrect file name is entered, an error message is displayed in the Properties view and all WSDL properties are blank. If the node was created by dropping a WSDL file from a message set onto the Message Flow editor, this property is preset to the name of the WSDL file. This property takes a string value. The following situations result in an error condition: • The WSDL file does not belong to a message set project, or the WSDL file was not imported correctly; see “Importing from WSDL” on page 2946 and “Importing WSDL definitions from the command line” on page 2948. • The WSDL file contains no HTTP or JMS bindings. • The WSDL file contains no port type. • The WSDL file that is specified in the field does not exist. WSDL properties are disabled when the node is configured to act in gateway mode.

Property	M	C	Default	Description
Port type	Yes	No	By default, the first `Port type` found in the WSDL file, that has an associated HTTP binding with it, is selected.	This property type is String. The field lists all the `Port types` defined in WSDL file selected in the `WSDL file name` property. Error Conditions: • Selected `Port type` does not contain at least one operation. WSDL properties are disabled when the node is configured to act in gateway mode.
Imported binding	Yes	No		This property type is String. This property is updated every time that the `Port type` value changes. The field lists the imported SOAP bindings with HTTP or JMS transport associated with the selected `Port type`. When you select a binding, the property tab for the associated transport is enabled; otherwise, it is disabled. Bindings are listed in the same order in which they appear in the WSDL file. The selected binding is the one that has both ports and operations. If there is no such binding, then binding with ports is selected. If no bindings have ports then the first binding in the list is selected. Error Conditions: • No SOAP bindings (with HTTP or JMS transport) in the WSDL file are associated with the `Port type`. • The selected binding does not have any operations. WSDL properties are disabled when the node is configured to act in gateway mode.
Binding operation	Yes	No		This property type is String. The `Binding operation` box contains all the operations defined by the selected binding. The first operation in the list is selected by default. This property is updated every time the selected binding value changes WSDL properties are disabled when the node is configured to act in gateway mode.
Service port	Yes	No		This property type is String. This field is updated every time that the selected binding is updated. This field lists all the WSDL ports that point to the selected binding. The first service port for the binding is selected by default. This property is updated every time the selected binding value changes. Error Conditions: • No ports point to the selected binding. WSDL properties are disabled when the node is configured to act in gateway mode.
Target namespace	Yes	No		`Target namespace` is implemented as a read-only field. This hidden property type is String. It is updated with the `Target namespace` of the WSDL file when the `WSDL file name` is configured. WSDL properties are disabled when the node is configured to act in gateway mode.

Property	M	C	Default	Description
Transport	No	No		This property is set automatically when the `Imported binding` property is selected. The value of this property shows the transport used by the selected WSDL binding; for example, `HTTP` or `JMS`. If you choose to switch the transport from `JMS` to `HTTP`, a dialog box displays, which allows you to reset the JMS-specific properties. You must reset the JMS properties to deploy the message flow to a runtime environment version prior to fix pack V7.0.0.1.

The SOAPRequest node HTTP Transport properties are described in the following table. These settings are used only when the node uses HTTP transport

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Web service URL	Yes	Yes	SOAP address of the selected port	The URL of the SOAP address selected. This property is automatically derived from the `<soap:address>` element of the selected `Service port`. Whenever the selected port is updated, the `Web service URL` is updated accordingly. However, if you override the value then your value persists and the URL is no longer updated from the service port. If you choose to override this property you must specify it in the form http://<hostname>[:<port>]/[<path>] where: • http://<hostname> must be specified. • <port> has a default of 80. If you specify a value, you must include the colon : before the port number. • <path> has a default of /. If you specify a value, you must include the / before the path. For more details of how to override this property, see Changing the default URL for a SOAPRequest node or a SOAPAsyncRequest node request.	webServiceURL
Request timeout (in seconds)	No	Yes	120	The number of seconds that the client waits for a remote server to respond with a 'message received' acknowledgment. The timeout might take up to one second longer than the value specified. If no response is received in this time, a SOAP Fault exception is raised and is propagated to the Failure terminal.	
HTTP(S) proxy location	No	Yes	Blank	The location of the proxy server to which requests are sent.	httpProxyLocation

Property	M	C	Default	Description	mqsiapplybaroverride command property
Protocol (if using SSL)	No	Yes	TLS	The selected protocol if you use SSL. This property type is Enumerate. The following options are available: **SSL** This option attempts to connect by using the SSLv3 protocol first, but allows the handshake to fall back to the SSLv2 protocol where the SSLv2 protocol is supported by the underlying JSSE provider. **SSLv3** This option attempts to connect with the SSLv3 protocol only. Fallback to SSLv2 is not allowed. **TLS** The default. This option attempts to connect with the TLS protocol only. Fallback to SSLv3 or SSLv2 is not allowed. **TLSv1** This option attempts to connect with the TLS v1.0 protocol only. Fallback to SSLv3 or SSLv2 is not allowed. **TLSv1.1** This option attempts to connect with the TLS v1.1 protocol only. Fallback to SSLv3, SSLv2, or TLSv1.0 is not allowed. **TLSv1.2** This option attempts to connect with the TLS v1.2 protocol only. Fallback to SSLv3, SSLv2, TLSv1.0, or TLSv1.1 is not allowed. **SSL_TLS** This option enables all SSL v3.0 and TLS v1.0 protocols. Fallback to SSLv2 is not allowed. **SSL_TLSv2** This option enables all SSL v3.0 and TLS v1.0, v1.1, and v1.2 protocols. Fallback to SSLv2 is not allowed. Both ends of an SSL connection must agree on the protocol to use; therefore, the chosen protocol must be one that the remote server can accept.	sslProtocol

Property	M	C	Default	Description	mqsiapplybaroverride command property
Allowed SSL ciphers (if using SSL)	No	Yes	None	The specific SSL cipher, or ciphers, that you are using. This setting allows you to specify a single cipher (such as SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA) or a list of ciphers that are the only ones used by the connection. This set of ciphers must include one or more that are accepted by the remote server. You can specify a list of ciphers in priority order. The server selects the first acceptable cipher in the list. If none of the ciphers in the list are suitable, the server returns a handshake failure alert and closes the connection. A comma is used as a separator between the ciphers. The default value is an empty string, which allows the node to use any, or all, of the available ciphers during the SSL connection handshake. This method allows the greatest scope for making a successful SSL connection.	allowedSSLCiphers
Use compression	No	No	None	This property controls whether the content of the HTTP request is compressed. Valid values are none, gzip, zlib (deflate) and deflate. If the request is compressed, the Content-Encoding header is set to indicate that the content is compressed. zlib (deflate) represents RFC 1950 + RFC 1951 combined. deflate represents RFC 1951 only.	requestCompressionType
Accept compressed responses by default	No	Yes	Cleared	This property indicates whether the request accepts compressed responses. If this option is selected, it is possible for the request to receive responses with a Content-Encoding of gzip or deflate. If such a response is received, the content is decoded and the Content-Encoding header is removed. If the Request Header does not contain an Accept-Encoding header then selecting this option sets the Accept-Encoding header to "gzip, deflate".	acceptCompressedResponses
Perform hostname checking (if using SSL)	No	Yes	No	This property specifies if the host name of the server that is receiving the request must match the host name in the SSL certificate.	hostnameChecking

The SOAPRequest node JMS Transport properties are described in the following table. These settings are used only when the node uses JMS transport

Property	M	C	Default	Description	mqsiapplybaroverride command property
Destination	Yes	Yes	None	The destination to which the node sends outgoing messages. If the SOAPRequest node is to be used to send point-to-point messages, enter the Destination queue name for the JMS queue name that is listed in the bindings file. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `Destination` is set to the value of `destinationName` found in the WSDL if a W3C-style URI is found, or `destination` if an IBM-style URI is found.	jmsDestination
Reply To Destination	No	Yes	None	The name of the JMS destination to which the receiving application must send a reply message. This property is not used if the JMS operation is one way. For a reply message to be returned to this JMS destination, the JMS destination name must be known to the domain of the JMS provider that is used by the receiving client. If you do not specify a reply-to destination, a temporary dynamic queue is used as the reply-to destination. If you do not specify a reply-to destination and you are using the WebSphere MQ JMS provider, you must configure JMS temporary dynamic queues. For more information about configuring JMS temporary dynamic queues, see "Configuring JMS temporary dynamic queues for the WebSphere MQ JMS provider" on page 4848. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `Reply To Destination` is set to the value of `replyToName` found in the WSDL if a W3C-style URI is found, or to the first of `replyToName`, `replyTo`, `replyToDestination`, or `replyDestination` if an IBM-style URI is found. If any of these other properties are present, they display as a name-value pair in the `User Parameters` table.	jmsReplyToDestination
Request timeout (in seconds)	No	Yes	120	The time the client waits for a remote server to send a response message before timing out.	requestTimeout

Property	M	C	Default	Description	mqsiapplybaroverride command property
JMS provider name	Yes	No	WebSphere MQ	Select a JMS vendor name from the list, or enter a name of your choice. The name must match the name of a configurable service that is defined for the broker to which you deploy the message flow. When you select a name from the list, the Initial context factory property is updated automatically with the relevant Java class. If you enter your own JMS provider name, you must also enter a value for the Initial context factory.	
Initial context factory	Yes	Yes	com.sun.jndi.fscontext.RefFSContextFactory	The starting point for a JNDI namespace. A JMS application uses the initial context to obtain and look up the connection factory and queue or topic objects for the JMS provider. If you select a JMS provider name from the list in JMS provider name, the Initial context factory property is updated automatically with the relevant Java class. If you enter your own JMS provider name, you must also enter a value for the Initial context factory. The default value is com.sun.jndi.fscontext.RefFSContextFactory, which defines the file-based Initial context factory for the WebSphere MQ JMS provider. This property takes its initial value from a WSDL URI property, depending on whether the WSDL address URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. Initial context factory is set to the value of jndiInitialContextFactory found in the WSDL if a W3C-style URI is found, or initialContextFactory if an IBM-style URI is found.	initialContextFactory

Property	M	C	Default	Description	**mqsiapplybaroverride** command property
JNDI URL bindings location	Yes	Yes		The system path or the LDAP location for the bindings file. The bindings file contains definitions for the JNDI administered objects that are used by the SOAPRequest node. This property is disabled when the `Initial context factory` is `com.ibm.mq.jms.Nojndi`. When you enter a value for `JNDI URL bindings location`, ensure that it complies with the following instructions: • Construct the bindings file before you deploy a message flow that contains a SOAPRequest node. • Do not include the file name of the bindings file in this field. • If you have specified an LDAP location that requires authentication, configure the LDAP principal (userid) and LDAP credentials (password) separately. These values are configured at broker level. For information about configuring these values, see "**mqsicreatebroker** command" on page 3831 and "**mqsichangebroker** command" on page 3723. • The string value must include a supported URL prefix that has a URL handler that is available on the class path. For information about constructing the JNDI administered objects bindings file, see the JMS provider documentation. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `JNDI URL bindings location` is set to the value of `jndiURL` found in the WSDL if a W3C-style URI is found, or `jndiProviderURL` if an IBM-style URI is found.	locationJndiBindings

Property	M	C	Default	Description	mqsiapplybaroverride command property
Connection factory name	Yes	Yes		The name of the connection factory that is used by the SOAPRequest node to create a connection to the JMS provider. This property is initially configured from the imported WSDL. This name must exist in the bindings file. The `Connection factory name` must be a JMS QueueConnectionFactory. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `Connection factory name` is set to the value of `jndiConnectionFactoryName` found in the WSDL if a W3C-style URI is found, or `connectionFactory` if an IBM-style URI is found.	connectionFactoryName
User Parameters	No	No		This table describes user properties that have been defined in the request. The properties are name-value pairs that exist in the WSDL and are not used by other properties of the SOAPRequest node.	
JNDI parameters	No	No		A table mapping JNDI context parameters to their type. These properties take their initial values from any W3C-style WSDL properties starting with `jndi-`. IBM-style WSDL does not support JNDI parameters, but you can set these properties on the node.	

The SOAPRequest node Message Delivery properties are described in the following table. This sub tab is enabled only if the selected binding in the Basic tab uses JMS transport.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Target Service	No	No	None	Used by the SOAPRequest node when dispatching the service request. This property takes its initial value from the `targetService` WSDL property.	targetService

Property	M	C	Default	Description	mqsiapplybaroverride command property
Delivery mode	No	Yes	Persistent	This property controls the persistence mode that a JMS provider uses for a message. Valid values are: • `Persistent`: the message survives if the JMS provider has a system failure. • `Non Persistent`: the message is lost if the JMS provider has a system failure. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `Delivery mode` is set to the value of `deliveryMode` found in the WSDL if a W3C-style URI is found, or to the first of `deliveryMode` or `persistence` if an IBM-style URI is found. If both these properties are present, the second property displays as a name-value pair in the `User Parameters` table.	deliveryMode
Message Priority	No	Yes	4	This property assigns relative importance to the message and can be used for message selection by a receiving web service. Select a value between 0 (lowest priority) and 9 (highest priority). The default value is 4, which indicates medium priority. Priorities in the range 0 - 4 indicate typical delivery. Priorities in the range 5 - 9 indicate faster delivery. This property takes its initial value from a WSDL URI property, depending on whether the WSDL `address` URI is formatted in the W3C (standards) style, or the IBM (proprietary) style. `Priority` is set to the value of `priority` found in the WSDL if a W3C-style URI is found, or to the first of `priority` or `Priority` if an IBM-style URI is found. If both these properties are present, the second property displays as a name-value pair in the `User Parameters` table.	messagePriority
Message Expiration (ms)	No	Yes	0	This property controls the length of time, in milliseconds, for which the JMS provider keeps the output JMS message. The default value, 0, is used to indicate that the message must not expire. This property takes its initial value from the `timeToLive` WSDL property.	messageExpiration
Message Type	No	Yes	bytes	Select a value from the list to configure the type of JMS message that is produced by the SOAPRequest node.	messageType

The SOAPRequest node Transactions properties are described in the following table. This setting does not apply when the node uses HTTP transport.

Property	M	C	Default	Description
Transaction Mode	Yes	No	Automatic	This property controls whether the message is output under a JMS transaction. Valid values are `Yes`, `No`, and `Automatic`. Select `No` to output the message using a non-transactional JMS session. Select `Yes` to output the message using a transactional JMS session. The JMS transaction can be either local or global. To use a global transaction, using an XA JMS session, you must also select the message flow property `Coordinated Transaction` in the BAR file properties. Select `Automatic` if you want the message transactionality to be inherited from the `Transaction mode` setting on the Input node at the start of the flow. This value is only used when the selected operation is one-way. See "Configuring for coordinated JMS transactions" on page 4846.

The SOAPRequest node Advanced properties are described in the following table.

Property	M	C	Default	Description
WSDL-defined SOAP response headers	No	No		This table is read-only, and is populated by the SOAP headers defined in the output part of the selected operations. By default, the check boxes, in the second column of the table, are cleared for all entries in the `WSDL-defined SOAP response headers` table. You must select the relevant check box to add the header to the `must understand headers` list. SOAP headers that are part of the `must understand headers` list are incorporated into the flow rather than causing a SOAP fault. Adding headers to the `must understand headers` list stops SOAP faults being generated by SOAP headers. You do not need to add `must understand headers` for WS-Addressing and WS-Security as they are understood if you configure **WS Extensions**.The table is updated automatically when the selected operation is updated. This property is generated in the CMF file. When the node is configured to act in gateway mode, with no WSDL required, this table is cleared. The original values of these fields are restored if the operation mode of the node is changed back to WSDL mode.
User-defined SOAP response headers	No	Yes	None	You can add custom headers (headers that are not defined in the WSDL file) in this table. Use **Add**, **Edit**, and **Delete** for this table. You must select the check box, in the second column of the table, to ensure that the newly added custom header is added to the `must understand headers` list. This property is generated in the CMF file.

The SOAPRequest node WS Extensions properties are described in the following table.

Property	M	C	Default	Description	
Use WS-Addressing	No	No		This property specifies whether to use WS-Addressing. For more details about WS-Addressing with the SOAPRequest node, see "WS-Addressing with the SOAPRequest node" on page 1653.	

Property	M	C	Default	Description	
Place WS-Addressing headers into LocalEnvironment	No	No	Cleared	This property specifies whether the node puts WS-Addressing headers received in the response message into the local environment tree. WS-Addressing headers are not accessible to the flow if this check box is cleared because by default, all headers are processed and removed.	
Allow MTOM	No	Yes	No	This property controls whether MTOM is enabled for the parser. Valid values are `Yes`, `No`, and `Inherit`. For more information about using SOAP MTOM with the SOAPReply, SOAPRequest, and SOAPAsyncRequest nodes, see "Using SOAP MTOM with the SOAPReply, SOAPRequest, and SOAPAsyncRequest nodes" on page 1678. MTOM support is disabled when the node is configured to act in gateway mode.	allowMTOM
WS-Security	No	Yes		This complex property is in the form of a table and consists of two columns: • `Alias` • `XPath Expression` You can add XPath expressions with an associated `Alias` value to the `WS-Security` table. The `Alias` is resolved in a Policy Set that is created by the administrator. The Policy Set resolves the `Alias` to either encrypt or sign the part of the message referred to by the `XPath Expression`. You can **Add**, **Edit**, and **Delete** in this table.	

The SOAPRequest node Response Message Parsing properties are described in the following table.

Property	M	C	Default	Description
Message domain	No	No	SOAP	The domain that is used to parse the response message. By default, the message that is propagated from the SOAPInput node is in the SOAP domain. You cannot specify a different domain. For more information, see "SOAP parser and domain" on page 1082. The Response Message Parsing properties are disabled when the node is configured to act in gateway mode.

Property	M	C	Default	Description
Message set	Yes	No	Set automatically from the `WSDL file name` property.	The name of the message set in which the response message is defined. This property is automatically set to the message set that contains the WSDL file, when the WSDL is associated with the node. If you set this property, then later update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message set` property, or restore the reference to this message set project. The Response Message Parsing properties are disabled, and this property is cleared, when the node is configured to act in gateway mode.
Message type	No	No		The name of the response message. The node detects the message type automatically. You cannot set this property.
Message format	No	No		The name of the physical format of the response message. You cannot set this property.

The SOAPRequest node Parser Options properties are described in the following table.

Property	M	C	Default	Description
Parse timing	No	No	`On demand`	This property controls when a response message is parsed. Valid values are `On demand`, `Immediate`, and `Complete`. The default value, `On demand`, causes parsing of the message to be delayed. For a full description of this property, see "Parsing on demand" on page 4173.
Build tree using XML schema data types	No	No	Set	This property controls whether the syntax elements in the message tree have data types taken from the XML Schema. The `SOAP Parser Options` properties determine how the SOAP parser operates. The SOAP parser options are passed through to the XMLNSC parser. For more information, see "Manipulating messages in the XMLNSC domain" on page 2546. This property is cleared and disabled when the node is configured to act in gateway mode.
Retain mixed content	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in a response message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in a response message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in a response message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.

Property	M	C	Default	Description
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the input message that are to be opaquely parsed. Opaque parsing is performed only if validation is not enabled (that is, if `Validate` is `None`); entries that are specified in `Opaque Elements` are ignored if validation is enabled.

The SOAPRequest node Validation properties are described in the following table. These properties apply only to the response message; the request message is not validated.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Validate	No	Yes	`Content and value`	This property controls whether the SOAP parser validates the body of each response message against XML Schema generated from the message. Valid values are `None`, `Content and value`, and `Content`. By default, validation is enabled. The SOAP parser starts the XMLNSC parser to validate the XML body of the SOAP Web service. If a message is propagated to the Failure terminal of the node, it is not validated. For more details, see "Validating messages" on page 1478 and "Validation properties" on page 4169. Validation properties are disabled, and the `Validate` property is set to `None`, when the node is configured to act in gateway mode.	validateMaster
Failure action	No	No	`Exception`	This property controls what happens if validation fails. You can set this property only if you set `Validate` to `Content` or `Content and value`. Valid values are `User trace`, `Local error log`, `Exception`, and `Exception list`. The Validation properties are disabled when the node is configured to act in gateway mode.	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

Working with WrittenDestination data:
After the request has been made, the WrittenDestination folder in the local environment is updated with the WS-Addressing (if in use), compression details (if in use) and transport details. A WrittenDestination for a SOAPRequest node has

the following format, with WS-Addressing and Compression present only if it is used, where *jmsDestination* is the name of your JMS destination:

```
WrittenDestination = (
   SOAP  = (
      Request = (
         WSA = (
            To = 'URI'
            MessageID = 'id'
            Action = 'doAllTheStuff'
         )
         Transport = (
            HTTP = (
               WebServiceURL = 'http://server:8080/thing'
               Compression   = (
                  OriginalSize   = 775
                  CompressedSize = 411
            )
            JMS = (
               Destination = jmsDestination
            )
         )
      )
   )
)
```

Local environment overrides:
You can dynamically override set values in the local environment in the same way as setting values in other elements of a message. For a full list of values you can override in the local environment, see Local environment overrides.

HTTPRequest headers:
To control the contents of a HTTPRequest header that is included in a message, you must include a Compute node to add a HTTPRequest header to the input message before the HTTPRequest node in the message flow.

If a SOAPAction is set to an empty string in the HTTPInput header, it is overridden, unless the action is set explicitly in the HTTPRequest header, for example:

```
SET OutputRoot.HTTPRequestHeader.SOAPAction = InputRoot.HTTPInputHeader.SOAPAction
```

Related concepts:

"Message flow aggregation" on page 2718
Aggregation is the generation and fan-out of related requests that are derived from a single input message, and the fan-in of the corresponding replies to produce a single aggregated reply message.

"What is SOAP?" on page 1604
SOAP is an XML message format used in Web service interactions. SOAP messages are typically sent over HTTP or JMS, but other transport protocols can be used. The use of SOAP in a specific Web service is described by a WSDL definition.

"SOAP tree overview" on page 1611
This tree format allows you to access the key parts of the SOAP message in a convenient way.

"EndpointLookup node output" on page 1894
Use an EndpointLookup node to retrieve the endpoint addresses for WSDL service definitions held in WebSphere Service Registry and Repository (WSRR).

"SOAP nodes" on page 1609
The SOAP nodes act as points in the flow where Web service processing is configured and applied. Properties on the SOAP nodes control the processing carried out and can be configured by supplying a WSDL definition, or by

manually configuring properties, or both.

"WSDL URI formats for JMS" on page 1668
You must use WSDL to configure SOAP nodes. When using WSDL with a JMS transport, different URI formats can exist in the `address` element in the WSDL, which affect how properties are parsed and applied to the configured nodes.

"Using compression with HTTP and SOAP nodes" on page 1597
You can configure HTTP and SOAP nodes to use HTTP compression and decompression when sending and receiving messages.

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

"Configuring aggregation flows" on page 2721
Use aggregation message flows to generate and fan-out a number of related requests, fan-in the corresponding replies, and compile those replies into a single aggregated reply message, by using the AggregateControl, AggregateRequest, and AggregateReply nodes.

"Editing configurable properties" on page 3227
You can edit configurable properties in the deployment descriptor file (`broker.xml`) of your broker archive.

"Configuring authentication with HTTP basic authentication" on page 451
Use a security profile to configure HTTP basic authentication in the HTTPRequest or SOAPInput nodes.

"Importing from WSDL" on page 2946
You can use the New Message Definition File wizard in the WebSphere Message Broker Toolkit to create a new message definition from WSDL.

"Importing WSDL definitions from the command line" on page 2948
WSDL definitions can be imported using the (**`mqsicreatemsgdefsfromwsdl`**) command.

"Configuring JMS temporary dynamic queues for the WebSphere MQ JMS provider" on page 4848
Configure JMS temporary dynamic queues for the WebSphere MQ JMS provider, so that you can use them with SOAPRequest nodes, by using WebSphere MQ Explorer.

Related reference:

"SOAPAsyncResponse node" on page 4777
Use the SOAPAsyncResponse node in conjunction with the SOAPAsyncRequest node to construct a pair of message flows that call a Web service asynchronously.

"SOAPAsyncRequest node" on page 4750
Use the SOAPAsyncRequest node with the SOAPAsyncResponse node to construct a pair of message flows that call a Web service asynchronously.

"SOAPInput node" on page 4795
Use the SOAPInput node to process client SOAP messages, so that the broker operates as a SOAP Web Services provider.

"SOAPExtract node" on page 4790
Use the SOAPExtract node to remove SOAP envelopes, allowing just the body of a SOAP message to be processed. It can also route a SOAP message based on its operation name. Both functions are optional; they are contained in one node because they are often used together.

"SOAPReply node" on page 4819
Use the SOAPReply node to send SOAP messages from the broker to the originating client in response to a message received by a SOAPInput node.

"HTTPRequest node" on page 4488
Use the HTTPRequest node to interact with a web service.

"EndpointLookup node" on page 4407
Use the EndpointLookup node to retrieve service endpoint information held in the WebSphere Service Registry and Repository (WSRR). The entities that match the specified search criteria are stored in the local environment. Depending on the node configuration, the Web service URL destination used by the SOAP and HTTP request nodes can also be set. The input message is not modified.

"WS-Addressing with the SOAPRequest node" on page 1653
Various options are available when you use WS-Addressing with the SOAPRequest node.

"Configuring for coordinated JMS transactions" on page 4544
Configure your message flow to receive or output messages under coordinated transactions.

Configuring for coordinated JMS transactions:

Configure your message flow to receive or output messages under coordinated transactions.

When you include a node using JMS transport in a message flow, such as the JMSInput or SOAPInput node when using JMS transport, the value that you set for `Transaction mode` defines whether messages are received under sync point.

- If you set this property to `Global`, the message is received under external sync point coordination; that is, within a WebSphere MQ unit of work. Any messages that are sent later, by an output node in the same instance of the message flow, are put under sync point, unless the output node overrides this setting explicitly.
- If you set this property to `Local`, the message is received under the local sync point control of the node. Any messages that are sent later, by an output node in the flow, are not put under local sync point, unless an individual output node specifies that the message must be put under local sync point.
- If you set this property to `None`, the message is not received under sync point. Any messages that are sent later, by an output node in the flow, are not put under sync point, unless an individual output node specifies that the message must be put under sync point.

To receive messages under external sync point, you must take additional configuration steps, which need be applied only the first time that a specific node using JMS transport is deployed to the broker for a particular JMS provider.

- On distributed systems, the external sync point coordinator for the broker is WebSphere MQ. Before you deploy a message flow in which the `Transaction mode` property is set to `Global` or `Yes`, and is intended to use globally coordinated transactions, modify the queue manager `.ini` file to include extra definitions for each JMS provider resource manager that participates in globally coordinated transactions.
  - Windows On Windows:
    1. Start WebSphere MQ Explorer.
    2. Right-click the queue manager name in the left pane and click **Properties**.
    3. Click **XA resource managers** in the left pane.
    4. Click **Add...** .

5. Set the options as follows:
   - Set `Name` to any value.
   - On Windows on x86 systems, set the `SwitchFile` property to *`install_dir`*`\bin\JMSSwitch.dll`. On Windows on x86-64 systems, set the `SwitchFile` property to `JMSSwitch.dll`.
   - Set the `XAOpenString` property to a string value as follows: *`Initial Context`*`,`*`location JNDI`*`,`*`Optional_parms`*.
   - Set the `ThreadOfControl` property to `Thread`.
6. On Windows on x86-64 systems only, copy the switch file *JMSSwitch32.dll* to the `\exits` subdirectory in the WebSphere MQ installation directory, and rename it to `JMSSwitch.dll`. Copy the switch file `JMSSwitch.dll` to the `\exits64` subdirectory in the WebSphere MQ installation directory.

For more information, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

– Linux UNIX On Linux and UNIX systems, add a stanza to the queue manager `.ini` file for each JMS provider.

For example:

```
XAResourceManager:
Name=Jms_Provider_Name
SwitchFile=/install_dir/bin/ JMSSwitch.so
XAOpenString=Initial Context,location JNDI,Optional_parms
ThreadOfControl=THREAD
```

Where:

Name is an installation defined name that identifies a JMS provider resource manager.

SwitchFile
is the file system path to the JMSSwitch library that is supplied in the `bin` directory of the broker.

XAOpenString can have the following values:

– *Initial Context* is the value that is set in the JMSInput node property `Initial context factory`.

– *location JNDI* is the value that is set in the JMSInput node property `Location JNDI bindings`. This value must include a supported URL prefix that has a URL handler that is available on the class path.

The following parameters are optional:

– `LDAP Principal` matches the value that is set for the broker by using the **`mqsicreatebroker`** or **`mqsichangebroker`** commands.

– `LDAP Credentials` matches the value that is set for the broker by using the **`mqsicreatebroker`** or **`mqsichangebroker`** commands.

– `Recovery Connection Factory Name` is the JNDI administered connection factory that is defined in the bindings file. If a value is not specified, you must add a default value for `recoverXAQCF` to the bindings file. In either case, the Recovery Connection Factory must be defined as an XA Queue Connection Factory for the JMS provider that is associated with the `Initial context factory`.

The optional parameters are comma-separated and are positional. Therefore, any parameters that are missing must be represented by a comma. For example:

```
com.sun.jndi.fscontext.RefFSContextFactory,file:/C:/webservices/SOAP/JMS/JNDIXA,,,QCF
```

1. Update the Java CLASSPATH environment variable for the queue manager of the broker to include a reference to `xarecovery.jar`; for example:

install_dir/classes/xarecovery.jar

2. Update the Java PATH environment variable for the queue manager of the broker to point to the bin directory in which the SwitchFile is located; for example:

   install_dir/bin

Finally, ensure that you have taken the following configuration steps:

- In the message flow, ensure that the coordinated property is enabled by using the WebSphere Message Broker Archive editor.
- Ensure that each node that must be part of the XA transaction is set to the global transaction mode.
- Ensure that the service ID that is used for the broker and the queue manager is the same user ID.
- Ensure that the JNDI connection factory objects that the JMS nodes use for a global transaction are configured to be of the type MQXAConnectionFactory, MQXAQueueConnectionFactory, or MQXATopicConnectionFactory.
  - If you create the bindings using WebSphere Message Broker Explorer, ensure the `Support XA Transactions` option is checked when you define your connection factory.
  - If you create the bindings using JMSAdmin, use the command **DEF XAQCF** or **DEF XATCF**, instead of **DEF QCF** or **DEF TCF**, when you define your connection factory.

For more information, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

- z/OS On z/OS, the external sync point manager is Resource Recovery Services (RRS). The only JMS provider that is supported on z/OS is WebSphere MQ JMS. The only transport option that is supported for WebSphere MQ JMS on z/OS is the bind option.

  Sync point control for the JMS provider is managed with RRS sync point coordination of the queue manager of the broker. You do not have to modify the `.ini` file.

Configuring JMS temporary dynamic queues for the WebSphere MQ JMS provider:

Configure JMS temporary dynamic queues for the WebSphere MQ JMS provider, so that you can use them with SOAPRequest nodes, by using WebSphere MQ Explorer.

About this task

Complete this task before using JMS temporary dynamic queues with the WebSphere MQ JMS provider in your message flow applications.

If the model queue SYSTEM.JMS.MODEL.QUEUE already exists on your system, start at step 6 on page 4849 and enter `SYSTEM.JMS.MODEL.QUEUE` when you are asked to enter your JMS temporary dynamic model queue name.

Procedure

To set up JMS temporary dynamic queues:

1. In the Navigator view of WebSphere MQ Explorer, expand **Queue Managers** > ***QueueManager***, where *QueueManager* is the name of your queue manager, click **Queues**.

2. Right-click **Queues**, then click **New** > **Model Queue**. The New Model Queue wizard opens.
3. Enter a name for your JMS temporary dynamic model queue, for example `SYSTEM.JMS.MODEL.QUEUE`, then select `SYSTEM.DEFAULT.MODEL.QUEUE` as the object from which to copy attributes, and click **Next**.
4. Under **Change Properties**, click **Extended** and change the following properties:
   a. In the **Shareability** field, select `Shareable`.
   b. In the **Default input open options** field, select `Input shared`.
5. To create your model queue, click **Finish**.
6. In the Navigator view of WebSphere MQ Explorer, expand **JMS Administered Objects** > ***JNDIRepository***, where *JNDIRepository* is the name of your JNDI repository, click **Connection Factories**. A list of Connection Factories is displayed in the Content view.
7. Right-click the Connection Factory that you want to use, then click **Properties**.
8. In the Properties window, click **Temporary queues**.
9. In the **Temporary model queue** field, enter the name of the JMS temporary dynamic model queue that you created previously, then click **Apply**.
10. To save your changes, click **OK**.

Results

You have created a model queue, and configured your queue manager to create JMS temporary dynamic queues you can use with the WebSphere MQ JMS provider.

What to do next

You can now use JMS temporary dynamic queues in your message flow applications with the WebSphere MQ JMS provider.

Local environment overrides for the SOAPRequest node:

You can dynamically override values in the local environment in the same way as setting values in other elements of a message.

Other local environment overrides are available for WS-Addressing. See "WS-Addressing with the SOAPRequest node" on page 1653.

You can set the following properties in the SOAPRequest node under `LocalEnvironment.Destination.SOAP.Request`. These local environment overrides also apply to the SOAPAsyncRequest node.

Setting	Description
Operation	Overrides the `Operation` property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Operation = 'myOperation';`

TransportType	Overrides the `Transport` property on the node to switch transport. For example, if the node is configured to use the JMS transport, use the following to switch to HTTP transport:
	`SET OutputLocalEnvironment.Destination.SOAP.Request.TransportType = 'http';`
	
	To switch to JMS transport:
	`SET OutputLocalEnvironment.Destination.SOAP.Request.TransportType = 'jms';`
	
	This overrides the request and response transport for this message.

UserContext	You can store BLOB context data in the following location in the local environment. The SOAPAsyncResponse node can later retrieve this data. `SET OutputLocalEnvironment.Destination.SOAP.Request.UserContext = x'aabbccddeeff1122334455667788990';` Data stored in the UserContext must be in BLOB format. This field is included in the message bitstream, and therefore increases the message size. This setting applies only to the SOAPAsyncRequest node and is ignored by a SOAPRequest node.

LocalEnvironment overrides for HTTP transport

You can set the following HTTP properties in the SOAPRequest node under `LocalEnvironment.Destination.SOAP.Request.Transport.HTTP`. These properties apply only when using HTTP transport. You can switch between HTTP and JMS transport using the `TransportType` override, or the WS-Addressing `To` field; see "WS-Addressing information in the local environment" on page 1656.

Setting	Description
Compression	Overrides the `Use compression` property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.Compression = 'gzip';`

Setting	Description
HTTPVersion	Overrides the HTTPVersion. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.HTTPVersion = 'HTTP/1.1';`
Method	Overrides the Method. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.Method = 'GET';`

ProxyConnectHeaders	Specifies additional headers that are used if the outbound request is an SSL connection through a proxy. These additional headers are sent with the initial CONNECT request to the proxy. For example, you can send proxy authentication information to a proxy server when you are using SSL. You can send multiple headers but each one must be separated by a carriage return and a line feed (ASCII 0x0D 0x0A), in accordance with RFC2616; for example:
	`DECLARE CRLF CHAR CAST(X'0D0A' AS CHAR CCSID 1208);`
	`SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.ProxyConnectHeaders = 'Proxy-Authorization: Basic Zm5lcmJsZTpwYXNzd29yZA==' || CRLF ||`
	`'Proxy-Connection: Keep-Alive' || CRLF;`
	
	This setting is used only if the request is an SSL request through a proxy server. To send proxy authentication information for a non-SSL request, specify the individual headers in the HTTPRequestHeader folder, as shown in the following example:
	`SET OutputRoot.HTTPRequestHeader."Proxy-Authorization" = 'Basic Zm5lcmJsZTpwYXNzd29yZA==';`
	`SET OutputRoot.HTTPRequestHeader."Proxy-Connection" = 'Keep-Alive';`

ProxyURL	Overrides the HTTP(S) proxy location property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.ProxyURL = 'my.proxy';`
RequestURI	Overrides the RequestURI, which is the path after the URL and port. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.RequestURI = '/abc/def?x=y&g=h';`
SSLCiphers	Overrides the Allowed SSL Ciphers (if using SSL) property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.SSLCiphers = 'SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA';`
SSLProtocol	Overrides the SSLProtocol property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.SSLProtocol = 'TLS';` Valid values are SSL, SSLv3, and TLS.
Timeout	Overrides the Request timeout (in seconds) property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.Timeout = 42;`
TimeoutMillis	Overrides the Request timeout (in seconds) property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.TimeoutMillis = 5000;` This property defines the timeout in milliseconds. The value of TimeoutMillis overrides the value for Timeout if both values are set.
WebServiceURL	Overrides the Web service URL property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.WebServiceURL = 'http://ibm.com/abc/';`

LocalEnvironment overrides for JMS transport

You can set the following JMS properties in the SOAPRequest node under `LocalEnvironment.Destination.SOAP.Request.Transport.JMS`. These properties apply only when using JMS transport. You can switch between HTTP and JMS transport using the `TransportType` override, or the WS-Addressing `To` field; see "WS-Addressing information in the local environment" on page 1656.

Some JMS local environment overrides for the SOAPRequest node have equivalent properties in the JMSTransport header. If you specify a local environment override, it takes precedence over any equivalent property set in the JMSTransport header.

Setting	Description
BindingsLocation	Overrides the JNDI URL bindings location property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.JNDI.BindingsLocation = 'file:/C:/mqsi6/Webservices/SOAP/JMS/JNDI';`
ConnectionFactoryName	Overrides the Connection factory name property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.JNDI.ConnectionFactoryName = 'QCF';`

ContextParameters	Specify JNDI context parameters in addition to the JNDI context parameters defined on the node. You can define specific JNDI context parameters, for example:
	`SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.JNDI.ContextParameters.property1 = 'value1';`
	`SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.JNDI.ContextParameters.property2 = 'value2';`

CorrelationID	Sets the request message CorrelID. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.CorrelationID = 'myCorrelID';`
CorrelationPattern	Sets the request message correlation pattern. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.CorrelationPattern = 1;` The allowed values are the integers 1 and 2: • 1 indicates that the messages should be automatically correlated by the CorrelID if one is present. Otherwise, the messages are correlated by the message ID. This is the default behavior. • 2 forces the messages to be correlated by the message ID, even if a CorrelID is present.
DeliveryMode	Overrides the DeliveryMode property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.DeliveryMode = 'NON_PERSISTENT';` Allowed values for this property are PERSISTENT and NON_PERSISTENT. If the UriFormat is ibm, 1 and 0 are additional allowed values for DeliveryMode.
Destination	Overrides the Destination property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.Destination = 'REPLYTOQ2';`
DestinationURI	You can override multiple JMS properties at the same time in the local environment using the DestinationURI setting. Properties that you set in this way can be overridden by setting local environment overrides for individual JMS properties as shown in the following tables. `SET OutputLocalEnvironment.Destination.SOAP.Reply.Transport.JMS.DestinationURI = 'jms:jndi:INPUTQ1?jndiConnectionFactoryName=QCF& replyToName=REPLYTOQ2& jndiInitialContextFactory=com.sun.jndi.fscontext.RefFSContextFactory& jndiURL=file:/C:/Webservices/SOAP/JMS/JNDI& userParam1=value1& userParam2=value2& timeToLive=30000';` This local environment override can be set with either a W3C-style or IBM-style URI format. For more information, see “WSDL URI formats for JMS” on page 1668.
Expiration	Overrides the Expiration property on the node. This property is specified in milliseconds. For example, to set an expiration of 100 milliseconds: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.Expiration = '100';`

Setting	Description
InitialContextFactory	Overrides the Initial context factory property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.JNDI.InitialContextFactory = 'com.sun.jndi.fscontext.RefFSContextFactory';`
MessagePriority	Overrides the MessagePriority property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.MessagePriority = '7';`
MessageType	Overrides the MessageType property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.MessageType = 'text';` Allowed values for this property are textand bytes.
ProviderName	Overrides the JMS provider name property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.ProviderName = 'WebSphere MQ';`
ReplyToDestination	Overrides the ReplyToDestination property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.ReplyToDestination = 'REPLYTOQ3';`
TargetService	Overrides the TargetService property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.TargetService = 'testService';`
Timeout	Overrides the Timeout property on the node. This value is specified in seconds. For example, to set a timeout value of 30 seconds: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.Timeout = '30';`
TransactionMode	Overrides the Transaction mode property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.TransactionMode = 'Yes';` Allowable values for this property are Yes, No and ForceLocal. • No means that no transaction takes place, and is equivalent to None. • Yes means that a local transaction takes place if the flow's Coordinated Transaction is not selected, or a global transaction takes place if the flow's Coordinated Transaction property is selected. • ForceLocal means that a local transaction is always used, even if the flow's Coordinated Transaction property is selected.
UriFormat	Overrides the UriFormat property on the node. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.UriFormat = 'w3c';` Allowable values for this property are w3c and ibm.

UserProperties	Specify user context parameters in addition to the user context parameters defined on the node. You can define specific user context parameters, for example:
	`SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.JNDI.UserProperties.property1 = 'value1';`
	`SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.JMS.JNDI.UserProperties.property2 = 'value2';`

Setting	Description
OneWay	Instructs the node that the inbound message was a one-way message and that no reply message is needed. For example: `SET OutputLocalEnvironment.Destination.SOAP.Request.Gateway.OneWay = True` If the message is sent over the HTTP transport, the node waits for an acknowledgment HTTP 202 response message from the remote server. If the message is sent over the JMS transport no response is expected. In this example the outbound message has no Reply-To queue, and the node does not wait for any response. For more information, see "One-way messages in Gateway mode" on page 1648.

TCPIPClientInput node

Use the TCPIPClientInput node to create a client connection to a raw TCP/IP socket, and to receive data over that connection.

This topic contains the following sections:

Purpose:

The TCPIPClientInput node opens connections to a remote server application that is listening on a TCP/IP port. The connections are not made directly by the node but are obtained from a connection pool managed by the WebSphere Message Broker execution group. The execution group uses the default TCPIPClient configurable service to determine which attributes are used for the socket connection. However, if the configurable service is set on the node, the configurable service is used for all the properties, including the host and port number.

You can configure the broker to use SSL for TCP/IP nodes; see "SSL and the TCP/IP nodes" on page 551.

When a connection is opened by the connection pool, it is sent to a TCPIPClientInput node (if the Open terminal of the node is connected). The input event is sent to only one TCPIPClientInput node on the connection.

The node requests a client connection that contains data ready for reading. Until such a connection is available, the node is paused, waiting for data (in a similar way to the MQInput node). Therefore, two criteria must be met before the node becomes available:

- A client connection has been made
- At least one byte of data is available to be processed

By default (as set in the configurable service), no client connections are made by the input node. The node relies on the creation of client connections by output or request nodes. In this mode of operation, an input node is never started until an output or request node starts an interaction.

You can change the mode on the configurable service to create a pool of client connections ready for processing. To use this function, `minimumConnections` must be set to a value larger than zero. The execution group then ensures that the specified

number of connections are always available by creating them at the start, and continuing to create the connections until the minimum value is reached.

This behavior is different from the TCPIPServerInput node, which does not attempt to make a minimum number of connections. For more information, see "TCPIPServerInput node" on page 4890.

The client node also has a maximum value, which limits how many connections it can create. More connections than the minimum value can exist as a result of output nodes creating connections.

When connections are available, the second criterion is met when there is at least one byte of data to be processed; otherwise, the connection closes. In either case, the connection is given to the node and the event is processed.

The first record of data is detected in accordance with properties on the node and then sent to the Out terminal. If an error occurs, including a timeout waiting for data or the closure of a connection while waiting for the full record, the data is sent to the Failure terminal. If the connection closes and there is no data, a message is sent to the Close terminal. Although the message has no data, the local environment does have details of the connection that closed.

For both data and close events, the following local environment is created:

Table 253. Location in local environment

Location in local environment	Description
$LocalEnvironment/TCPIP/Input/ConnectionDetails/Type	The client.
$LocalEnvironment/TCPIP/Input/ConnectionDetails/Hostname	The host name used to make a connection.
$LocalEnvironment/TCPIP/Input/ConnectionDetails/Port	The port number used to make a connection.
$LocalEnvironment/TCPIP/Input/ConnectionDetails/OpenTimestamp	The time stamp when the connection was first opened.
$LocalEnvironment/TCPIP/Input/ConnectionDetails/CloseTimestamp	The time stamp when the connection was closed (null if not yet closed).
$LocalEnvironment/TCPIP/Input/ConnectionDetails/SequenceNumber/InputRecord	The sequence number of the message received on this connection. The first record has a sequencing number of 1; the second record has a sequencing number of 2, and so on.
$LocalEnvironment/TCPIP/Input/ConnectionDetails/SequenceNumber/OutputRecord	The sequence number of the message sent on this connection. The first record has a sequencing number of 1; the second record has a sequencing number of 2, and so on.
$LocalEnvironment/TCPIP/Input/ConnectionDetails/Id	The ID of the socket being used. This ID is an internal identifier used by the message broker to uniquely identify a connection.
$LocalEnvironment/TCPIP/Input/ConnectionDetails/ReplyId	The reply ID that has been stored on this connection. The value can be any text string.

When the node has constructed the record from the connection stream it releases the connection back to the connection pool for use by other nodes. Properties on the Advanced tab show how that connection can be used by other nodes in the

future. By default, the Advanced properties mark the input stream on the TCP/IP connection as being reserved, which means that no other input node can use it, until the current use of the message flow is finished. Alternatively, you can reserve the connection until it is unreserved by another node, or not to reserve it at all and permit any other node (or thread in this node) to use the connection straight away. Similar options are available on the output stream but it is kept unreserved by default.

Another node can access a reserved stream only if the ID of the connection is known. This behavior allows all the nodes in a message flow to access the same connection using the same ID while stopping any other flow acquiring the connection.

The TCPIPClientInput node is contained in the **TCPIP** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Message structure

The TCPIPClientInput node handles messages in the following message domains:

- XMLNSC
- DataObject
- JSON
- BLOB
- MIME
- MRM
- JMSMap
- JMSStream
- XMLNS

Using the TCPIPClientInput node in a message flow:
Look at the following samples to see how to use the TCPIPClientInput node:

- TCPIP Client Nodes
- TCPIP Handshake

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Configuring the TCPIPClientInput node:
When you have put an instance of the TCPIPClientInput node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

All mandatory properties that do not have a default value defined are marked with an asterisk.

Configure the TCPIPClientInput node:

1. Optional: On the **Description** tab, enter a `Short description`, a `Long description`, or both. You can also rename the node on this tab.

2. On the **Basic** tab, set the properties that determine how the TCP/IP connection is controlled.
   - Use the Connection details property to specify either the host name and port number to be used, or the name of a configurable service. This property is mandatory. The following formats are supported:
     - Configurable service name. This value is used to look up the port and host name in configurable services. For example, TCPIPProfile1.
     - <Hostname>:<Port>. This value is the host name followed by the port number (separated by a colon). For example, tcpip.server.com:1111.
     - <Port>. This value is the port number. In this case, the host name is assumed to be localhost.
   - Use the Timeout waiting for a data record (seconds) property to specify how long the node listens on a connection for more data after the first byte of data has arrived. You can specify any length of time in seconds. The default is 60 seconds. When the specified time has been exceeded, all available data is sent to the Failure terminal.
3. On the **Advanced** tab, set the properties that determine how the data stream is controlled.
   - Use the Close connection property to specify when and how to close the connection.
     - Select No to leave the connection open. This value is the default.
     - Select After timeout to close the connection when a timeout occurs.
     - Select After data has been received to close the connection when the end of the record is found.
     - Select At end of flow to close the connection after the flow has been run.
   - Select Close input stream after a record has been received to close the input stream as soon as the data has been retrieved. When the connection input stream is reserved, no other node can use it without specifying the ID. This property is not selected by default.
   - Use the Input Stream Modification property to specify whether to reserve the input stream for use only by input and receive nodes that specify the connection ID, or to release the input stream at the end of the flow. These options are available only if you have not selected the Close input stream after a record has been received property.
     - Select Leave unchanged to leave the input stream as it was when it entered the node. This value is selected by default.
     - Select Reserve input stream (for use by future TCPIP input and receive nodes) to specify that this input stream can be used only by this node and by other receive nodes that request it by specifying the connection ID. When the connection input stream is reserved, no other nodes can use it without specifying the correct connection ID.
     - Select Reserve input stream (for use by future TCPIP input and receive nodes) then release at end of flow to specify that this input stream can be used only by this node and receive nodes that request it by specifying the correct connection ID. After the flow has been run, this input stream is returned to the pool and becomes available for use by any input or receive node.
   - Use the Output Stream Modification property to specify whether to release the output stream.
     - Select Leave unchanged to leave the output stream as it was when it entered the node. This value is selected by default.

- Select `Release output stream and reset ReplyID` to specify that this output stream is returned to the pool and is available for use by any output node. The ReplyID is passed in the LocalEnvironment when leaving this node, but is reset for the next record on this connection.

4. On the **Input Message Parsing** tab, set values for the properties that the node uses to determine how to parse the incoming message.

   If the incoming message has an MQRFH2 header, you do not have to set values for the Input Message Parsing properties because the values are derived from the `<mcd>` folder in the MQRFH2 header; for example:

   ```
   <mcd><Msd>MRM</Msd><Set>DHM4UO906S001</Set><Type>receiptmsg1</Type>
   <Fmt>XML</Fmt></mcd>
   ```

   If you set values that differ from those in the MQRFH2 header, the values in the MQRFH2 header take precedence.

   - In `Message domain`, select the name of the parser that you are using from the list. The default is `BLOB`. You can choose from the following options:
     - XMLNSC
     - DataObject
     - JSON
     - BLOB
     - MIME
     - MRM
     - JMSMap
     - JMSStream
     - XMLNS

     You can also specify a user-defined parser, if appropriate.
   - If you are using the MRM or IDOC parser, or the XMLNSC parser in validating mode, select the `Message set` that you want to use. This list is populated with available message sets when you select MRM, XMLNSC, or IDOC as the domain.
   - If you are using the MRM parser, select the correct message type from the list in `Message type`. This list is populated with available message types when you select the MRM parser.
   - If you are using the MRM or IDOC parser, select the correct message format from the list in `Message format`. This list is populated with available message formats when you select the MRM or IDOC parser.
   - Specify the message coded character set ID in `Message coded character set ID`.
   - Select the message encoding from the list in `Message encoding` or specify a numeric encoding value. The default is `Broker System Determined`. You can choose from the following options:
     - Little Endian, with IEEE Floating Point (546)
     - Big Endian, with IEEE Floating Point (273)
     - Big Endian, with S390 Floating Point (785)
     - Broker System Determined

     For more information about encoding, see "Data conversion" on page 1151.

5. On the **Parser Options** subtab:

   - `Parse timing` is, by default, set to `On Demand`, which causes parsing of the message to be delayed. To cause the message to be parsed immediately, see "Parsing on demand" on page 4173.
   - If you are using the XMLNSC parser, set values for the properties that determine how the XMLNSC parser operates. For more information, see "Manipulating messages in the XMLNSC domain" on page 2546.

6. Use the **Retry** tab to define how retry processing is performed when a flow fails. You can set the following retry processing:
   - `Retry mechanism` determines the action that occurs if the flow fails. The following choices can be set:
     - Select `Failure` for the node to report a failure without any retry attempts.
     - Select `Short retry` for the node to retry before reporting a failure if the condition persists. The number of times that it retries is specified in `Retry threshold`.
     - Select `Short retry and long retry` for the node to retry, first using the value in `Retry threshold` as the number of attempts to make. If the condition persists after the `Retry threshold` has been reached, the node uses the `Long retry interval` between attempts.
   - Specify the `Retry threshold`. The number of times the node retries the flow transaction if the `Retry mechanism` property is set to either `Short retry` or `Short retry and long retry`.
   - Specify the `Short retry interval`. The length of time, in seconds, to wait between short retry attempts.
   - Specify the `Long retry interval`. The length of time to wait between long retry attempts until a message is successful, the message flow is stopped, or the message flow is redeployed. The broker property **`MinLongRetryInterval`** defines the minimum value that the `Long retry interval` can take. If the value is lower than the minimum, the broker value is used.
7. Use the **Records and Elements** tab to specify how the data is interpreted as records:
   - Use the `Record detection` property to determine how the data is split into records, each of which generates a single message. Choose from the following options:
     - `End of stream` specifies that all of the data sent in the data stream is a single record.
     - `Fixed Length` specifies that each record is a fixed number of bytes in length. Each record must contain the number of bytes specified in the `Length` property, except possibly a shorter final record in the file.
     - Select `Delimited` if the records you are processing are separated, or terminated, by a DOS or UNIX line end or by a sequence of user-defined delimiter bytes. Specify the delimiter and delimiter type in the `Delimiter` and `Delimiter type` properties.
     - Select `Parsed Record Sequence` if the data contains a sequence of one or more records that are serially recognized by the parser that is specified in `Message domain`. The node propagates each recognized record as a separate message. If you select this `Record detection` option, the parser specified in `Message domain` must be either XMLNSC or MRM (either CWF or TDS physical format).
   - If you set `Record detection` to `Fixed Length`, use `Length` to specify the required length of the output record. This value must be in the range 1 byte through 100 MB. The default is `80` bytes.

     If you set `Record detection` to `Connection closed`, `Fixed Length`, or `Delimited`, a limit of 100 MB applies to the length of the records. If you set `Record detection` to `Parsed Record Sequence`, the TCPIPClientInput node does not determine or limit the length of a record. Nodes that are downstream in the message flow might try to determine the record length, or process a long record. If you intend to process large records in this way, ensure that your broker has sufficient memory. You might have to apply

flow techniques described in the Large Messaging sample to best use the available memory; see Large Messaging.

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

- If you set `Record detection` to `Delimited`, use `Delimiter` to specify the delimiter to be used. Choose from:
  - `DOS or UNIX Line End`, which, on UNIX systems, specifies the line feed character (<LF>, X'0A'), and, on Windows systems, specifies a carriage return character followed by a line feed character (<CR><LF>, X'0D0A'). The node treats both of these strings as delimiters, irrespective of the system on which the broker is running. If they are both displayed in the same record, the node recognizes both strings as delimiters. The node does not recognize X'15', which, on z/OS systems, is the 'newline' byte; specify a value of `Custom Delimiter` in this property and a value of 15 in the `Custom delimiter` property if your input file is coded using EBCDIC new lines, such as EBCDIC files from a z/OS system.
  - `Custom Delimiter`, which permits a sequence of bytes to be specified in `Custom delimiter`.
- In `Custom delimiter`, specify the delimiter byte or bytes to be used when `Custom delimiter` is set in the `Delimiter` property. Specify this value as an even-numbered string of hexadecimal digits. The default is X'0A' and the maximum length of the string is 16 bytes (represented by 32 hexadecimal digits).
- If you specify `Delimited` in `Record detection`, use `Delimiter type` to specify the type of delimiter. Permitted values are:
  - `Infix`. If you select this value, each delimiter separates records. If the data ends with a delimiter, the (zero length) data following the final delimiter is still propagated, although it contains no data.
  - `Postfix`. If you specify this value, each delimiter terminates records. If the data ends with a delimiter, no empty record is propagated after the delimiter. If the data does not end with a delimiter, it is processed as if a delimiter follows the final bytes of the data. `Postfix` is the default value.
- The TCPIPClientInput node considers each occurrence of the delimiter in the input as either separating (infix) or terminating (postfix) each record. If the data begins with a delimiter, the node treats the (zero length) contents preceding that delimiter as a record and propagates an empty record to the flow. The delimiter is never included in the propagated message.

8. Use the **Validation** tab to provide validation based on the message set for predefined messages. For more information about validation, see "Validating messages" on page 1478. For information about how to complete this tab, see "Validation tab properties" on page 4169.
9. On the **Transactions** tab, set the transaction mode. Although TCP/IP operations are non-transactional, the transaction mode on this input node determines whether the rest of the nodes in the flow are to be run under point of consistency. Select `Yes` if you want the flow updates to be treated transactionally (if possible) or `No` if you do not. The default for this property is `No`.
10. Optional: On the **Instances** tab, set values for the properties that show the additional instances (threads) that are available for a node. For more details, see "Configurable message flow properties" on page 4020.

Terminals and properties:
The terminals of the TCPIPClientInput node are described in the following table.

Terminal	Description
Open	The output terminal to which a message is routed when a connection is first opened. Use the Open terminal if processing is required when a connection is opened rather than when data first arrives. The connection associated with the message is reserved from the general connection pool until propagation to the Open terminal has finished. However, the connection can be accessed using the connectionId specified in the local environment. Each connection that is created is sent to the Open terminal, including any connections that are created mid-flow by a TCPIPClientReceive node or TCPIPClientOutput node. If the Open terminal is not attached, open events are automatically made available in the connection pool.
Failure	The output terminal to which the message is routed if an error occurs. This value includes failures caused by retry processing. Even if the Validation property is set, messages propagated to this terminal are not validated.
Out	The output terminal to which the message is routed if it is successfully retrieved from an external resource. If no errors occur within the input node, a message received from an external resource is always sent to the Out terminal first.
Close	The output terminal to which the message is routed if the connection closes.
Catch	The output terminal to which the message is routed if an exception is issued downstream and caught by this node. Exceptions are caught only if this terminal is attached.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file for deployment).

The Description properties of the TCPIPClientInput node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	TCPIPClientInput	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the TCPIPClientInput node are described in the following table.

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
Connection details	Yes	Yes		A string containing either the host name and port number to be used, or the name of a configurable service.	connectionDetails
Timeout waiting for a data record (seconds)	Yes	Yes	`60`	Specifies how long the node listens on a connection for more data after the first byte of data has arrived. You can specify any length of time in seconds.	timeoutWaitingForData

The Advanced properties of the TCPIPClientInput node are described in the following table.

Property	M	C	Default	Description
Close connection	Yes	No	`No`	Controls when the connection is closed, or if it remains open. Valid options are: • `No` • `After Timeout` • `After Data has been Received` • `At End of Flow`
Close input stream after a record has been received	Yes	No	Cleared	Specifies whether to close the input stream as soon as the data has been retrieved. When the connection input stream is reserved, no other node can use it without knowing the ID. This property is not selected by default.
Input Stream Modification	No	No	`Leave unchanged`	Specifies whether to reserve the input stream for use only by input and receive nodes that specify the connection ID, or to release it at the end of the flow. Valid options are: • `Leave unchanged` • `Reserve input stream (for use by future TCPIP nodes)` • `Reserve input stream (for use by future TCPIP nodes) then release at end of flow` When the connection input stream is reserved, no other nodes can use it without specifying the correct connection ID. If the input stream is released at the end of the flow, it is returned to the pool and becomes available for use by any input or receive node.
Output Stream Modification	No	No	`Leave unchanged`	Specifies whether this output stream is released and returned to the pool for use by any output node. Valid options are: • `Leave unchanged` • `Release output stream and reset ReplyID` If you select `Release output stream and reset ReplyID`, the ReplyID is passed in the LocalEnvironment when leaving this node, but is reset for the next record on this connection.

The TCPIPClientInput node Input Message Parsing properties are described in the following table.

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
Message domain	No	No		The domain that is used to parse the incoming message.	
Message set	No	No		The name or identifier of the message set in which the incoming message is defined. If you set this property, then later update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message Set` property, or restore the reference to this message set project.	
Message type	No	No		The name of the incoming message.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Message format	No	No		The name of the physical format of the incoming message.	
Message coded character set ID	Yes	No	`Broker System Default`	The ID of the coded character set used to interpret the data being read.	messageCodedCharSetIdProperty
Message encoding	Yes	No	`Broker System Determined`	The encoding scheme for numbers and large characters used to interpret the data being read. Valid values are `Broker System Determined` or a numeric encoding value. For more information about encoding, see "Data conversion" on page 1151.	messageEncodingProperty

The Parser Options properties of the TCPIPClientInput node are described in the following table.

Property	M	C	Default	Description
Parse timing	No	No	`On Demand`	This property controls when an input message is parsed. Valid values are: • `On Demand` • `Immediate` • `Complete` For a full description of this property, see "Parsing on demand" on page 4173.
Build tree using XML schema data types	No	No	Cleared	This property controls whether the syntax elements in the message tree have data types taken from the XML schema.
Use XMLNSC compact parser for XMLNS domain	No	No	Cleared	This property controls whether the XMLNSC Compact Parser is used for messages in the XMLNS Domain. If you set this property, the message data is displayed under XMLNSC in nodes that are connected to the output terminal when the input MQRFH2 header or Input Message Parsing property, `Message Domain`, is XMLNS.
Retain mixed content	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in an input message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in an input message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in an input message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the input message that are to be opaquely parsed by the XMLNSC parser.

The Records and Elements properties of the TCPIPClientInput node are described in the following table:

Property	M	C	Default	Description
Record detection	Yes	No	`End of Stream`	The mechanism used to identify records in the input data. Valid options are: • `End of Stream` • `Fixed Length` • `Delimited` • `Parsed Record Sequence`
Length (bytes)	Yes	No	`0`	The length of each record, in bytes, when `Fixed Length` record detection is selected.
Delimiter	Yes	No	`DOS or UNIX Line End`	The type of delimiter bytes that separate, or end, each record when `Delimited` record detection is selected. Valid options are: • `DOS or UNIX Line End` • `Custom Delimiter (Hexadecimal)`
Custom delimiter (hexadecimal)	No	No		The delimiter bytes, expressed in hexadecimal, when `Delimited` record detection and `Custom Delimiter` are selected. This property is mandatory only if the `Delimiter` property is set to `Custom Delimiter (Hexadecimal)`.
Delimiter type	Yes	No	`Postfix`	The location of the delimiter when `Delimited` record detection and `Custom Delimiter (Hexadecimal)` are selected. Valid options are: • `Infix` • `Postfix` This property is ignored unless the `Delimiter` property is set to `Custom Delimiter (Hexadecimal)`.

The Retry properties of the TCPIPClientInput node are described in the following table:

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Retry mechanism	Yes	No	`Failure`	How the node handles a flow failure. Valid options are: • `Failure` • `Short Retry` • `Short and Long Retry`	
Retry threshold	Yes	Yes	`0`	The number of times to retry the flow transaction when `Retry mechanism` is `Short retry`.	retryThreshold
Short retry interval	No	Yes	`0`	The interval, in seconds, between each retry if `Retry threshold` is not zero.	shortRetryInterval
Long retry interval	No	Yes	`300`	The interval between retries if `Retry mechanism` is `Short and long retry` and the retry threshold has been exhausted.	longRetryInterval

The Validation properties of the TCPIPClientInput node are described in the following table.

For a full description of these properties, see “Validation properties” on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	Yes	None	This property controls whether validation takes place. Valid values are • None • Content and Value • Content	validateMaster
Failure action	No	No	Exception	This property controls what happens if validation fails. Valid values are: • User Trace • Local Error Log • Exception • Exception List	

The Transactions properties of the TCPIPClientInput node are described in the following table:

Property	M	C	Default	Description
Transaction mode	No	Yes	No	The transaction mode on this input node determines whether the rest of the nodes in the flow are run under point of consistency. Valid options are: • No • Yes

The Instances properties of the TCPIPClientInput node are described in the following table. For a full description of these properties, see "Configurable message flow properties" on page 4020.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Additional instances pool	No	Yes	Use Pool Associated with Message Flow	The pool from which additional instances are obtained. • If you select Use Pool Associated with Message Flow, additional instances are obtained from the message flow pool. • If you select Use Pool Associated with Node, additional instances are allocated from the additional instances of the node based on the number specified in the Additional instances property.	componentLevel
Additional instances	No	Yes	0	The number of additional instances that the node can start if the Additional instances pool property is set to Use Pool Associated with Node.	additionalInstances

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

If you are writing ESQL to process messages in the XMLNSC domain, it is helpful to learn about the structure of the message tree that the XMLNSC parser builds.

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

"Editing configurable properties" on page 3227
You can edit configurable properties in the deployment descriptor file (`broker.xml`) of your broker archive.

Related reference:

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

"Configurable message flow properties" on page 4020
When you add a message flow to a broker archive (BAR) file in preparation for deploying it to a broker, you can set additional properties that influence its run time operation. These properties are available for review and update when you select the **Manage and Configure** tab for the broker archive file.

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

"**mqsicreateconfigurableservice** command" on page 3849
Use the **mqsicreateconfigurableservice** command to create an object name for a broker external resource.

"**mqsireportproperties** command" on page 3937
Use the **mqsireportproperties** command to display properties that relate to a broker, an execution group, or a configurable service.

"**mqsichangeproperties** command" on page 3756
Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

"TCPIPClientOutput node"
Use the TCPIPClientOutput node to create a client connection to a raw TCP/IP socket, and to send data over that connection to an external application.

"TCPIPServerOutput node" on page 4903
Use the TCPIPServerOutput node to create a server connection to a raw TCP/IP socket, and to send data over the connection to an external application.

"TCPIPClientReceive node" on page 4877
Use the TCPIPClientReceive node to receive data over a client TCP/IP connection.

"TCPIPServerReceive node" on page 4913
Use the TCPIPServerReceive node to receive data over a server TCP/IP connection.

"TCPIPServerInput node" on page 4890
Use the TCPIPServerInput node to create a server connection to a raw TCPIP socket, and to receive data over that connection.

TCPIPClientOutput node

Use the TCPIPClientOutput node to create a client connection to a raw TCP/IP socket, and to send data over that connection to an external application.

This topic contains the following sections:
- "Purpose"
- "Using the TCPIPClientOutput node in a message flow" on page 4869
- "Configuring the TCPIPClientOutput node" on page 4869
- "Terminals and properties" on page 4873

Purpose:
The TCPIPClientOutput node opens connections to a remote server application that is listening on a TCP/IP port. The connections are not made directly by the node but are obtained from a connection pool managed by the WebSphere Message Broker execution group. The execution group uses the default TCPIPClient configurable service to determine which attributes are used for the socket

connection. However, if the configurable service is set on the node, the configurable service is used for all the properties, including the host and port number.

You can configure the broker to use SSL for TCP/IP nodes; see "SSL and the TCP/IP nodes" on page 551.

The TCPIPClient configurable service is used to create a pool of client connections ready for processing. To use this function, the `minimumConnections` property must be set to a value larger than zero. The execution group ensures that the specified number of connections are always available by creating them at the start, and continuing to create the connections until the minimum value is reached.

The node requests a client connection, and, if no connections are available for sending data, the output node requests that the pool creates a new connection. If the `maximumConnections` property has not been exceeded, a new connection is created.

When the connection has been established, the data is sent. If the data has not been sent successfully within the time limit specified by the node's `Timeout sending a data record` property, an exception is thrown.

Properties in the local environment can override the TCP/IP connection used by the node:

Table 254. Input local environment properties

Location in local environment	Description
$LocalEnvironment/Destination/TCPIP/Output/Hostname	The host name used to make a connection.
$LocalEnvironment/Destination/TCPIP/Output/Port	The port number used to make a connection.
$LocalEnvironment/Destination/TCPIP/Output/Id	The ID of the socket being used. This value is an internal identifier used by WebSphere Message Broker to uniquely identify a connection.
$LocalEnvironment/Destination/TCPIP/Output/ReplyId	The Reply ID that has been stored on this connection. It can be any text string.
$LocalEnvironment/Destination/TCPIP/Output/Timeout	The timeout value used when sending data to the TCP/IP client connection. This value overrides the `Timeout sending a data record` property specified on the node.

You can dynamically choose the connection details (host name and port number), and the connection used (ID), by using this property. You can also set the Reply ID on the connection. The Reply ID enables a string to be stored in the connection and to be seen in the local environment. You can use this connection to store Reply IDs from other TCPIP nodes or from other transports, such as WebSphere MQ

The output of the node contains the same information as the input, and any fields that were missing from the input are updated with details from the connection used. For example, if the `Id` property is not provided as input (because you want to create a new connection or reuse a pool connection), the output local environment contains the ID of the connection that is used.

Table 255. Output local environment properties

Location in local environment	Description
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/Hostname	The host name used to make a connection.
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/Port	The port number used to make a connection.
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/OpenTimestamp	The time stamp when the connection was first opened.
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/CloseTimestamp	The time stamp when the connection was closed (null if not yet closed).
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/SequenceNumber	The sequence number of the message received on this connection. The first record has a sequencing number of 1; the second record has a sequencing number of 2, and so on.
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/Id	The ID of the socket being used. This ID is an internal identifier used by WebSphere Message Broker to uniquely identify a connection.
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/ReplyId	The Reply ID that has been stored on this connection. It can be any text string.

If the connection closes (or any other type of exception occurs) while using the TCP/IP transport, an exception is thrown. This exception goes to the Failure terminal if it is connected, otherwise the exception returns back down the flow.

The node also has a Close input terminal. If a message is sent to this terminal, the connection is closed using a combination of the details provided in the node and the local environment.

The TCPIPClientOutput node is contained in the **TCPIP** drawer of the palette and is represented in the workbench by the following icon:

Using the TCPIPClientOutput node in a message flow:
The TCPIPClientOutput node can be used in any message flow that needs to send data to an external application. Look at the following samples to see how to use this node:

- TCPIP Client Nodes
- TCPIP Handshake

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Configuring the TCPIPClientOutput node:
When you have put an instance of the TCPIPClientOutput node into a message flow, you can configure it (for more information, see “Configuring a message flow node” on page 1503). The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk in that view.

To configure the TCPIPClientOutput node:

1. Optional: On the **Description** tab, enter a short description, a long description, or both. You can also rename the node on this tab.
2. On the **Basic** tab, set the properties that determine how the TCP/IP connection is controlled.
   - Use the `Connection details` property to specify either the host name and port number to be used, or the name of a configurable service. This property is mandatory. The following formats are supported:
     - `Configurable service name`. This value is used to look up the port and host name in configurable services. For example, `TCPIPProfile1`.
     - `<Hostname>:<Port>`. This value is the host name followed by the port number (separated by a colon). For example, `tcpip.server.com:1111`.
     - `<Port>`. This value is the port number. In this case, the host name is assumed to be `localhost`.
   - Use the `Timeout sending a data record (seconds)` property to specify how long the node waits when trying to send data. You can specify any length of time in seconds. When the specified time has been exceeded, all available data is sent to the Failure terminal. The default is `60` seconds.
3. On the **Advanced** tab, set the properties that determine how the data stream is controlled.
   - Use the `Send to` property to specify whether the data is to be sent to one connection or to all available connections:
     - Select `One connection` to send the message to only one connection, as specified by the node properties and message overrides. This value is the default.
     - Select `All available connections` to send the data to all available connections.
   - Use the `Close connection` property to specify when and how to close the connection.
     - Select `No` to leave the connection open. This value is the default.
     - Select `After timeout` to close the connection when a timeout occurs.
     - Select `After data has been sent` to close the connection when the end of the record has been sent.
   - Select `Close output stream after a record has been sent` to close the output stream as soon as the data has been sent. This property is not selected by default.
   - Use the `Output Stream Modification` property to specify whether to reserve or release the output stream. These options are available only if you have not selected the `Close output stream after a record has been sent` property.
     - Select `Leave unchanged` to leave the output stream as it was when it entered the node. This value is selected by default.
     - Select `Release output stream` to specify that this output stream is returned to the pool and is available for use by any output node.
     - Select `Reserve output stream (for use by future TCPIP output nodes)` to specify that this output stream can be used only by this node and by other output nodes that request it by specifying the connection ID. When the connection input stream is reserved, no other nodes can use it without specifying the correct connection ID.
     - Select `Reserve output stream (for use by future TCPIP output nodes) then release after propagate` to specify that this output stream can be used only by this node and output nodes that request it by specifying the

correct connection ID. After the message has been propagated, this output stream is returned to the pool and becomes available for use by any output node.

- Use the `Input Stream Modification` property to specify whether to reserve the input stream for use only by input and receive nodes that specify the connection ID, or to release it at the end of the flow.
  - Select `Leave unchanged` to leave the input stream as it was when it entered the node. This value is selected by default.
  - Select `Release input stream` to specify that this input stream is returned to the pool and is available for use by any input or receive node.
  - Select `Reserve input stream (for use by future TCPIP input and receive nodes)` to specify that this input stream can be used only by this node and by other input or receive nodes that request it by specifying the connection ID. When the connection input stream is reserved, no other nodes can use it without specifying the correct connection ID.
  - Select `Reserve input stream (for use by future TCPIP input and receive nodes) then release after propagate` to specify that this input stream can be used only by this node and receive nodes that request it by specifying the correct connection ID. After the message has been propagated, this input stream is returned to the pool and becomes available for use by any input or receive node.

4. On the **Request** tab, specify the location of the data to be written. You can specify the properties on this tab as XPath or ESQL expressions. Content Assist is available in the properties pane and also in the XPath Expression Builder, which you can invoke by clicking **Edit** to the right of each property.
   a. In `Data location`, specify the input data location. This value is the location in the input message tree that contains the record to be written. The default value is `$Body`, which is the entire message body (`$InputRoot.Body`).

      When you are specifying this property, and the data in the message tree that it identifies is owned by a model-driven parser (such as the MRM parser or XMLNSC parser), consider the following issues:

      - If you are using MRM CWF format, ensure that the identified message tree exists as a message definition. If this value is defined as a global element only, exceptions BIP5180 and BIP5167 are generated.
      - If you are using MRM TDS format, the serialization of the identified message is successful if the element is defined as a global element or message. However, if the identified field is not found as a global element or message, note that:
        - If this value is a leaf field in the message tree, the field is written as self-defining. No validation occurs even if validation is enabled.
        - If this value is a complex element, an internal exception is generated, BIP5522, indicating that the logical type cannot be converted to a string.
      - If you are using MRM XML, the events are similar as for the MRM TDS format except that, if the field is a complex element, it is written as self-defining.
      - If you use the XMLNSC parser, no validation occurs even if validation is enabled.

   b. In `Hostname location`, specify the location of the value to override the `Hostname` set in the `Connection details` property of the **Basic** tab. If you do not specify a location, the default value is `$LocalEnvironment/Destination/TCPIP/Output/Hostname`.

c. In Port location, specify the location of the value to override the Port number set in the Connection details property of the **Basic** tab. If you do not specify a location, the default value is $LocalEnvironment/Destination/TCPIP/Output/Port.

d. In ID location, specify the location of the Id of the socket being used. This internal identifier is used by WebSphere Message Broker to uniquely identify a connection. If you do not specify a location, the default value is $LocalEnvironment/Destination/TCPIP/Output/Id.

e. In Reply ID location, specify the location of the Reply ID that is stored on the connection being used. The Reply ID can be used when data is returned in an input node. If you do not specify a location, the default value is $LocalEnvironment/Destination/TCPIP/Output/ReplyId.

5. Use the **Records and Elements** tab to specify how the TCPIPClientOutput node writes the record that is derived from the message.
   - In Record definition, choose from:
     - Record is Unmodified Data to specify that records are left unchanged. This value is the default.
     - Record is Fixed Length Data to specify that records are padded to a specified length if necessary. You specify this length in the Length property. If the record is longer than the value specified in Length, the node generates an exception. Use the Padding byte (hexadecimal) property to specify the byte to be used for padding the message to the required length.
     - Record is Delimited Data to specify that records are separated by a delimiter and accumulated by concatenation. The delimiter is specified by the Delimiter, Custom delimiter, and Delimiter type properties. The file is finished only when a message is received on the Finish File terminal.
   - In Length (bytes), specify the length (in bytes) of records when Record is Fixed Length Data is specified in Record definition. Records longer than this value cause an exception to be issued. This value must be in the range 1 byte through 100 MB. The default is 80 bytes.
   - When Record is Fixed Length Data is specified in Record definition, use Padding byte (hexadecimal) to specify the byte to be used when padding records to the specified length if they are shorter than this length. Specify this value as 2 hexadecimal digits. The default value is X'20'.
   - In Delimiter, specify the delimiter to be used if you specify Record is Delimited Data in Record definition. Choose from:
     - Broker System Line End to specify that a line end sequence of bytes is used as the appropriate delimiter for the file system on which the broker is to run. This value is the default. For example, on Windows systems, this value is a 'carriage-return, line-feed' pair (X'0D0A'); on UNIX systems, this value is a single 'line-feed' byte (X'0A'); on z/OS systems, this value is a 'newline' byte (X'15').
     - Custom Delimiter (hexadecimal) to specify that the explicit delimiter sequence defined in the Custom delimiter property is to be used to delimit records.
   - In Custom delimiter (hexadecimal), specify the delimiter sequence of bytes to be used to delimit records when Custom Delimiter is specified in the Delimiter property. Specify this value as an even-numbered string of hexadecimal digits. The default is X'0A' and the maximum length of the string is 16 bytes.

- If you specify `Record is Delimited Data` in `Record definition`, use `Delimiter type` to specify how the delimiter is to separate records. Choose from:
  - `Postfix` to specify that the delimiter is added after each record that is written. This value is the default.
  - `Infix` to specify that the delimiter is only inserted between any two adjacent records.

6. On the **Validation** tab, specify the parser validation properties of the node. For more information about validation, see "Validating messages" on page 1478. For information about how to complete this tab, see "Validation tab properties" on page 4169.

Terminals and properties:
The TCPIPClientOutput node terminals are described in the following table.

Terminal	Type	Description
In	Input data	The input terminal that accepts a message for processing by the node.
Close	Input control	The input terminal to which a message is routed when the connection given in the local environment is closed.
Out	Output data	The output terminal to which the message is routed if it is successfully sent to an external resource. The message received on the In terminal is propagated to the Out terminal and is left unchanged except for the addition of status information.
Close	Output control	The output terminal to which a message propagated from the Close input terminal is routed.
Failure	Output data	The output terminal to which the message is routed if a failure is detected in the node.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the TCPIPClientOutput node are described in the following table:

Property	M	C	Default	Description
Node name	No	No	TCPIPClientOutput	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the TCPIPClientOutput node are described in the following table:

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
Connection details	Yes	Yes		A string containing either the host name and port number to be used, or the name of a configurable service.	connectionDetails

Property	M	C	Default	Description	mqsiapplybaroverride command property
Timeout sending a data record (seconds)	Yes	Yes	60	Specifies how long the node waits when attempting to send data. You can specify any length of time in seconds.	timeoutSendingData

The Advanced properties of the TCPIPClientOutput node are described in the following table.

Property	M	C	Default	Description
Close connection	Yes	No	No	Controls when the connection is closed, or if it remains open. Valid options are: • No • After Timeout • After Data has been Sent
Close output stream after a record has been sent	Yes	No	Cleared	Specifies whether to close the output stream as soon as the data has been sent. This property is not selected by default.
Output Stream Modification	No	No	Leave unchanged	Specifies whether to reserve this output stream or release it and return it to the pool for use by any output node. Valid options are: • Leave unchanged • Release output stream • Reserve output stream (for use by future TCPIP nodes) • Reserve output stream (for use by future TCPIP nodes) then release at end of flow
Input Stream Modification	No	No	Leave unchanged	Specifies whether to reserve the input stream for use only by input and receive nodes that specify the connection ID, or to release it at the end of the message flow. Valid options are: • Leave unchanged • Release input stream • Reserve input stream (for use by future TCPIP nodes) • Reserve input stream (for use by future TCPIP nodes) then release at end of flow When the connection input stream is reserved, no other nodes can use it without specifying the correct connection ID. If the input stream is released after the message has been propagated, it is returned to the pool and becomes available for use by any input or receive node.
Send to:	Yes	No	One Connection	Specifies whether the data is to be sent to one connection or to available connections. Valid options are: • One Connection • All Available Connections

The Request properties of the TCPIPClientOutput node are described in the following table:

Property	M	C	Default	Description
Data location	Yes	No	`$Body`	The location in the input message tree containing the record to be written.
Hostname location	Yes	No	`$LocalEnvironment/Destination/TCPIP/Output/Hostname`	The message element location containing the host name.
Port location	Yes	No	`$LocalEnvironment/Destination/TCPIP/Output/Port`	The message element location containing the port.
ID location	Yes	No	`$LocalEnvironment/Destination/TCPIP/Output/Id`	The message element location containing the ID.
Reply ID location	Yes	No	`$LocalEnvironment/Destination/TCPIP/Output/ReplyId`	The message element location containing the reply ID.

The Records and Elements properties of the TCPIPClientOutput node are described in the following table:

Property	M	C	Default	Description
Record definition	Yes	No	`Record is Unmodified Data`	This property controls how the records derived from the message are written. Valid options are: • `Record is Unmodified Data` • `Record is Fixed Length Data` • `Record is Delimited Data`
Length (bytes)	Yes	No	`0`	The required length of the output record. This property applies only when `Record is Fixed Length Data` is specified in `Record definition`.
Padding byte (hexadecimal)	Yes	No	`20`	The two-digit hexadecimal byte to be used to pad short messages when `Record is Fixed Length Data` is specified in `Record definition`.
Delimiter	Yes	No	`Broker System Line End`	The delimiter to be used when `Record is Delimited Data` is specified in `Record definition`. Valid options are: • `Broker System Line End` • `Custom Delimiter (Hexadecimal)`
Custom delimiter (hexadecimal)	No	No	None	The delimiter byte sequence to be used when `Record is Delimited Data` is specified in the `Record definition` property and `Custom Delimiter (Hexadecimal)` is specified in the `Delimiter` property.
Delimiter type	Yes	No	`Postfix`	This property specifies the way in which the delimiters are to be inserted between records when `Record is Delimited Data` is specified in `Record definition`. Valid options are: • `Infix` • `Postfix`

The Validation properties of the TCPIPClientOutput node are described in the following table.

For a full description of these properties, see “Validation properties” on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	Yes	Inherit	This property controls whether validation takes place. Valid values are: • None • Content and Value • Content • Inherit	validateMaster
Failure action	No	No	Exception	This property controls what happens if validation fails. You can set this property only if you set Validate to Content or Content and Value. Valid values are: • User Trace • Local Error Log • Exception • Exception List	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

TCPIPClientReceive node

Use the TCPIPClientReceive node to receive data over a client TCP/IP connection.

This topic contains the following sections:
- "Purpose"
- "Using the TCPIPClientReceive node in a message flow" on page 4879
- "Configuring the TCPIPClientReceive node" on page 4879
- "Terminals and properties" on page 4884

Purpose:
The TCPIPClientReceive node waits for data to be received on a TCP/IP connection, and retrieves the data. If the connection is closed, an exception is thrown.

You can configure the broker to use SSL for TCP/IP nodes; see "SSL and the TCP/IP nodes" on page 551.

When a connection is established, the data is sent to the TCPIPClientReceive node. If the TCPIPClientReceive node fails to receive all of the data within the time

specified in the `Timeout waiting for a data record` property, the message is sent to the timeout terminal; if no timeout terminal is connected, an exception is thrown.

Properties in the local environment can override the TCP/IP connection used by the node.

Table 256. Input local environment properties

Location in local environment for input to node	Description
$LocalEnvironment//TCPIP/Receive/Hostname	The host name used to make a connection.
$LocalEnvironment//TCPIP/Receive/Port	The port number used to make a connection.
$LocalEnvironment/TCPIP/Receive/Id	The ID of the socket being used. This ID is an internal identifier used by WebSphere Message Broker to uniquely identify a connection.
$LocalEnvironment/TCPIP/Receive/ReplyId	The Reply ID to be stored on this connection. This ID can then be used when data is returned on an input node. The Reply ID can be any text string.
$LocalEnvironment/TCPIP/Receive/Timeout	The timeout value used when waiting for data on the TCP/IP client connection. This value overrides the `Timeout waiting for a data record` property specified on the node.
$LocalEnvironment/TCPIP/Receive/Length	The value used to override the number of bytes to be read when using fixed size records. This value overrides the `Length (bytes)` property specified on the node. If the `Record detection` property is set to anything other than `Fixed Length`, the local environment field is ignored. If this field is not present or evaluates to null, it is ignored and the value on the node is used.

These properties enable the connection details (host name and port number) and the connection used (ID) to be selected dynamically. You can also set the Reply ID on the connection, which enables a string to be stored in the connection and to be seen in the local environment of any data that is received back from this connection. You can use this connection to store Reply IDs from other TCPIP nodes or from other transports, such as WebSphere MQ.

When a record has been retrieved, the ConnectionDetails field in the local environment is populated with the details of the connection that is being used.

Table 257. Output local environment properties

Location in local environment for output from node	Description
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/Type	The client.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/Hostname	The host name used to make a connection.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/Port	The port number used to make a connection.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/OpenTimestamp	The time stamp when the connection was first opened.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/CloseTimestamp	The time stamp when the connection was closed (null if not yet closed).

Table 257. Output local environment properties (continued)

Location in local environment for output from node	Description
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/ SequenceNumber/InputRecord	The sequence number of the message that is received on this connection. The first record has a sequencing number of 1; the second record is 2; and so on.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/ SequenceNumber/OutputRecord	The sequence number of the message sent on this connection. The first record has a sequencing number of 1; the second record is 2; and so on.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/ Id	The ID of the socket being used. This ID is an internal identifier used by WebSphere Message Broker to uniquely identify a connection.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/ ReplyId	The Reply ID that is stored on this connection. This ID can be any text string.

The TCPIPClientReceive node is contained in the **TCPIP** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Message structure

The TCPIPClientReceive node handles messages in the following message domains:

- XMLNSC
- DataObject
- JSON
- BLOB
- MIME
- MRM
- JMSMap
- JMSStream
- XMLNS

Using the TCPIPClientReceive node in a message flow:
Look at the following samples to see how to use the TCPIPClientReceive node:

- TCPIP Client Nodes
- TCPIP Handshake

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Configuring the TCPIPClientReceive node:
When you have put an instance of the TCPIPClientReceive node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

All mandatory properties that do not have a default value defined are marked with an asterisk.

Configure the TCPIPClientReceive node:

1. Optional: On the **Description** tab, enter a `Short description`, a `Long description`, or both. You can also rename the node on this tab.
2. On the **Basic** tab, set the properties that determine how the TCP/IP connection is controlled.
   - Use the `Connection details` property to specify either the host name and port number to be used, or the name of a configurable service. This property is mandatory. The following formats are supported:
     - `Configurable service name`. This value is used to look up the port and host name in configurable services. For example, `TCPIPProfile1`.
     - `<Hostname>:<Port>`. This value is the host name followed by the port number (separated by a colon); for example, `tcpip.server.com:1111`
     - `<Port>`. This value is the port number. In this case, the host name is assumed to be `localhost`.
   - Use the `Timeout waiting for a data record (seconds)` property to specify how long the node listens on a connection for more data after the first byte of data has arrived. You can specify any length of time in seconds. The default is `60` seconds. When the specified time has been exceeded, all available data is sent to the Failure terminal.
3. On the **Advanced** tab, set the properties that determine how the data stream is controlled.
   - Use the `Close connection` property to specify when and how to close the connection.
     - Select `No` to leave the connection open. This value is the default.
     - Select `After timeout` to close the connection when a timeout occurs.
     - Select `After data has been received` to close the connection when the end of the record is found.
   - Select `Close input stream after a record has been received` to close the input stream as soon as the data has been retrieved. By default this property is not selected. When the connection input stream is reserved, no other node can use it without knowing the ID.
   - Use the `Input Stream Modification` property to specify whether to reserve the input stream for use only by input and receive nodes that specify the connection ID, or to release the input stream at the end of the flow.
     - Select `Leave unchanged` to leave the input stream as it was when it entered the node. This value is selected by default.
     - Select `Release input stream` to specify that this input stream is returned to the pool and is available for use by any input or receive node.
     - Select `Reserve input stream (for use by future TCPIP input and receive nodes)` to specify that this input stream can be used only by this node and by other input or receive nodes that request it by specifying the connection ID. When the connection input stream is reserved, no other nodes can use it without specifying the correct connection ID.
     - Select `Reserve input stream (for use by future TCPIP input and receive nodes) then release after propagate` to specify that this input stream can be used only by this node and receive nodes that request it by specifying the correct connection ID. After the message has been propagated, this input stream is returned to the pool and becomes available for use by any input or receive node.

- Use the Output Stream Modification property to specify whether to reserve or release the output stream. These options are available only if you have not selected the Close output stream after a record has been sent property.
  - Select Leave unchanged to leave the output stream as it was when it entered the node. This value is selected by default.
  - Select Release output stream to specify that this output stream is returned to the pool and is available for use by any output node.
  - Select Reserve output stream (for use by future TCPIP output nodes) to specify that this output stream can be used only by this node and by other output nodes that request it by specifying the connection ID. When the connection input stream is reserved, no other nodes can use it without specifying the correct connection ID.
  - Select Reserve output stream (for use by future TCPIP output nodes) then release after propagate to specify that this output stream can be used only by this node and output nodes that request it by specifying the correct connection ID. After the message has been propagated, this output stream is returned to the pool and becomes available for use by any output node.

4. On the **Request** tab, specify the location of the data to be written. You can specify the properties on this tab as XPath or ESQL expressions. Content Assist is available in the Properties view and also in the XPath Expression Builder, which you can run by clicking **Edit** to the right of each property.
   - In Hostname location, specify the location of the value to override the Hostname that is set in the Connection details property of the **Basic** tab. If you do not specify a location, the default value is $LocalEnvironment/TCPIP/Receive/Hostname.
   - In Port location, specify the location of the value to override the Port that is set in the Connection details property of the **Basic** tab. If you do not specify a location, the default value is $LocalEnvironment/TCPIP/Receive/Port.
   - In ID location, specify the location of the Id of the socket being used. This internal identifier is used by WebSphere Message Broker to uniquely identify a connection. If you do not specify a location, the default value is $LocalEnvironment/TCPIP/Receive/Id.
   - In Reply ID location, specify the location of the Reply ID that is stored on the connection that is being used. The Reply ID can be used when data is returned in an input node. If you do not specify a location, the default value is $LocalEnvironment/TCPIP/Receive/ReplyId.
5. On the **Result** tab, set values for the properties that determine where the reply is stored.
   - Use the Output data location property to specify the start location in the output message tree where the parsed elements from the bit string of the message are stored. The default value is $OutputRoot.
   - Use the Copy local environment property to specify whether the local environment is copied to the output message.
     - If Copy local environment is selected, a new copy of the local environment is created in the tree, and it is populated with the contents of the local environment from the preceding node. Therefore, if a node changes the local environment, the upstream nodes are not affected by those changes because they have their own copies. This value is the default.

- If Copy local environment is not selected, the node does not generate its own copy of the local environment, but uses the local environment that is passed to it by the preceding node. Therefore, if a node changes the local environment, the changes are reflected by the upstream nodes.

6. On the **Input Message Parsing** tab, set values for the properties that the node uses to determine how to parse the incoming message.

   If the incoming message has an MQRFH2 header, you do not have to set values for the Input Message Parsing properties because the values are derived from the <mcd> folder in the MQRFH2 header; for example:

   ```
   <mcd><Msd>MRM</Msd><Set>DHM4UO906S001</Set><Type>receiptmsg1</Type>
   <Fmt>XML</Fmt></mcd>
   ```

   If you set values, and if they differ from the values in the MQRFH2 header, the values in the MQRFH2 header take precedence.

   - In Message domain, select the name of the parser that you are using from the list. The default is BLOB. You can choose from the following options:
     - XMLNSC
     - DataObject
     - JSON
     - BLOB
     - MIME
     - MRM
     - JMSMap
     - JMSStream
     - XMLNS

     You can also specify a user-defined parser, if appropriate.
   - If you are using the MRM or IDOC parser, or the XMLNSC parser in validating mode, select the Message set that you want to use. This list is populated with available message sets when you select MRM, XMLNSC, or IDOC as the domain.
   - If you are using the MRM parser, select the correct message type from the list in Message type. This list is populated with available message types when you select the MRM parser.
   - If you are using the MRM or IDOC parser, select the correct message format from the list in Message format. This list is populated with available message formats when you select the MRM or IDOC parser.
   - Specify the message coded character set ID in Message coded character set ID.
   - Select the message encoding from the list in Message encoding or specify a numeric encoding value. For more information about encoding, see "Data conversion" on page 1151.

7. On the **Parser Options** subtab:
   - Parse timing is, by default, set to On Demand, which causes parsing of the message to be delayed. To cause the message to be parsed immediately, see "Parsing on demand" on page 4173.
   - If you are using the XMLNSC parser, set values for the properties that determine how the XMLNSC parser operates. For more information, see "Manipulating messages in the XMLNSC domain" on page 2546.

8. Use the **Records and Elements** tab to specify how the data is interpreted as records. Only one record is retrieved each time the TCPIPClientReceive node is invoked; therefore, if the TCP/IP stream contains multiple logical messages, you must call the node multiple times to receive all the messages.

- Use the Record detection property to determine how the data is split into records, each of which generates a single message. Choose from the following options:
  - Connection closed specifies that all of the data sent during a connection is a single record.
  - Fixed Length specifies that each record is a fixed number of bytes in length. Each record contains the number of bytes specified in the Length property, except possibly a shorter final record in the file.
  - Select Delimited if the records that you are processing are separated, or terminated, by a DOS or UNIX line end or by a sequence of user-defined delimiter bytes. Specify the delimiter and delimiter type in the Delimiter and Delimiter type properties.
  - Select Parsed Record Sequence if the data contains a sequence of one or more records that are serially recognized by the parser specified in Message domain. The node propagates each recognized record as a separate message. If you select this Record detection option, the parser specified in Message domain must be either XMLNSC or MRM (either CWF or TDS physical format).
- If you set Record detection to Fixed Length, use Length to specify the required length of the output record. This value must be in the range 1 byte through 100 MB. The default is 80 bytes.

  If you set Record detection to Connection closed, Fixed Length, or Delimited, a limit of 100 MB applies to the length of the records. If you set Record detection to Parsed Record Sequence, the TCPIPClientReceive node does not determine or limit the length of a record. Nodes that are downstream in the message flow might try to determine the record length or process a long record. If you intend to process large records in this way, ensure that your broker has sufficient memory. You might have to apply flow techniques described in the Large Messaging sample to best use the available memory.
- If you set Record detection to Delimited, use Delimiter to specify the delimiter to be used. Choose from the following options:
  - DOS or UNIX Line End, on UNIX systems, specifies the line feed character (<LF>, X'0A'), and, on Windows systems, specifies a carriage return character followed by a line feed character (<CR><LF>, X'0D0A'). The node treats both of these strings as delimiters, irrespective of the system on which the broker is running. If both strings can be seen in the same record, the node recognizes both as delimiters. The node does not recognize X'15' which, on z/OS systems, is the 'newline' byte; set this property to Custom Delimiter and set Custom delimiter to 15 if your input file is coded using EBCDIC new lines.
  - Custom Delimiter (hexadecimal), permits a sequence of bytes to be specified in Custom delimiter (hexadecimal)
- In Custom delimiter (hexadecimal), specify the delimiter byte or bytes to be used when Delimiter is set to Custom delimiter (hexadecimal). Specify this value as an even-numbered string of hexadecimal digits. The default is X'0A' and the maximum length of the string is 16 bytes (represented by 32 hexadecimal digits).
- If you set Record detection to Delimited, use Delimiter type to specify the type of delimiter. Permitted values are:
  - Infix. If you select this value, each delimiter separates records. If the data ends with a delimiter, the (zero length) data following the final delimiter is still propagated, although it contains no data.

– `Postfix`. If you specify this value, each delimiter terminates records. If the data ends with a delimiter, no empty record is propagated after the delimiter. If the data does not end with a delimiter, it is processed as if a delimiter follows the final bytes of the data. `Postfix` is the default value.

- The TCPIPClientReceive node considers each occurrence of the delimiter in the input as either separating (infix) or terminating (postfix) each record. If the data begins with a delimiter, the node treats the (zero length) contents preceding that delimiter as a record and propagates an empty record to the flow. The delimiter is never included in the propagated message.

9. Use the **Validation** tab to provide validation based on the message set for predefined messages. For more information about validation, see "Validating messages" on page 1478. For information about how to complete this tab, see "Validation tab properties" on page 4169.

Terminals and properties:
The terminals of the TCPIPClientReceive node are described in the following table.

Terminal	Description
In	The input terminal that accepts a message for processing by the node.
Out	The output terminal to which the message is routed if it is successfully retrieved from an external resource. If no errors occur in the input node, a message received from an external resource is always sent to the Out terminal first.
Timeout	The terminal to which a message is sent when the time specified in the `Timeout waiting for a data record` property has been exceeded. The message text is `timeout value is exceeded`.
Failure	The output terminal to which the message is routed if an error occurs. These errors include failures caused by retry processing. Even if the Validation property is set, messages propagated to this terminal are not validated.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the TCPIPClientReceive node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	TCPIPClientReceive	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the TCPIPClientReceive node are described in the following table.

Property	M	C	Default	Description	`mqsiapplybaroverride` command property
Connection details	Yes	Yes		A string containing either the host name and port number to be used, or the name of a configurable service.	connectionDetails

Property	M	C	Default	Description	mqsiapplybaroverride command property
Timeout waiting for a data record (seconds)	Yes	Yes	60	Specifies how long the node listens on a connection for more data after the first byte of data has arrived. You can specify any length of time in seconds.	timeoutWaitingForData

The Advanced properties of the TCPIPClientReceive node are described in the following table.

Property	M	C	Default	Description
Close connection	Yes	No	No	Controls when the connection is closed, or if it remains open. Valid options are: • No • After Timeout • After Data has been Received
Close input stream after a record has been received	Yes	No	Cleared	Specifies whether to close the input stream as soon as the data has been retrieved. When the connection input stream is reserved, no other node can use it without knowing the ID. By default, this property is not selected.
Input Stream Modification	No	No	Leave unchanged	Specifies whether to reserve the input stream for use only by input and receive nodes that specify the connection ID, or to release the input stream at the end of the flow. Valid options are: • Leave unchanged • Release input stream • Reserve input stream (for use by future TCPIP nodes) • Reserve input stream (for use by future TCPIP nodes) then release at end of flow When the connection input stream is reserved, no other nodes can use it without specifying the correct connection ID. If the input stream is released after the message has been propagated, it is returned to the pool and becomes available for use by any input or receive node.
Output Stream Modification	No	No	Leave unchanged	Specifies whether to reserve this output stream or release it and return it to the pool for use by any output node. Valid options are: • Leave unchanged • Release output stream • Reserve output stream (for use by future TCPIP nodes) • Reserve output stream (for use by future TCPIP nodes) then release at end of flow

The Request properties of the TCPIPClientReceive node are described in the following table:

Property	M	C	Default	Description
Host name location	Yes	No	$LocalEnvironment/TCPIP/Receive/Hostname	The message element location that contains the host name.

Property	M	C	Default	Description
Port location	Yes	No	`$LocalEnvironment/TCPIP/Receive/Port`	The message element location that contains the port.
ID location	Yes	No	`$LocalEnvironment//TCPIP/Receive/Id`	The message element location that contains the ID.
Reply ID location	Yes	No	`$LocalEnvironment/TCPIP/Receive/ReplyId`	The message element location that contains the Reply ID.
Record length location	No	No	`$LocalEnvironment/TCPIP/Receive/Length`	The message element location that contains the record length to be read. Specify the location of the value to override the `Length (bytes)` property on the **Records and elements** tab. If you do not specify a location, the default value is `$LocalEnvironment/TCPIP/Receive/Length`.

The Result properties of the TCPIPClientReceive node are described in the following table:

Property	M	C	Default	Description
Output data location	No	No	`$OutputRoot`	The start location in the output message tree where the parsed elements from the bit string of the message are stored.
Copy local environment	No	No	Selected	Specifies if the local environment is copied to the output message.

The Input Message Parsing properties of the TCPIPClientReceive node are described in the following table.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Message domain	No	No		The domain that is used to parse the incoming message.	
Message set	No	No		The name or identifier of the message set in which the incoming message is defined. If you set this property, then later update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message Set` property, or restore the reference to this message set project.	
Message type	No	No		The name of the incoming message.	
Message format	No	No		The name of the physical format of the incoming message.	

Property	M	C	Default	Description	mqsiapplybaroverride command property
Message coded character set ID	Yes	No	Broker System Default	The ID of the coded character set that is used to interpret the data being read.	messageCodedCharSetIdProperty
Message encoding	Yes	No	Broker System Determined	The encoding scheme for numbers and large characters used to interpret the data that is being read. Valid values are Broker System Determined or a numeric encoding value. For more information about encoding, see "Data conversion" on page 1151.	messageEncodingProperty

The Parser Options properties of the TCPIPClientReceive node are described in the following table.

Property	M	C	Default	Description
Parse timing	No	No	On Demand	This property controls when an input message is parsed. Valid values are: • On Demand • Immediate • Complete For a full description of this property, see "Parsing on demand" on page 4173.
Build tree using XML schema data types	No	No	Cleared	This property controls whether the syntax elements in the message tree have data types taken from the XML Schema.
Use XMLNSC compact parser for XMLNS domain	No	No	Cleared	This property controls whether the XMLNSC Compact Parser is used for messages in the XMLNS domain. If you set this property, the message datais displayed under XMLNSC in nodes that are connected to the output terminal when the input MQRFH2 header or Input Message Parsing property, Message Domain, is XMLNS.
Retain mixed content	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in an input message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in an input message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in an input message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the input message that are to be parsed opaquely by the XMLNSC parser.

The Records and Elements properties of the TCPIPClientReceive node are described in the following table:

Property	M	C	Default	Description
Record detection	Yes	No	`Connection Closed`	The mechanism used to identify records in the input data. Valid options are: • `Connection Closed` • `Fixed Length` • `Delimited` • `Parsed Record Sequence`
Length (bytes)	Yes	No	`0`	The length of each record, in bytes, when `Fixed Length` record detection is selected.
Delimiter	Yes	No	`DOS or UNIX Line End`	The type of delimiter bytes that separate, or ends, each record when `Delimited` record detection is selected. Valid options are: • `DOS or UNIX Line End` • `Custom Delimiter (Hexadecimal)`
Custom delimiter (hexadecimal)	No	No		The delimiter bytes, expressed in hexadecimal, when `Delimited` record detection and `Custom Delimiter (Hexadecimal)` are selected. This property is mandatory only if the `Delimiter` property is set to `Custom Delimiter (Hexadecimal)`.
Delimiter type	Yes	No	`Postfix`	The location of the delimiter when `Delimited` record detection and `Custom Delimiter (Hexadecimal)` are selected. Valid options are: • `Infix` • `Postfix` This property is ignored unless the `Delimiter` property is set to `Custom Delimiter (Hexadecimal)`.

The Validation properties of the TCPIPClientReceive node are described in the following table.

For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Validate	No	Yes	`None`	This property controls whether validation takes place. Valid values are • `None` • `Content and Value` • `Content` • `inherit`	validateMaster
Failure action	No	No	`Exception`	This property controls what happens if validation fails. You can set this property only if you set `Validate` to `Content` or `Content and Value`. Valid values are: • `User Trace` • `Local Error Log` • `Exception` • `Exception List`	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

If you are writing ESQL to process messages in the XMLNSC domain, it is helpful to learn about the structure of the message tree that the XMLNSC parser builds.

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

"Editing configurable properties" on page 3227
You can edit configurable properties in the deployment descriptor file (`broker.xml`) of your broker archive.

Related reference:

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

"Configurable message flow properties" on page 4020
When you add a message flow to a broker archive (BAR) file in preparation for deploying it to a broker, you can set additional properties that influence its run time operation. These properties are available for review and update when you select the **Manage and Configure** tab for the broker archive file.

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

"**mqsicreateconfigurableservice** command" on page 3849
Use the **mqsicreateconfigurableservice** command to create an object name for a broker external resource.

"**mqsireportproperties** command" on page 3937
Use the **mqsireportproperties** command to display properties that relate to a broker, an execution group, or a configurable service.

"**mqsichangeproperties** command" on page 3756
Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

"TCPIPClientInput node" on page 4854
Use the TCPIPClientInput node to create a client connection to a raw TCP/IP socket, and to receive data over that connection.

"TCPIPClientOutput node" on page 4867
Use the TCPIPClientOutput node to create a client connection to a raw TCP/IP socket, and to send data over that connection to an external application.

"TCPIPServerOutput node" on page 4903
Use the TCPIPServerOutput node to create a server connection to a raw TCP/IP socket, and to send data over the connection to an external application.

"TCPIPServerInput node"
Use the TCPIPServerInput node to create a server connection to a raw TCPIP socket, and to receive data over that connection.

"TCPIPServerReceive node" on page 4913
Use the TCPIPServerReceive node to receive data over a server TCP/IP connection.

TCPIPServerInput node

Use the TCPIPServerInput node to create a server connection to a raw TCPIP socket, and to receive data over that connection.

This topic contains the following sections:
- "Purpose"
- "Using the TCPIPServerInput node in a message flow" on page 4892
- "Configuring the TCPIPServerInput node" on page 4892
- "Terminals and properties" on page 4896

Purpose:
The TCPIPServerInput node listens on a port and, when a client socket connects to the port, the server socket creates a connection for the client. Unlike the TCPIPClientInput node, the TCPIPServerInput node does not attempt to make a

minimum number of connections, because the server end of the socket cannot initiate new connections, it can only accept them. The TCPIPServerInput node accepts connections up to a maximum value, which is specified in the MaximumConnections property of the TCPIPServer configurable service. By default, the broker can accept up to 100 server connections. For more information, see “**mqsicreateconfigurableservice** command” on page 3849 and “**mqsireportproperties** command” on page 3937.

You can configure the broker to use SSL for TCP/IP nodes; see “SSL and the TCP/IP nodes” on page 551.

When a connection is opened, a message containing details of the connection is sent to the Open terminal; no data is routed to this terminal. Use the Open terminal if processing is required when a connection is opened rather than when data first arrives. The output stream for the connection is reserved until the propagation of the open message has finished (which happens immediately if the terminal is not attached to any other nodes). The options on the **Advanced** tab of the node do not apply to open events; they are applicable only when the first data arrives on the connection and is propagated down the Out terminal.

The first record of data is detected in accordance with properties on the node and then sent to the Out terminal. If an error occurs, including a timeout waiting for data or the closure of a connection while waiting for the full record, the data is sent to the Failure terminal. If the connection closes and no data exists, a message is sent to the Close terminal. Although the message has no data, the local environment does have details of the connection that closed.

For both data and close events, the following local environment is created.

Table 258. Location in local environment

Location in local environment	Description
$LocalEnvironment/TCPIP/Input/ConnectionDetails/Type	The server.
$LocalEnvironment/TCPIP/Input/ConnectionDetails/Hostname	The host name used to make a connection.
$LocalEnvironment/TCPIP/Input/ConnectionDetails/Port	The port number used to make a connection.
$LocalEnvironment/TCPIP/Input/ConnectionDetails/OpenTimestamp	The time stamp when the connection was first opened.
$LocalEnvironment/TCPIP/Input/ConnectionDetails/CloseTimestamp	The time stamp when the connection was closed (null if not yet closed).
$LocalEnvironment/TCPIP/Input/ConnectionDetails/SequenceNumber/InputRecord	The sequence number of the message received on this connection. The first record has a sequencing number of 1; the second record has a sequencing number of 2; and so on.
$LocalEnvironment/TCPIP/Input/ConnectionDetails/SequenceNumber/OutputRecord	The sequence number of the message sent on this connection. The first record has a sequencing number of 1; the second record has a sequencing number of 2; and so on.
$LocalEnvironment/TCPIP/Input/ConnectionDetails/Id	The ID of the socket being used. This ID is an internal identifier used by WebSphere Message Broker to uniquely identify a connection.
$LocalEnvironment/TCPIP/Input/ConnectionDetails/ReplyId	The Reply ID that is stored on this connection. It can be any text string.

Table 258. Location in local environment (continued)

Location in local environment	Description
$LocalEnvironment/TCPIP/Input/ConnectionDetails/ ClientDetails/Hostname	The fully qualified domain name of the computer from which the client connected.
$LocalEnvironment/TCPIP/Input/ConnectionDetails/ ClientDetails/Address	The IP address of the computer from which the client connected.

The TCPIPServerInput node is contained in the **TCPIP** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Message structure

The TCPIPServerInput node handles messages in the following message domains:

- XMLNSC
- DataObject
- JSON
- BLOB
- MIME
- MRM
- JMSMap
- JMSStream
- XMLNS

Using the TCPIPServerInput node in a message flow:
Look at the following samples to see how to use the TCPIPServerInput node:

- TCPIP Client Nodes
- TCPIP Handshake

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Configuring the TCPIPServerInput node:
When you have put an instance of the TCPIPServerInput node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

All mandatory properties that do not have a default value defined are marked with an asterisk.

Configure the TCPIPServerInput node:

1. Optional: On the **Description** tab, enter a `Short description`, a `Long description`, or both. You can also rename the node on this tab.
2. On the **Basic** tab, set the properties that determine how the TCPIP connection is controlled.

- Use the Connection details property to specify the port number to be used, or the name of a configurable service. This property is mandatory. The following formats are supported:
  - Configurable service name. This value is used to look up the port number in configurable services. For example, TCPIPProfile1.
  - <Port>. This value is the port number. For example, 1111
- Use the Timeout waiting for a data record (seconds) property to specify how long the node listens on a connection for more data after the first byte of data has arrived. You can specify any length of time in seconds. The default is 60 seconds. When the specified time has been exceeded, all available data is sent to the Failure terminal.

3. On the **Advanced** tab, set the properties that determine how the data stream is controlled.
   - Use the Close connection property to specify when and how to close the connection.
     - Select No to leave the connection open. This value is the default.
     - Select After timeout to close the connection when a timeout occurs.
     - Select After data has been received to close the connection when the end of the record is found.
     - Select At end of flow to close the connection after the flow has been run.
   - Select Close input stream after a record has been received to close the input stream as soon as the data has been retrieved. When the connection input stream is reserved, no other node can use it without specifying the ID. This property is not selected by default.
   - Use the Input Stream Modification property to specify whether to reserve the input stream for use only by input and receive nodes that specify the connection ID, and, if reserved, whether to release the input stream at the end of the flow. These options are available only if you have not selected the Close input stream after a record has been received property.
     - Select Leave unchanged to leave the input stream as it was when it entered the node. This value is selected by default.
     - Select Reserve input stream (for use by future TCPIP input and receive nodes) to specify that this input stream can be used only by this node and by other receive nodes that request it by specifying the connection ID. When the connection input stream is reserved, no other nodes can use it without specifying the correct connection ID.
     - Select Reserve input stream (for use by future TCPIP input and receive nodes) then release at end of flow to specify that this input stream can be used only by this node and receive nodes that request it by specifying the connection ID. After the flow has been run, this input stream is returned to the pool and becomes available for use by any input or receive node.
   - Use the Output Stream Modification property to specify whether to release the output stream.
     - Select Leave unchanged to leave the output stream as it was when it entered the node. This value is selected by default.
     - Select Release output stream and reset ReplyID to specify that this output stream is returned to the pool and is available for use by any output node. The ReplyID is passed in the local environment when leaving this node, but is reset for the next record on this connection.

4. On the **Input Message Parsing** tab, set values for the properties that the node uses to determine how to parse the incoming message.

   If the incoming message has an MQRFH2 header, you do not have to set values for the Input Message Parsing properties because the values are derived from the <mcd> folder in the MQRFH2 header; for example:

   ```
   <mcd><Msd>MRM</Msd><Set>DHM4UO906S001</Set><Type>receiptmsg1</Type>
   <Fmt>XML</Fmt></mcd>
   ```

   If you set values, and those values differ from those in the MQRFH2 header, the values in the MQRFH2 header take precedence.

   - In Message domain, select the name of the parser that you are using from the list. The default is BLOB. You can choose from the following options:
     - XMLNSC
     - DataObject
     - JSON
     - BLOB
     - MIME
     - MRM
     - JMSMap
     - JMSStream
     - XMLNS

     You can also specify a user-defined parser, if appropriate.
   - If you are using the MRM or IDOC parser, or the XMLNSC parser in validating mode, select the Message set that you want to use. This list is populated with available message sets when you select MRM, XMLNSC, or IDOC as the domain.
   - If you are using the MRM parser, select the correct message type from the list in Message type. This list is populated with available message types when you select the MRM parser.
   - If you are using the MRM or IDOC parser, select the correct message format from the list in Message format. This list is populated with available message formats when you select the MRM or IDOC parser.
   - Specify the message coded character set ID in Message coded character set ID.
   - Select the message encoding from the list in Message encoding or specify a numeric encoding value. For more information about encoding, see "Data conversion" on page 1151.
5. On the **Parser Options** subtab:
   a. Parse timing is, by default, set to On Demand, which causes parsing of the message to be delayed. To cause the message to be parsed immediately, see "Parsing on demand" on page 4173.
   b. If you are using the XMLNSC parser, set values for the properties that determine how the XMLNSC parser operates. For more information, see "Manipulating messages in the XMLNSC domain" on page 2546.
6. Use the **Retry** tab to define how retry processing is performed when a flow fails. You can set the following properties:
   - Retry mechanism determines the action that occurs if the flow fails. Choose from the following values:
     - Select Failure for the node to report a failure without any retry attempts.
     - Select Short retry for the node to retry before reporting a failure if the condition persists. The number of times that it retries is specified in Retry threshold.

- Select Short retry and long retry for the node to retry, first using the value in Retry threshold as the number of attempts it should make. If the condition persists after the Retry threshold has been reached, the node then uses the Long retry interval between attempts.

- Specify the Retry threshold:The number of times the node retries the flow transaction if the Retry mechanism property is set to either Short retry or Short retry and long retry.
- Specify the Short retry interval:The length of time, in seconds, to wait between short retry attempts.
- Specify the Long retry interval:The length of time to wait between long retry attempts until a message is successful, the message flow is stopped, or the message flow is redeployed. The broker property **MinLongRetryInterval** defines the minimum value that the Long retry interval can take. If the value is lower than the minimum, the broker value is used.

7. Use the **Records and Elements** tab to specify how the data is interpreted as records.
   - Use the Record detection property to determine how the data is split into records, each of which generates a single message. Choose from the following options:
     - End of stream specifies that all of the data sent in the data stream is a single record.
     - Fixed Length specifies that each record is a fixed number of bytes in length. Each record contains the number of bytes specified in the Length property.
     - Select Delimited if the records that you are processing are separated, or ended, by a DOS or UNIX line end or by a sequence of user-defined delimiter bytes. Specify the delimiter and delimiter type in the Delimiter and Delimiter type properties.
     - Select Parsed Record Sequence if the data contains a sequence of one or more records that are serially recognized by the parser specified in Message domain. The node propagates each recognized record as a separate message. If you select the Record detection option, the parser specified in Message domain must be either XMLNSC or MRM (either CWF or TDS physical format).
   - If you set Record detection to Fixed Length, use Length to specify the required length of the output record. This value must be in the range 1 byte through 100 MB. The default is 80 bytes.

     If you set Record detection to End of stream, Fixed Length, or Delimited, a limit of 100 MB applies to the length of the records. If you set Record detection toParsed Record Sequence, the TCPIPServerInput node does not determine or limit the length of a record. Nodes that are downstream in the message flow might try to determine the record length or process a long record. If you intend to process large records in this way, ensure that your broker has sufficient memory. You might have to apply flow techniques described in the Large Messaging sample to best use the available memory.
   - If you set Record detection to Delimited, use Delimiter to specify the delimiter to be used. Choose from the following values:
     - DOS or UNIX Line End, which, on UNIX systems, specifies the line feed character (<LF>, X'0A'), and, on Windows systems, specifies a carriage return character followed by a line feed character (<CR><LF>, X'0D0A'). The node treats both of these strings as delimiters, irrespective of the system on which the broker is running. If both strings are seen in the same record, the node recognizes both as delimiters. The node does not

recognize X'15', which, on z/OS systems, is the 'newline' byte; specify a value of `Custom Delimiter` in this property and a value of `15` in the `Custom delimiter` property if your input data is coded using EBCDIC new lines.

– `Custom Delimiter`, which permits a sequence of bytes to be specified in `Custom delimiter`

- In `Custom delimiter`, specify the delimiter byte or bytes to be used when `Delimiter` is set to `Custom delimiter`. Specify this value as an even-numbered string of hexadecimal digits. The default is X'0A' and the maximum length of the string is 16 bytes (represented by 32 hexadecimal digits).
- If you set `Record detection` to `Delimited`, use `Delimiter type` to specify the type of delimiter. Permitted values are:
  – `Infix`. If you select this value, each delimiter separates records. If the data ends with a delimiter, the (zero length) data that follows the final delimiter is still propagated although it contains no data.
  – `Postfix`. If you specify this value, each delimiter ends records. If the data ends with a delimiter, no empty record is propagated after the delimiter. If the data does not end with a delimiter, it is processed as if a delimiter follows the final bytes of the data. `Postfix` is the default value.
- The TCPIPServerInput node considers each occurrence of the delimiter in the input as either separating (infix) or terminating (postfix) each record. If the data begins with a delimiter, the node treats the (zero length) contents preceding that delimiter as a record and propagates an empty record to the flow. The delimiter is never included in the propagated message.

8. Use the **Validation** tab to provide validation based on the message set for predefined messages. For more information about validation, see "Validating messages" on page 1478. For information about how to provide validation for this tab, see "Validation tab properties" on page 4169.
9. On the **Transactions** tab, set the transaction mode. Although TCPIP operations are non-transactional, the transaction mode on this input node determines whether the rest of the nodes in the flow are to be run under point of consistency or not. Select `Yes` if you want the flow updates to be treated transactionally (if possible) or `No` if you do not. The default for this property is `No`.
10. Optional: On the **Instances** tab, set values for the properties that determine the additional instances (threads) that are available for a node. For more details, see "Configurable message flow properties" on page 4020.

Terminals and properties:
The terminals of the TCPIPServerInput node are described in the following table.

Terminal	Description
Failure	The output terminal to which the message is routed if an error occurs. These errors include failures caused by retry processing. Even if the Validation property is set, messages propagated to this terminal are not validated.
Open	The output terminal to which a message is routed when it is first opened. Use the Open terminal if processing is required when a connection is opened rather than when data first arrives.
Out	The output terminal to which the message is routed if it is successfully retrieved from an external resource. If no errors occur within the input node, a message that is received from an external resource is always sent to the Out terminal first.
Close	The output terminal to which the message is routed if the connection closes.

Terminal	Description
Catch	The output terminal to which the message is routed if an exception is thrown downstream and caught by this node. Exceptions are caught only if this terminal is attached.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file to deploy it).

The Description properties of the TCPIPServerInput node are described in the following table.

Property	M	C	Default	Description
Node name	No	No	TCPIPServerInput	The name of the node.
Short description	No	No		A brief description of the node.
Long description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the TCPIPServerInput node are described in the following table.

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Connection details	Yes	Yes		A string containing the port number to be used, or the name of a configurable service.	connectionDetails
Timeout waiting for a data record (seconds)	Yes	Yes	`60`	Specifies how long the node listens on a connection for more data after the first byte of data has arrived. You can specify any length of time in seconds.	timeoutWaitingForData

The Advanced properties of the TCPIPServerInput node are described in the following table.

Property	M	C	Default	Description
Close connection	Yes	No	`No`	Controls when the connection is closed, or if it remains open. Valid options are: • `No` • `After Timeout` • `After Data has been Received` • `At End of Flow`
Close input stream after a record has been received	Yes	No	Cleared	Specifies whether to close the input stream as soon as the data has been retrieved. When the connection input stream is reserved, no other node can use it without knowing the ID. By default, this option is not selected.

Property	M	C	Default	Description
Input Stream Modification	No	No	`Leave unchanged`	Specifies whether to reserve the input stream for use only by input and receive nodes that specify the connection ID, and, if reserved, whether to release the input stream at the end of the flow. Valid options are: • `Leave unchanged` • `Reserve input stream (for use by future TCPIP nodes)` • `Reserve input stream (for use by future TCPIP nodes) then release at end of flow` When the connection input stream is reserved, no other nodes can use it without specifying the correct connection ID. If the input stream is released at the end of the flow, it is returned to the pool and becomes available for use by any input or receive node.
Output stream modification	No	No	`Leave unchanged`	Specifies whether this output stream is released and returned to the pool for use by any output node. Valid options are: • `Leave unchanged` • `Release output stream and reset ReplyID` If you select `Release output stream and reset ReplyID`, the ReplyID is passed in the local environment when leaving this node, but is reset for the next record on this connection.

The TCPIPServerInput node Input Message Parsing properties are described in the following table.

Property	M	C	Default	Description	**`mqsiapplybaroverride` command property**
Message domain	No	No		The domain that is used to parse the incoming message.	
Message set	No	No		The name or identifier of the message set in which the incoming message is defined. If you set this property, then later update the project dependencies to remove this message set reference, a warning is issued. Either update the `Message Set` property, or restore the reference to this message set project.	
Message type	No	No		The name of the incoming message.	
Message format	No	No		The name of the physical format of the incoming message.	
Message coded character set ID	Yes	No	`Broker System Default`	The ID of the coded character set used to interpret the data being read.	messageCodedCharSetIdProperty
Message encoding	Yes	No	`Broker System Determined`	The encoding scheme for numbers and large characters used to interpret the data being read. Valid values are `Broker System Determined` or a numeric encoding value. For more information about encoding, see "Data conversion" on page 1151.	messageEncodingProperty

The Parser Options properties of the TCPIPServerInput node are described in the following table.

Property	M	C	Default	Description
Parse timing	No	No	`On Demand`	This property controls when an input message is parsed. Valid values are: • `On Demand` • `Immediate` • `Complete` For a full description of this property, see "Parsing on demand" on page 4173.
Build tree using XML schema data types	No	No	Cleared	This property controls whether the syntax elements in the message tree have data types taken from the XML Schema.
Use XMLNSC compact parser for XMLNS domain	No	No	Cleared	This property controls whether the XMLNSC Compact Parser is used for messages in the XMLNS Domain. If you set this property, the message data is displayed under XMLNSC in nodes that are connected to the output terminal when the input MQRFH2 header or Input Message Parsing property, `Message Domain`, is XMLNS.
Retain mixed content	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters mixed text in an input message. If you select the check box, elements are created for mixed text. If you clear the check box, mixed text is ignored and no elements are created.
Retain comments	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters comments in an input message. If you select the check box, elements are created for comments. If you clear the check box, comments are ignored and no elements are created.
Retain processing instructions	No	No	Cleared	This property controls whether the XMLNSC parser creates elements in the message tree when it encounters processing instructions in an input message. If you select the check box, elements are created for processing instructions. If you clear the check box, processing instructions are ignored and no elements are created.
Opaque elements	No	No	Blank	This property is used to specify a list of elements in the input message that are to be opaquely parsed by the XMLNSC parser.

The Records and Elements properties of the TCPIPServerInput node are described in the following table:

Property	M	C	Default	Description
Record detection	Yes	No	`End of Stream`	The mechanism used to identify records in the input data. Valid options are: • `End of Stream` • `Fixed Length` • `Delimited` • `Parsed Record Sequence`
Length (bytes)	Yes	No	`0`	The length of each record, in bytes, when `Fixed Length` record detection is selected.

Property	M	C	Default	Description
Delimiter	Yes	No	DOS or UNIX Line End	The type of delimiter bytes that separates, or ends, each record when Delimited record detection is selected. Valid options are: • DOS or UNIX Line End • Custom Delimiter (Hexadecimal)
Custom delimiter (hexadecimal)	No	No		The delimiter bytes, expressed in hexadecimal, when Delimited record detection and Custom Delimiter (Hexadecimal) are selected. This property is mandatory only if the Delimiter property is set to Custom Delimiter (Hexadecimal).
Delimiter type	Yes	No	Postfix	The location of the delimiter when Delimited record detection and Custom Delimiter (Hexadecimal) are selected. Valid options are: • Infix • Postfix This property is ignored unless the Delimiter property is set to Custom Delimiter (Hexadecimal).

The Retry properties of the TCPIPServerInput node are described in the following table:

Property	M	C	Default	Description	mqsiapplybaroverride command property
Retry mechanism	Yes	No	Failure	How the node handles a flow failure. Valid options are: • Failure • Short Retry • Short and Long Retry	
Retry threshold	Yes	Yes	0	The number of times to retry the flow transaction when Retry mechanism is Short retry.	retryThreshold
Short retry interval (seconds)	No	Yes	0	The interval, in seconds, between each retry if Retry threshold is not zero.	shortRetryThreshold
Long retry interval (seconds)	No	Yes	300	The interval between retries if Retry mechanism is Short and Long Retry and the retry threshold has been exhausted.	longRetryThreshold

The Validation properties of the TCPIPServerInput node are described in the following table.

For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	Yes	None	This property controls whether validation takes place. Valid values are • None • Content and Value • Content	validateMaster

Property	M	C	Default	Description	mqsiapplybaroverride command property
Failure action	No	No	Exception	This property controls what happens if validation fails. Valid values are: • User Trace • Local Error Log • Exception • Exception List	

The Transactions properties of the TCPIPServerInput node are described in the following table:

Property	M	C	Default	Description
Transaction mode	No	Yes	No	The transaction mode on this input node determines whether the rest of the nodes in the flow are executed under point of consistency. Valid options are: • Yes • No

The Instances properties of the TCPIPServerInput node are described in the following table. For a full description of these properties, see "Configurable message flow properties" on page 4020.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Additional instances pool	No	Yes	Use Pool Associated with Message Flow	The pool from which additional instances are obtained. • If you select Use Pool Associated with Message Flow, additional instances are obtained from the message flow pool. • If you select Use Pool Associated with Node, additional instances are allocated from the additional instances of the node, based on the number specified in the Additional instances property.	componentLevel
Additional instances	No	Yes	0	The number of additional instances that the node can start if the Additional instances pool property is set to Use Pool Associated with Node.	additionalInstances

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

"**mqsireportproperties** command" on page 3937
Use the **mqsireportproperties** command to display properties that relate to a broker, an execution group, or a configurable service.

"**mqsichangeproperties** command" on page 3756
Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

"TCPIPClientInput node" on page 4854
Use the TCPIPClientInput node to create a client connection to a raw TCP/IP socket, and to receive data over that connection.

"TCPIPClientOutput node" on page 4867
Use the TCPIPClientOutput node to create a client connection to a raw TCP/IP socket, and to send data over that connection to an external application.

"TCPIPServerOutput node"
Use the TCPIPServerOutput node to create a server connection to a raw TCP/IP socket, and to send data over the connection to an external application.

"Validation properties" on page 4169
You can control validation by setting properties on the Validate and Parser Options tabs for the nodes that are listed in the following table.

TCPIPServerOutput node

Use the TCPIPServerOutput node to create a server connection to a raw TCP/IP socket, and to send data over the connection to an external application.

This topic contains the following sections:
- "Purpose"
- "Using the TCPIPServerOutput node in a message flow" on page 4905
- "Configuring the TCPIPServerOutput node" on page 4905
- "Terminals and properties" on page 4908

Purpose:
The TCPIPServerOutput node listens on a TCP/IP port and waits for a client node to make a connection with the port. When the client node connects to the port, the server node creates a connection for the client. The connections are not made directly by the node but are obtained from a connection pool managed by the WebSphere Message Broker execution group.

The execution group uses the default TCPIPServer configurable service to determine which attributes are used for the socket connection. However, if the configurable service is set on the node, the configurable service is used for all the properties, including the host and port number.

When the connection has been established, the data is sent. If the data is not sent successfully within the time limit specified by the node's `Timeout sending a data record` property, an exception is thrown.

You can configure the broker to use SSL for TCP/IP nodes; see "SSL and the TCP/IP nodes" on page 551.

Properties in the local environment can override the TCP/IP connection used by the node.

Table 259. Input local environment properties

Location in local environment	Description
$LocalEnvironment/Destination/TCPIP/Output/Hostname	The host name used to make a connection.
$LocalEnvironment/Destination/TCPIP/Output/Port	The port number used to make a connection.
$LocalEnvironment/Destination/TCPIP/Output/Id	The ID of the socket being used. This ID is an internal identifier used by WebSphere Message Broker to uniquely identify a connection.
$LocalEnvironment/Destination/TCPIP/Output/ReplyId	The Reply ID that is stored on this connection. It can be any text string.
$LocalEnvironment/Destination/TCPIP/Output/Timeout	The timeout value used when sending data to the TCP/IP server connection. This value overrides the `Timeout sending a data record` property specified on the node.

You can dynamically select the connection details (host name and port number), and the connection used (ID), using these properties. The Reply ID can also be set on the connection, which enables a string to be stored in the connection and to be displayed in the local environment. This behavior can be used to store Reply IDs from other TCPIP nodes or from other transports such as WebSphere MQ.

The output of the node contains the same information as the input, and any fields that are missing from the input are updated with details from the connection used. For example, if the `Id` property is not provided as input (because you want to create a connection or reuse a pool connection), the output local environment contains the ID of the connection that is used.

Table 260. Output local environment properties

Location in local environment	Description
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/Hostname	The host name used to make a connection.
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/Port	The port number used to make a connection.
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/OpenTimestamp	The time stamp when the connection was first opened.
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/CloseTimestamp	The time stamp when the connection was closed (null if not yet closed).
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/SequenceNumber	The sequence number of the message received on this connection. The first record has a sequencing number 1, the second record has a sequencing number 2, and so on.
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/Id	The ID of the socket being used. This ID is an internal identifier used by WebSphere Message Broker to uniquely identify a connection.
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/ReplyId	The Reply ID that is stored on this connection. It can be any text string.
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/ClientDetails/Hostname	The fully qualified domain name of the computer from which the client connected.
$LocalEnvironment/WrittenDestination/TCPIP/Output/ConnectionDetails/ClientDetails/Address	The IP address of the computer from which the client connected.

If the connection closes (or any other type of exception occurs) while using the TCP/IP transport, an exception is thrown. This exception goes to the Failure terminal if it is connected, otherwise the exception goes back down the message flow.

The node also has a Close input terminal. If a message is sent to this terminal, the connection is closed using a combination of the details provided in the node and the local environment.

The TCPIPServerOutput node is contained in the **TCPIP** drawer of the palette and is represented in the workbench by the following icon:

Using the TCPIPServerOutput node in a message flow:
You can use the TCPIPServerOutput node in any message flow that must send data to an external application. Look at the following samples to see how to use it:

- TCPIP Client Nodes
- TCPIP Handshake

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Configuring the TCPIPServerOutput node:
When you have put an instance of the TCPIPServerOutput node into a message flow, you can configure it (for more information, see "Configuring a message flow node" on page 1503). The properties of the node are displayed in the Properties view. All mandatory properties for which you must enter a value (those that do not have a default value defined) are marked with an asterisk in that view.

To configure the TCPIPServerOutput node:

1. Optional: On the **Description** tab, enter a short description, a long description, or both. You can also rename the node on this tab.
2. On the **Basic** tab, set the properties that determine how the TCP/IP connection is controlled.
   - Use the `Connection details` property to specify the port number to be used, or the name of a configurable service. This property is mandatory. The following formats are supported:
     - `Configurable service name`. This value is used to look up the port number in configurable services; for example, `TCPIPProfile1`.
     - `<Port>`. This value is the port number; for example, `1111`
     - `<Port>`. This value is the port number. In this case the host name is assumed to be `localhost`.
   - Use the `Timeout sending a data record (seconds)` property to specify how long the node waits when trying to send data. You can specify any length of time in seconds. When the specified time has been exceeded, all available data is sent to the Failure terminal. The default is `60` seconds.
3. On the **Advanced** tab, set the properties that determine how the data stream is controlled.

- Use the Send to property to specify whether the data is to be sent to one connection or to all available connections.
  - Select One connection to send the message to only one connection, as specified by the node properties and message overrides. This value is the default.
  - Select All available connections to send the data to all available connections.
- Use the Close connection property to specify when and how to close the connection.
  - Select No to leave the connection open. This value is the default.
  - Select After timeout to close the connection when a timeout occurs.
  - Select After data has been sent to close the connection when the end of the record has been sent.
- Select Close output stream after a record has been sent to close the output stream as soon as the data has been sent. By default, this property is not selected.
- Use the Output Stream Modification property to specify whether to reserve or release the output stream. These options are available only if you have not selected the Close output stream after a record has been sent property.
  - Select Leave unchanged to leave the output stream as it was when it entered the node. This value is selected by default.
  - Select Release output stream to specify that this output stream is returned to the pool and is available for use by any output node.
  - Select Reserve output stream (for use by future TCPIP output nodes) to specify that this output stream can be used only by this node and by other output nodes that request it by specifying the connection ID. When the connection input stream is reserved, no other nodes can use it without specifying the correct connection ID.
  - Select Reserve output stream (for use by future TCPIP output nodes) then release after propagate to specify that this output stream can be used only by this node and output nodes that request it by specifying the correct connection ID. After the message has been propagated, this output stream is returned to the pool and becomes available for use by any output node.
- Use the Input Stream Modification property to reserve the input stream for use only by input and receive nodes that specify the connection ID, or to release the input stream at the end of the message flow.
  - Select Leave unchanged to leave the input stream as it was when it entered the node. This value is selected by default.
  - Select Release input stream to specify that this input stream is returned to the pool and is available for use by any input or receive node.
  - Select Reserve input stream (for use by future TCPIP input and receive nodes) to specify that this input stream can be used only by this node and by other input or receive nodes that request it by specifying the connection ID. When the connection input stream is reserved, no other nodes can use it without specifying the correct connection ID.
  - Select Reserve input stream (for use by future TCPIP input and receive nodes) then release after propagate to specify that this input stream can be used only by this node and receive nodes that request it by specifying the correct connection ID. After the message has been propagated, this input stream is returned to the pool and becomes available for use by any input or receive node.

4. On the **Request** tab, specify the location of the data to be written. You can specify the properties on this tab as XPath or ESQL expressions. Content Assist is available in the Properties view and also in the XPath Expression Builder, which you can call by using the **Edit** button to the right of each property.
   a. In `Data location`, specify the input data location, which is the location in the input message tree that contains the record to be written. The default value is `$Body`, which is the entire message body (`$InputRoot.Body`).

      When you specify this property, if the data in the message tree that it identifies is owned by a model-driven parser (such as the MRM parser or XMLNSC parser,) be aware of the following considerations:

      - If you are using MRM CWF format, ensure that the identified message tree exists as a message definition. If this message tree is defined as a global element only, exceptions BIP5180 and BIP5167 are generated.
      - If you are using MRM TDS format, the serialization of the identified message is successful if the element is defined as a global element or message. However, if the identified field is not found as a global element or message, note that:
        – If this field is a leaf field in the message tree, the field is written as self-defining. No validation occurs even if validation is enabled.
        – If this field is a complex element, an internal exception is generated, BIP5522, indicating that the logical type cannot be converted to a string.
      - If you are using MRM XML, the events are similar to the MRM TDS format except that, if the field is a complex element, it is written as self-defining.
      - If you use the XMLNSC parser, no validation occurs, even if validation is enabled.

   b. In `Port location`, specify the location of the value to override the `Port` that is set in the `Connection details` property of the **Basic** tab. If you do not specify a location, the default value is `$LocalEnvironment/Destination/TCPIP/Output/Port`.
   c. In `ID location`, specify the location of the `Id` of the socket being used. This internal identifier is used by WebSphere Message Broker to uniquely identify a connection. If you do not specify a location, the default value is `$LocalEnvironment/Destination/TCPIP/Output/Id`.
   d. In `Reply ID location`, specify the location of the Reply ID that is stored on the connection that is being used. The Reply ID can be used when data is returned in an input node. If you do not specify a location, the default value is `$LocalEnvironment/Destination/TCPIP/Output/ReplyId`.
5. Use the **Records and Elements** tab to specify how the TCPIPServerOutput node writes the record that is derived from the message.
   - In `Record definition`, choose from the following values:
     – `Record is Unmodified Data` specifies that records are left unchanged. This value is the default.
     – `Record is Fixed Length Data` specifies that records are padded to a specified length if necessary. You specify this length in the `Length` property. If the record is longer than the value specified in `Length`, the node generates an exception. Use the `Padding byte` property to specify the byte to be used for padding the message to the required length.
     – `Record is Delimited Data` specifies that records are separated by a delimiter and accumulated by concatenation. The delimiter is specified by

the Delimiter, Custom delimiter, and Delimiter type properties. The file is finished only when a message is received on the Finish File terminal.

- In Length, specify the length (in bytes) of records when Record definition is set to Record is Fixed Length Data. Records longer than this value cause an exception to be thrown. This value must be in the range 1 byte through 100 MB. The default is 80 bytes.
- When Record definition is set to Record is Fixed Length Data, use Padding byte to specify the byte to be used when padding records to the specified length if they are shorter than this length. Specify this value as two hexadecimal digits. The default value is X'20'.
- In Delimiter, specify the delimiter to be used if you set Record definition to Record is Delimited Data. Choose from:
  - Broker System Line End specifies that a line end sequence of bytes is used as the delimiter as appropriate for the file system on which the broker is running. This value is the default. For example, on Windows systems, this line end is a 'carriage-return, line-feed' pair (X'0D0A'); on UNIX systems, it is a single 'line-feed' byte (X'0A'); on z/OS systems, it is a 'newline' byte (X'15').
  - Custom Delimiter specifies that the explicit delimiter sequence defined in the Custom delimiter property is to be used to delimit records.
- In Custom delimiter, specify the delimiter sequence of bytes to be used to delimit records when Delimiter is set to Custom Delimiter. Specify this value as an even-numbered string of hexadecimal digits. The default is X'0A' and the maximum length of the string is 16 bytes.
- If you set Record definition to Record is Delimited Data, use Delimiter type to specify how the delimiter is to separate records. Choose from the following values:
  - Postfix specifies that the delimiter is added after each record that is written. This value is the default.
  - Infix specifies that the delimiter is inserted between any two adjacent records only.

6. On the **Validation** tab, specify the parser validation properties of the node. For more information about validation, see "Validating messages" on page 1478. For information about how to provide validation for this tab, see "Validation tab properties" on page 4169.

Terminals and properties:
The TCPIPServerOutput node terminals are described in the following table.

Terminal	Type	Description
In	Input data	The input terminal that accepts a message for processing by the node.
Close	Input control	The input terminal to which a message is routed when the connection given in the local environment is closed.
Out	Output data	The output terminal to which the message is routed if it is successfully sent to an external resource. The message received on the In terminal is propagated to the Out terminal and is left unchanged except for the addition of status information.
Close	Output control	The output terminal to which a message propagated from the Close input terminal is routed.
Failure	Output data	The output terminal to which the message is routed if a failure is detected in the node.

The following tables describe the node properties. The column headed M indicates whether the property is *mandatory* (marked with an asterisk if you must enter a value when no default is defined); the column headed C indicates whether the property is *configurable* (you can change the value when you add the message flow to the BAR file for deployment).

The Description properties of the TCPIPServerOutput node are described in the following table:

Property	M	C	Default	Description
Node name	No	No	TCPIPServerOutput	The name of the node.
Short Description	No	No		A brief description of the node.
Long Description	No	No		Text that describes the purpose of the node in the message flow.

The Basic properties of the TCPIPServerOutput node are described in the following table:

Property	M	C	Default	Description	**mqsiapplybaroverride command property**
Connection details	Yes	Yes		A string containing the port number to be used, or the name of a configurable service.	connectionDetails
Timeout sending a data record (seconds)	Yes	Yes	`60`	Specifies how long the node waits when trying to send data. You can specify any length of time in seconds.	timeoutSendingData

The Advanced properties of the TCPIPServerOutput node are described in the following table.

Property	M	C	Default	Description
Close connection	Yes	No	`No`	Controls when the connection is closed, or if it remains open. Valid options are: • `No` • `After Timeout` • `After Data has been Sent`
Close output stream after a record has been sent	Yes	No	Cleared	Specifies whether to close the output stream as soon as the data has been sent. By default, this property is not selected.
Output Stream Modification	No	No	`Leave unchanged`	Specifies whether to reserve this output stream or release it and return it to the pool for use by any output node. Valid options are: • `Leave unchanged` • `Release output stream` • `Reserve output stream (for use by future TCPIP nodes)` • `Reserve output stream (for use by future TCPIP nodes) then release at end of flow`

Property	M	C	Default	Description
Input Stream Modification	No	No	`Leave unchanged`	Specifies whether to reserve the input stream for use only by input and receive nodes that specify the connection ID, or to release the input stream at the end of the flow. Valid options are: • `Leave unchanged` • `Release input stream` • `Reserve input stream (for use by future TCPIP nodes)` • `Reserve input stream (for use by future TCPIP nodes) then release at end of flow` When the connection input stream is reserved, no other nodes can use it without specifying the correct connection ID. If the input stream is released after the message has been propagated, it is returned to the pool and becomes available for use by any input or receive node.
Send to:	Yes	No	`One connection`	Specifies whether the data is to be sent to one connection or to all available connections. Valid options are: • One Connection • All Available Connections

The Request properties of the TCPIPServerOutput node are described in the following table:

Property	M	C	Default	Description
Data location	Yes	No	`$Body`	The location in the input message tree that contains the record to be written.
Port location	Yes	No	`$LocalEnvironment/Destination/TCPIP/Output/Port`	The message element location that contains the port.
ID	Yes	No	`$LocalEnvironment/Destination/TCPIP/Output/Id`	The message element location that contains the ID.
Reply ID location	Yes	No	`$LocalEnvironment/Destination/TCPIP/Output/ReplyId`	The message element location that contains the Reply ID.

The Records and Elements properties of the TCPIPServerOutput node are described in the following table:

Property	M	C	Default	Description
Record definition	Yes	No	`Record is Unmodified Data`	This property controls how the records derived from the message are written. Valid options are: • `Record is Unmodified Data` • `Record is Fixed Length Data` • `Record is Delimited Data`
Length (bytes)	Yes	No	`0`	The required length of the output record. This property applies only when `Record definition` is set to `Record is Fixed Length Data`.
Padding byte (hexadecimal)	Yes	No	`20`	The two-digit hexadecimal byte to be used to pad short messages when `Record definition` is set to `Record is Fixed Length Data`.

Property	M	C	Default	Description
Delimiter	Yes	No	Broker System Line End	The delimiter to be used when Record definition is set to Record is Delimited Data. Valid options are: • Broker System Line End • Custom Delimiter (Hexadecimal)
Custom delimiter (hexadecimal)	No	No	None	The delimiter byte sequence to be used when Record definition is set to Record is Delimited Data and Delimiter is set to Custom Delimiter (Hexadecimal).
Delimiter type	Yes	No	Postfix	This property specifies the way in which the delimiters are inserted between records when Record definition is set to Record is Delimited Data. Valid options are: • Infix • Postfix

The Validation properties of the TCPIPServerOutput node are described in the following table.

For a full description of these properties, see "Validation properties" on page 4169.

Property	M	C	Default	Description	mqsiapplybaroverride command property
Validate	No	Yes	Inherit	This property controls whether validation takes place. Valid values are: • None • Content and Value • Content • Inherit	validateMaster
Failure action	No	No	Exception	This property controls what happens if validation fails. You can set this property only if you set Validate to Content or Content and Value. Valid values are: • User Trace • Local Error Log • Exception • Exception List	

The Monitoring properties of the node are described in the following table.

Property	M	C	Default	Description
Events	No	No	None	Events that you have defined for the node are displayed on this tab. By default, no monitoring events are defined on any node in a message flow. Use **Add**, **Edit**, and **Delete** to create, change or delete monitoring events for the node; see "Configuring monitoring event sources using monitoring properties" on page 3327 for details. You can enable and disable events that are shown here by selecting or clearing the **Enabled** check box.

"TCPIPServerInput node" on page 4890
Use the TCPIPServerInput node to create a server connection to a raw TCPIP socket, and to receive data over that connection.

"TCPIPClientReceive node" on page 4877
Use the TCPIPClientReceive node to receive data over a client TCP/IP connection.

"TCPIPServerReceive node"
Use the TCPIPServerReceive node to receive data over a server TCP/IP connection.

TCPIPServerReceive node

Use the TCPIPServerReceive node to receive data over a server TCP/IP connection.

This topic contains the following sections:
- "Purpose"
- "Using the TCPIPServerReceive node in a message flow" on page 4915
- "Configuring the TCPIPServerReceive node" on page 4915
- "Terminals and properties" on page 4919

Purpose:
The TCPIPServerReceive node waits for data to be received on a TCP/IP connection, and retrieves the data. If the connection is closed, an exception is thrown.

When a connection is established, the data is sent to the TCPIPServerReceive node. If the TCPIPServerReceive node fails to receive all the data within the time specified in the `Timeout waiting for a data record` property, the message is sent to the Timeout terminal; if no Timeout terminal is connected, an exception is thrown.

You can configure the broker to use SSL for TCP/IP nodes; see "SSL and the TCP/IP nodes" on page 551.

Properties in the local environment can override the TCP/IP connection used by the node.

Table 261. Input local environment properties

Location in local environment for input to node	Description
$LocalEnvironment//TCPIP/Receive/Hostname	The host name used to make a connection.
$LocalEnvironment//TCPIP/Receive/Port	The port number used to make a connection.
$LocalEnvironment/TCPIP/Receive/Id	The ID of the socket being used. This ID is an internal identifier used by WebSphere Message Broker to uniquely identify a connection.
$LocalEnvironment/TCPIP/Receive/ReplyId	The Reply ID to be stored on this connection. This ID can then be used when data is returned on an input node. The Reply ID can be any text string.
$LocalEnvironment/TCPIP/Receive/Timeout	The timeout value used when waiting for data on the TCP/IP server connection. This value overrides the `Timeout waiting for a data record` property specified on the node.

Table 261. Input local environment properties (continued)

Location in local environment for input to node	Description
$LocalEnvironment/TCPIP/Receive/Length	The value used to override the number of bytes to be read when using fixed size records. This value overrides the `Length (bytes)` property specified on the node. If the `Record detection` property is set to anything other than `Fixed Length`, the local environment field is ignored. If this field is not present or evaluates to null, it is ignored and the value on the node is used.

These properties enable the connection details (host name and port number) and the connection used (ID) to be selected dynamically. The Reply ID can also be set on the connection, which enables a string to be stored in the connection and to be displayed in the local environment. In this way, you can store Reply IDs from other TCPIP nodes or from other transports, such as WebSphere MQ.

When a record has been retrieved, the ConnectionDetails field in the local environment tree is populated with the details of the connection that is being used.

Table 262. Output local environment properties

Location in local environment for output from node	Description
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/Type	The Server.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/Hostname	The host name used to make a connection.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/Port	The port number used to make a connection.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/OpenTimestamp	The time stamp when the connection was first opened.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/CloseTimestamp	The time stamp when the connection was closed (null if not yet closed).
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/SequenceNumber/InputRecord	The sequence number of the message that is received on this connection. The first record has a sequencing number of 1; the second record is 2; and so on.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/SequenceNumber/OutputRecord	The sequence number of the message that is sent on this connection. The first record has a sequencing number of 1; the second record is 2; and so on.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/Id	The ID of the socket being used. This ID is an internal identifier used by WebSphere Message Broker to uniquely identify a connection.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/ReplyId	The Reply ID that is stored on this connection. It can be any text string.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/ClientDetails/Hostname	The fully qualified domain name of the computer from which the client connected.
$LocalEnvironment/TCPIP/Receive/ConnectionDetails/ClientDetails/Address	The IP address of the computer from which the client connected.

The TCPIPServerReceive node is contained in the **TCPIP** drawer of the palette, and is represented in the WebSphere Message Broker Toolkit by the following icon:

Message structure

The TCPIPServerReceive node handles messages in the following message domains:

- XMLNSC
- DataObject
- JSON
- BLOB
- MIME
- MRM
- JMSMap
- JMSStream
- XMLNS

Using the TCPIPServerReceive node in a message flow:
Look at the following samples to see how to use the TCPIPServerReceive node:

- TCPIP Client Nodes
- TCPIP Handshake

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Configuring the TCPIPServerReceive node:
When you have put an instance of the TCPIPServerReceive node into a message flow, you can configure it; see . The properties of the node are displayed in the Properties view.

All mandatory properties that do not have a default value defined are marked with an asterisk.

Configure the TCPIPServerReceive node:

1. Optional: On the **Description** tab, enter a `Short description`, a `Long description`, or both. You can also rename the node on this tab.
2. On the **Basic** tab, set the properties that determine how the TCP/IP connection is controlled.
   - Use the `Connection details` property to specify either the host name and port number to be used, or the name of a configurable service. This property is mandatory. The following formats are supported:
     - `Configurable service name`. This value is used to look up the port and host name in configurable services. For example, `TCPIPProfile1`.
     - `<Hostname>:<Port>`. This value is the host name followed by the port number (separated by a colon); for example, `tcpip.server.com:1111`
     - `<Port>`. This value is the port number. In this case, the host name is assumed to be `localhost`.
   - Use the `Timeout waiting for a data record (seconds)` property to specify how long the node listens on a connection for more data after the first byte

of data has arrived. You can specify any length of time in seconds. The default is 60 seconds. When the specified time has been exceeded, all available data is sent to the Failure terminal.

3. On the **Advanced** tab, set the properties that determine how the data stream is controlled.
   - Use the Close connection property to specify when and how to close the connection.
     - Select No to leave the connection open. This value is the default.
     - Select After timeout to close the connection when a timeout occurs.
     - Select After data has been received to close the connection when the end of the record is found.
   - Select Close input stream after a record has been received to close the input stream as soon as the data has been retrieved. By default this property is not selected. When the connection input stream is reserved, no other node can use it without knowing the ID.
   - Use the Input Stream Modification property to specify whether to reserve the input stream for use only by input and receive nodes that specify the connection ID, or to release the input stream at the end of the flow.
     - Select Leave unchanged to leave the input stream as it was when it entered the node. This value is selected by default.
     - Select Release input stream to specify that this input stream is returned to the pool and is available for use by any input or receive node.
     - Select Reserve input stream (for use by future TCPIP input and receive nodes) to specify that this input stream can be used only by this node and by other input or receive nodes that request it by specifying the connection ID. When the connection input stream is reserved, no other nodes can use it without specifying the correct connection ID.
     - Select Reserve input stream (for use by future TCPIP input and receive nodes) then release after propagate to specify that this input stream can be used only by this node and receive nodes that request it by specifying the correct connection ID. After the message has been propagated, this input stream is returned to the pool and becomes available for use by any input or receive node.
   - Use the Output Stream Modification property to specify whether to reserve or release the output stream. These options are available only if you have not selected the Close output stream after a record has been sent property.
     - Select Leave unchanged to leave the output stream as it was when it entered the node. This value is selected by default.
     - Select Release output stream to specify that this output stream is returned to the pool and is available for use by any output node.
     - Select Reserve output stream (for use by future TCPIP output nodes) to specify that this output stream can be used only by this node and by other output nodes that request it by specifying the connection ID. When the connection input stream is reserved, no other nodes can use it without specifying the correct connection ID.
     - Select Reserve output stream (for use by future TCPIP output nodes) then release after propagate to specify that this output stream can be used only by this node and output nodes that request it by specifying the correct connection ID. After the message has been propagated, this output stream is returned to the pool and becomes available for use by any output node.

4. On the **Request** tab, specify the location of the data to be written. You can specify the properties on this tab as XPath or ESQL expressions. Content Assist is available in the Properties view and also in the XPath Expression Builder, which you can run by clicking **Edit** to the right of each property.
   - In `Hostname location`, specify the location of the value to override the `Hostname` that is set in the `Connection details` property of the **Basic** tab. If you do not specify a location, the default value is `$LocalEnvironment/TCPIP/Receive/Hostname`.
   - In `Port location`, specify the location of the value to override the `Port` that is set in the `Connection details` property of the **Basic** tab. If you do not specify a location, the default value is `$LocalEnvironment/TCPIP/Receive/Port`.
   - In `ID location`, specify the location of the `Id` of the socket being used. This internal identifier is used by WebSphere Message Broker to uniquely identify a connection. If you do not specify a location, the default value is `$LocalEnvironment/TCPIP/Receive/Id`.
   - In `Reply ID location`, specify the location of the Reply ID that is stored on the connection that is being used. The Reply ID can be used when data is returned in an input node. If you do not specify a location, the default value is `$LocalEnvironment/TCPIP/Receive/ReplyId`.
5. On the **Result** tab, set values for the properties that determine where the reply is stored.
   - Use the `Output data location` property to specify the start location in the output message tree where the parsed elements from the bit string of the message are stored. The default value is `$OutputRoot`.
   - Use the `Copy local environment` property to specify whether the local environment is copied to the output message.
     – If `Copy local environment` is selected, a new copy of the local environment is created in the tree, and it is populated with the contents of the local environment from the preceding node. Therefore, if a node changes the local environment, the upstream nodes are not affected by those changes because they have their own copies. This value is the default.
     – If `Copy local environment` is not selected, the node does not generate its own copy of the local environment, but uses the local environment that is passed to it by the preceding node. Therefore, if a node changes the local environment, the changes are reflected by the upstream nodes.
6. On the **Input Message Parsing** tab, set values for the properties that the node uses to determine how to parse the incoming message.

   If the incoming message has an MQRFH2 header, you are not required to set values for the Input Message Parsing properties because the values are derived from the `<mcd>` folder in the MQRFH2 header; for example:

   ```
   <mcd><Msd>MRM</Msd><Set>DHM4UO906S001</Set><Type>receiptmsg1</Type>
   <Fmt>XML</Fmt></mcd>
   ```

   If you set values, and if they differ from the values in the MQRFH2 header, the values in the MQRFH2 header take precedence.
   - In `Message domain`, select the name of the parser that you are using from the list. The default is `BLOB`. You can choose from the following options:
     – XMLNSC
